The RDE module was implemented on a web-based LAMPS architecture (Linux, Apache, MySQL, Perl, SSL) according to the requirements identified above. Metadata was stored in an SQL database using an entity-attribute-value (EAV) schema [6] whereas medical data items were stored in the file system. The HL7 CDA format was chosen as a suitable format for storing the medical data of SDE forms and facilitating reusability and interoperability with EPRs. During the development of the RDE module only Release 1 of HL7 CDA was available, which did not provide standard templates for structured clinical content. Local markup was devised for storing the required clinical

content in CDA R1-compliant fashion. A proprietary XML format was developed to support the different types of required SDE forms, and an XSLT stylesheet was applied to render the medical data items into HTML screen forms (Fig. 1). To guarantee consistent relationships between the XML metadata, the XSLT stylesheet and the CDA/XML document, a revision control system was integrated.

Results

The RDE module was introduced into production use in 09/2005 at the multi-centric EB research network. For entering research data six distinct SDE forms have been developed covering medical topics like patient histories, physical exams and lab findings (Fig. 2). Two clinical centers have entered more than 200 patients, and more than 150 sessions with an average of 60 minutes per sessions have been carried out. The system is currently being adapted for the additional domain of pediatric oncology.

Figure 2 – Transformation of HL7 CDA to HTML

Discussion

Storing clinical documentation content in a human-readable and machine-processable XML format allows the flexible adaptation of SDE forms for various medical domains. Creating HTML output by means of XSLT stylesheets and an XSLT processor has proved to be a robust and efficient method [7]. The architecture described here presents a setting where HL7 CDA is used primarily for data storage. However, standards like HL7 CDA or CDISC ODM can contribute to a potential semantic integration of data exchange formats. Concepts for integration of semantic interoperability into these formats already exist but are not yet fully developed (e.g. HL7 CDA Templates). In order to gain better usability the implementation of skip logic should be considered. Also, to further improve data quality, the existing simple validation checks should be extended to allow complex plausibility control mechanisms.

Conclusions and outlook

In conclusion the developed system offers great flexibility and adaptability for the definition of SDE forms for various medical domains within the same RDE platform. Using standards like XML, XSLT and HL7 CDA contributed significantly towards the flexibility of the system and could in the future pave the way for semantic interoperability with other clinical IT systems. Further development will focus on rolling out the system in additional medical domains as well as implementing complex input validation and skip logic.

Integration of Domain-Specific User Interfaces for Structured Data Entry in a Telemedicine Platform for Multi-Centric Research Networks

Klein A, Prokosch HU, Ueckert F, Ganslandt T

Department of Medical Informatics
Research Network Epidermolysis Bullosa

Friedrich-Alexander-Universität
Erlangen-Nürnberg

Introduction (1)
Research Network Epidermolysis Bullosa

- Multi-centric research network [1]
  - Epidermolysis Bullosa (EB): rare hereditary skin disease
  - 7 centers within Germany involved
    - patient care (2 centers)
    - research (5 centers)
- Expectations
  - better understanding of disease mechanisms
  - development of new diagnostic services and therapies
  - more comprehensive documentation
- Challenges
  - effective data exchange between centers
  - effective collaboration and data sharing
  - suitable communication structures

Introduction (2)
Requirements RDE & SDE

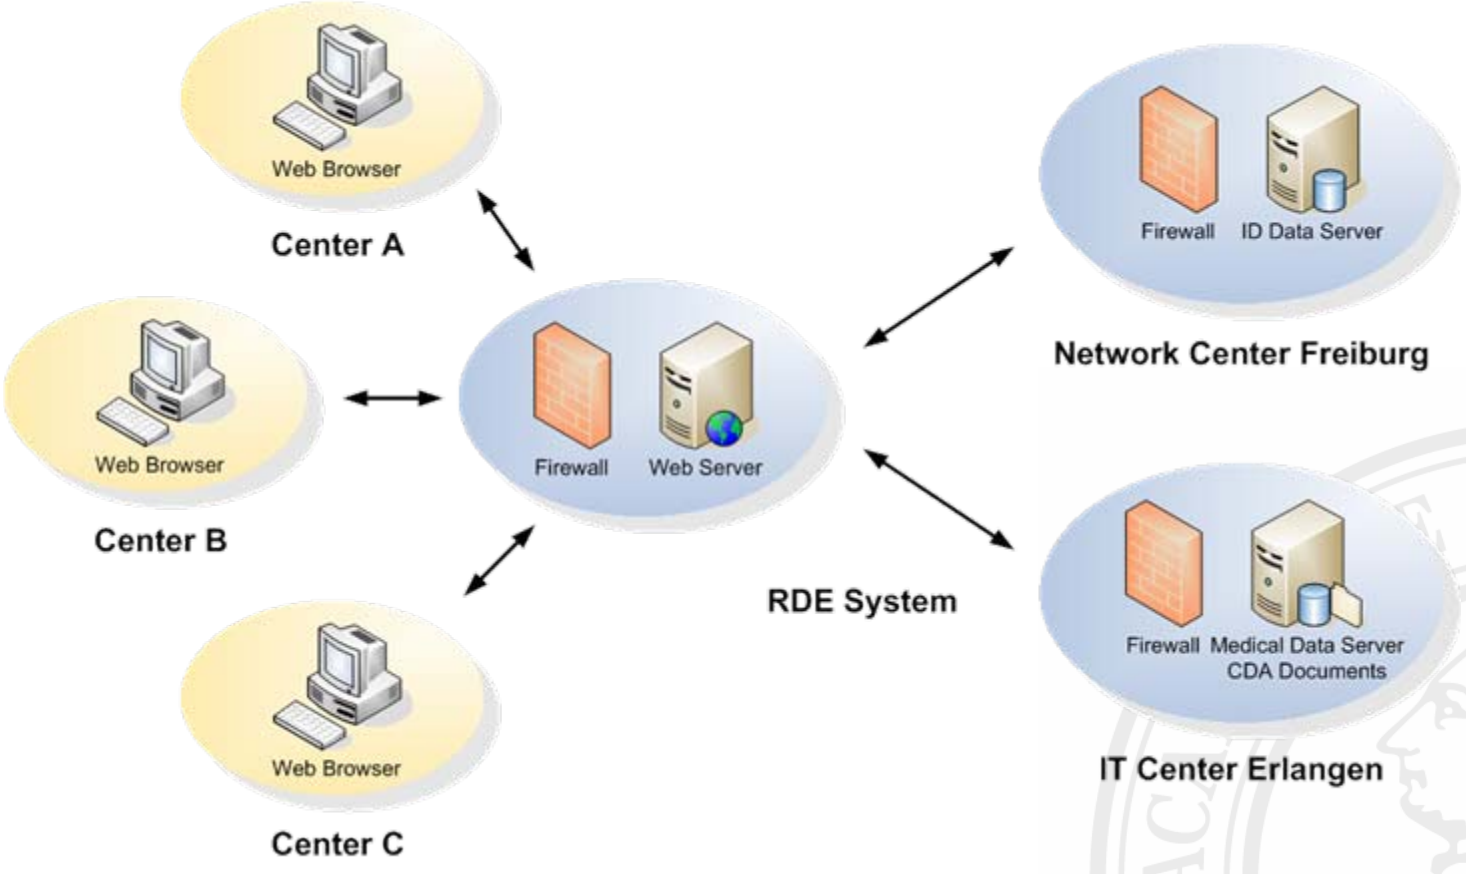
- Integrated telemedicine platform
  - remote data entry (RDE)
  - web-based
  - flexible and easily extensible platform
  - implementation of German data protection rules
  - acquisition and sharing of structured data, image data and genealogies
- Gathering requirements of structured data entry forms (SDE)
  - extraction of data items and grouping by topic and occurrence(s) within the clinical workflow
  - single-acquisition forms at patient recruitment
  - multiple-acquisition forms during course of study

Methods (1)
Components & Concepts

- Extension of existing telemedicine platform
  - addition of a web-based RDE module
  - LAMPS architecture (Linux, Apache, MySQL, Perl, SSL)
  - SDE forms
    - definition and meta information in XML file
    - parsing and rendering through XSLT
    - medical data in HL7 CDA R1
  - use of entity-attribute-value (EAV) concept for metadata storage
  - implementation of architecture requirements of the German Health Telematics Platform (TMF) [2]

Methods (2)
Data protection requirements

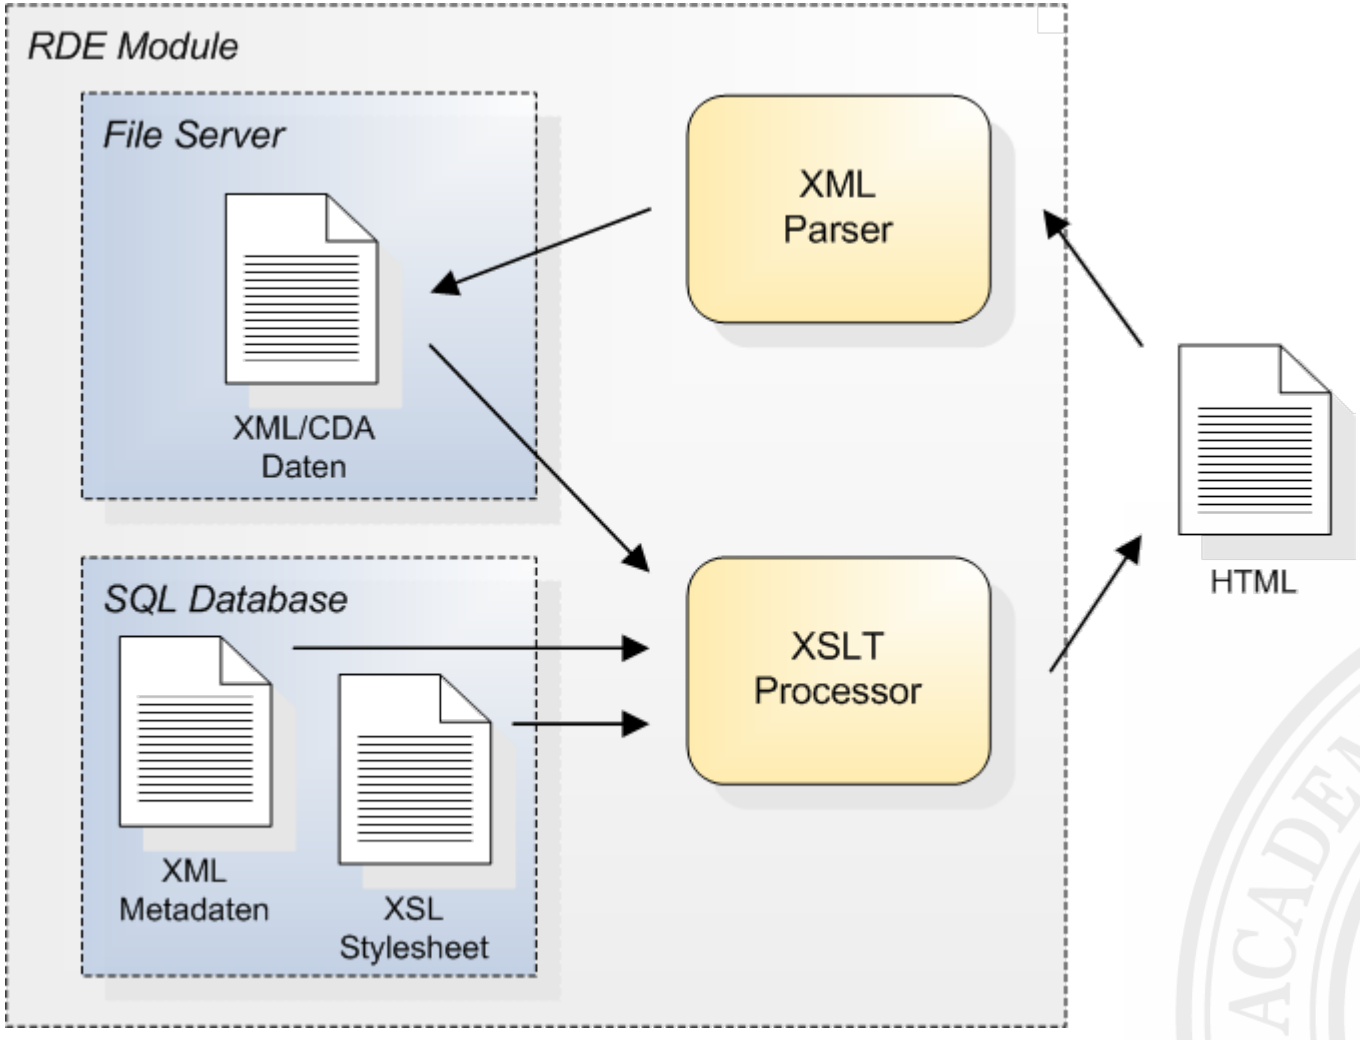
- separation of patient ID data and medical data



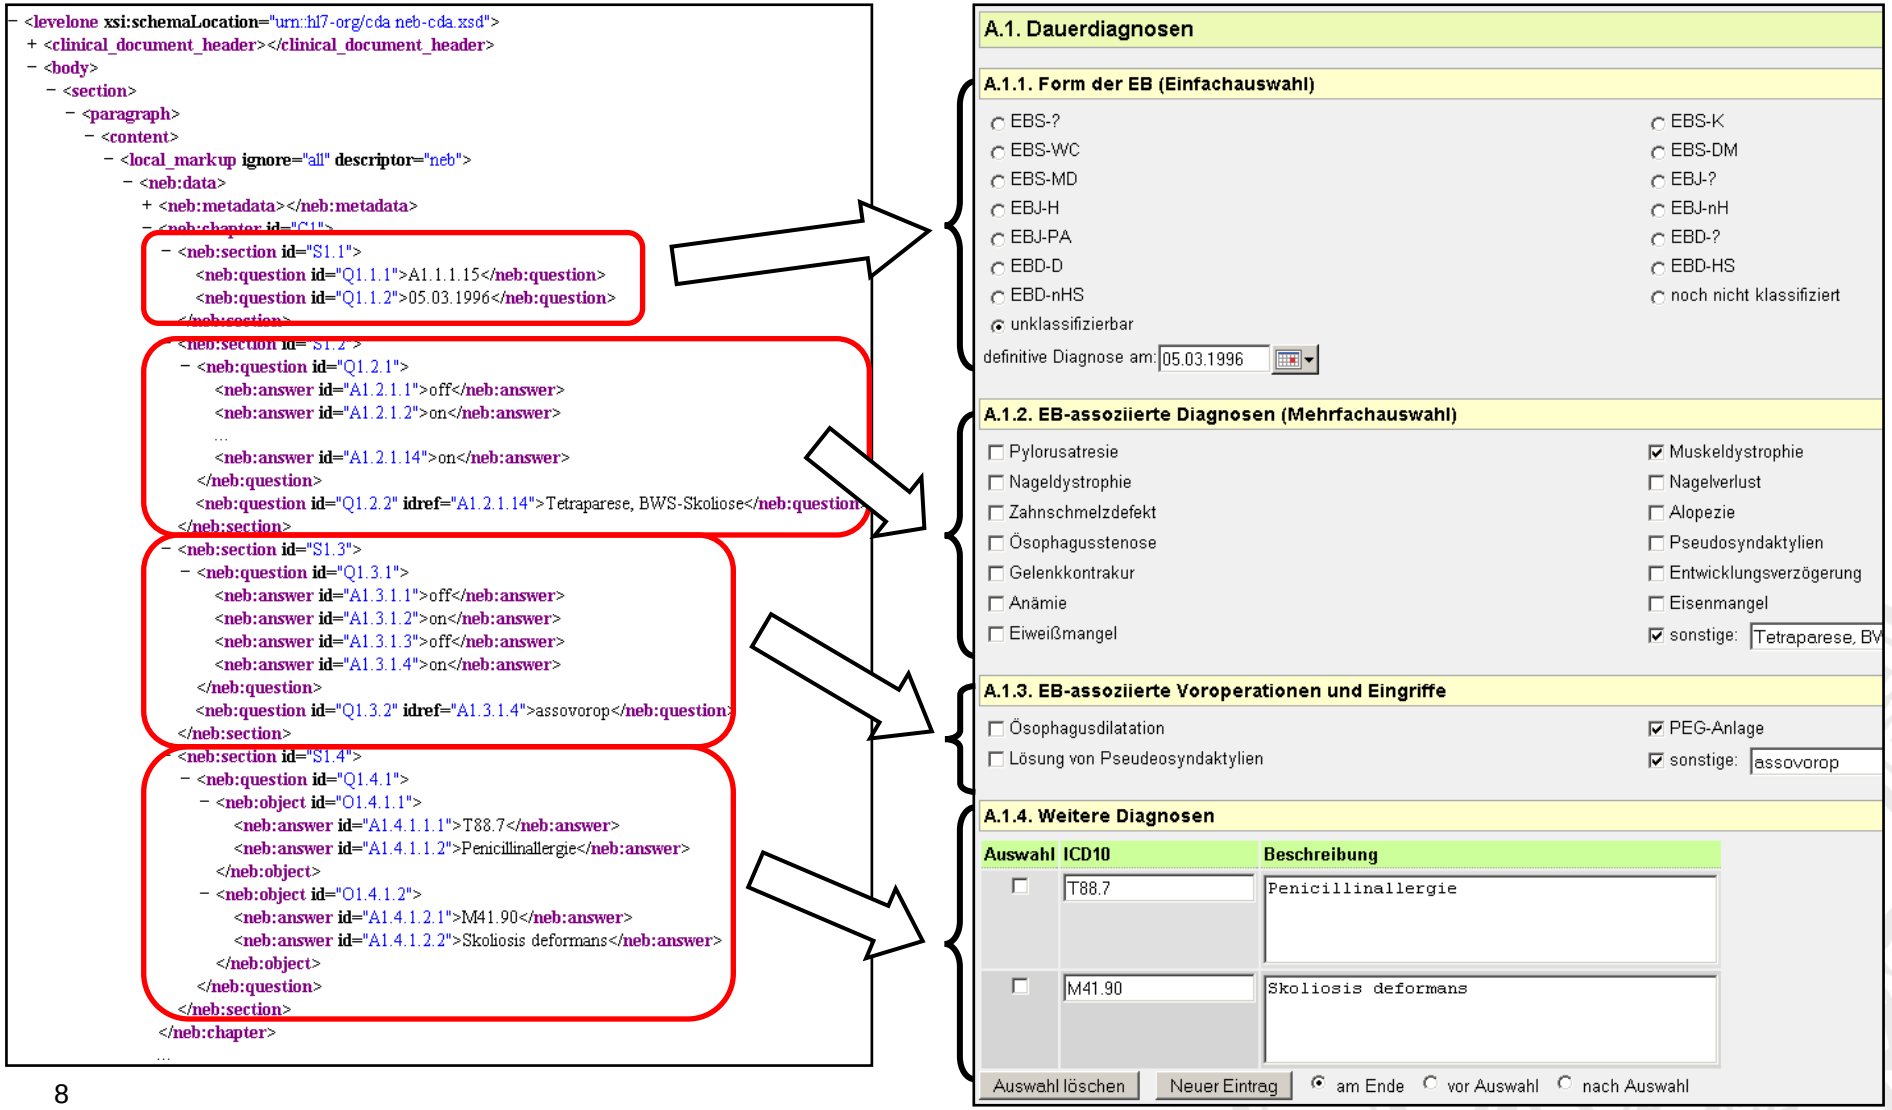
Methods (3)
Integration of HL7 v3 CDA R1

- CDA = Clinical Document Architecture
  - XML-based, 3 level architecture
  - header and body information (meta data/clinical data)
  - extensibility through <local-markup> segments
- proprietary namespace for local content
  - definable meta data elements for alignments, definitions and data containers
- validation of compatibility regarding all stored CDA data against the CDA schema
- suitable storage format for medical data

Methods (4)
XML-Architecture



Methods (5)
XSL-Transformation



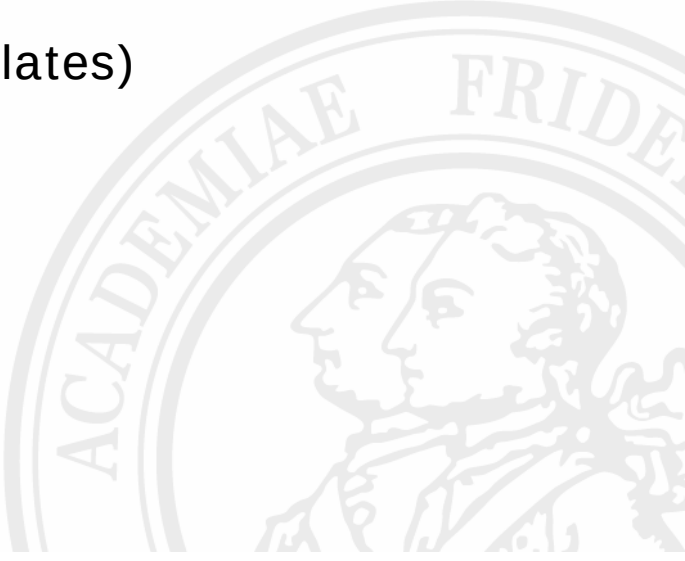
Results
Production use & features

- Production use since 09/2005
  - 150 sessions
  - 200 patients, 2 centers
  - 6 distinct acquisition forms (e.g. patient histories, physical exams, lab findings)
  - most complex document contains 111 items
  - CDA R1 structured elements primarily used for demographic data
  - adaptation for additional domain of pediatric oncology

- Features
  - integrated patient data management
  - flexible definable acquisition forms managed through revision control system
  - integration of existing graphical genealogies in Newick notation [3]
  - granular authorization management
  - plausibility checks
  - data export for further analysis

Discussion

- XML formats
  - flexible adaptation of SDE forms for various medical domains
- XSLT
  - robust and efficient method for generation of user interfaces
- HL7 CDA vs. CDISC ODM
  - data storage
  - still under development
  - semantic interoperability (HL7 CDA templates)
- Improved data quality
  - complex plausibility mechanisms



Conclusions and Outlook

- Flexibility and adaptability
  - definition of SDE forms for different medical domains
- Standards
  - XML, XSLT, HL7 CDA contribute to semantic interoperability and further interfaces to EHRs or EPRs
- Further development
  - roll out in additional medical domains
  - input validation
  - skip logic

Thanks for your attention!

Evaluation of Clinicians' Satisfaction of a Discharge Summary System (DSS) in a Taiwanese Teaching Hospital – The Reliability of an Evaluating Instrument

Yung-Yu Su[a], Khin Than Win[a], Herng-Chia Chiu[b], Gui-Fen Chiu[c], John Fulcher[a]

[b]. Graduate Institute of Healthcare Administration, Kaohsiung Medical University, Taiwan
[c]. Department of Information Management, Kaohsiung Municipal Hsiaokang Hospital, Taiwan

Abstract

Evaluation is important in determining the success of electronic medical records (EMRs). Thus, this study introduces how to use both qualitative and quantitative methods in such research. This study provides a suitable assessment questionnaire including dimensions and attributes revised from the "updated DeLone and McLean IS Successful Model" tailored to the Taiwanese medical environment. In short, this study demonstrates the reliability of this evaluation tool and we believe it could be incorporated into EMRs from the perspective of patient safety, healthcare administration, and health informatics.

Key words:

evaluation research, HIS evaluation, evaluation instrument

Introduction

The development of information technology has enabled health professionals to improve the efficiency and quality of patient care. A Hospital Information System (HIS) integrates lots of sub-systems, and has the potential to improve patient care, cost containment and improve the efficiency of work practice [1]. An Electronic Medical Record (EMR) system is a part of HIS. Adoption of EMR could lead to better quality and more efficient healthcare. An EMR contains sensitive health data of individual patients; thus, it is important to realize whether such a system is both secure and error free for patient care in a healthcare organization. Thus, in order to assess current-generation EMRs in Taiwan, we adopte "goal-based evaluation" [2] in designing an appropriate evaluation tool in this research.

The purpose of the study is to establish a suitable evaluation instrument which includes dimensions and attributes for the "EMR evaluation" based on "Patient Safety". Accordingly, this research was performed in a teaching hospital in the south of Taiwan. This sample hospital has been using a Discharge Summary System (DSS) to improve the quality of patient care for more than two years. In order to protect the privacy of patient records, only attending physicians, residents, interns, and nursing specialist practitioners (NSP) are permitted to use this system. Therefore, forty-six physicians were invited to join this evaluation study as they are the main stakeholders in this DSS.

Methods

This research combined and revised both the "updated DeLone and McLean Information System model" [3] and the dimension of "Safety Quality"[4] to generate a more comprehensive model in evaluating this DSS. A Likert-scale was used in the questionnaires and answers were assigned a value of 1 to 7 from "strongly disagree" to "strongly agree". Hence, forty seven questions with a free-text question were developed to measure 7 categories (Figure 1): **System Quality, Information Quality, Service Quality, Safety Quality, Use Frequency, Work Impact, and Overall Satisfaction.** Consequently, this research found evaluating attributes based on the above research model by using literature review to satisfy the requirements of the Taiwanese medical environment. The research uses "cross-sectional" design to achieve its goal. Thus, research questionnaires were provided for the physician's office and were collected every week by researchers from May to the middle of June in 2006.

Results

The respondse rate of this research was 71.7% (33 of 46), and the data were analyzed by using the SPSS statistical software package. Demographic data are shown in Table 1. "Reliability analysis" was conducted and the Cronbach's value of "reliability analysis" shown in Table 2. However, obeying the hypothesis of "Factor analysis", the ratio of variables to samples is 1:2 [5]. As the sample size is 33, only the reliability can be tested in this research. Consequently, the final scale contained 42 questions which comprise 7 dimensions: System Quality, Information Quality, Service Quality, Safety Quality, Use Frequency, Work Impact, and Overall Satisfaction. The results of "Reliability analysis" show that those 42 questions follow the same trend in this research questionnaire.

Discussion

This is a successful study because a suitable assessment instrument was designed based on statistical techniques. To summarize the salient features of the analysis, several findings are of interest, and three reasons could be cited to explain this result. **Firstly,** it demonstrates that both "literature review" and "Delphi method" are important techniques in designing a research questionnaire. **Secondly,** it is essential to adopt clinicians' suggestions, to realize end-users' opinions and use suitable wording in such an evaluation study. **Thirdly**, HIS/EMR evaluation is very difficult to perform in a real medical environment because healthcare professionals are extremely busy with patient care. Thus, it needs to get the support and cooperation with healthcare professionals' to complete and gain useful data from them.

In addition, the most significant finding is that **"Safety Quality"** could be incorporated of the "updated DeLone and McLean Information System model" based on the aspects of technology. However, it still needs further research to demonstrate this result by using "Factor analysis" with large samples (more than 200).

Conclusion

This research demonstrates that Quantitative and Qualitative approach of cross-sectional survey design, Literature review, Delphi method, clinicians' opinions, and cooperation with healthcare professionals are the essential factors in such evaluation research. Additionally, large samples could help researchers to complete a successful evaluation study. The next stage of this research will further refine this instrument for Taiwanese EMRs evaluation.

Introduction

- **Hospital Information System (HIS)**
  - An HIS integrates lots of sub-systems, and has the potential to improve patient care, cost containment and improve the efficiency of work practice [1].

- **Electronic Medical Records (EMRs) System**
  - An EMR contains sensitive health data of individual patients.
  - Adoption of EMR could lead to better quality and more efficient healthcare.

- **The purpose of the study**
  - To establish a suitable evaluation instrument which includes dimensions and attributes for the "EMRs evaluation" based on "Patient Safety" in Taiwan.

Background of sample hospital

- **This research was performed in a teaching hospital in the south of Taiwan.**
  - 19 clinical branches and 498 general beds

- **It has been using a Discharge Summary System (DSS) to improve the quality of patient care for more than two years.**
  - In order to protect the privacy of patient records, only limited members are permitted to use this DSS.
    - Attending physicians,
    - Residents,
    - Interns,
    - Nursing specialist practitioners (NSP)

Methods

- **Research Design**
  - The research uses "cross-sectional" design to achieve its goal.
  - It adopted "goal-based evaluation" [2] in designing an appropriate evaluation tool.

- **Participants**
  - Forty-six physicians were invited to join this evaluation study.

- **Evaluation Model**
  - A more comprehensive model (Figure 1) was generated in this DSS by combining and revising
    - the "updated DeLone and McLean Information System model" [3]
    - the dimension of "Safety Quality"[4]

- **Evaluation Instrument**
  - A Likert-scale was used in the questionnaires and answers were assigned a value of 1 to 7 from "strongly disagree" to "strongly agree".
  - Forty seven questions with a free-text question were developed to measure 7 dimensions.

- **Performing this research**
  - Research questionnaires were provided for the physicians in five clinical departments.
  - The questionnaire were collected from May to the middle of June in 2006.

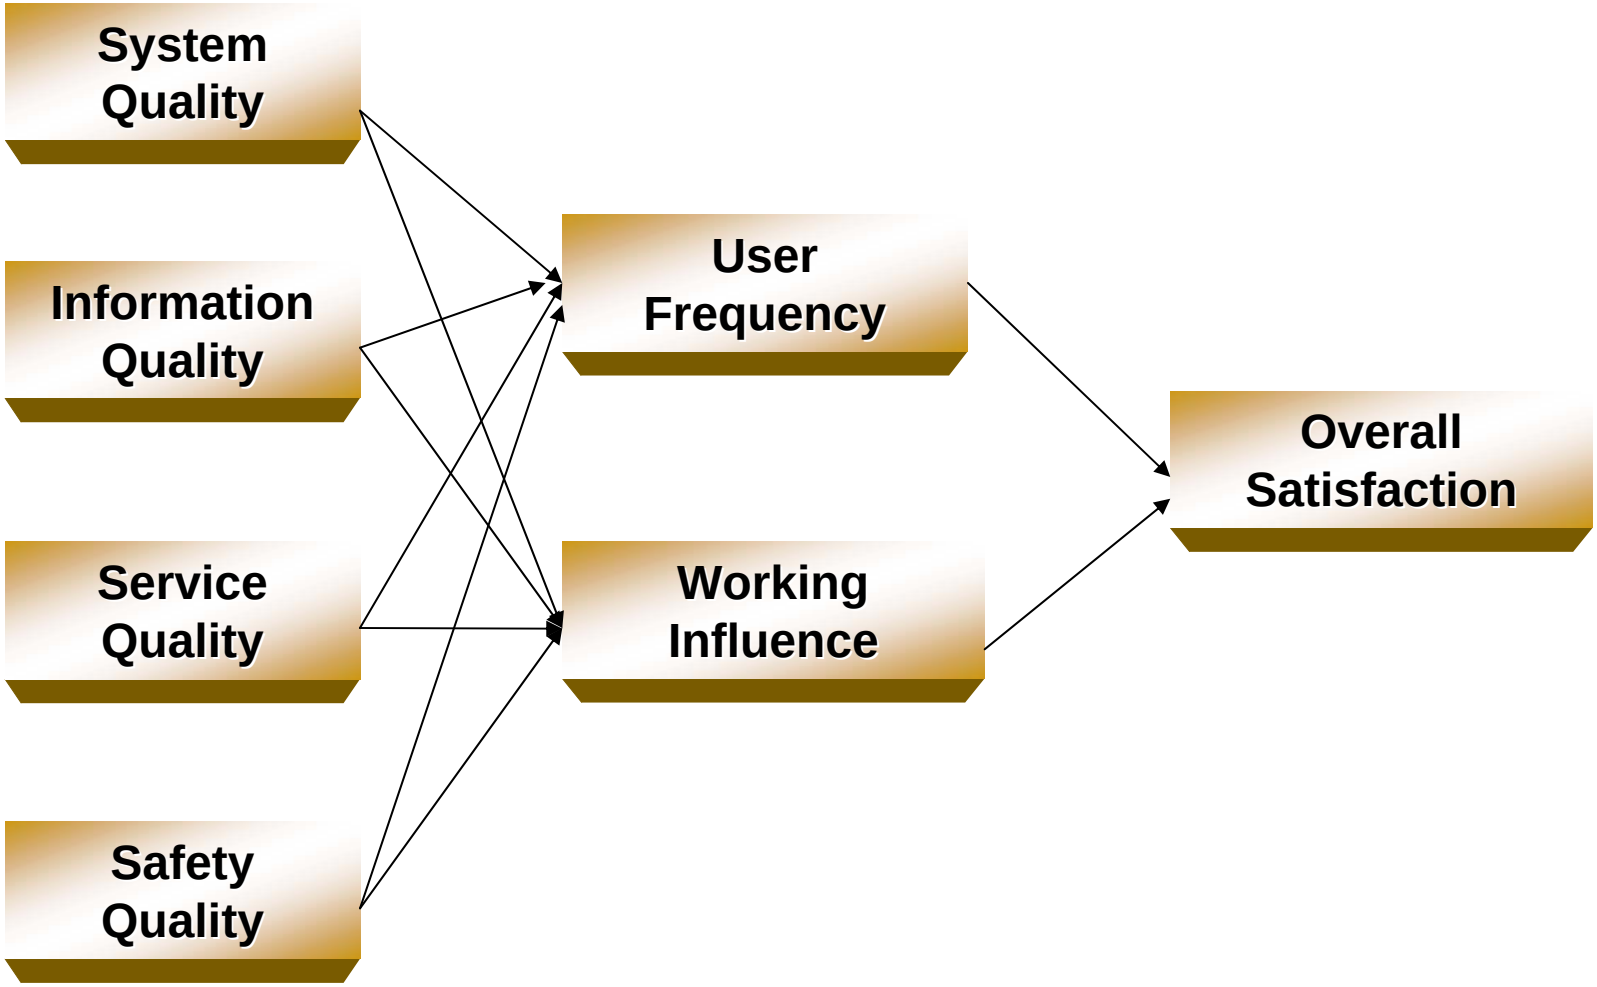

Figure 1 Evaluation model

Results

- The response rate of this research was 71.7% (33 of 46 physicians).
- The data were analyzed by using the SPSS 13.0 statistical software package.
- Demographic data are shown in Table 1.
- "Reliability analysis" was conducted and the Cronbach's α value of "reliability analysis" shown in Table 2.

Results

Table 1 Demographic Characteristics of Study Sample (N=33)

Characteristic		Sample	Percentage

α = 0.005

Discussion

- **To summarize the salient features of the analysis, several findings are of interest, and three reasons could be cited to explain this result.**
  - **Firstly**, both "literature review" and "Delphi method" are important techniques in designing a research questionnaire.
  - **Secondly**, it is essential to adopt clinicians' suggestions, to realize end-users' opinions and use suitable wording in such an evaluation study.
  - **Thirdly**, HIS/EMRs evaluation is very difficult to perform in a real medical environment because healthcare professionals are extremely busy with patient care.
    - Thus, it needs to get the support and cooperation of healthcare professionals' to complete and gain useful data from them.

Discussion

- **"Safety Quality" could be incorporated into the "updated DeLone and McLean Information System model" based on the aspects of technology.**
  - These attributes could be used to measure whether an EMR system could protect the privacy of patient records.

- **It still needs further research to demonstrate this result by using "Factor analysis" with large samples (more than 200) "[5].**
  - A "good" research questionnaire needs to satisfy the requirements of both "reliability" and "validity".

Conclusion

- **This research demonstrates the essential factors in such evaluation research.**
  - Quantitative and Qualitative approach of cross-sectional survey design,
  - Literature review,
  - Delphi method,
  - Cooperation with healthcare professionals to realize their insight opinions of implementing EMRs.

- **"Safety Quality" could be regards as an important dimension for EMRs evaluation study.**

- **The next stage of this research will further refine this instrument for Taiwanese EMRs evaluation.**

An Effective Approach for Development of Regional Medical Information System Using XML Technology

Masayuki Honda[a], Takehiro Matsumoto[a], Yoshiyuki Nakayama[b], Hiroaki Sudo[b], Kazuo Yanase[c], Ryuichi Fujita[c]

[a] *Department of Medical Informatics, Nagasaki University Hospital, Japan*
[b] *Government and Public Corporation Information Systems Division, Hitachi, Ltd., Tokyo, Japan*
[c] *kbsoft corporation, Nagasaki, Japan*

Abstract

The system proposed here accepts XML-documented patient records and transforms them into a common schema through the style sheet. Because we adopted an XML format, the users of this system will easily get the information exchanged among medical facilities. The characteristics of this system include; (1) automatic creation of an appropriate structure of database from the XML schema information for each hospital, enabling to store any records of XML format for which XML schema information is known in advance, (2) facilitation of a dynamic control of information flow by introducing an idea of standardized interface structure, (3) reduction of the costs at which regional medical information systems are built up and (4) increase of the number of hospitals sharing this DB of patient records by exploiting a common XML schema.

Keywords:

medical informatics, databases, information storage and retrieval

Introduction

XML is useful for both display of data (e.g., in a web browser) and also for electronic data interchange messaging between systems. Many trials other than those of our research are reported for structuring medical records with XML. In the United States, HL7 (Health Level Seven) is generally used to exchange medical information, and HL7 v2 messages have been translated into XML format; v3 messages will be exclusively in XML. In Japan, electronic medical records that are equipped and operating with an XML interface include OpenDolphin and Wine. Also expected to make an appearance are MML-supporting electronic medical records that are being newly sought in connection with a cooperative system of the Tokyo Medical Association (HOT Project).

Electronic exchange of medical for information among hospitals, it is necessary to standardize data formats. In Japan, however, exchanges of medical information are still underdevelopment, resulting in few hospitals which actually have their medical information exchanged with each other [1].

We proposed here an effective approach, for development of the regional medical information system and sharing patients DB among hospitals.

Methods

XML text Viewing and editing

We can create and edit XML files in a text format using the XML Schema design view of XMLspy (released by Altova).

Developing XML-to-XML Mappings

To develop an XML-to-XML mapping, what needs to get done is simply to load XML document and XML Schema in MapForce (released by Altova) and to drawn drag connecting lines between the elements or attributes of the source and target.

Generating Program Codes

MapForce generates XSLT style-sheets program codes for marshalling medical data from the source to the target content model. All code generated by MapForce can easily be used in XML data transforming.

Results

Exchange technology of medical information survey

There are no standards for medical information using XML interface, other than the MML until now in Japan. In European countries, the most popular standard is the Electronic Data Interchange (EDI) according to the UN/EDIFACT (United Nations/Electronic Data Interchange For Administration, Commerce and Transport standard) which is the message exchange standard for trading established by the United Nations to allow exchange of structured data. Furthermore, the Netherlands has developed a protocol called MEDEUR for medical purpose using the EDIFACT standard. The medical association in

the Netherlands is managing this system. In the United States, the Health Level Seven (HL7) is generally used to exchange medical information, and the HL7 SGML/XML Special Interest Group is developing the HL7 Document Patient Record Architecture. The MML is mainly designed to describe comprehensive medical information. In contrast, the HL7 is designed to exchange the database for each specific purpose (use case). Since many trials other than MML and HL7 are reported for structuring medical records with XML increasing need to transform one markup to another markup develops. ASTM E31.25 subcommittee, "XML DTDs for Health Care" is formed to enhance existing levels of interoperability among the various XML/SGML standardization efforts, products and systems in health care.

The rules for the exchange technology of the medical information are already in place. However, it is expected that various challenges and difficulties will happen at the next step when we start to use these technology in the medical information system [2]. Easy-to-use and the inexpensive system are hoped for as a medical information exchange system.

In the next stage of the survey of exchange technology of medical information, we will focus on a verifying effectiveness of the XML interface as the exchange standard while checking problems from implementation.

Proposed system architecture

As shown in Figure 1, although it was necessary to convert into common format on the client side, there were some problem in the user operation and in the cost. On the other hand, proposed system that to do data exchange in an integrated server is seem to be a ideal method. We expect that current problem can be solved (Fig.1).

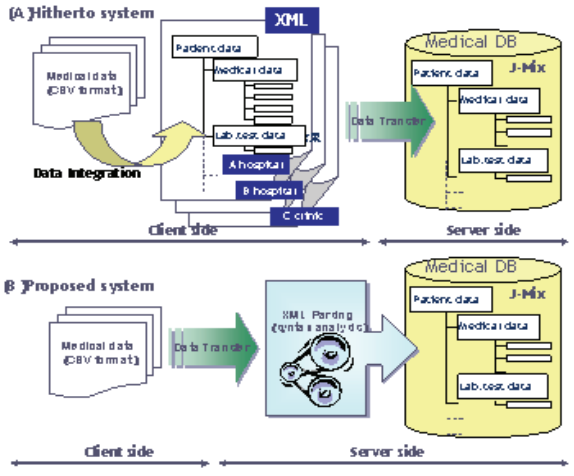

Figure 1 - Schematic diagram of Comparison between hitherto system and proposed system

XML schema design

First, to establish an analytical procedure of the medical data, the medical facilities were classified into the types of university hospitals, clinics, and National Hospitals. Medical information used by a certain medical facility type was described in terms of XML (XML document). Second, our XML schema was designed according to the types of university hospitals, clinics, and National Hospitals and data modeling (start XML schema). Furthermore, XML schema provides common medical information to each medical facility type (sample XML schema). Finally, we are aiming at making a model of XML schema for medical records that can be used in common with each medical facility group (model XML schema, as shown in the Figure 2 below. The XML element in this research was selected referring to J-Mix which is standardized medical terminology in Japan.

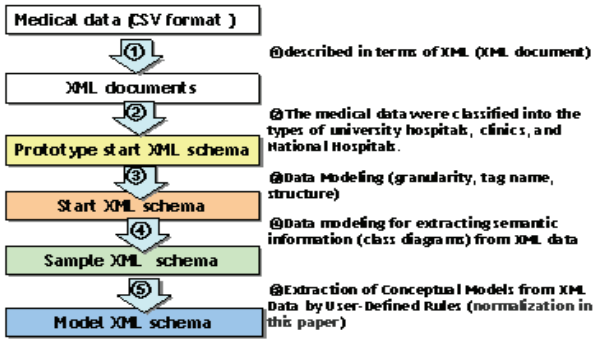

Figure 2 - Schematic diagram of making an model XML schema that can be used in common with each medical facility group

Conclusion

Our approach is also good for the infrastructure to improve the quality and accessibility of health care and to enable the delivery of integrated health care services (Fig.2). In the future, the technological approach for implementing the regional medical information system is based on XML, while its underlying capabilities allow for dynamic navigation according to personalized end-user preferences and authorities.

Methods

1.XML text Viewing and editing

We can create and edit XML files in a text format using the XML Schema design view of XMLspy (released by Altova).

2.Developing XML-to-XML Mappings

To develop an XML-to-XML mapping, what needs to get done is simply to load XML document and XML Schema in MapForce (released by Altova) and to drawn drag connecting lines between the elements or attributes of the source and target.

3.Generating Program Codes

MapForce generates XSLT style-sheets program codes for marshalling medical data from the source to the target content model. All code generated by MapForce can easily be used in XML data transforming.

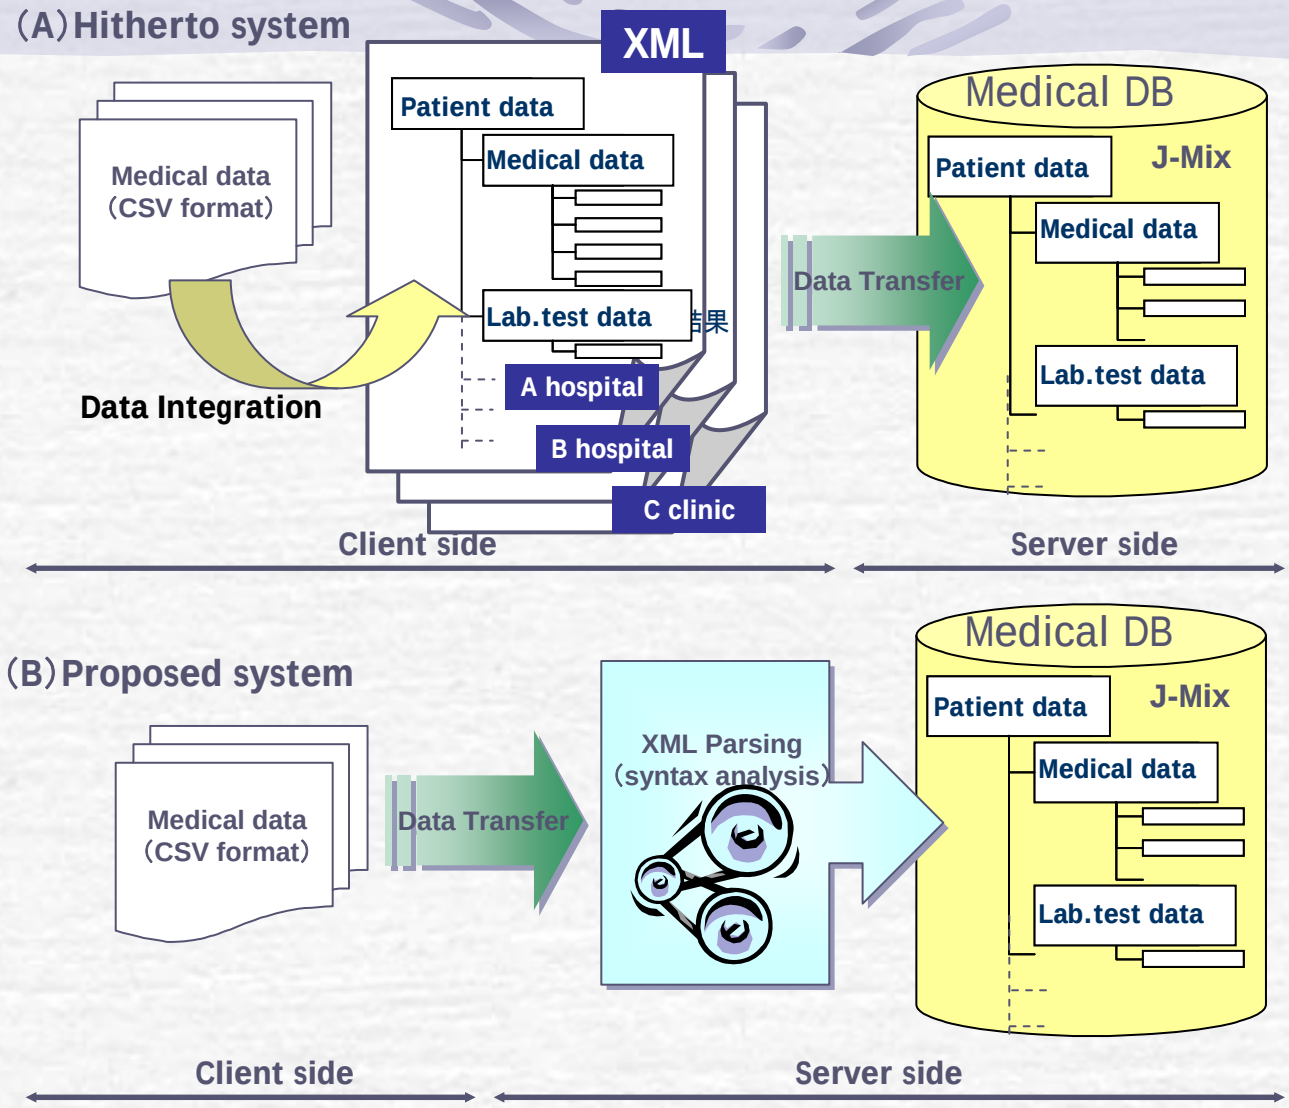

Fig. Comparison between hitherto system and proposed systems.

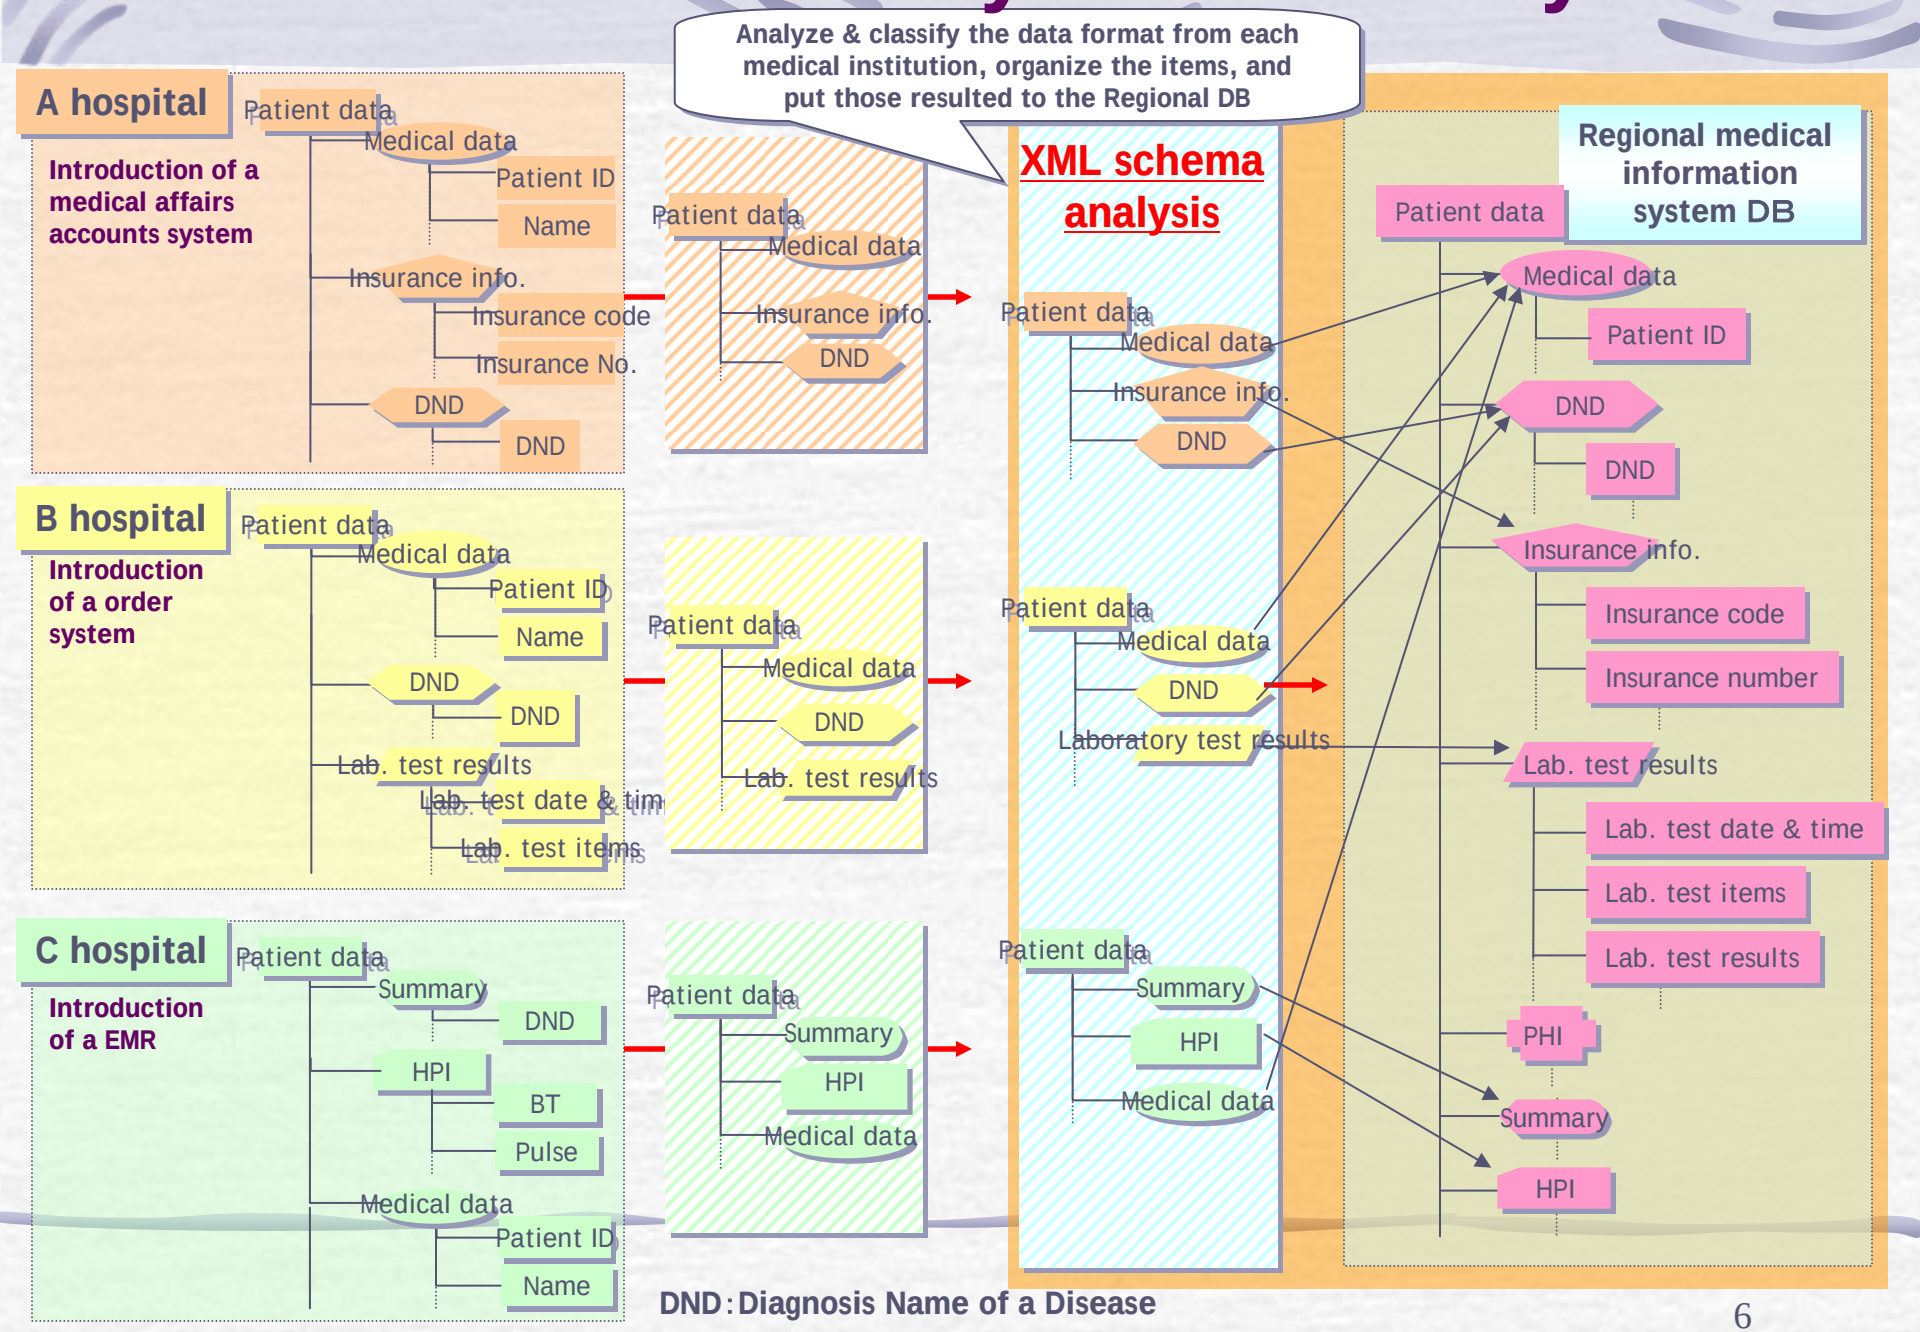
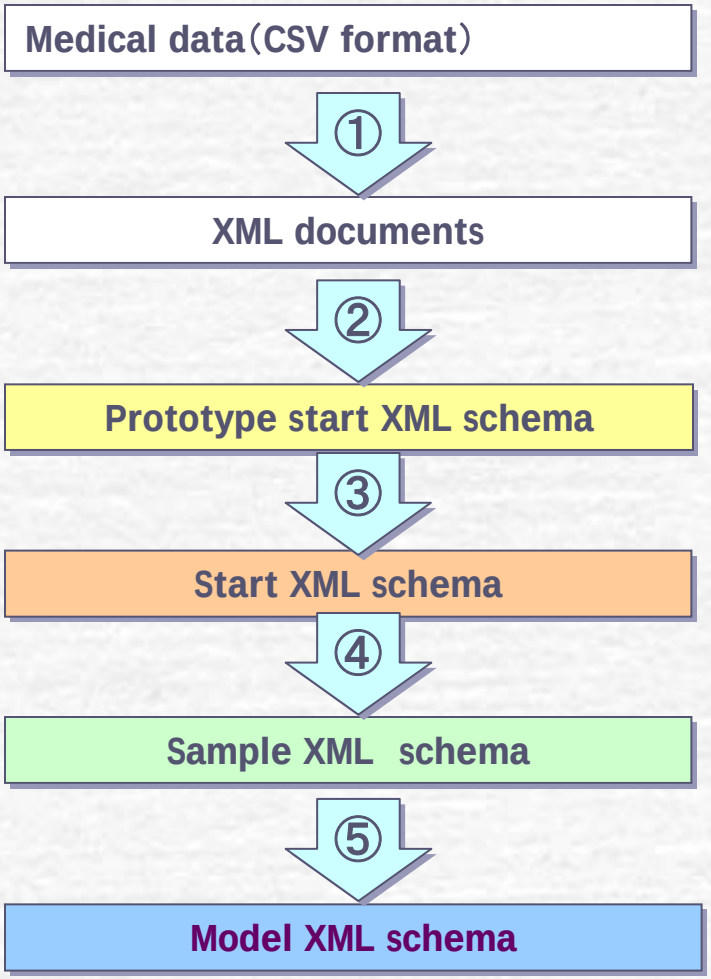
XML schema analytical summary





①described in terms of XML (XML document)

②The medical data were classified into the types of university hospitals, clinics, and National Hospitals.

③Data Modeling (granularity, tag name, structure)

④Data modeling for extracting semantic information (class diagrams) from XML data

⑤Extraction of Conceptual Models from XML Data by User-Defined Rules (normalization in this paper)

Everyone's a winner, baby?

Sue Whetton[a], Jon Hilton[b]

[a] *University Department of Rural Health, Tasmania*

Abstract

Electronic health records have the potential to become the cornerstone of sustainable health services for the future. Before this can occur there are a number of risks that need to be managed. Existing risks relate to finding the balance between privacy and adequate access, and to developing systems that minimise the potential for unauthorised or illegal use of information. Current approaches, at least in Australia, are somewhat chaotic. Nevertheless, it is anticipated that these risks will be managed. Future risks are a cause for concern. As the electronic health record becomes more comprehensive and more accessible, there will be increasing pressure from a range of non-health care organisations for access to the information. The proposed uses for this information may not always be in the interest of the consumer. Health informatics professionals should be aware of this possibility, should contribute to any discussion around potential future use of health information and understand that the systems they help to build may be used in such a way that not everyone will be a winner.

Key words:
privacy, security, electronic record, risks

Introduction: sustainable health services

Health informatics has the potential to support dramatic and widespread changes to the structures and processes of our health care systems. Such changes are increasingly viewed as essential for the sustainability of health services in the future [1, 2]. It is a view shared by health professionals and consumers alike. A 1998 survey of patient satisfaction, sponsored by the Harvard School of Public Health, found that in each of three countries—the USA, Canada and Australia—79 per cent of the population said their system needs either 'fundamental change' or to be 'completely rebuilt'. The same sentiment was expressed by 89 per cent in New Zealand and by 72 per cent in the United Kingdom [3]

There are different ideas about how a fundamentally changed and presumably more sustainable, health care system will look and operate. Berwick [1] envisions a system that offers '24/7/365 access to help that is uncompromising, meeting whatever need exists, whenever and wherever it exists, in whatever form requested.' While this is more than most think possible, or perhaps even desirable, there is consensus that in a sustainable system, information is the key and that the increasing use of technological and other information and communications systems to access this information will fundamentally change the way health care services are structured and accessed. And for many, the electronic health record will be at the heart of these changes. It is the electronic health record that will finally deliver the health informatics promise of more effective and efficient health services, better quality care and long-term positive health outcomes for individuals and the community as a whole.

At the same time, this vision is tempered by the realisation that we need to manage the very real risks inherent in the implementation of an electronic health record. These can be considered as existing risks and potential future risks. Existing risks are widely discussed in the literature and relate to the need to maintain the privacy of the individual consumer while ensuring appropriate access for health professionals involved directly in the provision of health care or seeking access to data for secondary purposes. Existing risks also include those around the potential for unauthorised access and use of data from electronic records. Future risks refer to the potential for a broadening the range of legitimate uses of health data. Griener [4] suggests that we need to be vigilant and not assume that these will always be benign. In other words, although it is widely anticipated that mechanisms will be developed to effectively manage the risks and facilitate the benefits, we should not assume that everyone's a winner (baby).

Managing existing risks

Efforts to manage existing risks focuses on maintaining the privacy of the individual, ensuring appropriate access for authorised health professionals and developing mechanisms to minimise unauthorised access and use of data.

The sensitive nature of much health data and information means that privacy and confidentiality need to be stringently protected. The consequences of breaches of privacy and confidentiality can range from embarrassment arising from disclosure of sensitive information to serious discrimination, including bias by health carers, insurance organisations, and employers. Enquiries suggest that abuse of personal health information is not uncommon, and offenders are often organisations who should know better [5]. However deciding on what information should be kept confidential is not always straightforward. The purpose of

an electronic health record is to ensure that useful and relevant information is available for use by properly authorised people. This raises the question: *what is relevant?* While some (health professionals in particular), might answer 'Why, everything, of course', others will not be so sure. As the NSW Ministerial Advisory Committee observes 'Even seemingly innocuous information can be contentious. The fact that a person was treated in a particular hospital or location, such as a prison or sexual health centre, could indirectly reveal information about the person. Even though summary information such as name of hospital and health provider may not appear to be 'health information' as such, to the extent that it reveals something about a person's health status it may need to be treated with the same sensitivity as other health information [5].

Nor is there a straightforward answer to the question of who might be considered as 'properly authorised.' Everyone seeking access to information may consider themselves properly authorised. Patients may not agree and this gives rise to one more question: *Who decides these things?*

The health care environment comprises many stakeholder groups with different, sometimes conflicting views and priorities. This is demonstrated at the strategic level where the perceived relative importance of privacy and confidentiality varies between different stakeholder groups. A Report on Research Challenges in E-Health Technologies identified patient privacy as a primary issue for both research and the practice of health information management [6]. Yet health executives responding to the Commonwealth Fund International Health Policy Survey [7] viewed privacy concerns as less of an issue than start-up costs, maintenance costs and lack of standards (Table 1).

Table 1- Major barriers to greater use of computer technology

Per cent naming	*Aust*	*Can*	*NZ*	*UK*	*USA*
High start-up costs	84	84	93	69	71
Projected maintenance costs	49	42	32	52	27
Lack of uniform standards	49	35	50	31	44
Privacy concerns	20	26	7	8	17

Commonwealth Fund International Health Policy Survey

This suggests that there will therefore be situations when a balance will need to be struck between the priorities of different stakeholders. Unfortunately all groups are not equally represented in such discussions. More powerful groups are often able to exert more influence than marginal groups and consequently there may be situations where everyone is not a winner. Consider the following perspectives:

- Health Minister, Tony Abbott has put federal health IT bureaucrats on notice saying he expects tangible results within a year – specifically, a functioning electronic health record and accompanying smartcard system – or heads would start to roll [8].
- I am writing to question the need for or value to be gained from a privacy forum. There seem to be many other issues that are more pressing…We feel that most practitioners are very familiar with general privacy requirements… the problem is really only around how privacy is handled in the electronic referral environment [9].
- Sure there'll be breaches in privacy – but we can deal with those as they happen – the main thing is to get an electronic health record out there [10].
- It's very hard to retrofit and put privacy in at the end…we say build it in…Health information is seen as sensitive, so there are extra safeguards that apply to it… potentially there are a lot of bad outcomes if health information isn't appropriately looked after… [11]

Arguably, all stakeholder views should be able to be accommodated. However, if we consider the role and relative influence of the stakeholder groups, the reality is that some stakeholder views prevail, while others are marginalised.

- Governments pass legislation, establish policies and provide many of the resources to enable health care organisations to develop electronic health records, particularly where health care is partially or fully resourced from public funds. This translates into a significant ability to shape the views and activities of organisations and services.
- Senior management within health care organisations also set strategic directions that shape the development of electronic health records. Health care organisations seek to provide high quality, efficient services to the greatest number of consumers at the lowest cost. For private health care organisations, a profit margin may also be part of the equation. Health organisations have finite resources and many demands for these. The views of senior management will set parameters around the nature, scope and priorities of electronic health record projects. A focus on efficiency, technology or quality care will produce different issues and different outcomes.
- Health professionals are concerned with providing high quality care for their patients. They will therefore view the development of electronic records in terms of

relevance to, and effectiveness in furthering this goal. While clinicians support the principle of the right information in the right place at the right time, many are reluctant to give up their role as owner of the medical record and possibly arbiter of 'the right information in the right place'. The traditional status of the clinician in the biomedical model of health care bestows a considerable ability to influence discussion around this issue.

- Health informatics professionals are also able to influence the form and functions of an electronic record, but may temper their views for pragmatic reasons such as government support for their organisations. Alternatively, as a recent survey by the Health Informatics Society of Australia (HISA) suggested, heath informatics professionals may consider privacy issues to be important, but do not necessarily view the non-technical elements as being in their domain (One comment illustrating this point was: *The problem with the privacy debate is that the Australian government has not set up clear privacy legislation*.)
- Consumers are arguably the least influential stakeholder group. Horsfield and Peterson [12] suggest that consumers are not only marginalised, but also mediated – issues identified as of importance to consumers may reflect the concerns of the mediating group. Consumer issues currently tend to focus 'educating them' about the benefits of an electronic health record and the meaning of informed consent. Consumer representation at the strategic level of discussion and decision making is limited. While limited representation is better than none at all it is clear that consumer influence is somewhat less than many other stakeholder groups.

The challenge of obtaining a balance between privacy and security issues, and appropriate access to information by properly authorised individuals becomes more pressing and more complex as the increasing sophistication of electronic health records enables more and more information to be collected, stored and disseminated across departments and organisations. The complex mix of users and technical standards found in the health care environment make privacy, security and appropriate access significant challenges.

Responding to existing risks

The current approach to managing the need for privacy and authorised access includes a combination of legislation and professional self-regulation in the form of codes of ethics, supported by governance arrangements the development and use of electronic health records.

Unfortunately, legislation in Australia at least, is not straightforward. Table 2 shows the multiple jurisdictions each with their own complex legislation.

Table 2 - Privacy Specific Legislation and Administrative Instructions

Jurisdiction	Public Sector	Private Sector
Commonwealth	Privacy Act 1988 (Cth)	Privacy Act 1988 (Cth)
Australian Capital Territory	Health Record (Privacy and Access) Act 1997 (ACT) Privacy Act 1988 (Cth)	Health Record (Privacy and Access) Act 1997 (ACT) Privacy Act 1988 (Cth)

Western Australia	None	Privacy Act 1988 (Cth)

(Source: NEHTA's Approach to Privacy Version 1.0, July 2006)

Most Australian privacy legislation is built around a set of *privacy principles* with the concept of *informed consent* playing a major role in their application. Inherent in the privacy principle is the understanding that the right to privacy can never be absolute. No matter what the jurisdiction or type of information, there will always be situations that require a decision to be made around competing rights: while consumers of health care have a reasonable expectation that they should be able to control access to their information, this right may conflict with health care providers need to access accurate and up to date information, with the public health official's need for information to prevent or manage major public health risks or even with the government official enacting overriding legislation such as the National Security Information (Criminal and Civil Proceedings) Act 2004. This Act, a response to perceived security threats, is a suite of legislation that can lead to individual privacy being overridden by "the common good", while protecting the administration's right to privacy in.

Informed consent therefore clearly should include the understanding that this is so. It should also include the understanding that legislation is always subject to change,

Health informatics professionals should understand the complexities of informed consent and the possible consequences arising from the systems they help to create. Professional codes of ethics are intended to provide guide-

lines to this end. The IMIA Code of Ethics, for example, outlines a number of principles and rules for ethical conduct such as 'HIPs have a duty to ensure, to the best of their ability, that appropriate structures are in place to evaluate the technical, legal and ethical acceptability of the data-collection, storage, retrieval, processing, accessing, communication, and utilization of data in the settings in which they carry out their work or with which they are affiliated' [13].

To facilitate effective privacy-confidentiality-access of electronic health records, legislation and codes of ethics need to be supported by strong governance arrangements. The broader the reach of an electronic health record, the greater the number of individuals seeking access and the greater the amount of information stored in such records, the greater will be the need for strong governance. Current responses to the need for broad-ranging governance structures are many and varied, and generally ad-hoc, This is almost inevitable in a health care environment where the ultimate responsibility for maintaining privacy falls to the health care provider. Practitioners who work for a publicly funded health service will also be accountable to that service, which will be accountable to a funding body or bodies. Private providers may be accountable to insurers, shareholders, medical indemnity organisations. All of these layers of governance will be involved to some extent with the privacy aspects of a shared EHR. It is, however, leading to 'uncoordinated silos… governance by default where mechanisms are introduced one at a time to address a particular need' [14]. This does little to address the potential risks inherent in electronic health records.

These risks relate to processes utilised in the collection, storage and sharing of health information in electronic health records. While they pose a significant challenge, it is not unrealistic to expect that mechanisms will be developed to effectively manage them and thus deliver the promise of more effective and efficient health services, better quality care and long-term positive health outcomes for individuals and the community as a whole. Everyone will be a winner.

The same may not be true of future risks which relate to potential new uses of information contained in an electronic health record

Future risks

The majority of discussions around privacy, confidentiality and access to information focus on minimising the risk of unauthorised and illegal use of information contained within the electronic health record. These discussions are underpinned by the assumption that those determining appropriate and legal use will get it right, while at the same time begging the question of whether what can legally be done with information is always in the interests of the individual.

There is some concern, however, that this may not always be the case. As the electronic health record becomes more comprehensive and more accessible, it is suggested that there will be increasing pressure from a range of non-health care organisations for access to the information and that the proposed uses may not always be in the interest of the consumer [4, 6, 15]. Indeed, there have been incidents already that suggest this may be so. The West Australian police recently used Guthrie test samples to match DNA samples taken from a crime scene [16]. This may well appear to be a legitimate use of such material – we all want to see criminals apprehended. However, would this still be acceptable if content from medical records were provided to insurance companies or employers? The New South Wales Ministerial Advisory Committee on Privacy and Health Information [5] flagged this possibility when it suggested that 'there may be increasing pressure and demands placed on the information by non-health care bodies (for example insurers, employers, law enforcement agencies and some government agencies)'.

A recent report published in the United States included homeland security in a list of potential uses for an electronic health record [4], while comments on the proposed Australian Department of Human Services Access Card noted that 'the government had played a clever game of avoiding engagement on privacy issues' [17] and 'the more details that are settled, the more certain is the loss of control over our personal information' [18].

It can be concluded that health data that we are happy to share now may become a liability in the future.

While we are not advocating cessation of work on the electronic health record, these future risks are a cause for concern. Clearly, there is a need for a wider, fully informed public debate, one in which we, the health informatics community, have a responsibility to speculate, debate and engage both our own members and the wider community.

A requirement is an open and public discussion about the legitimate uses of health information. Many of the proposed secondary uses have a great initial attraction, but others clearly require that much greater deliberation be carried out in a public setting [4].

Everyone's a winner, baby? (Risks relating to potential uses of health information in Australia)

Sue Whetton
University of Tasmania

Jon Hilton
Project Net Pty Ltd

The vision

- There is a vision that the electronic health record may deliver the health informatics promise of more effective and efficient health services, better quality care and long-term positive health outcomes for individuals and the community as a whole

Reality check

- At the same time, this vision must be tempered by the realisation that we need to manage some very real risks inherent in the implementation of an electronic health record
- Privacy and confidentiality are significant issues that need to be addressed

The focus

- The majority of discussions around privacy, confidentiality and access to information focus on minimising the risk of unauthorised and illegal use of information contained within the electronic health record

Assumptions

- These discussions are underpinned by the assumptions that
  - Those determining appropriate and legal use of information will get it right
  - What can legally be done with information is always in the interests of the individual
- This may not always be the case

Demands

- The New South Wales Ministerial Advisory Committee on Privacy and Health suggested:
  - As electronic health records become more comprehensive and more accessible, there may be increasing pressure and demands placed on the information by non-health care bodies (for example insurers, employers, law enforcement agencies and some government agencies) [1]

One example

- The proposed uses of this information may not always be in the interest of the consumer
  - The West Australian police recently used Guthrie test samples to match DNA samples taken from a crime scene [2]
  - This may appear to be a legitimate use of such data – we all want to see criminals apprehended

Widening access

- Would it still be acceptable if content from medical records were provided to insurance companies or employers?
- Or even, as flagged in a recent report published in the United States, for homeland security and other surveillance activities? [3]

Consider

- We need to be aware that health data that people are happy to share now may become a liability in the future
- Many of the proposed secondary uses have a great initial attraction, but others clearly require that much greater deliberation be carried out in a public setting

Tackling the issues

- The consequences of these potential legitimate uses of data are not being fully discussed
- Comments on the proposed Australian Department of Human Services Access Card noted that
  - the government had played a clever game of avoiding engagement on privacy issues [4] and
  - the more details that are settled, the more certain is the loss of control over our personal information [5]

Our responsibility

- We are not advocating cessation of work on the electronic health record, but these potential uses of health information need to be considered
- There is a need for a wider, fully informed public debate
- It should be a debate in which we, the health informatics community, have a responsibility to speculate, debate and engage both our own members and the wider community

The Solution for Consent Form in EMR System

Kyung-Duck Kim[a], Young Ah Kim[a], JungJin Park[b], Jung Ro Lee[b], Hyungil Lee[a], Yong Oock Kim[c], ByungChul Chang[d]

[a]Dept. of Medical Informatics, Yonsei Univ. Medical Center,
[b]Institute of EHR, Yonsei Univ. Medical Center
[c]Dept. of Plastic & Reconstructive Surgery, Yonsei Univ. College of Medicine,
[d]Dept. of Cardiovascular Surgery, Yonsei Univ. College of Medicine

Abstract and objective

The EMR(electronic medical records) system is a motive to stir up the various issues which exist already in medical areas, such as the protection of the privacy, sharing of medical information, the law of the signature etc.

Among those issues, the management of various consent forms in EMR system is one of the problem awaiting solution. Consent form for operation and various procedures etc should kept several numbers of written signatures because it is basic document for problem solving with insurance company or legal problem. In Korea, the originality of consent form is kept by written signature or seal, so it is strictly required for all the consent forms legally. However, there has been no specific solution of this issue for the EMR system, because there is no same strategic solution as same as paper based consent form (PBCF). This research is for suggestion of safe strategic solution of consent form and its signature for EMR system.

Keywords:

consent form, EMR, digital pen

Introduction

The number of Medical Consent Form (MCD) has been increased continuously due to legal problem and unique Korean medical system, which is characterized by fee for services. So, many consent forms are required not only operation and procedures, even for the payment of medicine. So, consent form directly affect the financial management of hospital in Korea. Many hospitals and private clinics are implementing new EMR system to adapt new environment of medical system, however, there is no proper legal policy for managing consent forms' signature and digital consent file, yet. Therefore every hospital use paper based consent form for direct hand written signature and keeping original document, and then uploads consent form to EMR system by individual scanning. This makes job duplication and difficulties on managing consent forms of two different characteristics.

This study was postulated to suggest strategic stream of electronic signature based on the Electronic Medical Consent Form (EMCF), and verify its technical possibility based on the concept of originality, confidentiality, reproducibility of EMCF.

Methods

Severance Hospital's EMR system has been developed on the Environment of C#.NET and Windows XP with Microsoft Framework v. 1.1. And as materials for Client, on the basis of Windows XP environment, we selected digital pen as s signature image tool and make consent form by MS WORD.

The postulated steps are as followed:

1. Separation of Signature from Consent Form
2. Endowment of authorization of signature via image file
3. Combination of authorized signature and consent form
4. Creation of one XML documentation with signature image & Public certification key
5. Storage of XML file & Deletion of image file of signature

Result

The strategy is postulated on the same basis of paper consent form. The consent form was composed written part and signature part, which should kept image of signature or seal. The one time signature can makes one original consent form securely through above steps. This process can keep the current concept of consent form, so called originality and confidentiality. The digital pen can create hand written image for EMCF same as for the paper. The originality can be kept by separation, combination, and deletion of signature image, which was done by individuals. The confidentiality can be kept by creation of one XML document with Public certification and deletion of all the other files. For these procedures, there has been a development of new interface modules and UI, master tables for management consent form.

Conclusion

Our suggestion of new strategy and technical solution would give breakthrough to solve the issue of digital consent form with same approach of paper based consent form, especially in Korea. This process can keep the originality, confidentiality, and reproducibility of ECMF.

MR Item as an Intermediate Terminology Between Terms and Clinical Document

Yong Oock Kim[a], Young Ah Kim[b], JungJin Park[c], Jung-Ro Lee[c], Kyung-Duck Kim[b], HanGi Park[d], Hyungil Lee[b], ByungChul Chang[d]

[a]Dept. of Plastic & Reconstructive Surgery, Yonsei Univ. College of Medicine,
[b]Dept. of Medical Informatics, Yonsei Univ. Medical Center,
[c]Institute of EHR, Yonsei Univ. Medical Center,
[d]Dept. of Cardiovascular Surgery, Yonsei Univ. College of Medicine

Abstract

Medical Record System is changing from paper document to electronic document. New era of electronic medical document system needs the basic terminology, however, it is difficult to realize Electronic Health Record (EHR) system through current terminology system. For the connection between terminology and clinical document (CD), the Medical Record (MR) item was innovated as a new concept. The basic concept and result of MR item is discussed.

Keywords:

terminology, EHR, MR item, CD

Introduction

The Clinical Document (CD) is a document that contains whole information derived from the process of interaction between patient and medical professionals. This kind of stored data should not be changed and interpreted differently as times go by. So, the structured terminology system has been developed, such as UMLS, SNOMED-CT, etc. However, authors find that terminology itself can not describe the interrelated characteristics of CD. We need more properties for the term and CD to express in reality. As an intermediate concept, so called MR item was used between terminology and CD.

Methods

All data was retrieved from the Electronic Health Record (EHR) system of one hospital located Seoul, Korea. The hospital has 2,100 beds, 2,500 clinicians, and 54 medical departments. All content item of CD were collected from 950 paper based CD. All items divided and subdivide by its usage and properties according to its own individual meaning. For this process, document analyzing tool was developed by the methodology of construction of database. This tool involves the variables of code, name of CD, type, unit, division, item group, and sub-item, etc. The collected data was transformed into Excel and MS SQL database to differentiate and extract same meaning in similar CD, same item from different CD, similar structure of items from different CD. The final items were managed by the MR item registration module.

Results

950 paper-based CDs were collected and analyzed. 63,232 terms are collected. The extracted final term with meaning properties, named MR item, are 13,287. Each MR item has 32 meaning variables, such as Type, Character Length, TxtBaseData, Numeric Base Data, Unit, Button Y/N, Action, Multi Line Y/N, Attribute, Width, Height etc. All clinical departments created 1,200 CDs through combination of MR items before implementation of EHR system. Continuous revision of MR item has been done for 1 year after implementation. 9,488 (41.7%) of MR items have been added (total 22,775) and 240 (1.8%) MR items have been changed.

Discussion

The priority of issue was how to create the vast of electronic CD easy to use and accurate to descript. The SNOMED CT has properties of term and concept as its characteristics. This enables to use one concept into several expressions. The other characteristic is the relation definition between terms. These characteristics enable the fine and self-controlled expression of clinical phenomenon. However, it can not express the objective of CD, the usability of CD. As an example, the item ‘admission path’ can be a same item in admission record and triage record of emergency room. if we hypothesize that this item is essential (should be recorded) item in admission record and is optional item in triage note, the SNOMED CT can not express this property, regardless of the content of record. This kind of property is significant for the working process in the real. This is a reason why the CD needs exchangeable property of meaning. It involves data type such as text, numeric, date, time, and etc. Also it involves the properties of check box, radio box, dropdown list, triggering event, whether or not to store in DB, and etc. These properties can be granted to MR item. The essentiality of ‘admission path’ could not be granted at the term level, instead it can be granted at higher level, MR item, in our

system. This intermediate concept of level can facilitate the usability of electronic CD and will maximize the efficiency of work process through CD.

The initial number of MR item has been increased continuously and only 1.8% of MR item has been changed. This means self-development and it would give maximum utility of EHR system.

Conclusion

The MR item, as an intermediate concept between terminology and clinical document, would facilitate the usage of clinical document and implementation of EHR system.

Functional Analysis of Health Information System in Public Health Centers Focusing on Health Business Programs

Eun-Jung Oha, Kyung-Hee Parka, Jin-Sun Kima Sun-Hee Choa,b
Sung-Hee Parka, b Jong-Min Kimc, Jeong-Wook Seo[d]

[a] *Center for Interoperable EHR, Korea*
[b] *Seoul National University College of Nursing, Korea*
[c] *Department of Neurology, Seoul National University College of Medicine, Korea*
[d] *Department of Pathology, Seoul National University College of Medicine, Korea*

Abstract

The purpose of this study is to analyze the functionalities of Health Information System in Public Health Centers focused on Health Business Program. Field research was performed in accordance with the business guidelines of the Ministry of Health and Welfare. After analyzing the users' requirement and the functionalities of the system, we suggest a model of functionalities for interoperable EHR system. This will help to promote application of health information system and to improve efficiency of Public Health Centers.

Keywords:

Health Information System, public health Centers, health business program, health electronic health record

Methods

There were many Health Business Programs in Public Health Centers. To analyze function, we had to choose several Health Business Programs, which were considered as a important business and each had different work processes.

Nine Health Business Programs which recognized as key Health Business Programs in Public Health Care were selected.

Then, they have classified into following three categories: The First includes the Health Business Program which was managed by the local Health Information System. Second category includes the Health Business Program which was not managed by the local Health Information System but was managed by web system in common. Consequently, the personnel in charge of Health Business Program can't manage the cases by using their own Health Information System. Third category includes the Health Business Program has no Health Information System, so it was performed manually.

The methods of this study are as follow.

Analysis of the work process

Questionnaires and field interview survey were conducted at six Public Health Centers in Korea. And people in charge of each health business program named business manager were interviewed. After their work processes were inspected carefully, the functions of health information system and works performed manually using MS Excel or Word were investigated.

To show the functionalities, Unified Modeling Language (UML) was used, which showed the work process functionally.

Analysis the system of health business programs

The functions of business process of Health Information System that the manager use were analyzed. Functions were categorized into following three: mega process, major process and sub process.

Results

Analysis the work process

The health business managers perform the work of Health Business Program. They register the clients in Health Business Program and perform it. For example, they visit client's home and provided health care service. They also support the medical finance to the clients that allowed to reimbursement. And then the business managers report the results and statistics to the superior part . By these process, the clients are managed.

In short, it was analyzed that they have three mega processes. We called these functions as "registration", "acting" and "management"(Figure 1).

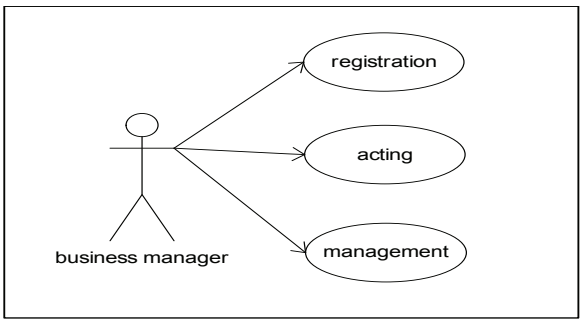

Figure 1 - Usecase Diagram: Health Business Program

Each Mega process was analyzed more detail level as following usecase diagram.(Figure2, 3, 4)

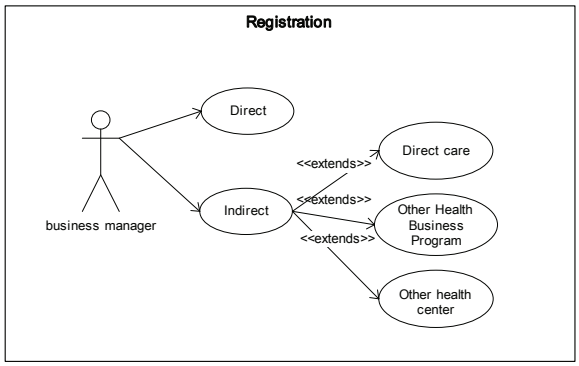

Figure 2 - Usecase Diagram: Registration

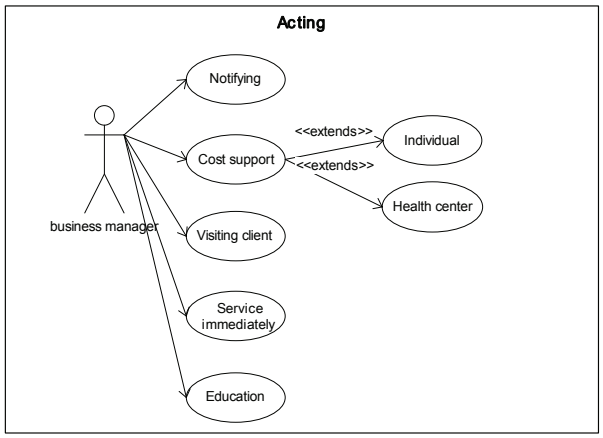

Figure 3 - Usecase Diagram: Acting

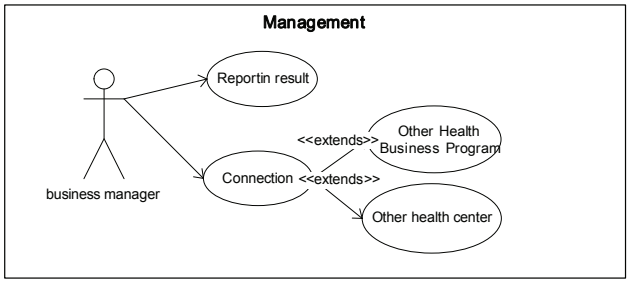

Figure 4 - Usecase Diagram: Management

Analysis the system of Health Business Programs

In Health Business Program, Health Information System hardly has been developed . Even in the case that the Health Information System has been developed, the business managers rarely use Health Information System., because the Health Information system in Public Health Centers couldn't support the functions that can interface among other Health Business Programs, and communicate between Public Health Center and other Health Centers. They are the most important functions for the business managers to perform their work. The functions of interface also are the core functions for the interoperable EHR system.

So, several symbols are marked. A Mark "" means that the function was performed by using Heath Information System in Public Health Center. A Mark "" means that the function was performed by using website in common system. Finally a mark "" means that the function doesn't have any Health Information System, so business managers performed manually.

Health Information System should be developed reflecting the end users' requirements. Our study could be helpful to engineers who develop Health Information System , so they could have a good understanding of medical domain. And that can help to reflect the users' requirements. Furthermore, the Health Information System would be adopted various Health Business Programs. Eventually these make increasing the efficiency of the user's business and make sure the implementation of interoperable Electronic Health Record System.

a Center for Interoperable EHR, Korea

b Seoul National University College of Nursing, Korea

c Department of Neurology, Seoul National University College of Medicine, Korea

d Department of Pathology, Seoul National University College of Medicine, Korea

Abstract

- The purpose of this study
  - is to analyze the functionalities of Health Information System in Public Health Centers focused on Health Business Program.
  - Field research was performed in accordance with the business guidelines of the Ministry of Health and Welfare. After analyzing the users' requirement and the functionalities of the system, we suggest a model of functionalities for interoperable EHR system.
  - This will help to promote application of health information system and to improve efficiency of Public Health Centers.

Methods (1)

- There were many Health Business Programs in Public Health Centers.
  - To analyze function, we had to choose several Health Business Programs, which were considered as a important business and each had different work processes.

- Nine Health Business Programs which recognized as key Health Business Programs in Public Health Care were selected.

Methods (2)

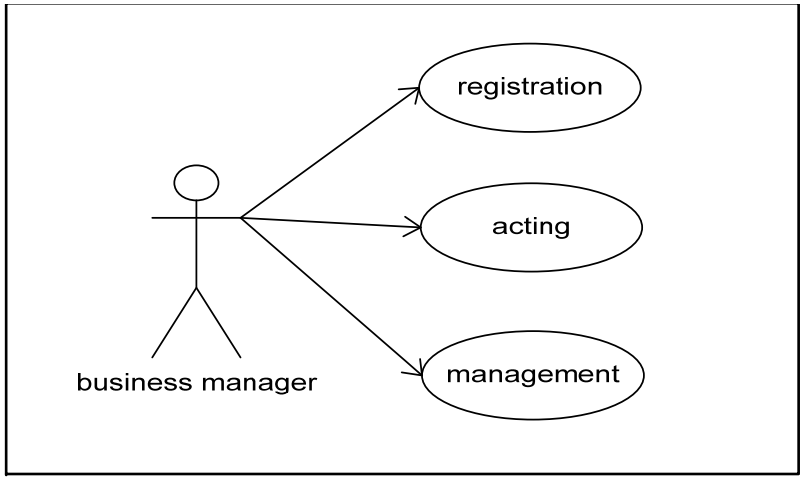
- Then, they have classified into following three categories:
  - The First includes the Health Business Program which was managed by the local Health Information System.
  - Second category includes the Health Business Program which was not managed by the local Health Information System but was managed by web system in common. Consequently, the personnel in charge of Health Business Program can't manage the cases by using their own Health Information System.
  - Third category includes the Health Business Program has no Health Information System, so it was performed manually.

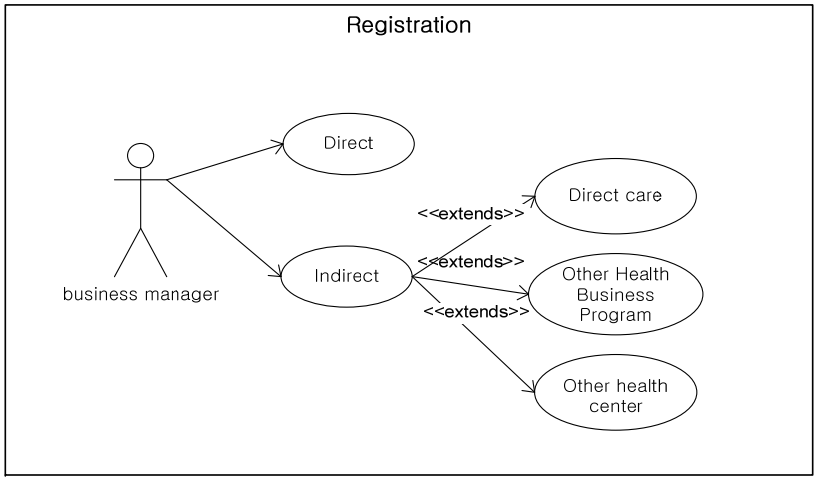
Methods (2)

- Analysis of the work process
  - Questionnaires and field interview survey were conducted at six Public Health Centers in Korea. And people in charge of each health business program named business manager were interviewed. After their work processes were inspected carefully, the functions of health information system and works performed manually using MS Excel or Word were investigated.
  - To show the functionalities, Unified Modeling Language (UML) was used, which showed the work process functionally.
- Analysis the system of health business programs
  - The functions of business process of Health Information System that the manager use were analyzed. Functions were categorized into following three: mega process, major process and sub process.

Results(1)

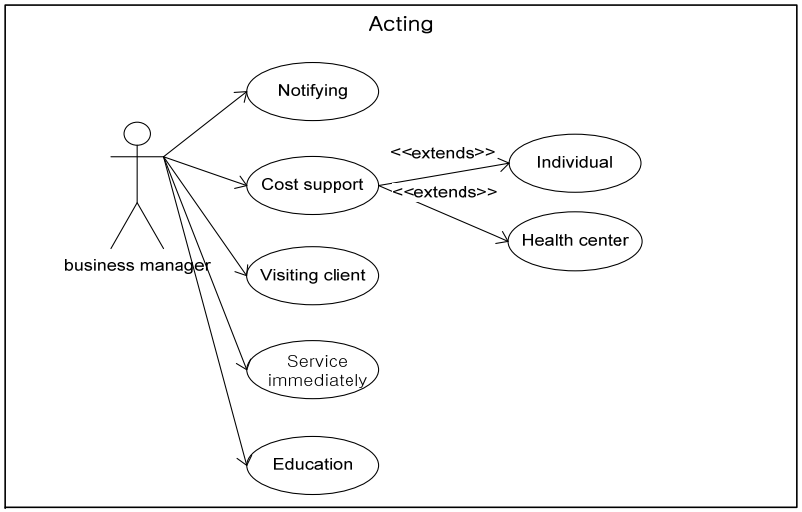
- Analysis the work process

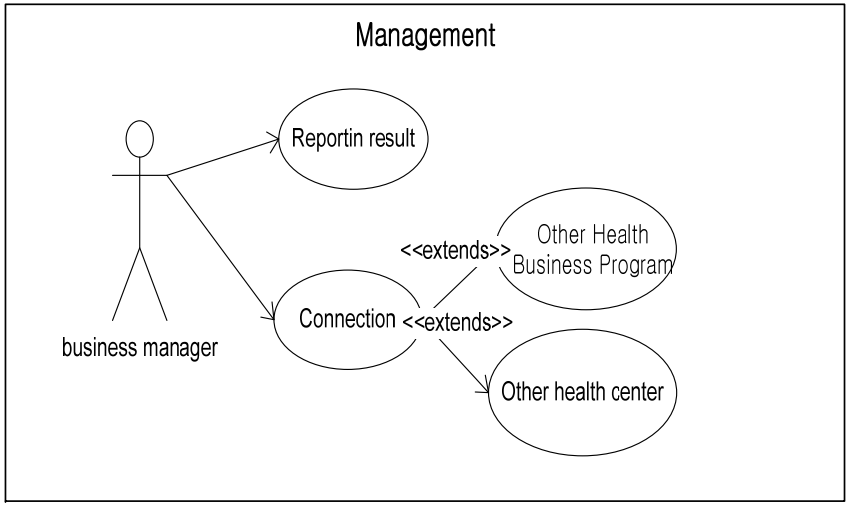




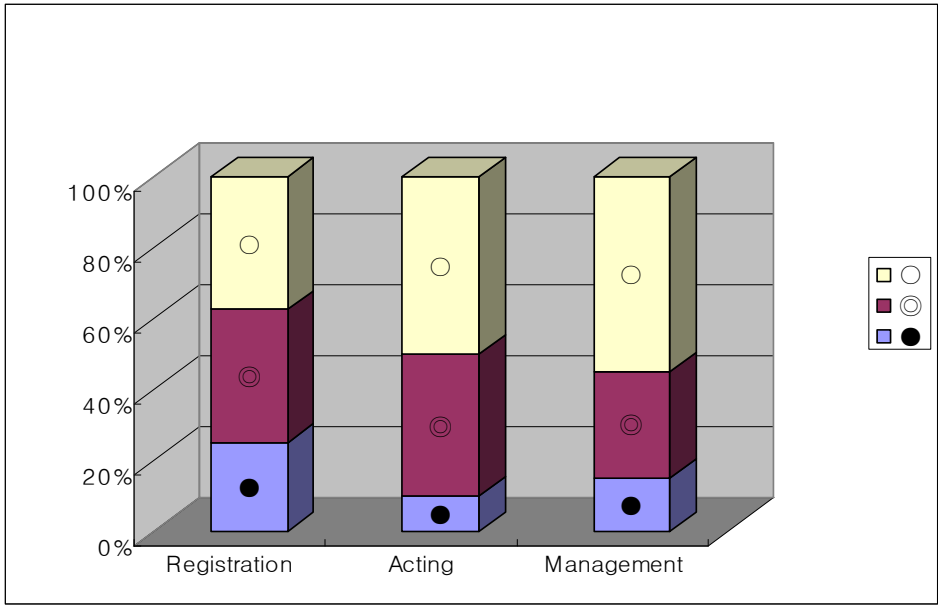
Results(2)

- Analysis the work process





Results(3)



Rate of functional using the Health Information System
(Sub process level)

Conclusion(1)

- Health business programs in public health center are recognized recently as essential activity of information system in Community Health. But actual condition can not support the effective management because there is little information system developed efficiently. From now on, establishing a health information system will be demanded for EHR system implementation.

- Health Information System offers an important infrastructure of efficient delivery and use of healthcare services. To develop the information system, it is important to develop a strategy covering the scope of work processes, public and private activities and adequate use of resources.

- So, in this study, we analyzed the function of Health Information System in Public Health Centers focused on Health Business Programs, which are recognized some core businesses in Public Health Centers.

Conclusion(2)

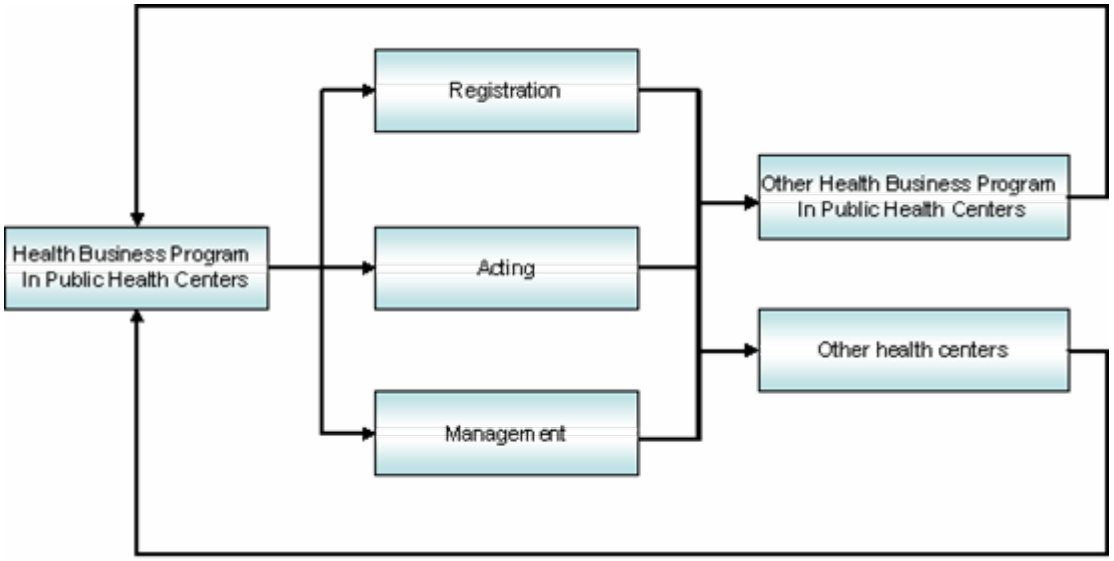
- In Public Health Centers, there are many different Health Business Programs. The Health Information System that supports the Health Business Programs was not integrated into a interoperable EHR system, but it has each Health Information System or has no Health Information System. This is why the functional analysis of Health Information System is significant.

- We showed that it lacks for interoperability on relations with the Systems of other Health Business Programs and the Systems in other health centers.

Conclusions(3)

- For the EHR functionality, health information systems should include functions we suggested. The model for interoperable EHR system will be derived.(Figure 6)

- *Figure 6. Model for interoperable EHR system in public health programs*



Conclusion(4)

- Electronic Health Record (EHR) systems need to offer a flexible framework for recording the consultation process, and accommodate the individuality of the clinician.[5]
- Health Information System should be developed reflecting the end users' requirements.
- Our study could be helpful to engineers who develop Health Information System , so they could have a good understanding of medical domain. And that can help to reflect the users' requirements. Furthermore, the Health Information System would be adopted various Health Business Programs. Eventually these make increasing the efficiency of the user's business and make sure the implementation of interoperable Electronic Health Record System.

Preliminary Design of the Interoperable EHR Data Architecture in Korea

Myoung-Ju Jeon[a], Ein-Jeong Hwang[a], Young-Hwan Choi[a], Yoon Kim[ab]

[a] *Center forInteroperable EHR, Korea*
[b] *College of Medicine, Seoul National University,Korea*

Abstract and objective

Today, interoperable EHR architecture is being developed by key advanced countries but at present time, it remains as a high level conceptual model. In Korea, the center for interoperable EHR is currently developing Interoperable EHR architecture[1] to implement efficient national healthcare information network (NHIN). This study presented preliminary level design to define data architecture of interoperable EHR. To this end, the data model derived from this study should be in accordance with international standards such as HL7 Reference Information Model or openEHR Archetype Model.

Keywords:

National Healthcare Information Network, interoperable electronic health record, data architecture

Introduction

International standards related with interoperable EHR are focused on lifetime health record and ensuring interoperability, their difference depends on the use of information model for EHR. According to the experience of countries including US, UK, Australia and Canada, various approach methods have been adopted. Research aiming to obtain semantic interoperability of EHR solution based on standardized terminology is underway, however none have been introduced in detail regarding health and medical related data actually exchanged between EHR solutions yet. The purpose of this study is to define the information to be shared in EHR architecture and to select data elements for providing the NHIN service.

Methods

At first, we surveyed and analyzed the shared clinical information elements in several domestic and foreign studies. In domestic studies conducted in 2000 and 2003 as part of a healthcare information project, standardized data elements were proposed for clinical information exchange among hospitals. Then we added the data elements abstracted from international researches, HealthConnect in Australia[2], Continuity Care of Record (CCR) in US, and the Japanese Set of Identifiers for Medical Record Information Exchange (JMIX) in Japan. In addition, we carried out research on the scope of clinical data exchange between the main hospital and the branch hospital in Korea and found out how they exchange patient referral and result for referral, discharge summary, clinical finding, and medication information. Secondly, clinical information was classified and derived from requirements in EHR business architecture. Also general requirements and information to support data domain classified from the EHR infrastructure were extracted. Lastly, we classified these data elements from above two steps as common and essential data elements.

Results

The sharable data elements in EHR system were suggested in two aspects. One is for the essential 27 data elements including patient demographic information and clinical information such as chief complaint, lab findings, principle diagnosis, etc. regarding discharge summary. The other is 29 information scopes and 377 data elements to exchange healthcare information. The result does not confirm EHR data architecture as the data model for Korea but proposes data items for shared clinical information through verifications made by expert group and survey on domestic medical institutions in the future. Furthermore compliance with international standard shall be considered and ultimately the logical level shall be detailed.

Acknowledgment

This study was supported by a grant of the Korea Health 21 R&D Project, Ministry of Health & Welfare in Republic of Korea (A050909).

Content

Abstract and Keywords

Abstract

Today, interoperable EHR architecture is being developed by key advanced countries but at present time, it remains as a high level conceptual model. In Korea, the center for interoperable EHR is currently developing Interoperable EHR architecture to implement efficient national healthcare information network (NHIN). This study presented preliminary level design to define data architecture of interoperable EHR. To this end, the data model derived from this study should be in accordance with international standards such as HL7 Reference Information Model or openEHR Archetype Model .

Keywords

National Healthcare Information Network, Interoperable Electronic Health Record, Data Architecture

Introduction

- Providing Lifetime EHR for ensuring consumer rights and improving self-care through Korea National Health Information Network
- Ensuring interoperability through International standards related with interoperable EHR
- But,

  according to countries such as US, UK, Australia and Canada, various approaches and information models for EHR have been adopted.
- Also,

  none have been introduced in detail regarding the actual clinical information that needs to be exchanged between medical institutions yet.

Methods

Approach → Survey & Analysis → Classification & Propositon

1 Survey and Analysis

- The shard clinical information elements in domestic studies
- The shard clinical information elements between domestic hospitals
- The shard clinical information elements in foreign studies

2 Classification

- From requirements in EHR business architecture
- From general requirements in EHR infrastructure
- Compared with shared items throughout the previous studies

3 Proposition of the sharable data elements

- The essential data elements regarding discharge summary
- The common data elements to exchange healthcare information

Methods

Approach → Survey & Analysis → Classification & Proposition

Survey and Analysis

Domestic Studies

- "Information Strategic Planning for Sharable Clinical Information" (1999)
- "Study on forming the basis of sharable clinical information" (2003)

Exchange Between Domestic Hospitals

- Surveyed on the scope of clinical data exchange between the main hospital and the branch hospital in Korea :

  Seoul National University Hospital, Inhwa University Hospital, Samsung Seoul Hospital, National Health Corporation Ilsan Hospital

Foreign Studies

- Abstracted form international researches :

  HealthConnect in Australia, Continuity Care of Record in US,

  The Japanese Set of Identifiers for Medical Record Information Exchange in Japan

Methods

Approach → Survey & Analysis → Classification & Proposition

Classification

Key Business Requirements

- Lifetime Health Record
- Sharing of Clinically Relevant Information
- Sharing EHR Information across regions and institutions
- Support of Potential Services
- Privacy and Security
- Consumer Consent

Requirements In EHR Infrastructure

- EHR shared support service
- EHR access support service
- Terminology & medicine supplies service
- Repository management services
- Registry management service
- Internal & External linking services

Comparison Between Surveys

- Considered the requirements mentioned above
- Compared between domains of clinical information derived from previous studies
- Compared between data elements derived from previous studies
- Classified and derived the shared data from the three steps mentioned above

Methods

Approach → Survey & Analysis → Classification & Proposition

Proposition

The essential data elements

- The essential data is related to the discharge summary.
- The essential data is necessary to exchange health information to a minimum.

The common data elements

- The common data is derived from the repetition of the same terminology in the previous surveys.
- It is sure that the common data will need to improve healthcare delivery and the interoperability among different information systems or hospitals to the maximum.

The essential 27 data elements regarding discharge summary

Data Items for Shareable EHR

Information Groups	Detailed Data Items	N

Discussion and Conclusion

- The purpose of this study is to propose data elements for providing the NHIN service.
- The proposed data elements are classified and derived from many researches in domestic and foreign countries, such as Korea medical ISP for sharable clinical information, data for exchange between hospitals in Korea, HealthConnect in Australia, and Continuity Care of Record in US.
- These data elements are valuable and important in terms of interoperable EHR. Also, They will be utilized for defining a conceptual data architecture that is an initial step of interoperable EHR architecture at the national level in Korea.
- Future work will be proceeded with verification by surveys and close examinations from experts.

Outline

- Common Scenario
- Purpose and Method
- Interoperable EHR Architecture
- Future Plan

Purpose of Common Scenarios

Explain the relationship between the typical healthcare scenarios supported with EHR system and the deliverables of research projects carried out by CiEHR

Projects of Headquarter

- NH-ICT Plan
- EHR Architecture
- Integrated Terminology Model
- CDSS

Projects of Sub Teams

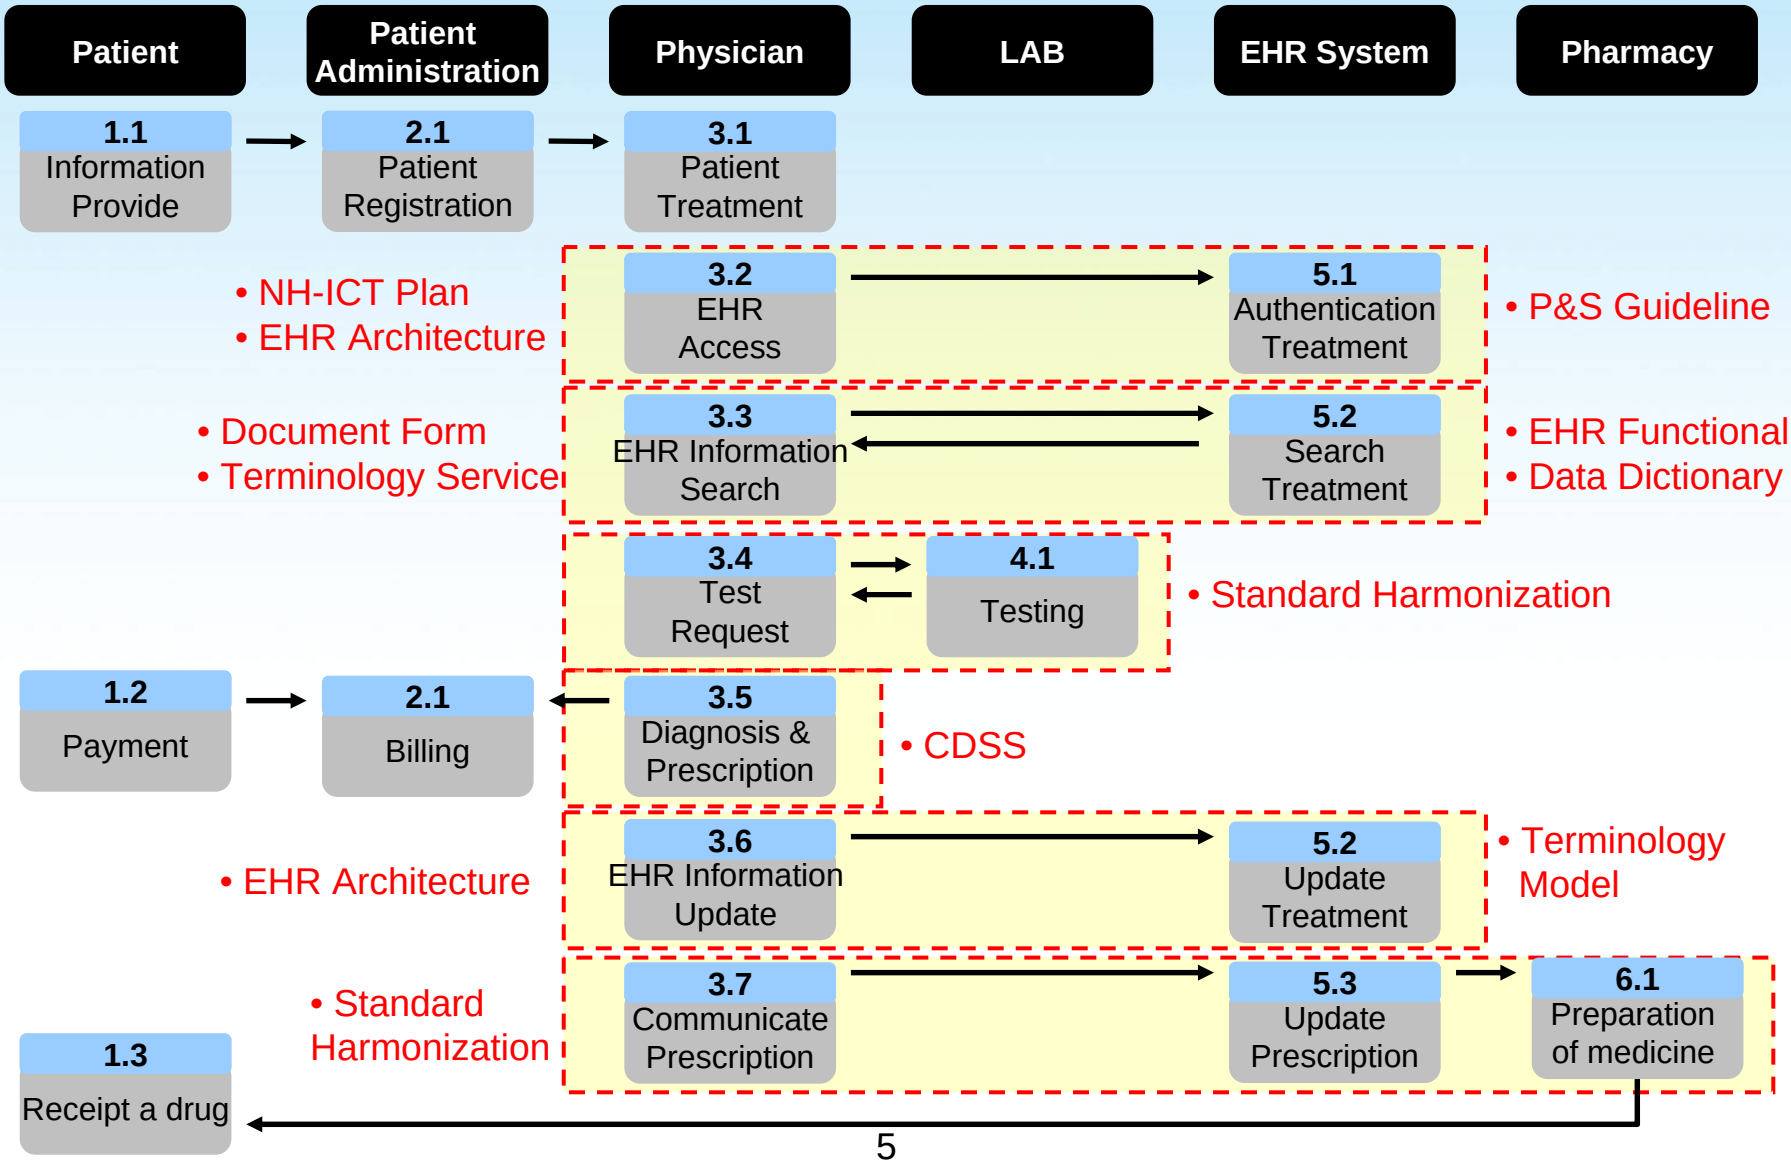
- EHR Functionality
- Data Dictionary and Document Form
- Standard Harmonization for Interoperability
- Terminology Service
- Private & Security Guidelines

Interoperability of Medical Record & Outpatient Clinic

1. Patient Mr. Kim visits Internal Medicine Department of HanGook Hospital.
2. Mr. Kim sees Dr. Lee after registering at the Patient Administration Department.
3. After receiving authentication for accessing EHR system, Dr. Lee accesses Mr. Kim's medical record in the hospital to review his past medical history.
4. Dr. Lee reviews recent information related to examination and test results of Internal Medicine Department.
5. Upon reviewing the EHR, Dr. Lee notes that Mr. Kim has been diagnosed for gastritis previously from another hospital and is allergic to 'A' medication.
6. Dr. Lee recommends and orders a gastroscopy to Mr. Kim for more detailed examination.
7. After completing the test, Dr. Lee makes the diagnosis, recurrent gastritis, to Mr. Kim.
8. Dr. Lee prescribes medication for the recurrent gastritis.
9. Mr. Kim pays the medical fee at the patient administration department of HanGook Hospital. He designates a pharmacy nearby his home to collect his medicine.
10. Mr. Kim collects his medicine prepared and ready for him at the designated pharmacy and returns home after paying for the medicine.

Common Scenario A – Workflow

Interoperability of Medical Record & Outpatient Clinic



Approach for Interoperable EHR

Business Architecture	**Framing Interoperability Business Scenario**	▪ General interoperable EHR scenario ▪ Emergency interoperable EHR scenario ▪ Bio-Surveillance scenario
	Definition of Interoperability Use-case	▪ Document EHR workflow about scenario ▪ Definition of EHR event and action
Purpose: Complement to EHR architecture using EHR use-case based on interoperability scenario		
Application Architecture	**Mapping of EHR Function and Application**	▪ Definition of EHR function using EHR event ▪ EHR application mapping based on the EHR function
	Major Decision Subject of EHR Architecture	▪ Patient Identifier ▪ Data Storage Format ▪ Adaptor System
	Definition of EHR Deployment Model	▪ Deployment of EHR service ▪ Deployment of EHR repository ▪ Definition of EHR deployment model
Purpose: Derive EHR function that support EHR business architecture. Definition of EHR deployment model based on analysis of considerable matters on EHR architecture.		

Framing Interoperability Business Scenario

Interoperable Business Scenario

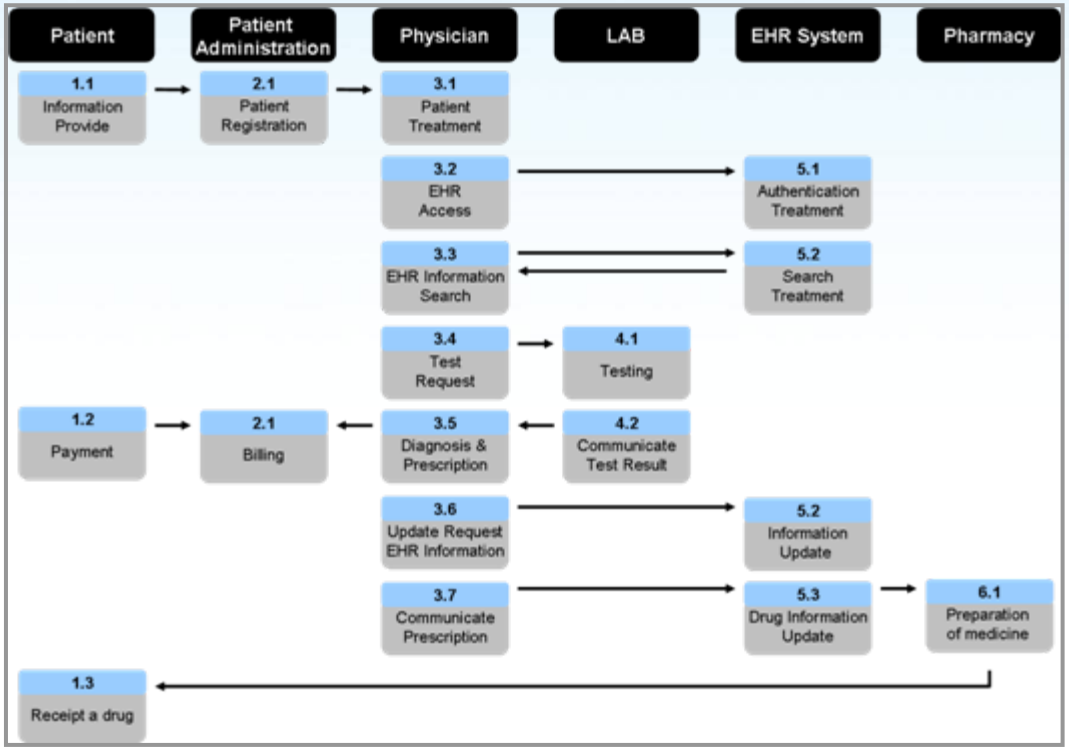
- A definition of scenarios in 3 main areas (the general interoperable EHR, emergency and Bio-Surveillance)
- 5 detail scenarios regarding general interoperable EHR.

EHR System Workflow

- A definition of a workflow between EHR system and major actors based on the scenarios.
- Description of how the EHR system works in order to realize each scenario.

Scenario of outpatient interoperability

Patient Mr. Kim visits Internal Medicine Department of HanGook Hospital. …



Events and Actions of EHR System

Derive event and action of EHR system: Bio-surveillance

- Definition of EHR events between actors and actions of the events
- Events and actions are connected with requirements of EHR function on EHR service

1.1 Surveillance Agency

- 1.1.1.0 Surveillance Policy Making
  - 1.1.1.1 Surveillance Target Selection
  - 1.1.1.2 Surveillance Policy Publication
- 1.1.2.0 Surveillance Policy Complete
  - 1.1.2.1 Policy Canceling Information Transmit
- 1.1.3.0 Surveillance Information Access
  - 1.1.3.1 EHR Service Registration
  - 1.1.3.2 EHR Service Access
  - 1.1.3.3 Surveillance Information Search
  - 1.1.3.4 Surveillance Information Download

1.2. IT Administrator

- 1.2.1.0 HIS Function Setting for Policy
  - 1.2.1.1 Event Registration / Cancellation
  - 1.2.1.2 Data Type Registration Process

1.4 EHR Service

- 1.4.1.0 User Management
  - 1.4.1.1 Grant EHR User ID
  - 1.4.1.2 Grant EHR Service Access Authority
- 1.4.2.0 Bio-Surveillance Access Control
  - 1.4.2.1 User Access Permission
  - 1.4.2.2 Reply Search Request
  - 1.4.2.3 Access Log Management
- 1.4.3.0 Report Management
  - 1.4.3.1 Terminology Mapping
  - 1.4.3.2 Form Creation
  - 1.4.3.3 Report Form Management
  - 1.4.3.4 Surveillance Information Transmit
  - 1.4.3.5 Transmit Log Management
  - 1.4.3.6 System Linking
- 1.4.4.0 Bio-Surveillance Information Mgt
  - 1.4.4.1 HIS Save Request Process
  - 1.4.4.2 Save Request Error Management

EHR Functions and Services

EHR Functional Requirements

- Derive EHR functional requirements from EHR actions of scenarios
- Definition of EHR service from EHR function Requirements.

Event	Action	Functional Requirements	Functions
Request for search of patient record	Verification Query	EHR system requires error verification function of query to search EHR information.	Error Management
		EHR system requires correct result transmit function of search query.	Search and Provide Result
	Authentication and Verification of Provider	EHR system must involve function providers authentication .	Authentication Management
	Permission of Medical Record Transmit	EHR system must verify authenticated user and patient consent and permit transmit information.	Authority Management
	Transmit Patient Medical Information to Provider	EHR system must have extraction function from EHR repository.	Extraction

Definition of EHR Service

- Definition EHR services on each scenarios

Child Leukemia Management System - A Pilot EHR Application Based on the *open*EHR Architecture

Rong Chen[a], Gunnar Klein[b]

[a] *Department of Biomedical Engineering, Linköping University, Sweden*
[b] *Department of Medicine, Karolinska Institutet, Sweden*

Abstract

The openEHR foundation has developed an innovative design [1,2] for interoperable and future-proof Electronic Health Record (EHR) systems based on a dual model approach with a stable reference information model complemented by archetypes for specific clinical purposes

This paper presents an early implementation of openEHR specifications based on the requirement for a dedicated EHR to manage child leukemia treatment, which would enable an overview of all key data on given therapy and relevant observations.

It seems possible to build an EHR application with dedicated purpose on a generic EHR architecture. The two-level modelling and archetypes based EHR architecture seems to be useful for its potentials to improve EHR interoperability and sustainability.

Keywords:

Electronic Health Records, archetypes, *open*EHR, child leukaemia

Introduction

The collaboration with the pediatric oncology department of the Karolinska University Hospital, Sweden was started in 2004 to investigate a new type of IT solution for the management of chemotherapy for children with Lymphoblastic Leukemia in maintenance stage. We selected to test the two-level modeling approach, developed by the *open*EHR foundation and also the basis for the new CEN and ISO 13606 EHR communication standards. Such systems are totally configurable by the clinical content specifications, a.k.a. Archetypes, therefore very adaptive and sustainable.

However, when this project was started there was no previous implementation of *open*EHR in the Java programming language which we wanted to use for several reasons. We therefore had to start by the implementation of all of the core specifications of *open*EHR before we could build the specific leukemia application with its user and other interfaces. This implementation of the *open*EHR specifications later became the reference implementation in Java as reported elsewhere [3].

Methods

The system was implemented in Java programming language and built according to the design specifications from *open*EHR, namely the Reference Information Model (RM) and Archetype Model (AM). Since there was no existing Java implementation at that time, the team started from scratch and made initial implementation of the RM, AM and Archetype Language (ADL) parser. A layered approach has been used in the system design (Figure 1).

The presentation layer of the application is web-based. It is based on an open source Web application framework called Maverick [4]. The screen forms are generated using XML from the application with XSL transformation.

The business layer consists of two sub-layers, one generic EHR services layer and the other more Leukemia treatment related and less generic application specific layer. The generic EHR services provide common features that are necessary for any serious EHR applications for managing health records with considerations on, e.g. security and clinical terminologies.

The clinical requirement specific to Child leukaemia treatment management are modelled as archetypes, which contain detailed knowledge on how to represent observations necessary for monitoring patient that is undergoing chemotherapy in leukaemia maintenance stage. These include list of lab investigations, observation on adverse events, evaluation by the clinician, and finally medication about oral chemotherapy.

The persistence layer utilizes an Object-Relational Mapping tool called Hibernate [5] and a Relational Database Management System product MySQL [6]. The system is deployed as a J2EE application on a JBoss Application server [7].

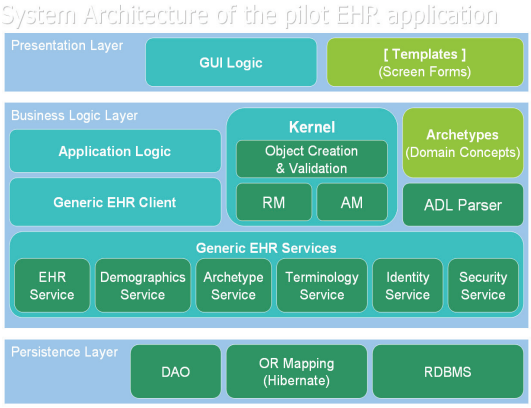

Figure 1- System Architecture of the pilot EHR application

Results

The Leukemia management system has been developed and is currently in the test phase. It records both demographic and clinical data for child leukemia treatment management. It renders all the information for a given patient and time period to a table or a diagram which gives the doctor an overview facilitating adjustment of oral chemotherapy. The clinical part of the system is totally driven by a Leukemia treatment archetype. Major part of the software has been donated to the openEHR Foundation and adopted as the Reference Implementation in Java [3, 7]. The implementation experience has been summarized in the openEHR Java Implementation Specification [8].

Discussion

The two-level modeling and archetype based EHR architecture used by this EHR application seems to be useful. It makes the system adaptive towards clinical requirement changes therefore more sustainable [9]. The separation between EHR system and EHR representation also improve the EHR interoperability [10]. But it also poses new challenges, e.g. term bindings between EHR data and external terminologies [11] and auto-generated screen forms based on archetypes [12, 13].

Conclusion

The fact that the Leukemia treatment management system is built on top of the *open*EHR architecture components proves that it is possible to build domain specific EHR applications in Java based on the generic design of *open*EHR with the two-level modelling approach. This work also led to the launch of the *open*EHR Java Reference Implementation Project and release of the core components as open source.

Child Leukemia Management System
A Pilot EHR Application Based on the *open*EHR Architecture

Rong Chen[a], Gunnar Klein[b]

a Department of Biomedical Engineering, Linköping University, Sweden

b Department of Medicine, Karolinska Institutet, Sweden

Introduction

- Collaboration with pediatric oncology department of the Karolinska University Hospital, Sweden
- Based on requirement for an integrated ICT support for child Leukemia treatment management
  - Auto-entered lab investigation results
  - On-going medications on oral chemotherapy
  - Observations on adverse-events
  - High-level overviews of records for given patient including all observations, adverse-events and medications
  - Clinical evaluation and adjustment of medications
  - Possibility for integrating decision support systems
- Testing two-level modelling and archetypes based EHR architecture

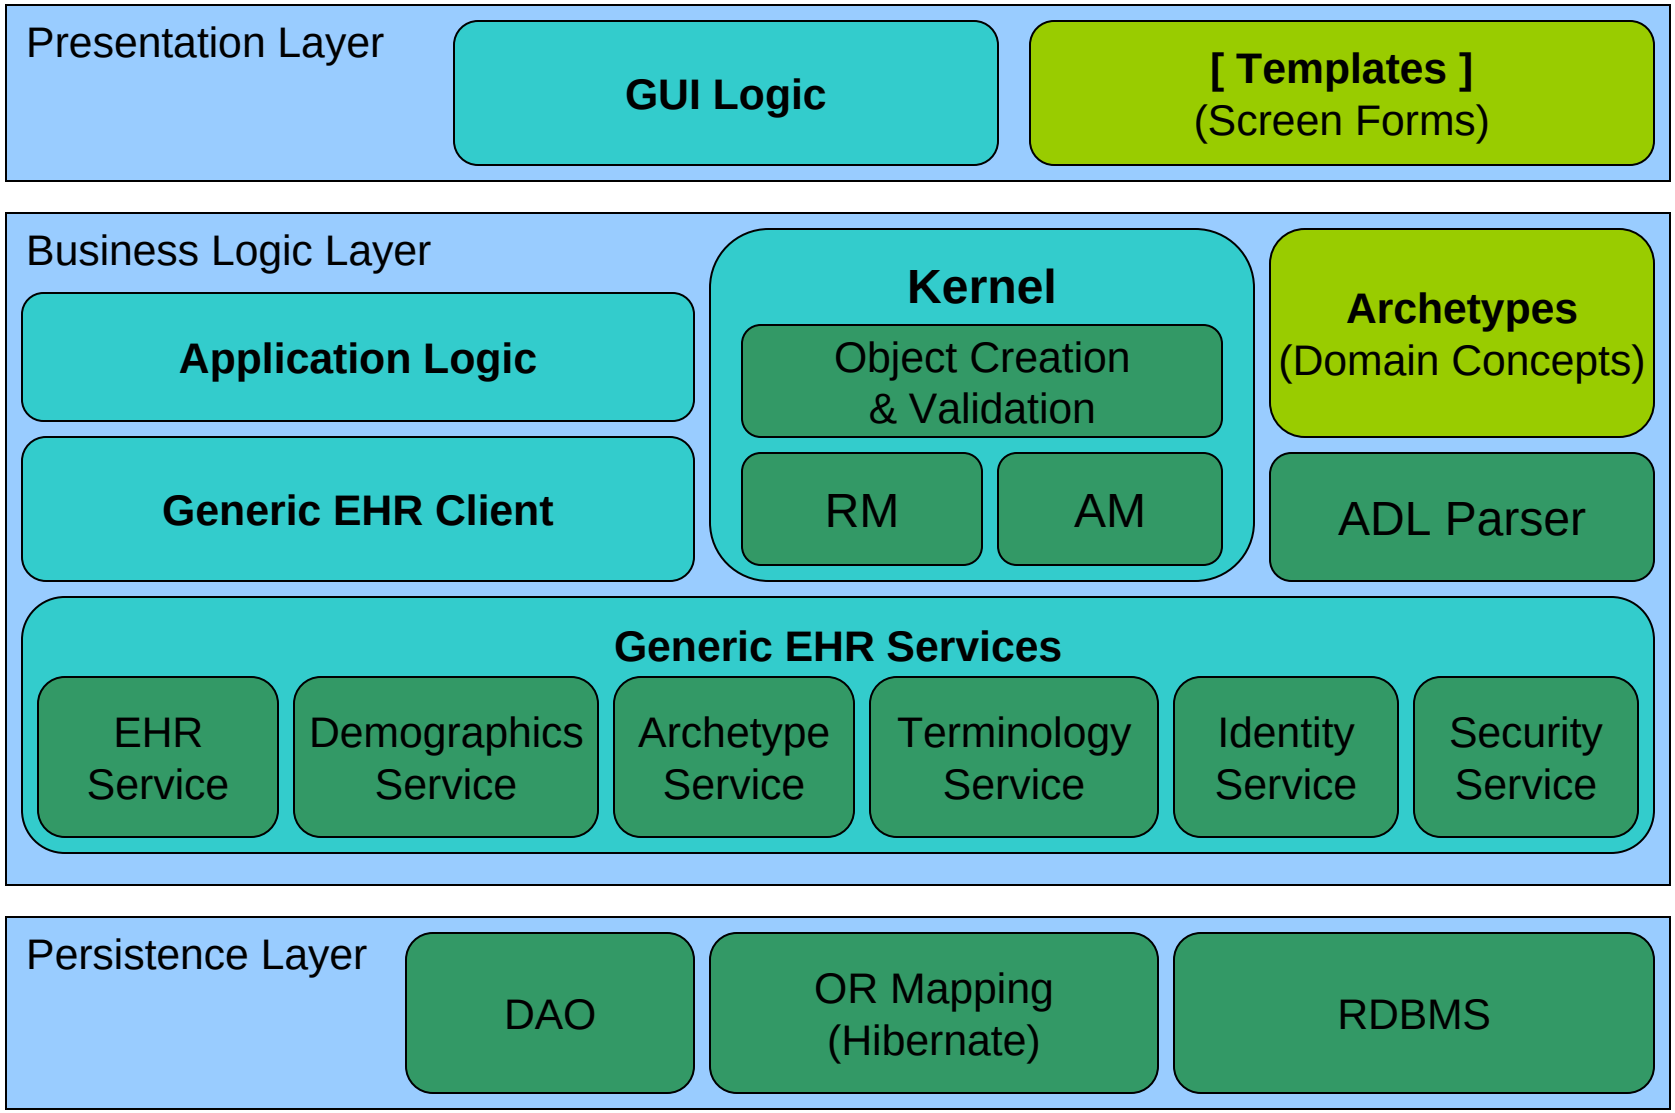
Methods

- Generic EHR system based on openEHR design specifications
  - Java implementation of the openEHR Reference Models and Archetype Model
  - Generic EHR Services
  - Application features: graphic or table overviews
- Clinical requirement modeled in archetypes
  - lab investigations
  - adverse-events
  - Overall evaluations
  - Medications: oral chemotherapy

Software methods

- Presentation layer
  - Web-based front-end using model-view-controller framework Maverick
  - Auto generated screen forms using XSLT transformation
- Business logic layer
  - Generic EHR services wired up using Spring Framework
  - Deployed in JBoss Application server
  - JAXB for XML data binding
  - JavaCC for producing Archetype Definition Language (ADL) parser
- Persistence layer
  - Hibernate for Object-relational mapping
  - MySQL as DBMS

System Architecture of the pilot EHR application



The main EHR archetype

-EHR-COMPOSITION.leukemia_treatment.v3.adl - Eclipse SDK

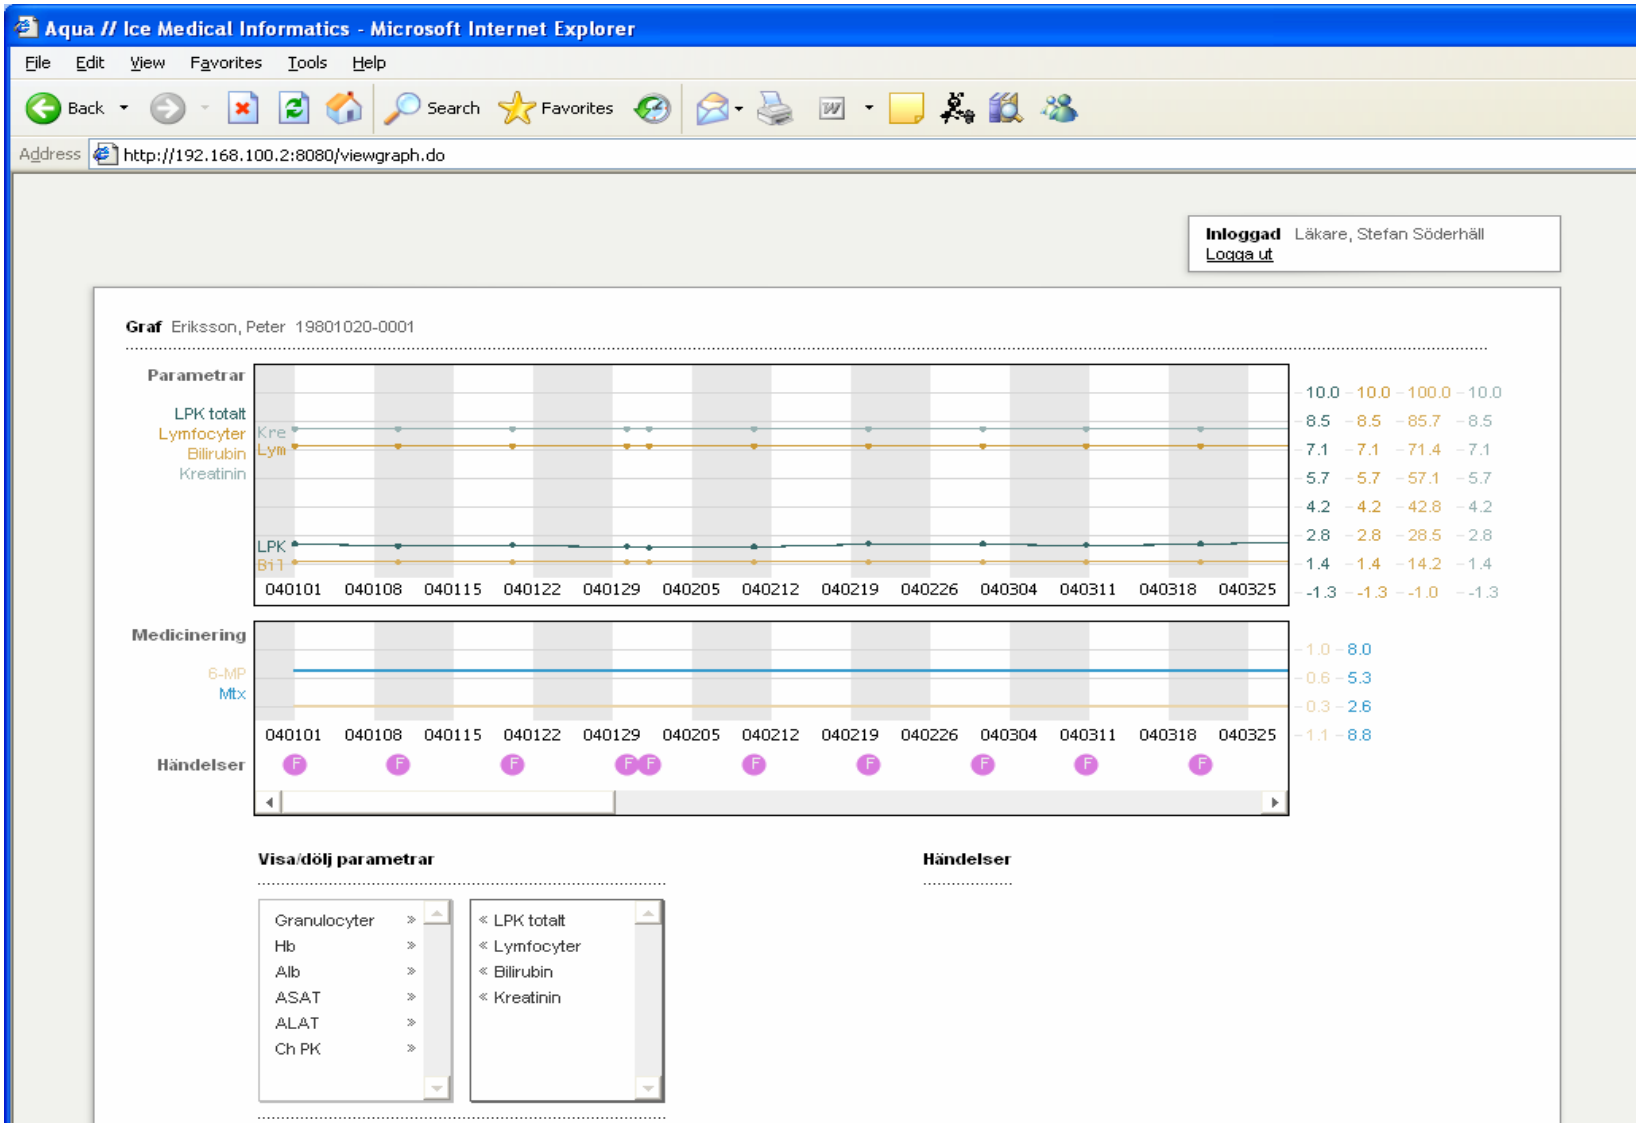
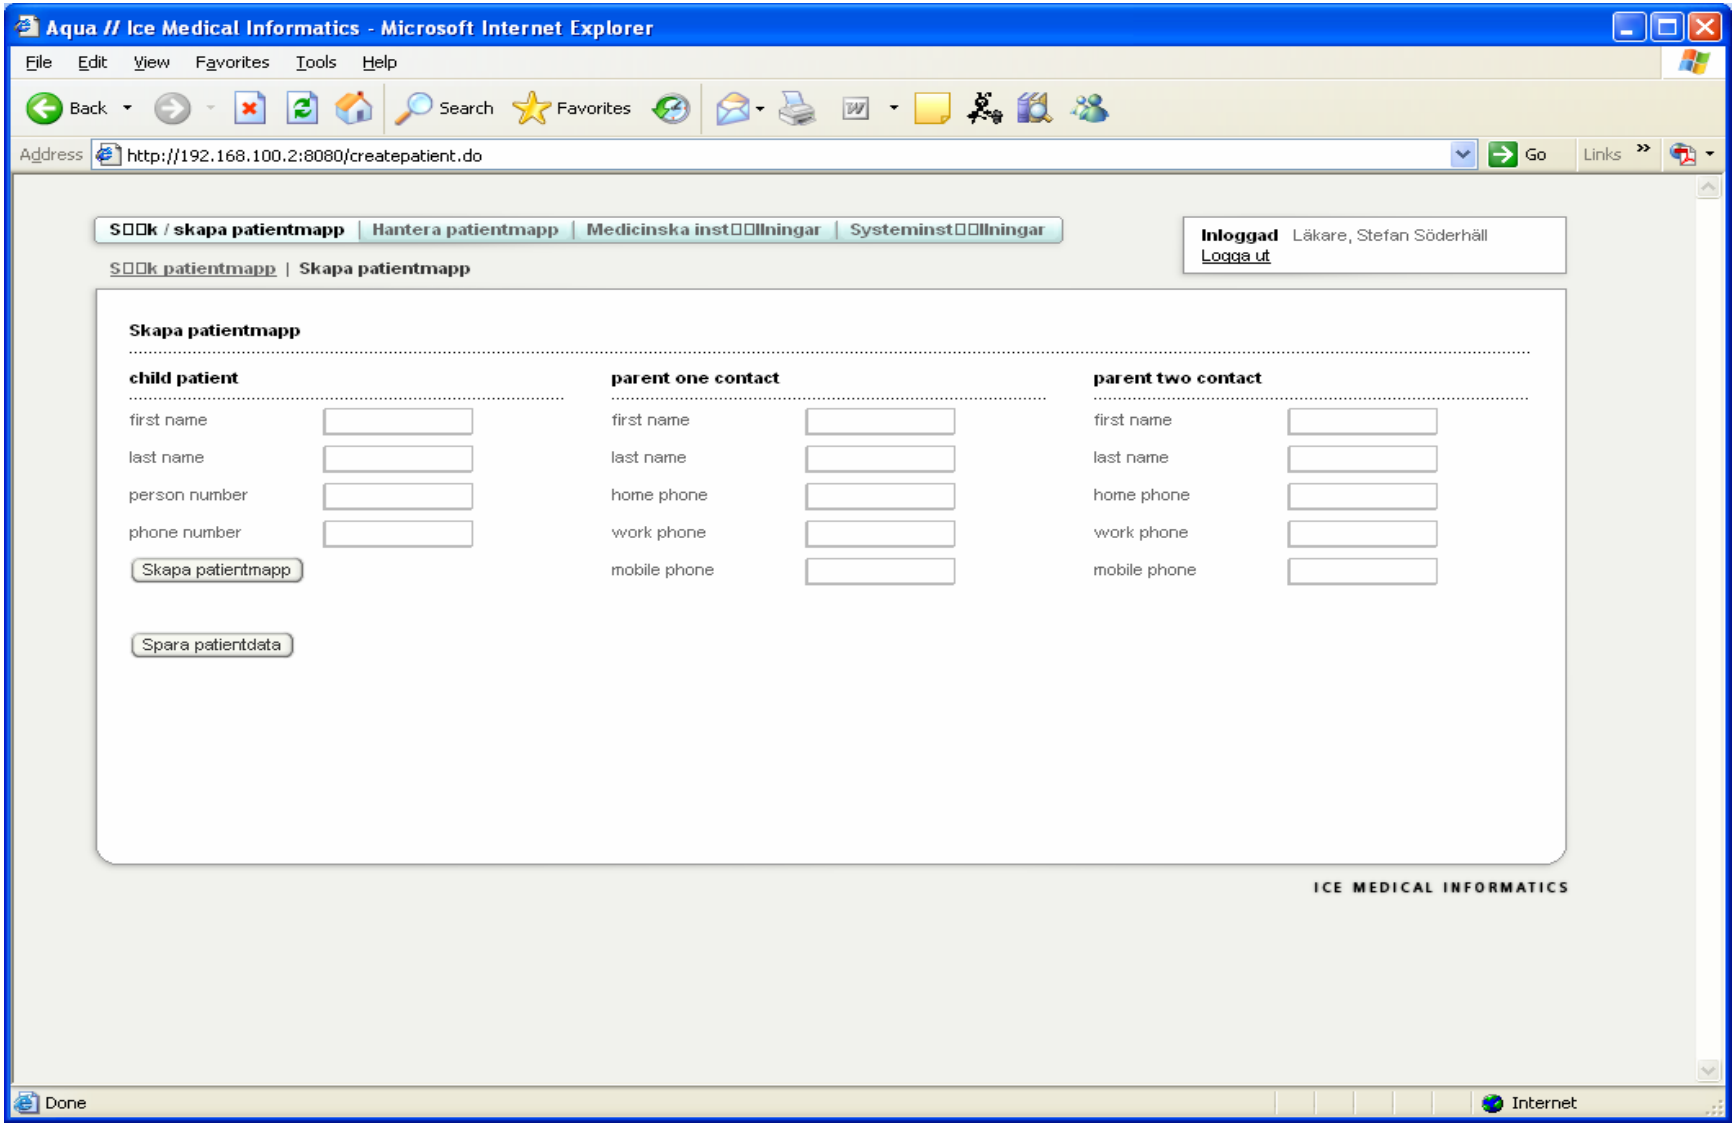
The graph overview



Auto-generated screen form based on demographics archetype



Discussion

- Two-level model and archetype based EHR Architecture – a paradigm shift for building EHR applications
- More adaptive EHR Systems
  - Detailed clinical requirement modeled as archetypes unforeseeable by EHR developers
  - Generic EHR systems driven by archetypes authored by clinical professionals
  - Challenges
    - auto-generated screen forms based on archetype
    - Scalable persistence layer for fine-grained objects
    - integration between archetypes-driven part and non-archetypes-driven part of the system
- Improved EHR Interoperability
  - EHR models based on standards
  - Machine interpretable archetypes
  - Towards semantic interoperability by sharing meaning of expressions and terms thru bindings between EHR nodes and terminologies
  - Challenges
    - archetype governance
    - term bindings between EHR nodes and terminologies
    - effective EHR query based on archetypes

Conclusion

- Two-level modelling and archetypes based EHR architecture seems to be useful
- EHR independent EHR representation improves EHR interoperability
- Possible to build EHR applications for specific need based on generic EHR architecture

Plan of Interoperable EHR in Korea

Hyun-Sook Lim[a], Ein-Jeong Hwang[a], Myoung-Ju Jeon[a], Young-Hwan Choi[a], Yoon Kim[a,b]

[a] *Center for Interoperable EHR, Korea*
[b] *College of Medicine, Seoul National University,Korea*

Abstract

This study describes the plan of development of interoperable EHR as the core element of National Information Network (NHIN) Framework in Korea. At the present time center for interoperable EHR is try to preparing architecture for EHR implementation. The EHR architecture could be composed of EHR functionality, data dictionary, standards, and Privacy and Security and these are essential elements for interoperable architecture design and Healthcare Information Technology (HIT) adoption of hospitals.

Keywords:

interoperable EHR, National Information Network, Healthcare Information Technology

Introduction

The aim of EHR implementation in Korea includes a Healthcare Information Technology (HIT) adoption of public hospitals and an interoperable EHR. Architecture for EHR implementation includes primary and secondary users' requirements, To-Be model related to EHR system functionality, standard documents, guideline of healthcare information exchange, and privacy and security.

Methods

In 2007, the plan of EHR architecture is aimed for implementing logical level. The steps of implementation are follows. First, the analysis of requirements for primary and secondary users as a clinical information exchange for patient care and a use of policy decision-making and research etc., respectively) and current status of general circumstance should be done. Second, EHR functionality with the work process To-Be model in the middle and large-sized hospitals is produced. Third, data dictionary will be structured by analyzing clinical documents of public hospitals. Standard clinical documents will be defined by users' agreements and then will be modeling CDA (Clinical Document Architecture)-based document structure. After third step, EHR functionality and stand clinical document will be matched.

Fourth, for implementing EHR services we will design a technical architecture for application architecture and technical standard. The shard EHR data (Laboratory, medication, health summary, image) has written scenarios and use case. Lastly, we make a Standard and Privacy and Security (P&S) guideline for interoperable EHR. In order to interoperable EHR, it is necessary to standard and P&S. Figure 1 shows the fundamental connection design for implementing EHR logical architecture.

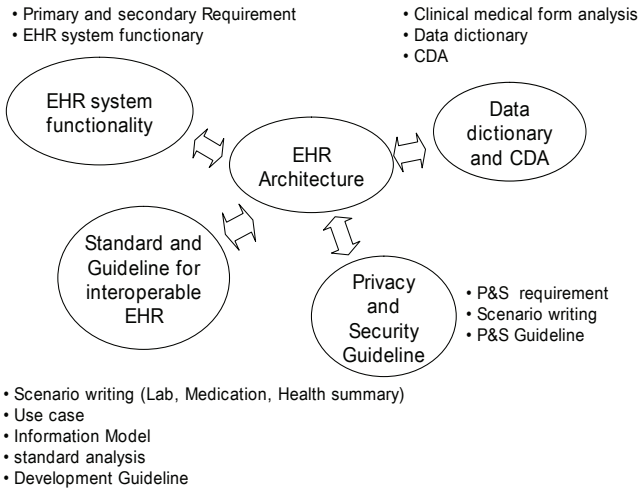

Figure 1-Fundamental connection design for EHR logical architecture

Results

This study presented a plan of implementing for EHR logical architecture. From now on, a more prescriptive approach will be needed to solve this EHR architecture.

Acknowledgments

This study was supported by a grant of the Korea Health 21 R&D Project, Ministry of Health & Welfare in Republic of Korea (A050909).

Development of Critical Pathway System based on Hospital Information System

Sachiko Yoshimoto, Yasushi Matsumura, Hiroshi Takeda

Department of Medical Information Science, Osaka University Hospital, Japan

Abstract and objective

Usefulness of Critical Pathway (CP) method is widely recognized. However, there are still few examples of utilizing information technology for CP. We developed Electronic Critical Pathway System (e-Path) based on our Hospital Information System (HIS). Users can place orders from the e-Path and records made on e-Path are automatically transferred to Electronic Medical Record. Variance analysis and clinical assessment can be done by this system.

Keywords:

Critical Pathways, Hospital Information System

Introduction

Critical pathway (CP) is a useful tool for improvement of quality and efficiency of medical care. So far, more than 100 paper-based CPs have been prepared in Osaka University Hospital. There are some dissatisfactions in paper-based CPs. Entry columns are too small for daily record, so that doctors have to do a lot of redundant office duties such as order entry, nursing instruction and chart entry. Information of the patient is dispersed; coherence becomes tend to be lost in paper-based CP, which becomes the result where the advantages of CP are impaired. We developed e-Path which is well linked to MIS to solve these problems.

Description of e-Path

Overview

In our e-Path, a course of medical treatment can be divided into some periods (steps), in every period, orders are fixed and at the time of step end outcome assessment is done.

Our e-Path system consists of three parts: Path Editor, Path Entry and Path Application. First, users register s new CP in advance, various order information as well as nursing plan and nursing instruction can be set in the system. After a CP is applied to a patient by Path Entry, a concrete plan is displayed in overview form. With Path Application, the orders are processed by step. These consecutive records are recorded to the progress note of the Electronic Medical Record automatically.

Path Editor, Path Entry and Path Application

Path Editor is a system to design a new set of CP. First, base date such as admission day and day of surgery is set. Then what order should be placed on the relative day counted at the base date, and what nursing plan should be done is registered. Further, the item which is not order item such as verification matter and schedule of explanation can be registered. Variance which is expected in each CP is registered to the list in advance. The outcome of each step can be set, and the assessment item that is the condition to have to fill the outcome be set.

A patient is selected from the list in HIS, and a CP is applied to the patient concerned is selected. Some small adjustment can be made such as rescheduling surgery date due to holiday.

Path Application is a body of our e-Path System. All orders prior registered within current step are transferred ordering server and nursing plan is placed. Order correction can be made. There are check boxes to check non-order items when they are processed. In order to advance to the following step, outcome item must be achieved. When variance that should deviate from CP is occurred, the variance is registered, and CP is discontinued. After CP ends, the evaluation of the entire CP can be registered.

Integration with the Electronic Medical Record

Most information such as e-Path entry information, orders, outcomes, assessments, variances, non-order items, comments can be seen in progress notes or flow sheets in EMR. It is also possible to add and various records from the progress note as usual.

Results

The e-Path was introduced to respiratory ward in June 2006. Between June 1 and November 30, total number of cases is 52. Final evaluation had been done in 26 cases, 24 cases (92%) were appreciated that e-Path is effective.

Some disadvantages of e-Path have been point out. Individual order correction is more difficult than paper-based CP. Since medical documents of our institution have not fully computerized yet, staff still have to do redundant paperwork.

The Need of an Electronic Version of Child Health Record. Development of Child Health Record Web Application, Pilot Phase

Michael G. Theodosiou, Dimitris Ch. Zikos, Marianna I. Diomidous

Health Informatics Laboratory, Faculty of Nursing, National and Kapodistrian University of Athens, Greece

Abstract

Young children's health care is both an important and a complex need and it is related both to the surveillance of their physical and their psychological development. These data are mainly recorded in special booklets whose publication is under the supervision of the Ministry of Health. The Health Informatics Laboratory of the Faculty of Nursing of the National and Kapodistrian University of Athens, in an attempt to improve the process of obtaining data and the recording conditions of the aforementioned data, created the "Child Health Record Web Application" program. This is an electronic version of the Child Health Booklet (CHB), which is aimed at both parents and doctors, and which will contribute to the formation of health policies by the National Health System. The "Child Health Record" is an application that is accessed with a Web browser over the Internet. The program is at an early, trial stage, during which evaluations and views by a sample of possible future users are being assembled.

Keywords:

Medical Records Systems, computerized, child, internet

Introduction

The value and significance of preventive medicine is a generally accepted fact in the field of professional Health Care. Preventive medicine is advantageous in relation to therapeutic medicine since it has a greater influence on illness rates [1]. In paediatrics, more than any other medical specialty, preventive medicine has an especially significant place. Periodic preventive health surveillance takes up about 33% of the working time of the primary care paediatrician. This has the goal of preserving and improving child health [2].

In light of the obvious need for a program of systematic health inspection for children, the Ministry of Health has applied the institution of Child Health Booklet since 1976 [3]. In 1989 it established a program of child health inspection made up of pre-established clinical preventive examinations, whose results are noted in set individual health reports included in the CHB [4].

Many studies have concerned themselves with the evaluation of the CHB use in all these years [3], [5]-[9]. As a summary of these we can state that, despite the fact that the CHB has been introduced to everyday medical action, both parents and health professionals consciously or unconsciously ignore the greater part of its purpose with the result that the important value of the information it may carry with it, is lost. Far from the purpose it was designed to serve, the CHB is frequently just used as a vaccinations record card.

The reasons for CHB misuse go deeper than mere ignorance and should be sought out mainly in the areas of ergonomic value, availability and the principles of its design in general.

The need of an electronic version of the CHB

The CHB is a medical document, in which is recorded particular information concerning the child's health. In effect, it is part of the child's medical record. The well known and proved disadvantages of a manuscript health record, which are overcome by an electronic form, as well as the many advantages that the latter carries with it, are especially relevant in the case of children's health records.

The fact that children need to be treated differently from adults by medical professionals is one that cannot be ignored. Correspondingly, a child's health record partly differs from an adult's health record. There are special characteristics indispensable to an electronic system that seeks to support children's medical treatment. The fulfilment of these prerequisites – in addition to the basic fundamentals that apply in the case of adults – will result in the realization of all the advantages of an E-version of the CHB. There are differences in the following areas between a child's and an adult's health record:

1. Type of data (development information, newborn's name, special paediatric glossary, range of normal rates per age, time of birth).
2. Data processing (vaccinations, special requirements for instructions to the parents, standard reports).
3. System design (special issues of confidentiality, paediatric work conditions, family links, connections with the national district offices) [10].

Materials and methods

Description of the construction

The web page contains basic information regarding the CHB. It aims to draw the interest of health professionals, students in Health faculties and parents. It exists in a Greek and an English language version.

The electronic address of the web page is as follows: http://www.childhealthrecord.com. The apposite screen analysis is 1280X1024 pixels (Figure 1).

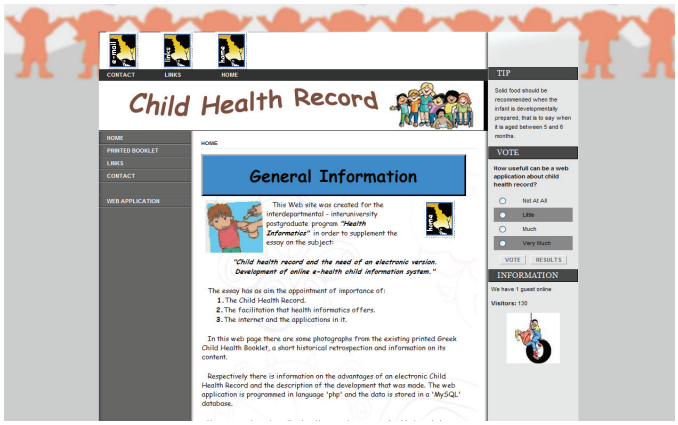

Figure 1- The first web page of the English version of the site

The creation of the application was done in PHP programming language, which has a high compatibility with the MySQL database. This language was used because it is considered as having the most advantages among programming languages such as ASP, Java [11]. JavaScript code was also used.

The application's graphics are HTML pages, frequently combined with CSS. The tables of the database – planned previous to programming – were created representing the subject of the data.

The application's window is of sized 780X600 pixels. The window does not demonstrate the menu and toolbars that normally go with the web browser.

Actors

The application users are divided in three roles. The user might be a parent, who will only be able to browse information, a doctor, who may browse and edit information and the administrator, who will be able to add or delete children in addition to the above uses.

Entrance to the application is enabled through inputting the username and password that the user is required to type on the application's first page.

Contents

All screens were designed in such a way as to be pleasant to look at and easily read in the analyses used by today's majority of monitors. The site has created a friendly 'environment', since it is not only aimed at health professionals in search of an ergonomic site, but also to parents, who are to make up the majority of the site's users.

In almost all of the sites 'screens' there is a right-hand button named 'information', which directs the user to information or groups of information that are mainly directed to parents, explaining the contents and answering questions. The 'information' pages are connected to the initial report pages so that each time the information connected to the relevant data of the application appears.

The thematic units developed are those that exist in the printed version of the CHB, updated and completed. Each unit appears in the form of a 'tag' and navigation is enabled through a bar at its lower part (Figure 2).

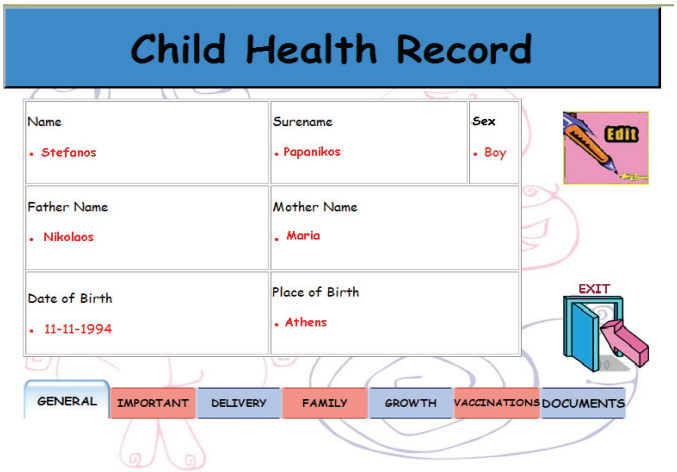

Figure 2 -"General" tag of the web application

Initially, there is the general information – demographic data concerning the child (Name, Date of Birth etc).

A separate 'card' is devoted to important information of which the doctor should be aware, such as allergies, enzyme deficiencies, serious illnesses and conditions.

Next, follow information concerning pregnancy and delivery (time, problems).

The parents' personal data and any chronic health problems are mentioned in detail.

The development card contains a powerful tool which enables the appearance of the child's somatometric data on the growth chart which presents the normal rates (Figure 3). In this card there is also contained information on the first infant examinations, psychokinetic development sup-

ported by images showing the attained abilities and dental problems.

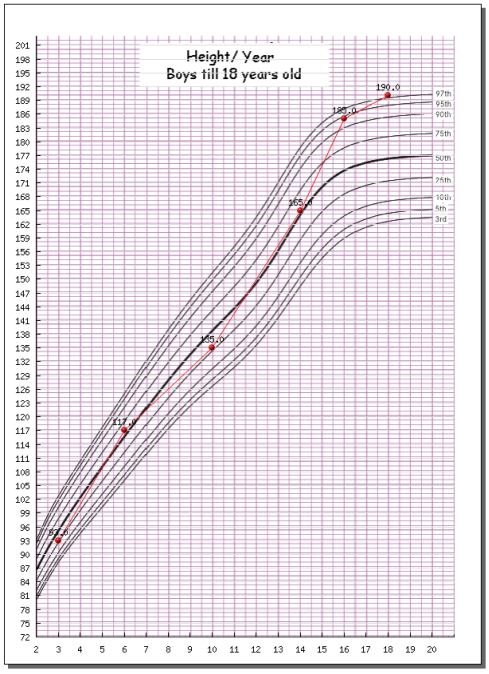

Figure 3 - Height growth chart for a boy (3 to 18 years old)

The vaccinations card, which demonstrates, in concentrated form, the diagram of compulsory vaccinations in Greece could not have been omitted from this card. There is also space for other vaccinations and for recording the date and type of the next planned vaccination (Figure 4).

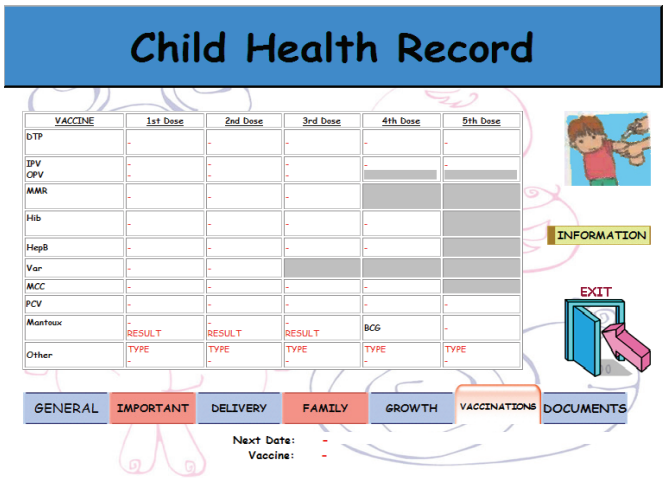

Figure 4 - Vaccinations card

The final card demonstrates three documents that need to be completed for the child's registration at school or the district office and during intervallic check-ups. They can be completed and printed electronically.

The doctor may alter the information by pressing the 'EDIT' button, which only appears if the password given belongs to a doctor. The rates for the relevant fields at the given time appear and the doctor is not obliged to re-enter all the data if s/he only wishes to change one. During the filing process, the process of selection is made easier as the doctor is requested to choose out of prepared answers that exhaust all possibilities (for example, sex: BOY/ GIRL). The input of all dates is done through an electronic calendar. During the input of a vaccination the doctor is requested to choose the vaccine and the dose. If the combination is wrong, the system will indicate the fact.

The date of birth is processed so that the child's age may be found and certain functions calculated automatically, such as the automatic choice of the correct category for filing the development data (A, B newborn examination, 0-36 months or 3-18 years).

The doctor – and the parent – is enabled, by pressing the 'information' button, to see the time-plan of the child's vaccinations and the period in which the child will be at the time will be highlighted in yellow, through an automatic calculation based on the date of birth.

In the same way, sex defines which development diagrams will be chosen and presented to the user. If sex has not been filed, the user will be requested to indicate sex.

Finally, the administrator will be able to view, analyze and make copies of all tables included in the database. The most important of these are the tables showing who entered the site and when, the changes s/he made and when s/he left the site. Apart from this, however, there are two buttons for the simplification of routine tasks, such as the addition of a new child or the deletion or edition of the data of another. During the addition of a new child to the database, two passwords are agreed upon, one for the parents and one for the doctor. The same combination of username as that of another child is forbidden, as also the identical passwords. In deletion-edition, there is a search filter for the child, who can then be deleted or its data edited.

Evaluation

A questionnaire containing 15 evaluation questions was created and 100 students from the faculty of nursing were asked to use the application and answer the questions as future health providers, parents and health system managers. The questions requested of the students to evaluate the application regarding completeness of the contents, availability, speed, safety, ergonomic value, possible contribution to health, general impressions and to add a comment. Each question had a scale of 5 answers with 1 as the lowest level and 5 as the highest level of achievement.

Pre-evaluation by possible users may have much to offer as far as improvement and completion of the application are concerned, prior to the distribution of the application to real users.

Results

The outcome is well presented in Table 1.

Discussion

The choice of the critical sector of the paediatric health record brought us face to face with three groups of people using it: the parents, the health professionals and the health system managers. The results of the pre-evaluation can be easily explained by analyzing the views, expectations and reservations of each group separately.

The parents' views

The children's parents are well aware of the fact that health care is made up of many and complex information drawn from various sources and they have certain worries regarding the way in which the data concerning the health of their children are filed. Parents are well aware of the need for regular health checks, evaluation, vaccination and preventive services for their children and there is a general acceptance among them of electronic systems for the coordination of health care.

However, families with multiple sources of health care are quick in realizing that access to and movement of information may become problematic, with delays and difficulties in ER, specialized surgeries, public hospitals etc. Parents also report that frequently they themselves have to act as mediators between the suppliers for test results, clinical instructions, pharmaceutical prescriptions and in general for all information concerning the past, in a struggle to keep at bay the possibility of unsuitable treatments due to lost information.

Many parents worry that easy access to their children's health records is not available and they often report reactions to wrong medicines as examples of things that could be avoided through an electronic system. Parents are also aware of the importance of timely vaccinations, as they are conscious of the fact that the challenge lies in changing the progressively more complex programs of archive conservation required for the introduction of medical care in schools.

A small, but often effusive percentage of parents appear to be suspicious of large, centralized data systems in private, and even more so in public hands. So parents want to actively hold and manage their child's medical record themselves, and request access to recordings as well as the right to insert their own comments. Some parents are further concerned with the fact that data are given to employers, parents that have not been granted child custody etc, and they request the deletion of certain information.

All parents hold the view that there should be a way in which they may be informed in simple words on the various matters connected to childcare. They are asking for an information system, which will supply them with expert information and advice on such topics as breastfeeding, nutrition, correct child development etc [12].

The health professionals' views

Electronic health records exist so as to transport data to and from the suppliers of health services. Doctors, understandably give more thought to the information that they should receive than to the information they are requested to disclose. They recognize, nevertheless, the needs and expenses of both centralized and decentralized channels. They would rather have access to an efficient, friendly, flexible, reliable incremental source of all they should know, as well as an incremental, economical 'device' for passing on data.

They believe that such a health information system would be able to give them fuller and more reliable information regarding vaccinations, medication and certain examinations and for extra-medical services that their patients receive. The system should also enable them to send this information to colleagues, schools etc. They require from

the system to automatically produce notifications, parent reminders, diagrams showing the gaps in immunization, notifications regarding critical laboratory rates or allergies to medicine and other important data. The doctors always have the most important share in the quality of care, but they know that these systems can improve this quality even further in everyday practice.

An information system like the one described above facilitates the securing of quality in medical practice. This, however, can turn against professionals as much as it acts favourably towards them. The profiles of clinical efficiency for the medical practice in a number of areas – such as the immunization percentages and screening tests – become higher and more sensitive, both for professionals and outside observers, such as insurance companies and health authorities. Doctors are sometimes worried that this data will be used to evaluate their work but without any consideration of the complex needs of the children under surveillance or of the working environment. In addition, the economic data are usually made accessible to insurance companies as well and these latter may discourage any new investments.

The doctors and the rest of the medical staff are also quite suspicious of large systems of electronic data, after years of disillusionment with older systems. They either had had to turn vanguard staff to people responsible for the difficult and painful task of recording data in an electronic form, or they never used the system. All this constitutes doctors suspicious towards new, demanding electronic systems in their offices.

Health Systems

Public health is part of both the distribution of information and the application of the population based policies and operations. As dispensers of paediatric services, public health programs share many of the hopes and qualms related to electronic versions of CHB. The public health sector is responsible for comprehensive preventive services as well as for the surveillance of patients, the regulation of health care and the state collection and analysis of health data. Each of the above has specific needs for information, which would be better collected if the electronic CHB had been in use.

The first objective of an electronic health data system is the reinforcement of the preventive health services for children, usually in the form of vaccination archives. The advantages of an electronic form include the system for newborns' screening tests, the evaluation of diet and the other services and these make the electronic version a much richer source of data for community practices, management and leadership of public health.

The allocation of licenses to suppliers of health services to children, such as paediatric clinics and private surgeries, is not subject to any form of control or monitoring. An overview of clinical data for each supplier would allow a health control panel to focus more on the quality and the outcome based value of health care provided, rather than spending itself on inspection raids.

Apart from the roles mentioned above, the health system also runs population based operations, in cooperation with community and private health care, such as the goal setting health promotion and the regular control of disease, which allow access to health care, health awareness at the workplace and the differences in the health level of minorities. Each one of these projects has a strong stem in childhood illnesses and could use the population's clinical data in order to improve the planning and evaluation of a program [13].

Conclusion

The transition to an electronic version of CHB can contribute significantly in the promotion of children's health and of society's health in general and can become a powerful tool for parents, professionals and state health planning.

In Greece, as in many other countries, the traditional, manuscript health records are still preserved. We believe that through the present study we can contribute to the acceleration of the changes towards an e-health system for children.

A Survey on Shared Electronic Health Record Architectures in Europe

Raimund Vogl[a], Christian Laucher[a], Robert Penz[a], Patricia Schirmer[a], Thomas Schabetsberger[b], Elske Ammenwerth[b]

[a]HITT health information technology tirol, Leopoldstrasse 1, A-6020 Innsbruck, Austria
[b]UMIT – University for Health Sciences, Medical Informatics and Technology, Eduard Wallnöfer Zentrum 1, A-6060 Hall, Austria

Abstract

The EU e-Health action plan has initiated activities across Europe for e-Health and the creation of Shared Electronic Health Records (SEHR). Most of the member states are preparing or already have roadmaps and programs. Information on these activities, especially on the more technical aspects, is of great importance for informed decision making but very hard to find – due to the early stages and transitory phases in which those programs are currently in, with communication being considered no priority. To gain first hand insight, a survey was conducted amongst active experts in the field of SEHR, identified by having given topical presentations at selected international conferences in 2006. The survey was conducted online, with 35 participants (19.4 % of all approached) answering the questionnaire on general e-Health strategy, the SEHR program in general and technical aspects of the program. Of the participants, 80% know of an SEHR program in their country they could answer questions on. The majority judges the programs to be in their early stages and is sceptical against official statements for program completion timeframes. Trans-national (EU level) interoperability is only seen by 56% of the participants as an issue. The Internet protocol is exclusively seen as means of transport for the exchange of SEHR data. The majority foresees a mostly decentral federated architecture with central patient index, but federated metadata registries and data repositories for the SEHR. HL7 V3 CDA, DICOM and IHE XDS achieve highest ranking as standards and technical frameworks for realization of the SEHR. SEHR projects currently are in an early stage where specifications are not finalized and still subject to change. Research and pilot projects, that have in some cases been initiated more than a decade ago, are present in some countries giving directions for how pervasive solutions could work and have to be incorporated into future infrastructures.

Keywords:

electronic health records, e-Health, IHE, system architecture

Introduction

In its 2004 e-Health action plan [1], aligned with the eEurope action plan [2], the commission of the EU set ambitious goal to establish a European e-Health infrastructure until 2009. Several measures were defined, amongst them the development of national or regional roadmaps for e-Health by each member state by the end of 2005, the definition of a common approach to patient identification and interoperability standards for health data messages and electronic health records by the end of 2006, the deployment of health information networks for e-Health in the period 2004-2008, the provision of online services such as teleconsultation, e-prescription, e-referral, telemonitoring and telecare by the majority of European health organisations by the end of 2008, and a baseline for a standardised European qualification for e-Health services in clinical and administrative settings by the end of 2009.

This has sparked substantial activities among the EU member states, with a large variety of national and regional projects being started (see for instance [3] for the work on e-Health strategy in Austria).

One of the key elements for e-Health strategies is to establish a Shared Electronic Health Record (SEHR) for all citizens, meaning that elevant health related data for citizens is electronically shared across different providers in all the sectors of healthcare. Substantial benefits in terms of quality and productivity in a collaborative care setting are enabled by such infrastructure [4] and seen as indispensable in the future health system [5]

Even though the commission has also agreed in the e-Health action plan, that it will publish a study on the state of the art in deployment, examples of best practices, and the associated benefits biannually in the period 2004-2010 for benchmarking already resulting in valuable studies eg. in the e-Health ERA project [6,7,8], it is still very hard to find information on the functional and technical approaches pursued in the member states in the establishment of shared electronic health records. Studies on certain aspects of shared electronic health records with special focus on EU-wide interoperability like the one on patient summaries conducted in the e-Health ERA project [9] have become available, but also here, only 9 official state-

ments (by the national Ministry of Health or the national e-Health competence centre) were received and issues of health record system architecture were not considered.

Methods

Since information on the various approaches to these technical aspects are of great interest for those contributing to SEHR projects themselves, and currently reports are rarely available, a survey with this focus was made amongst those experts working on SEHR projects to collect their opinion on the scope and status of these projects. It is also interesting to see how e-Health strategies an SEHR programs are viewed by national experts, sometimes in disagreement with the statements of national strategies.

For the recruitment of participants for that survey, persons were identified who had either authored or co-authored papers related SEHR given at various conferences[1] in 2006 (to ensure that they are currently actively involved in this field) or who are representatives of national competence centres for e-Health. Additionally, the national representatives of EFMI (European Federation of Medical Informatics) were approached. Since the survey was conducted online, 180 persons were invited via email to participate on Nov 2 2006. With a reminder after one week, the survey was answered by 35 participants (19.4%) unt it was closed on Nov 20 2006.

Scope of the survey and participation

The online survey was composed of 23 questions in there groups: general questions on the e-Health program, questions on the SEHR program, questions on the SEHR architecture and functionality.

The 35 participants were from 18 countries – mostly European, with additional participation from Russia and Israel (5 from AT and NO, 4 from DE, 3 from IT, 2 from CH, DK, EE, SE, and 1 from FI, FR, GR, IL, IS, LT, PL, PT, RO, RU).

The participant judged themselves mostly as competent or very competent to answer the survey (Table 1):

Table 1 – Competence of participants

How competent do you feel to make statements on the national eHealth strategy with regard to shared electronic health records in that country?	participants
very competent (ie. actively involved in the national e-Health effort)	16 (46%)
competent (ie. expert on the subject with good insight into the national e-Health effort)	9 (26%)
slightly competent (ie. involved in certain aspects of the national e-Health effort)	9 (26%)
not competent (ie. not involved with the national e-Health effort)	1 (2%)

Of those 28 participants who stated there is an SEHR program in their country, their involvement with this program was characterized as described in Table 2:

Table 2 – Involvement in SEHR program

How are you involved with this SEHR program?	participants
Decision maker	3 (11 %)
Consultant	10 (36%)
Program team member	4 (14%)
Member of a stakeholder organization of the program	3 (11%)
Other - not directly affiliated with the program	8 (28%)

Since there were several participants from some of the countries, the agreement between those participants from the same country on selected questions could be determined to have a measure for the reliability of the survey results. The agreement was determined as the percentage of participants from one country giving the top ranking answer for one of 7 selected questions[2]. Taking the arithmetic mean of these values, an overall agreement of 79% was found. This indicates that there is generally a good consensus accurately reflecting the e-Health situation, but it also shows that there is a certain controversy in the expert opinion caused mainly by the transitory phase in which most of the countries are with respect to their e-Health programs (eg. the Austrian participants disagreed if there is an Austrian e-Health strategy – the strategy was completed by an expert group in December 2005 [3] but has not yet been official adopted by the Ministry of Health). It was noted by several participants that the sur-

1 The conferences considered are: Nordic e-Health Conference 2006 (Copenhagen, DK), EU e-Health Conference 2006 (Malaga, ES), e-Health Benchmarking 2006 (Hall, AT), Telemed 2006 (Berlin, DE), EuroPACS 2006 (Trondheim, NO), ICICTH 2006 (Samos, GR), MIE 2006 (Maastricht, NL), GMDS 2006 (Leipzig, DE), MIR 2006 (Budapest, HU).

2 Questions: Is there a national e-Health strategy in your country? When was it formulated? Estimate for the completion of SEHR program? Trans-national interoperability considered? Basis for patient identification? Basis for health professional identification? Network infrastructure?

vey does not allow to describe the transition phase in which some projects currently are and the coexistence of regional and national programs for SEHR within one country.

General results on e-Health strategy and the SEHR program

The initial question of the survey was on the existence of a national e-Health strategy in the respective country. A majority of 83% of the answers was positive (with disagreement from the Austrians whether the current document on the e-Health strategy can be considered official, and uncertainty from the Norwegians whether there is an official e-Health strategy in their country). Only PL, PT, RO, RU were definitely negative. This result is in good agreement with [8], where it is stated that 21 out of the 25 EU member states (84%) report having adopted a national e-Health roadmap (unfortunately, [8] is not specific with regard to the countries).

The time of formulation of the e-Health strategy was given as indicated in Table 3:

Table 3 – National strategy

Time of formulation of the eHealth strategy	participants
Currently being formulated or in draft status	6 (20%)
Formulated/last updated 2006	8 (27 %)
Formulated/last updated 2005	6 (20%)
Formulated/last updated 2000-2004	7 (23%)
Formulated/last updated before 2000	1 (3%)
Uncertain	2 (7%)

The agreement amongst the participants from one nation is not very good for this question – for Austria there is only 50% agreement, with one group stating that the 2005 strategy paper is the strategy, the others considering this preliminary and seeing the strategy currently being formulated.

With respect to the existence of a national SEHR program on which they can make statements on, 57% of the participants gave a positive answer (details in table 4). This is in good agreement with [8], where electronic health records are claimed to be on the e-Health roadmaps of 14 (of 25) European member states. For Austria, we see disagreement among the participants if there is one national program or several regional programs aligned with the national strategy – and one participant reports on a research focused program.

Table 4 – SEHR program in strategy

Type of program	participants	countries
national level public sector program part of national e-health strategy	15 (43%)	AT(2), DE(2), DK, EE, FI, IL, IT, LT, SE
regional level public sector program aligned with national e-health strategy	2 (6%)	AT(2)
regional level public sector program independent of national e-health strategy	2 (6%)	RO, PL
national level private sector program	0 (0%)	
regional level private sector program	1 (3%)	PT
research focused preparatory program	8 (23%)	AT(1), CH, DE(2), GR, IT, NO(1), RU
No SEHR program	7 (20%)	CH, FR, IS, NO(4)

Also for Germany, one part of the participants makes statements on the national program (which is currently not specific about SEHR but focused on e-prescription [10]), the other on research projects. Among the participants from Norway, one reports on a research program for SEHR, whereas the others see no SEHR program in their country. The vast majority sees national level public sector SEHR programs in their countries. Private sector SEHR programs are very rare.

Table 5 – SEHR timeframe

SEHR timeframe	According to official statements	According to private opinion
2006/already available	3 (12%)	1 (4%)
2007	4 (15%)	2 (8%)
2008	5 (19%)	1 (4%)
2009	1 (4%)	5 (19%)
2010	5 (19%)	7 (27%)
2011	0 (0%)	1 (4%)
2012 or later	1 (4%)	8 (31%)
No statement	7 (27%)	1 (4%)

The high percentage of research focused programs mentioned shows that SEHR is still very much in a transitory state, with concepts still being formulated. The names of

the SEHR projects given by the participants are listed in table 6.

The timeframe for the completion of a working SEHR with advanced functionality and coverage is seen fairly sceptical by the participants, with their private opinion being far behind official statements (table 5), with the majority seeing the completion of the SEHR project beyond 2012.

Table 6 – SEHR projects

Project name	Country	inhabitants covered
RTS-Rede Telemática da Saúde	PT	150
Electronic health certificate project (preliminary)	RU	
National EPR service	FI	5 million
bIT4Health, Telematikinfrastruktur und elektronische Gesundheitskarte	DE(4)	80 million
Israel National EHR Program	IL	5 million
Estonian Digital Health Record	EE	1.4 million
National e-Health System (NESS)	LT	3.5 million
Research and development programme for electronic health record, Norwegian University of Science and Technology (NTNU)	NO(1)	
Silesian startup project for national EPR	PL	Currently 5 million (of 39 million planned)
National IT Strategy for the Health Care Service 2003-2007	DK	5 million
"Sanità Elettronica 2010" (e-Health 2010)	IT	60 million
ELGA (Elektronische Gesundheitsakte), eHI (eHealth Initiative)	AT(4)	8 millions
MediNET	RO	200.000
National patient summary	SE	9 million

The current percentage of completion of the project is generally seen to be in the very early stages (with very good agreement among participants from one nation), with only the small scale Portuguese project claiming imminent completion (Table 7). Even the representatives from Denmark, well known for its avant-garde position in e-Health and SEHR, claim only to be between 25% and 50% complete.

Table 7 – Percentage of completion

Current percentage of completion of SEHR	participants
0% - 25% (preparatory phase)	16 (61%)
25% - 50% (pilot projects)	9 (35%)
50% - 75% (full rollout)	0 (0%)
75% - 100% (finishing)	1 (4%)

Special results on the technical aspects of the SEHR programs

The question, if trans-national (especially European-level) interoperability was a concrete issue in the SEHR project was surprisingly negated by 37% of the participants (56% were positive, 7% uncertain), which shows the importance of EU initiatives to foster interoperability.

The means for patient identification are given (in very good agreement amongst the participants) in Table 8

Table 8 – Means of patient identification

Means of patient identification	participants
Patient health chipcard or identification token	9 (32%)
eGovernment citizen chipcard or identification token	1 (4%)
Unique national citizen identification number	11 (39%)
Unique national patient identification number	3 (11%)
Social insurance number	0 (0,0%)
Master Patient Index systems for the federation of patient data between healthcare organizations	0 (0,0%)
Not decided yet	3 (11%)
Uncertain	1 (4%)

National citizen identification numbers are the top means of identification, with patient chipcards coming next (also in [8], it is stated that health cards are on the roadmaps of 10 of 25 European countries). The social insurance number is nowhere used for patient identification.

The means to identify health professionals are given in table 9.

Table 9 – Means of health professional identification

Means of health professional identification	participants
Health professional card	14 (52%)
Identification token stored on some other medium	0 (0%)
User accounts maintained in the SEHR or connected systems	7 (26%)
Not decided yet	5 (18%)
Uncertain	1 (4%)

The health professional card is clearly predominant, but also in national projects (Estonia and Lithuania), user accounts maintained in the SEHR or connected systems serve as means for user identification (and access control).

With regard to the network infrastructure and protocols used for access to the SEHR, the Internet protocol is clearly undisputed. A secluded intranet is the prime choice, but also encrypted connections via the public Internet are considered (see table 10).

Table 10 – Type of network infrastructure

Type of network infrastructure	participants
Secluded Intranet for the Healthcare sector based on Internet Protocol	13 (52%)
Secluded network for the Healthcare sector based on some other protocol	0 (0%)
Public Internet with appropriate encryption	9 (36%)
Uncertain	3 (12%)

For the additional services that are to be offered together with the SEHR for patients and health professionals, the results are shown in figure 1.

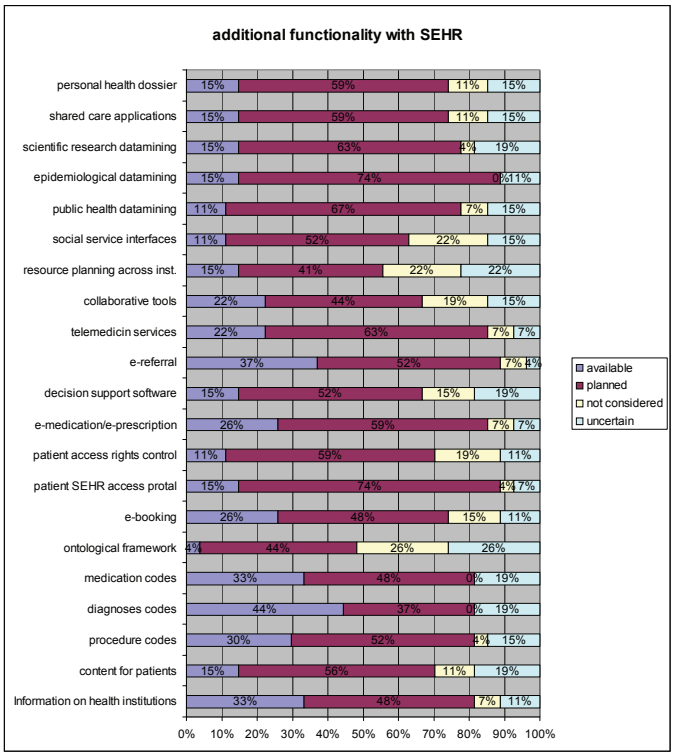

Figure 1 – Additional services

Among the currently available functionalities, common nomenclatures for diagnoses, medication and procedures, e-medication/e-prescription and e-booking along with information on healthcare institutions are predominant. Patient portals are mostly being planned, with various participants stating that functionality for patients to control access rights to their health record data is not considered. Complete ontological frameworks are considered least important.

For the central question for this survey, the design of the SEHR architecture, the participants were given the choice between 5 different designs, ranging from a completely centralized approach for the storage of all SEHR data to completely unfederated decentralized SEHR:

- Completely central architecture (with limited number of national data centres): Central Patient Index; Central Metadata Index and Patient Summary Data Repository; Central Repository for full SEHR data
- Mostly central architecture (all core data stored in limited number of national centres): Central Patient Index; Central Metadata Index and Patient Summary Data Repository; Decentral Repository for full SEHR data
- Mostly decentral federated architecture: Central Patient Index; Decentral Metadata Index and Patient Summary Data Repository; Decentral Repository for full SEHR data

- Completely decentral federated architecture (federation of RHIO's with cross community data access): Decentral Patient Indices; Decentral Metadata Index and Patient Summary Data Repository; Decentral Repository for full SEHR data
- Completely decentral unfederated architecture (unfederated RHIOs): Decentral Patient Indices without cross enterprise federation; Decentral Metadata Index and Patient Summary Data Repository; Decentral Repository for full SEHR data

The results found are given in Table 11:

Table 11 – Architecture type

Architecture type	participants	countries
Compl. central architecture	1 (4%)	FI
Mostly central architecture	6 (22%)	AT(2),DK, EE,GR,LT
Mostly decentral federated architecture	9 (33%)	AT(3),CH,DE,EE,RO,SE
Completely decentral federated architecture	3 (11%)	DE,IT(2)
Completely decentral unfederated architecture	1 (4%)	IL
Other/not yet decided	5 (19%)	DE,DK,NO, PL,RU
Uncertain	2 (7%)	NO,PT

Only one participant from Finland sees the national SEHR effort directed towards an all central architecture. The mostly central and mostly decentral architectures prevail – for pragmatic reasons (eg. the amount of actual EHR data that would have otherwise to be stored centrally).

Table 12 – Regulation for data in SEHR

Regulation for data in SEHR	Participants
National regulation exists	4 (15%)
Regional regulation exists	2 (7%)
National regulation is planned	12 (44%)
Regional regulation is planned	1 (4%)
No regulations are planned - agreements between healthcare will do	5 (19%)
Uncertain	3 (11%)

The situation with not yet final specifications for SEHR architectures has its impact on the disagreement between the participants (in Austria, the e-Health strategy prepared by the e-Health Initiative favours a mostly decentral architecture, whereas the preliminary results from a government commissioned feasibility study tend towards a mostly central architecture).

Regarding the question, whether there are regulations on what data items are to be published into the SEHR, the participants gave the answers in table 12.

The data items considered to be available via the SEHR (currently or in the future) were named to be:

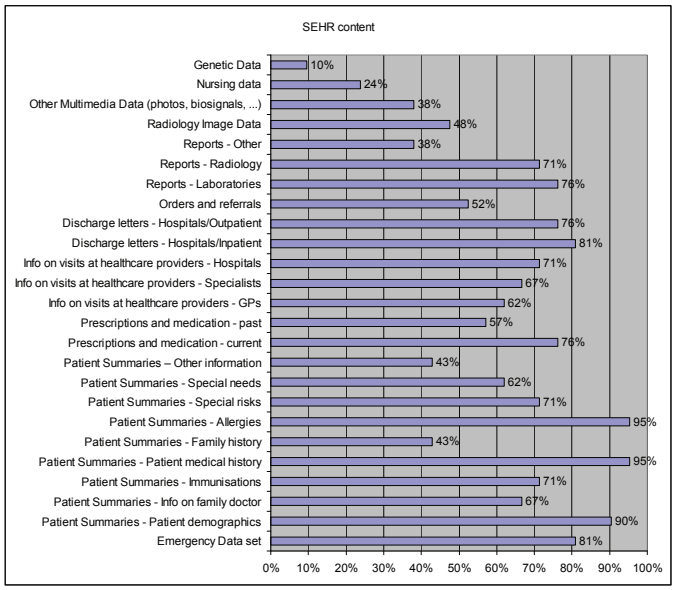

Figure 2 –Data items in SEHR

For the Israeli program, it was mentioned that a unified discharge summary based on HL7 V3 CDA was considered and confidential information on sexual abuse might also be part of the SEHR.

On the question regarding the standards and technical frameworks considered for the content and the communication of the SEHR, the participants gave the priorities listed in Figure 3. The participants see a clear prevalence of HL7 CDA (eg. over CEN 13606) for the SEHR content. IHE XDS is also very popular as a set of protocols for access to SEHR data – but only slightly in advance over CEN EN 13606 EHRCOM, in which's scope transmission of healthcare information is also contained. Even though CEN EN 13606 will be a harmonized European standard once completed, the HL7 CDA as ANSI and ISO standard has good reception since its adoption by industry is much better. The good acceptance of ICD and ICMP does not come as a surprise. SNOMED CT is very well considered with 42 %. The popularity of DICOM can also be seen. For Denmark, it was pointed out that the national B-EPR standard which is akin to CEN 13606 is being used. For Italy, the compliance of the SEHR with the "Sistema Pubblico di Cooperazione (SPCoop, Public Cooperation System)" as a national standard was noted. This compilation gives an impression of the importance of various standards, technical frameworks and nomenclatures in the eyes of experts in the field. Since in most cases, the SEHR programs are

still in their very early stages with room for adaptation driven by the national experts, possible directions for the adoption of standards can be seen, where there are no binding regulations yet.

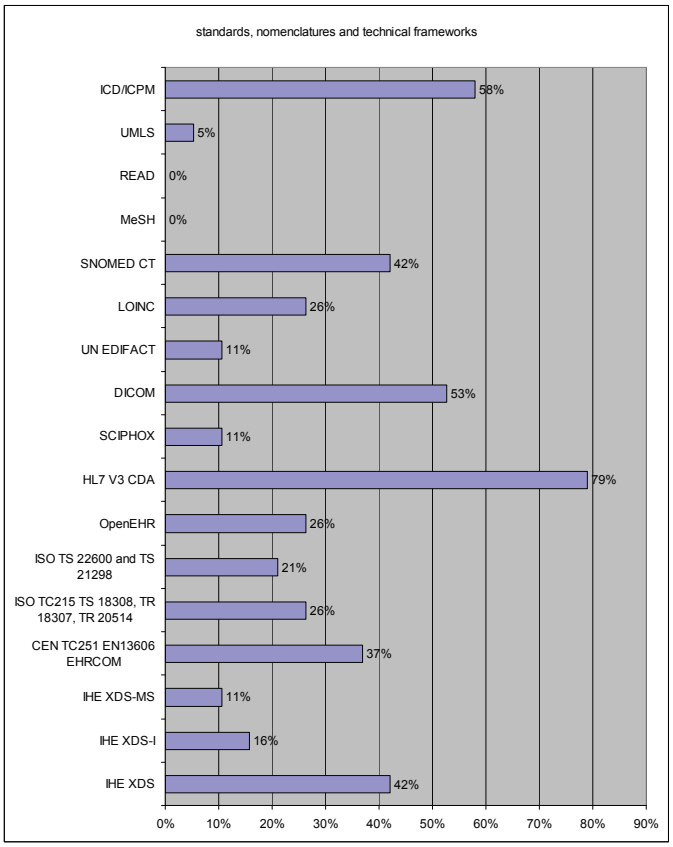

Figure 3 –Standards and technical framework

Conclusion

Contrary to the approach in [9], not national governments or e-Health competence centres were approached with questions on the technical aspects of the national SEHR programs but experts working on these projects. This brings in a certain bias from the individual viewpoints of these experts, but also "official" statements by government institutions (Ministry of Health, national competence centres) do not have to reflect the situation indisputably – apart from being very hard to obtain on a technical level. Looking on the agreement between multiple participants from one nation, it can be seen that there is generally good consensus on the main technical issues. Most disagreement comes from early stage of the programs and transitory phase from pilots and basic infrastructure to full SEHRs. The SEHR programs are in an early stage where specifications are not finalized and still subject to change. Research and pilot projects, that have in some cases been initiated more than a decade ago, are present in some countries giving directions for how pervasive solutions could work and have to be incorporated into future infrastructures. Regional and national activities coexist to form together the SEHR functionality. National approaches are fairly different across Europe and trans-national interoperability is not seen as a core issue. Industry standards and initiatives (HL7 CDA, DICOM, IHE) are most influential amongst the experts and thus have the potential to lead to basically similar and interoperable architectures for SEHR across Europe. The European standardization effort (CEN EN 13606) is not seen as so important. For the SEHR architecture, most participants foresee a mostly decentralized design with central patient index, but distributed metadata registries and data repositories. The Internet protocol is undisputed as basic transport medium – where secluded intranets as platforms for the utilization of the SEHR are predominant over encrypted communication via the public Internet. Chipcards are seen as one of the main means for patient identification for the SEHR, and health professional cards are rated top for identification of healthcare professions. The timeframe for completion of the SEHR programs is seen by most experts in their private opinion more sceptical than in the official statements, foreseeing completion mainly in a timeline 2010 or later.

Data protection in shared health records: requirements and challenges

Yara Mohammad
Dr Lampros K. Stergioulas
Dr Maryati Mohd Yusof

School of information Systems, Computing & Mathematics, Brunel University, UK

Introduction

With the advent of computers and computer networks, collecting and storing all clinical information about a patient in electronic files became reality [1].

An electronic health record (EHR) system offers improved access to patient-specific information and has major benefits in terms of the quality of health care and the quality of life of clinicians in practice [2].

The internet has offered us the capability to access medical information from anywhere, anytime, transforming the patient-doctor relationship, particularly with respect to sharing decision making between patient and doctors [3].

Privacy, Confidentiality and Security

Rindfleisch distinguished among privacy, confidentiality and security in protecting health care information [4]:

- **Privacy**: The right and desire of a person to control the disclosure of personal health information.

- **Confidentiality**: The controlled release of personal health information to a care provider or information custodian under an agreement that limits the extent and conditions under which that information may be used or released further.

- **Security**: A collection of policies, procedures, and safeguards that help maintain the integrity and availability of information systems and control access to their contents.

Electronic health records characteristics

Fritsche et al. noted that collection of comprehensive and valid scientific medical data through EHR should be [1]:

- Easy to install and maintain thus being less expensive.
- Time-saving for the medical staff (users) in their daily work.
- Able to store all medical information (including picture etc.) in retrievable format.
- Able to provide data validation by repeated use of the data in patient care.

Electronic health records characteristics

Shortliffe and Fagan argue that there are at least four major issues that have consistently constrained the efforts to build effective health record systems [2]:

- Standards are needed in the area of clinical terminology;
- Concerns about data privacy, confidentiality, and security;
- Challenge of data entry by physicians;
- And difficulties related to integration of record systems with other information and data in healthcare settings.

Electronic health records requirements

The basic requirements of shared health records are:

- Comprehensiveness
- Confidentiality
- Accessibility
- Liability
- Authentication
- Flexibility
- Permission
- Accessibility in emergency cases
- Maintaining Integrity of the health record

Electronic health records requirements

There are some legal Issues regarding health records such as:

- Jurisdiction
- Legally valid agreements
- Legal implications of shared practice of medicine
- Patient's right to review and release their records

Achieving Privacy in Electronic health records

In some cases to protect privacy and confidentiality, EHR data must be:

- Anonymised, and
- De-identified.

Anonymisation usually involves stripping patient identifiers (name, address, social security number, hospital record number, etc.) from records or substituting a false identifier for the real identifier [5].

De-identification entails removing the specific identifiers listed in the privacy rule and determine there is no other information that may identify the individual [6].

Current and future challenges of data protection in shared health records

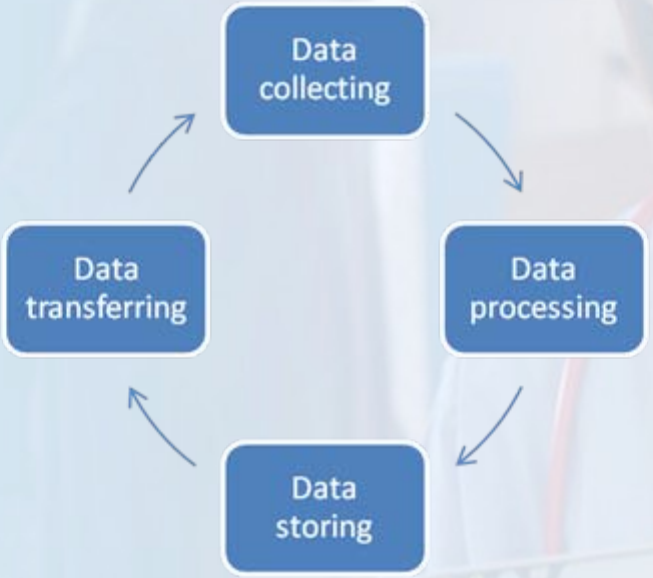
- Some patients and doctors have expressed concerns about the use of the new technology in shared health care record services. Most of these concerns are related to data protection and confidentiality issues.

- Some issues should be considered while moving from a paper-based record system to a computer-based one, such as the needed time of transmission, resources, management and administration tolls and staff, and basic technology infrastructure [2, 7].

- Some people will find ways to get secure information by exploiting human weakness to bring pressure to bear on someone with legitimate access to health information [7].

Current and future challenges of data protection in shared health records

Data could pass through four stages:



Data protection abuse could happen in any of these stages.

Conclusion

- The concept of security is intrinsically correlated with other aspects of EHR, including legal, technical, social, political and financial. The nature of these relationships between security and other issues depends on the specific user of the electronic patient records.

- The advanced technologies needed for implementing secure systems almost always make the use of the system more complex for the users. This complexity can reduce the benefits of using new technology and limit its advantages. The grand challenge for the future will be to provide a secure and at the same time user friendly electronic health record system.

Information Extraction from Medical Notes

Scott Kraus[a], Catherine Blake[a], Suzanne L. West[b]

[a] School of Information and Library Science,
[b] School of Public Health, University North Carolina at Chapel Hill, USA

Abstract

Health providers tend to prefer free text when describing drug dosages prescribed to their patients. However, unstructured text is not amenable to large scale analysis such as data mining. In this paper, we explore four methods that automatically identify drug, dosage,and method of delivery information from transcribed physician notes.

Our final method uses just one extraction heuristic, and achieves an average precision of 96.74% on a training set and 96.70% on the test set and average recall of 69.48% on the training set and 79.72% on the test set. These results suggest that a small number of heuristics can provide accurate extraction of drug, dosage and method of delivery information in medical notes.

Keywords:

information science, medical; Clinical Laboratory Information Systems; information extraction

Introduction

Health professionals need the flexibility of unstructured text to express their diagnoses and treatment strategies. Thus, the presence of unstructured text is inevitable, but, for data mining, information systems are required to convert the unstructured text to a structured representation for analysis.

There are two key approaches used to extract information from unstructured medical text: supervised learning, and a knowledge-based approach. Successful supervised learning models that have been demonstrated on biology include maximum entropy models[1], hidden Markov models[2], naïve Bayes, and decision trees[3]. In contrast to supervised learning, a knowledge based approach does not require labeled examples. Instead, dictionary lookups and heuristics help in extracting key facts from text. Successful implementations of knowledge-based approaches can be found for medical literature[4][5], radiology[6], and histopathology[7].

Materials and methods

The data used in these experiments comprised narrated notes for 12,222 patients in the University of North Carolina at Chapel Hill (UNC) hospital system. The notes were transcribed and anonymized prior to our analysis as part of a parent UNC DEcIDE project. The goal in the parent project is to identify treatment and outcome patterns for newly diagnosed patients with type II diabetes mellitus, some of whom have cardiovascular comorbid conditions. The parent project had access to both structured and unstructured data, but, our experiments consider only the patient note.

Method 1, the first experiment, used a subset of diabetes drugs to trigger the text extraction. This experiment used the GNU Awk (gawk) script language. We worked closely with experts from the DEcIDE team who were familiar with drugs commonly used to treat diabetes. The output from this experiment was used for discussion with the DEcIDE team, and was instrumental in the design of future methods.

Our goal in Method 2 was to provide DEcIDE team members information to help them identify patients who already had diabetes. The script identified sentences that contained (a) the word "diabetes," (b) drugs commonly prescribed for diabetes, or (c) the word insulin. The input to this method was the result of a program that split notes into separate sentences.

The first two experiments revealed a surprising degree of regularity in the way physicians described the drug and dosages prescribed. Our goal in Method 3 differed in two ways: (1) identify *any* drug, and (2) focus on the drug *and* the amount of drug prescribed. Thus, Method 3 moves the trigger term from a drug to an amount and dosage combination.

We used enhanced grep (egrep), a UNIX text processor for Method 3. We added a UNIX C-Shell (csh) script to the framework, which enabled us to modify and document the regular expression more easily than in previous methods.

We constructed a training set comprised of 30 notes we selected at random from the complete set. Based on the training set, a single regular expression was selected for the final experiment. It ultimately identified words at least 4 letters in length, followed by a numeral or a number, and a unit of measurement. Parameters such as how the drug is to be taken and the frequency of the dosage will be extracted.

Results and discussion

We applied the script for Method 1 on the complete set of 12,222 patients. The script output included the patient ID, the date of treatment, and 50 characters before and after the drug that triggered the extraction. Our goal with Method 1 was to verify the text processing pipeline, which worked as expected.

Method 2 was applied to records belonging to 1,933 unique patients identified by the DEcIDE researchers. A test set of 166 patients was chosen randomly. The third author, using the criterion of successfully detecting diabetes patients, evaluated the results of this set manually. The method was found to have a precision of 61.33% and recall of 77.13%. The relatively low precision and recall were because our script did not account for negation. The most common error was family history of diabetes as opposed to diagnosis.

Our goal with Method 3 was to identify prescribed drugs and corresponding dosages. We also extracted the drug's prescribed frequency and method of delivery, if available. Drugs without dosages tended to refer to the patient's reaction, allergies, or other factors unrelated to current prescriptions.

A machine learning approach inspired our evaluation of the regular expression used in Method 3. We created a training set by selecting 30 random patient notes from the complete set. We then wrote the regular expression based on notes in the training set. Once the expression was complete, we selected an additional 40 patient notes at random to form a test set. We checked to see that the training and test sets were similar and found an average of 4.83 drug dosages per patient. A test set was derived from a random set of 40 patient notes, with an average of 3.78 drugs per patient.

The error analysis of the training set in Method 3 revealed that the most important factor is detecting a number followed by an SI unit. The analysis also revealed several legitimate dosages in the notes that Method 3 did not detect. The primary error in recall was due to unexpected units of measurement in the text. The second most important factor was correctly extracting the drug name. Three key reasons caused the drug extraction to fail:

1. The drug name did not precede the dosage.
2. The drug contained multiple words.
3. Short drug names. Method 3 requires that a drug name be 3 or more characters long.

We developed a fourth and final regular expression based on the underlying causes of error in Method 3. We made the following changes to Method 4:

1. Added floating point (decimal) numbers,
2. Improved the set measurement units used to trigger the heuristic, by expanding the list of SI units and added apothecary units, and
3. Removed unnecessary delivery abbreviation.

Without any background knowledge of drug names, Method 4 performed surprisingly well on drug extraction for the training and test sets (see Table 1). An informal analysis showed that drugs paired with dosages were usually associated with current prescriptions rather than drugs used previously.

Table 1 – Method 4 Detailed Training and Test Set Results

	Training		*Test*	
	Precision	***Recall***	***Precision***	***Recall***
Drug	86.96%	82.76%	86.81%	82.78%
Amount	100.00%	91.39%	100.00%	96.08%
Method of delivery	100.00%	62.03%	100.00%	91.89%
Prescribed frequency	100.00%	41.73%	100.00%	48.15%
Average	**96.74%**	**69.48%**	**96.70%**	79.72%

Precision for drug amount was 100% for both training and test sets because the method uses an explicit pattern match on the unit of measurement and its quantifier. The prescribed frequency recall, while low (41.73%/48.15%), is on par with other methods, as is the method of delivery in the training set (62.03%). This is due to variances in how the notes report frequency. We are continuing to work on methods to improve the currently low retrieval rate of prescribed frequency.

Conclusion

Our results show that a single extraction rule achieves precision of 96.72% and recall of 74.60% on a set of randomly selected notes. Precision was lowest for drug extraction (86.81%), and consistently high (100%) for amount, method of delivery and frequency. Recall was 44.94% for the prescribed frequency, but remained high for the other data.

Our final method ran at a rate of 24-26 notes per second with an Intel Pentium 4 2.0 GHz processor. This suggests that a single well defined extraction rule would scale well to larger numbers of notes, and result in precision and recall that are competitive with systems that employ deep natural language processing methods. Further research that characterizes high precision rules is critical if we are to

move towards a completely generalizable and scalable model of information extraction from medical records.

Information Extraction From Medical Notes

Scott Kraus

Catherine Blake

Suzanne West

University of North Carolina at Chapel Hill, USA

Motivation

- Medical Notes
  - Thousands of medical notes in any hospital system
  - Unstructured text not amenable for data mining
- Goal :
  - Accurately extract information from each note
    - Drug
    - Dosage
    - Method of delivery

Materials

- Data Set
  - Transcribed dictated notes
  - 12,222 patients in UNC Hospital
  - Anonymized
- Part of UNC DEcIDE project
  - Identify over-dosage of diabetes patients
- Gold standard
  - structured data sets
  - Physician annotated

Method Summary

Method	Trigger	Output
1	Drug name	± 50 chars from drug
2	Drug name or 'Insulin' or 'Diabetes	•Sentence •Trigger
3/4	Word > 3 letters & Number & Measurement Unit	•Drug •Amount •Method of delivery

Example – Method 1

- Trigger: drug name

Trigger: Drug name

We will begin the patient on her home dose of **Glucotrol**, 5 milligrams PO QD and we will give sliding scale insulin as needed.

- Output: 50 characters either side of drug

We will begin the patient on her home dose of **Glucotrol**, 5 milligrams PO QD and we will give sl

50 Character limit

Example – Method 2

- Trigger: drug, ‘diabetes’, ‘insulin’

Trigger: ‘diabetes’

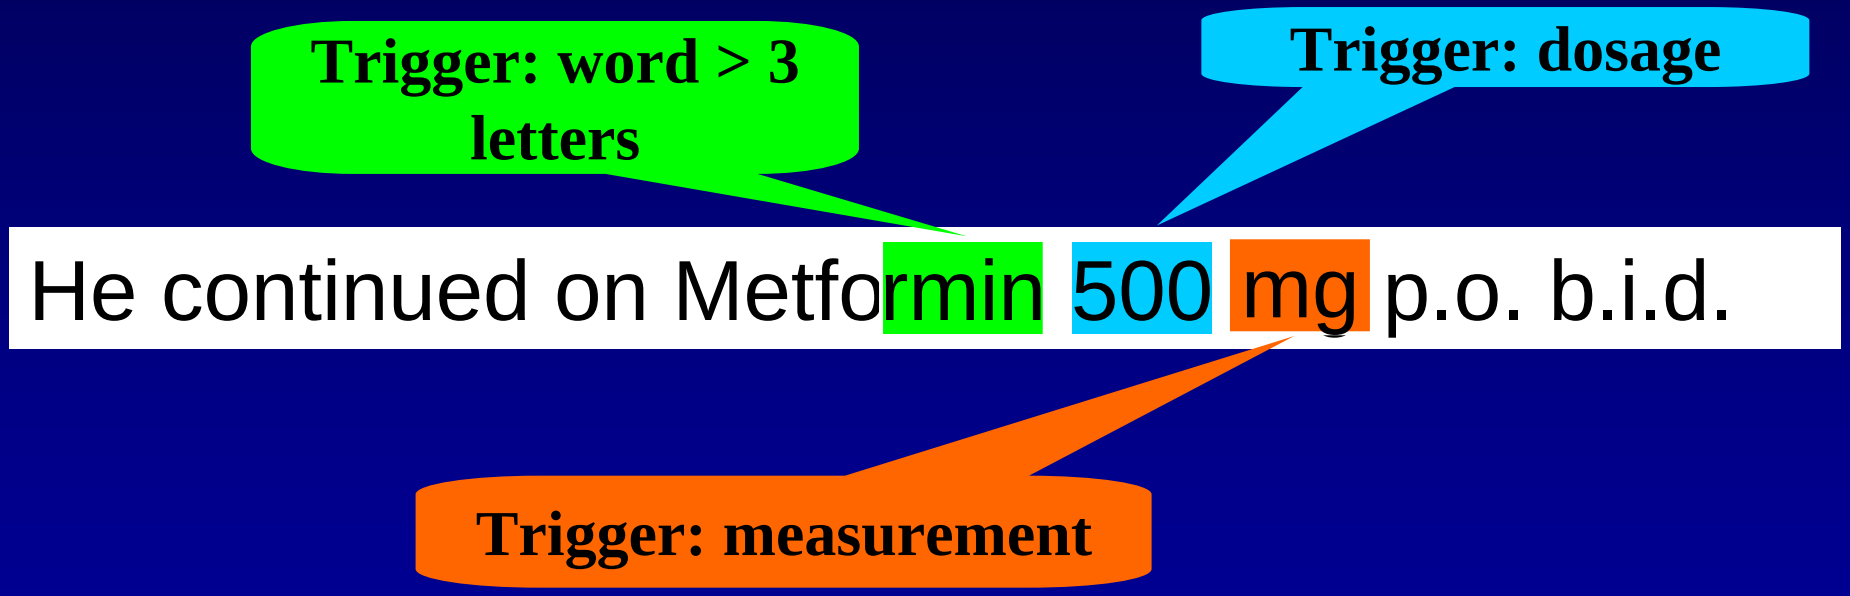
The other diabetes related medications are Actos 45 mg and Lantus at bedtime 20 units.

Trigger: Drug name

- Output: Entire Sentence

Example – Method 3/4

- Trigger: word > 3 letters, dosage, measurement

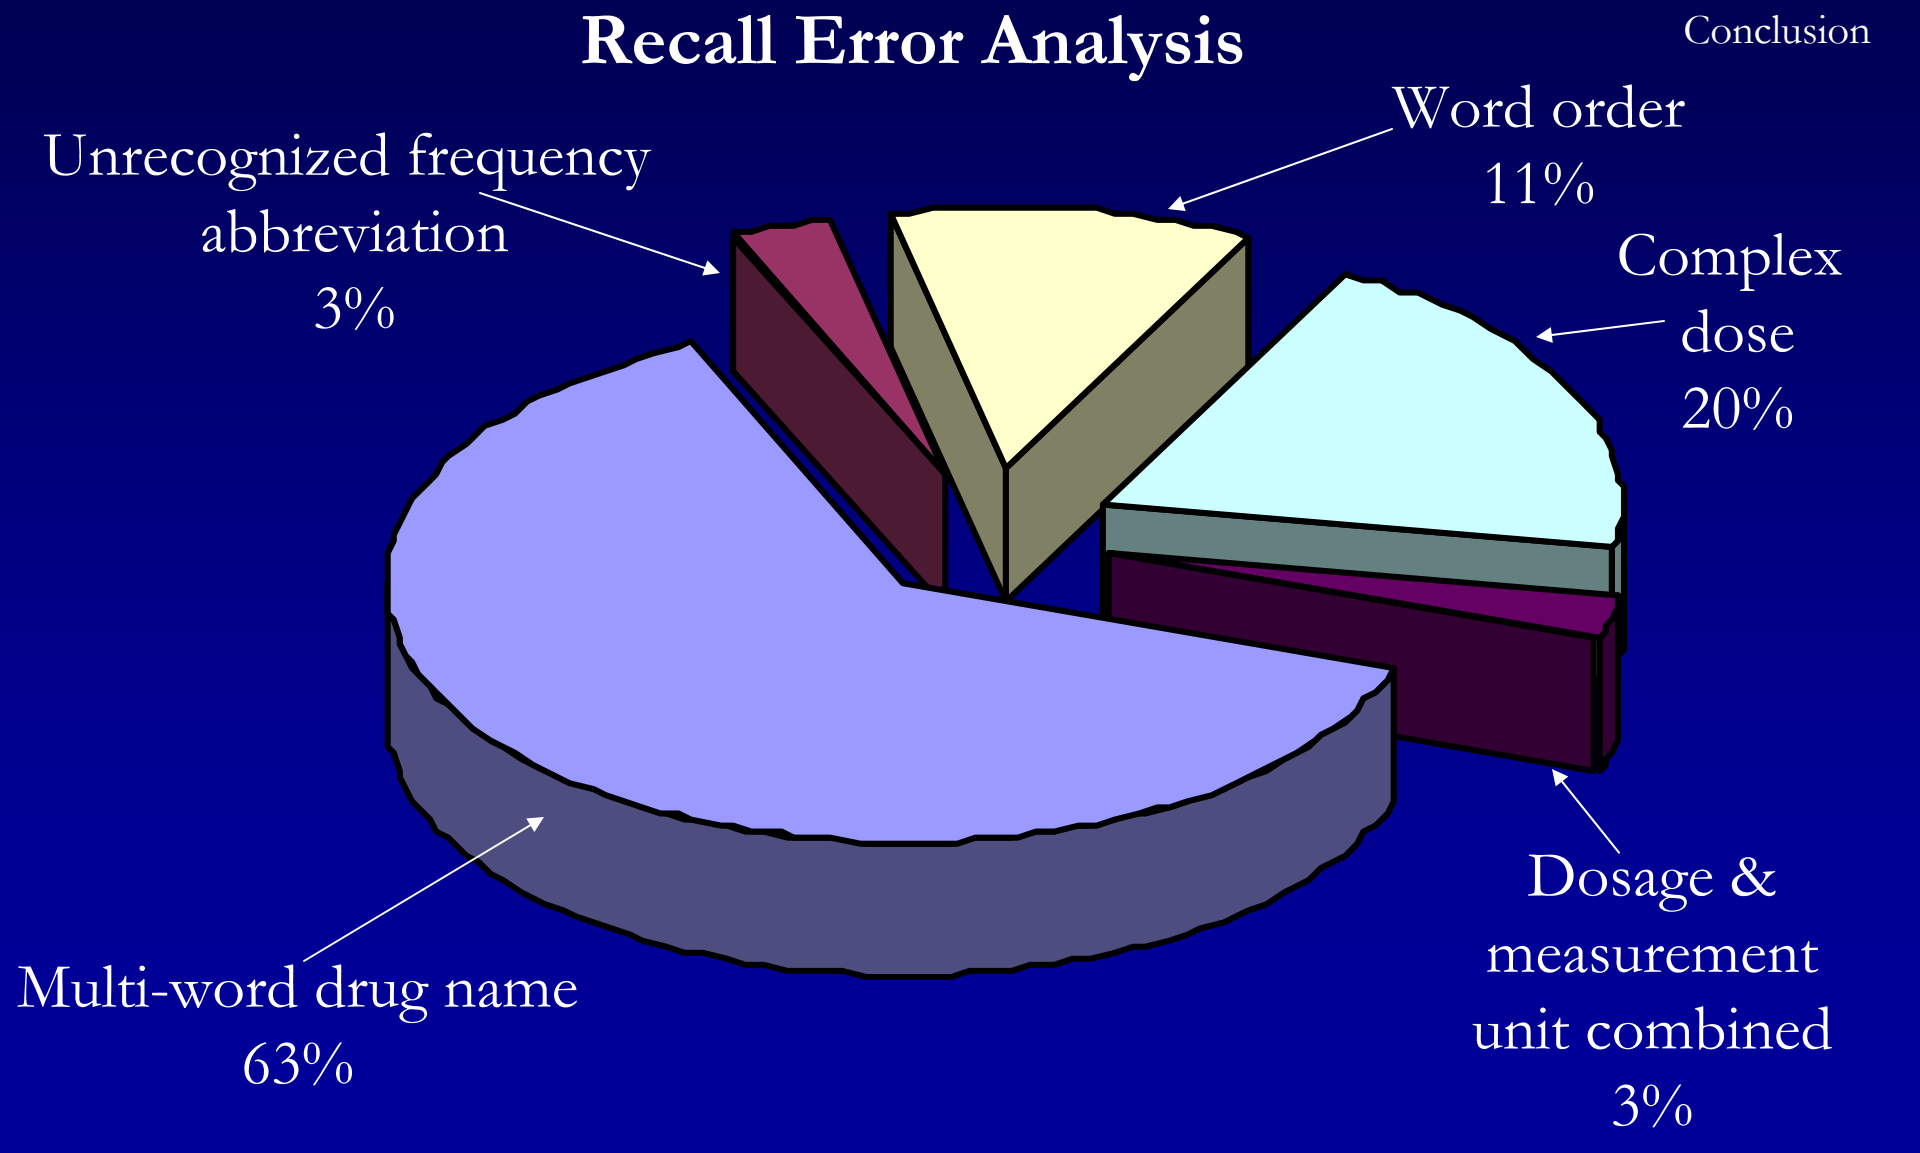


- Output: Drug, dosage, unit, delivery, frequency

Method 3/4 – Advantages

- Processing Speed
  - 24-26 patient notes/sec
  - Pentium 4 2.0GHz processor
- Drug name not used in trigger
  - Identifies new drugs
  - Missing or obscure drugs do not lower performance

Method 4 Limitations



Results of Method 4

	Training Set		Test Set	
	Precision	Recall	Precision	Recall
Drug	86.96%	82.76%	86.81%	82.78%
Amount	100%	91.39%	100%	96.08%
Method of Delivery	100%	62.03%	100%	91.89%
Prescribed Frequency	100%	41.73%	100%	48.15%
Average	**96.74%**	**69.48%**	**96.70%**	**79.72%**

Conclusion

- Average F-Measure (Test Set)
  - Drug 84.80%
  - Amount 98.04%
  - Method of Delivery 95.95%
  - Prescribed Frequency 74.06%
  - **Average** **88.21%**
- Scales well : 24-26 patient notes/sec

Developmental Context: Evolvement of the EHR Systems in the Russian Federation

Petr P. Kuznetsov, Andrey P. Stolbov, MS, Vadim V. Budenkov, Konstantin J. Chebotaev

Medical Centre for Information and Analysis of the Russian Academy of Medical Sciences

Abstract

Today's milieu of healthcare information systems on the post-USSR territories is a loose alloy of the inherited pre-perestroika structures with the modern healthcare governance initiatives, against the background of the rapidly developing private sector in the medical IT-industry. By providing a general picture of the diverse infrastructure that the new IT-systems of today rely on for better care delivery, we have tried to outline and accentuate the following: a growing degree of awareness of the need to develop this sector, to eliminate the inefficiencies of the triple-channel system of care budgeting, with each of the three elements – the Social Insurance Fund, the Obligatory Insurance Fund, and the Pension Fund of the Russian Federation – often serving literally the same means, and the developmental context for the formation of a nation-wide system of the personal socio-medical records in the Russian Federation.

Keywords:

medical record systems, computerized; academies and institutes; social security; insurance; funds; public health; data collection; registries; Russia; Russian Federation; Moscow; center, academic medical; pensions; retirement benefits; international health problems.

Introduction

In the Russian Federation, electronic medical records as such have been first delved into in the mid-sixties. That is when the first Russian works on information technologies in healthcare were published. The era of the seventies was marked with the first IT-systems applied at medical organizations, followed by the first corporative clinical information systems.

In the late seventies the USSR had its first computerized analytical centers at both national and regional levels. The systems primarily tended to the state's needs in aggregating medical statistical data.

These analytical systems matured through the 80s into the 90s, and at the moment the USSR ceased to exist in 1991, the network, comprised of these centers, was devoid of its vertical administrative support structure. From then on they went through a number of transformations to become the medical information-analytical centers as we know them today.

Today more than 40 constituent territories of the Russian Federation have their own medical information-analytical centers. Other territories of the Russian Federation have their own medical statistics bureaus within their healthcare governance structures. The Russian Academy of Medical Sciences, the top-level executive organ in medicine for the whole Federation, established its own Medical Center for Information and Analysis as a not-for-profit, non-governmental organization in 1997. Its primary function was registration of the data related to the high-cost federal budget care delivery and scientific research in the field of public healthcare (see Figure 1 and 2).

Current context

There evolved, and are functional, ten systems that register personalized information about the population of the Russian Federation (see Figure 1). All ten systems formed in different historical periods, vary greatly as to the motives for their establishment and are supported by different resources.

The State Automated System "Elections" [1] provides for personalized registration of all voters across the territory of the Russian Federation. All the voting-age citizens of the Russian Federation are registered by the computerized Information System which collects the following data: full name, date and place of birth, sex, citizenship, place of residence, and type of the identification document. Every citizen has the right of full access to his or her personal file.

The Visa and Passport Service within the Ministry of Internal Affairs that collect all personal data related to issuing passports and granting Russian citizenship.

The Civil Registry Office registers all the personal data pertinent to institution of marriage.

There are more than 800 clinical information systems across all the medical organizations in Russia today [2]. The non-state structures that form their own databases of socio-medical nature for the purpose of conducting their own business are various insurance companies and retirement funds, medical organizations, medical information-analytical centers, such corporations of the national scale as JSC Russian Railways, and JSC Gazprom, etc.

Seven of them are of the socio-medical character.

Figure 1 – current systems for the personalized registration of data in the Russian Federation

Taking into account their technical, human, and financial resources, three of them are capable of becoming system generators for a common system of the population data registration based on personal health records. All three are also public services – three of the government-established non-budget funds: the Pension Fund of Russia, a block of 91 Funds of the Obligatory Medical Insurance, and the Social Insurance Fund. There are rapidly developing mechanisms of exchanging information between all of them (see Figure 2).

The Social Insurance Fund [3] pays for medical care rendered to the disabled citizens, patient transfer to the organization where they have been referred to receive expensive hi-tech services, long-term care facilities for senior citizens, resort spa-and-rehabilitation packages, medical leaves, pregnancy and maternity leaves until the child reaches the age of 3 years old, and occupational disease and incapacitation compensations. This Fund, with its structure, resources, and mechanisms, has been inherited from the former USSR.

The Fund of Obligatory Medical Insurance [4] is a new formation (founded in 1993). It finances medical care rendered to the citizens of the Russian Federation within the framework of the State social guarantees toward free medical care provision. It has a system of registration of the personified data on services rendered.

The Pension Fund of the Russian Federation [5] collects the data on all the retired and working-age citizens – all employers are obligated to report to the Fund the number of their employees and the amount of their wages. Apart from that, there is a well-established data link for information exchange between the Fund of the Obligatory Medical Insurance and the Pension Fund for the purpose of providing medical care and medications to the retired. The key element of the Pension Fund is its unique system of the social security numbers that it assigns to each citizen of Russia. This number has a counterpart within the structure of the Obligatory Medical Fund and its 90 territorial branches – the unique number of the personal insurance police. As there is no federal-level uniformity amongst the subsystems (every Obligatory Medical Fund of each region has its unique ways of assigning numbers that evolved historically), it is considered highly desirable and productive to merge all the Obligatory Funds around the stem of the Pension Fund with its social security numbers identification system.

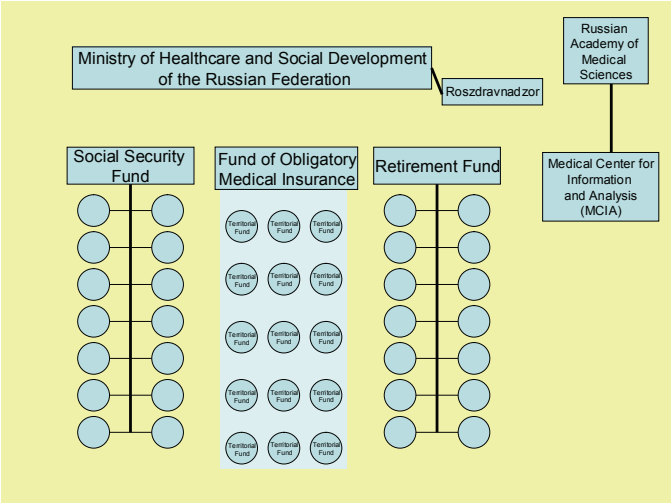

Figure 2 – Three existing systems capable of becoming central in the national health information system

Licensing, supervision, and control functions are carried out by the federal executive organ in the system of healthcare and social guarantees – ROSZDRAVNADZOR [6] as a federal service within the Ministry of Healthcare and Social Development of the Russian Federation.

The national system of the personified socio-medical data registration is in its stage of active development. There is an evident need to define a nation-wide approach, to develop normative rules and creation standards, to actualize the system of aggregating, processing, and maintaining personified data of socio-medical character on the basis of personal socio-medical records.

In order to achieve a high level of interoperability and general performance with a national model, it is necessary to accept and adopt international guidelines, classifications and protocols of exchanging and safeguarding information.

Consolidated efforts of the information and communication technologies of the country should be directed at developing a national system in the nearest future. The "rules of the game" are a pre-requisite for this step – there

should be an architecture design as well as normative rules for establishing a national system of the socio-medical data with the basis on the personal socio-medical records.

A national system for the personified registration of the socio-medical data is developed and structured with the aim of improving social care delivery and making social care more accessible, extending the nations' life-expectancy, and improving its health. In this capacity, the system will become a fundamental element of the national priority project in healthcare.

Rapid evolvement of the global tendencies in public healthcare is inevitable, so is the quantitative aggregation and qualitative advancements in the development of the world-wide clinical databases (applied medicine, etc.). Russian model of the system for the personified socio-medical data registration is technologically the most advanced on the post-USSR territories. For the purpose of registration of the personalized socio-medical data it is necessary for the European, North-American and Russian systems to be maximally synchronized for best results.

Provider actions in response to drug alerts generated in the Composite Health Care System

Fola Parrish, Nhan Do, Nancy Orvis

Department of Defense, TRICARE Management Activity, Falls Church, Virginia, USA

Background

- Composite Health Care System (CHCS) is an integrated enterprise computerized provider order entry system (CPOE) used by the US Department of Defense

- CHCS is deployed at over 500 medical treatment treatment facilities worldwide

CHCS

- CHCS performs medication order checks for:
  - drug to drug interaction
  - drug to allergy
  - drug dosage
  - drug duplication
  - drug under-utilization
  - drug over-utilization

Study Objective

- To assess provider actions in response to drug alerts generated in the CHCS

Method

- Survey of prescribing providers was conducted at two military treatment facility (MTF) clinics:
  - Military Family Health Clinic at the Bethesda National Naval Medical Center
  - General Medicine Clinic at Walter Reed Army Medical Center

Survey Participants

- Physicians (17)
- Physician assistants (5)
- Nurse Practitioners (6)
- Dentist (1)
- Pharmacist (1)

Demographics

Gender

- Male 15 (50%)
- Female 15 (50%)

Specialty

- Family Practice/Family Medicine 19 (63.3%)
- General Internal Medicine 5 (16.7%)
- Pediatrics 2 (6.7%)
- Other 4 (13.3%)

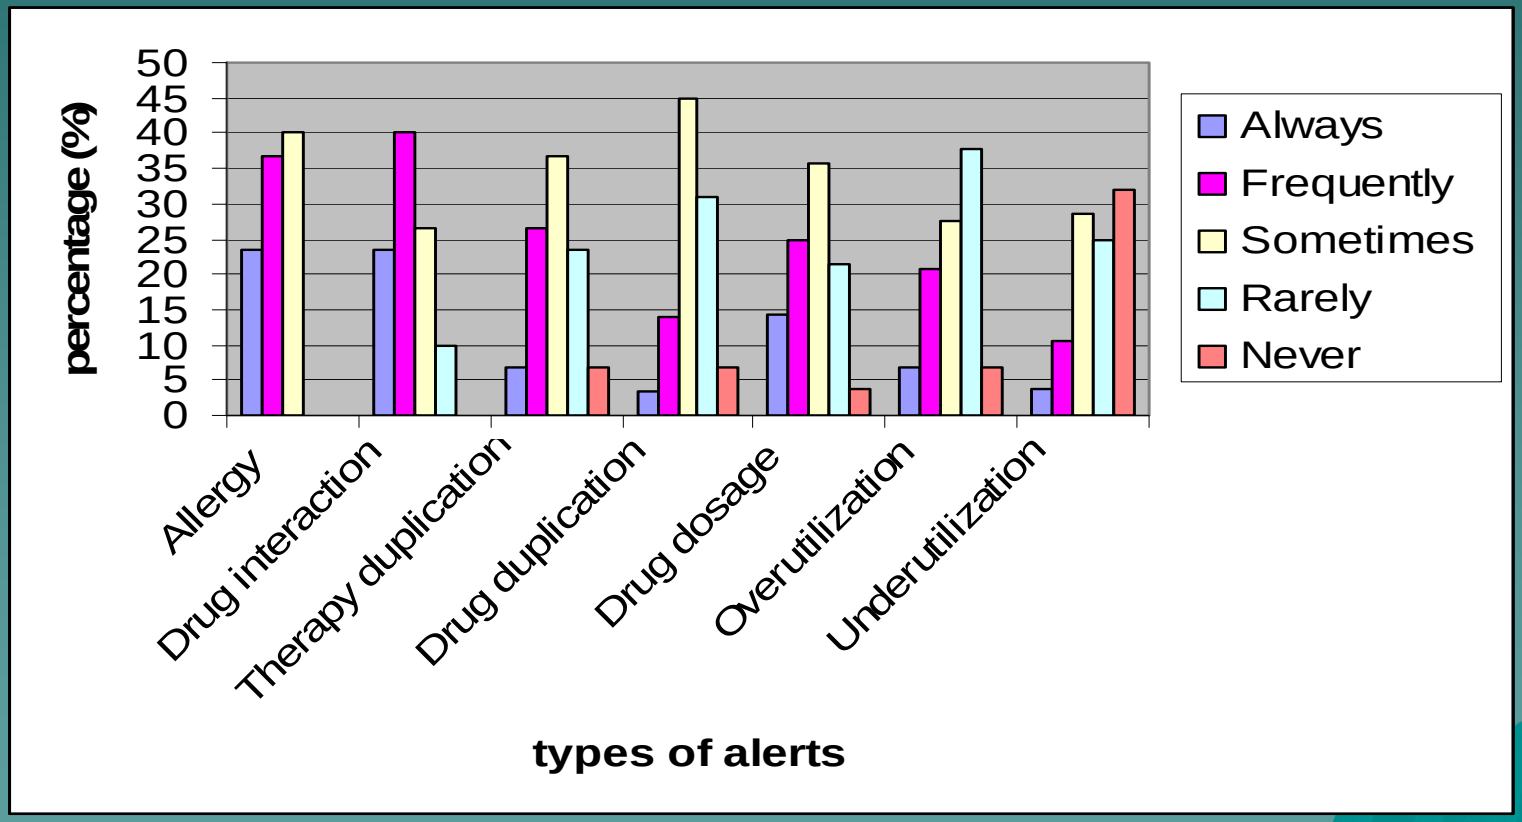
Usefulness of alert types

Type of Alert	Always N (%)	Frequently N (%)	Sometimes N (%)	Rarely N (%)	Never N (%)	Total N (%)
Drug-allergy	7 (23.3)	11 (36.7)	12 (40.0)	–	–	30 (100)
Drug–drug interaction	7 (23.3)	12 (40.0)	8 (26.7)			30 (100)
Therapeutic duplication	2 (6.7)	8 (26.7)	11 (36.7)	7 (23.3)	2 (6.7)	30 (100)
Drug duplication	1 (3.5)	4 (13.8)	13 (44.8)	9 (31.0)	2 (6.9)	29 (100)
Drug dosage	4 (14.3)	7 (25.0)	10 (35.7)	6 (21.4)	1 (3.6)	28 (100)
Drug over-utilization	2 (6.9)	6 (20.7)	8 (27.6)	11 (37.9)	2 (6.9)	29 (100)
Drug under-utilization	1 (3.6)	3 (10.7)	8 (28.6)	7 (25.0)	9 (32.1)	28 (100)

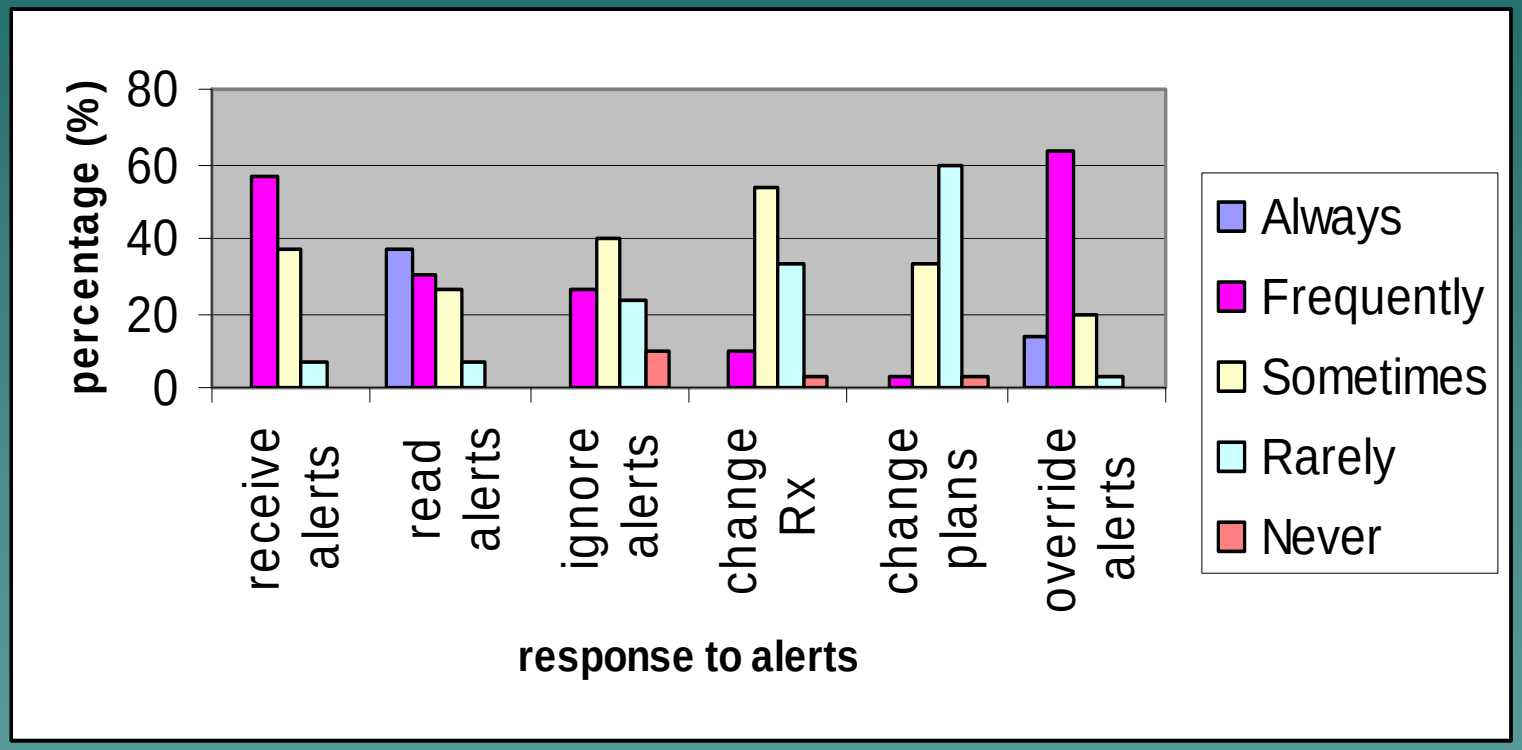
Provider actions to alerts

Provider action	Always N (%)	Frequently N (%)	Sometimes N (%)	Rarely N (%)	Never N (%)	Total N (%)
Receive alerts	–	17 (56.7)	11 (36.7)	2 (6.7)	–	30 (100)
Read alerts	11 (36.7)	9 (30.0)	8 (26.7)	2 (6.7)	–	30 (100)
Ignore alerts	–	8 (26.7)	12 (40.0)	7 (23.3)	3 (10.0)	30 (100)
Change prescription	–	3 (10.0)	16 (53.3)	10 (33.3)	1 (3.3)	30 (100)
Change / monitoring plans	–	1 (3.3)	10 (33.3)	18 (60.0)	1 (3.3)	30 (100)
Override alerts	4 (13.3)	19 (63.3)	6 (20.2)	1 (3.3)	–	30 (100)

Usefulness of alert types by percentages



Provider response to alerts by percentage



Conclusion

- Providers frequently do not consider alert warnings or messages in_making their prescribing decisions

- Eliminating specific alerts can improve system integrity and increase provider acceptance

Provider Actions in Response to Drug Alerts Generated in the Composite Health Care System

Fola Parrish, Nhan Do, Nancy Orvis

Department of Defense, Tricare Management Activity, Falls Church, Virginia, USA

Abstract

Computerized provider order entry combined with clinical decision support systems can alert prescribers to significant drug interactions, but growing evidence indicates that most providers often override these drug alerts. We conducted a survey of military prescribing providers in order to better understand their perceptions and actions in response to the drug alerts generated in the Composite Health Care System (CHCS). The majority of providers found certain types of alerts such as drug-drug interaction (63%) and drug-allergy alerts (60%) to be more useful than drug underutilization, drug over utilization, and drug duplication. More than three-quarters (77%) of providers indicated that they frequently overrode drug alerts during the medication ordering process. The results of our study suggest problems with the specificity and sensitivity of the alerts generated in the CHCS.

Keywords:

drug interactions, drug-allergy interactions, drug alerts, clinical decision support, medication errors, computerized provider order entry, CPOE

Introduction

CHCS is the computerized provider order entry (CPOE) system used by the Department of Defense (DoD) in over 500 medical treatment facilities (MTFs) worldwide. CHCS is integrated with clinical decision support systems and performs order checks for drug-allergy, drug-drug interaction, drug duplication, drug dosage, drug underutilization and drug over-utilization.

Methods

The questionnaire was given to prescribing providers at two busy military health clinics and to participants of a monthly workgroup meeting. Providers were required to indicate their agreement or disagreement to each statement or question on a five-point Likert-type scale.

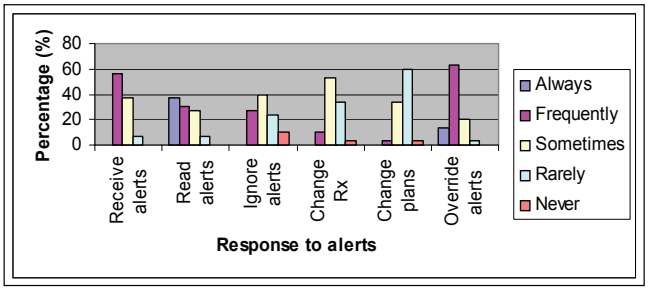
Results

Of the 32 questionnaires distributed to providers, 30 (94%) were completed and analyzed for this study. Demographically, survey participants were evenly divided between male (50%) and female (50%), and almost half had used the CHCS for over ten years (45%).

Providers found drug-allergy (60%) and drug-drug interaction (63%) alerts to be the most useful types of alerts while drug underutilization (57%), drug over-utilization (45%), and drug duplication (38%) alerts were found to be rarely or never useful.

More than half of the providers (57%) indicated that they frequently received drug alerts. A significant number of respondents (77%) admitted to always or frequently overriding drug alerts, 67% admitted to always or frequently reading drug alerts, and 27% admitted to frequently ignoring drug alerts (see Figure 1). Overall, 37% of physicians rarely or never changed their initial prescription decision based on the drug alert they received, and 63% rarely or never changed a patient's clinical or monitoring plans because of a drug alert. This could indicate that providers do not consider drug alert messages or warnings they receive in making prescribing decisions.

Figure 1 - Provider response to drug alerts



Conclusion

The high frequency of alert overrides expressed by providers may reflect problems with the sensitivity and specificity of the alerts generated by the system. Eliminating specific alerts or alert types that providers do not find useful can improve system integrity and increase provider acceptance of the CPOE. The findings of this study are consistent with results from studies conducted in civilian and private health care institutions.

Does Integrated EHR System Assure Safety Patient Management?

Kiyomu Ishikawa[a], Hidehiko Tsukuma[a], Norikazu Iwata[a], Takeshi Tanaka[a], Hisashi Ohmichi[b], Yoshimasa Umesato[b], Hitoshi Terasaki[b], Nakao Konishi[c],Akie Kawamura[d], Kayo Sakata[d], Teruko Sainohara[d], Miyuki Sugimura[d], Reiko Umemoto[e], Masashi Tooya[f]

[d] *Department of Nurse, Hiroshima University Hospital, Hiroshima, Japan*
[e] *Health Record Management Division, Hiroshima City Hospital, Hiroshima, Japan*
[f] *Department of Safety Management, Japan Council for Quality Health Care, Tokyo, Japan*

Abstract and Objective

To argue about a recent attack towards a policy to develop integrative networked Electronic Health Record (EHR) system as a basis for cooperation among care teams and with patients and in support of care for patient safety in Japan.

Keywords:

Electronic Health Record (EHR) system, Data use, Patient Data Protection, Confidential Information, Disclosure.

Introduction

Though the EHR is expected to decrease the variation in record quality, there is still no consensus on its social role. The idea that it is just the computerized version of the paper record still prevails. In our view, it will be necessary to develop it beyond that into the key medium for interaction of specialists in medical care.

Methods

As the basis for our work, two questionnaire surveys were executed by the author headed commission developing policy for Health Record structure and its computerization (E-Chart Taskforce). One survey assessed the attitudes towards a next step of EHR system in the Hiroshima university hospital and its affiliate hospitals. The other survey assessed the current state of safety management of EHR systems in the hospitals certified by Japan Council for Quality Health Care (JCQHC).

Results

The survey of the above hospitals showed that most have computer supported administrative procedures, but only few computer-based health records. The attitudes of the Hiroshima EHR users show that while they expect efficiency and quality improvements, there is also apprehension that the system in use might lower practical efficiency and compromise patient safety. Accordingly, health recording requirements and storage policy have been restructured and communicated to the hospitals.

Conclusion

Despite our effort to reflect the care process in the system operation, the current system in the opinion of medical staff is so complicated and unusable that it might impinge on operational efficiency and threaten patient safety. We are guided by the notion that the standardization of the EHR will lead to standardizing the safety of the healthcare process.
In order for the standardized EHR to become the basic medium for the interaction of specialists and patients in the practice process, we have to comprehend the EHR from the perspective of safety and quality of healthcare and reevaluate its computerization to arrive at a better blueprint for the next generation health system, which is worth while to disclose for patients.

[c] *health information technologies tirol GmbH, Leopoldstraße 1/1, Innsbruck, Tyrol, Austria*

Abstract

In an aging society with continuously increasing number of multi-morbid patients rising costs of the health care system are expected. The availability of relevant medical data across institutional boundaries is expected to improve quality and efficiency in health care services. In this work an IHE-XDS compliant architecture for Shared Electronic Health Records with a concept for End-to-End security is described. Therefore a security model with Role Based Access Control mechanism (RBAC) has been designed.

Keywords:

Computerized Medical Records System, community care networks, computer security

Introduction

In an aging society with continuously increasing number of multi-morbid patients rising costs of the health care system are expected. The electronic processing of medical data, which is expected to improve quality and efficiency of health care services [1] will lead to an increasing amount of medical data exchanged across institutional boundaries [2, 3].

A variety of existing standards for Shared Electronic Health Records (SEHRs) have been analyzed and the IHE Cross Enterprise Document Sharing Profile (XDS) turned out to offer a high level of interoperability while providing concrete recommendations for implementation [4]. XDS does not specify the underlying network architecture, nor are security aspects addressed.

End-to-End security, in contrast to Point-to-Point security, allows secured information to be transmitted via intermediate nodes without breaking security. Therefore securing of information, such as encryption and digital signing is handled by communicating applications and not by the network protocol as performed for Point-to-Point security.

According to national and international rules and regulations data security is a vital aspect of SEHRs. Medical Data GRIDs seem to be appropriate to address both, interoperability required by the IHE XDS profile and demands for End-to-End security regulated by the Austrian federal law for health telematics. This approach is currently beeing developed in health@net, a large scale project for trans-regional interconnection of major health care actors in Western Austria (about 700.000 inhabitants, 1600 GPs, 12 hospitals including one University Hospital).

Materials and methods

In an initial step functional requirements for a SEHR have been analyzed [5]. Based on this analysis a technical specification has been elaborated as requirements document. To ensure the highest possible level of security and data protection, functional requirements have been analyzed along with security requirements for trans institutional workflows in a SEHR.

Therefore a methodology known as SECTET is used to develop UML models that specify workflows between the participating partners. A starting point is the document model that defines the basic objects that are managed and exchanged by the system. In parallel a role model is developed that reflects the permissions and capabilities of the users of the system. These models guide through the elicitation of security requirements [6].

IHE – XDS (Cross Enterprise Document Sharing)

The IHE Cross Enterprise Document Sharing Profile (XDS) provides an architectural approach for document sharing in heterogeneous health care environments [4].

At the Document Source medical documents are produced, which are then stored at the Document Repository and made available to the end user (Document Consumer). The Document Registry is for indexing and search functions, the PatientID source provides a unique patient identification.

Medical Data GRIDs

The architecture is designed to be highly scalable and secure, to offer standardized interfaces and provide for interoperability across institutional boundaries. For this

reason an architecture following the blueprint of Medical Data GRIDs, that is an adaptation of Data GRIDs [7] to the requirements of the medical domain, seems to be most appropriate.

Role Based Access Control (RBAC)

Role Based Access Control is a concept for specifying and enforcing enterprise protection policies, where users can be assigned roles and individual roles can be assigned access permissions [8]. RBAC is a concept successfully used in various access control systems.

Architecture

Currently an open source prototype architecture based on the IHE XDS specification is being developed. The architecture and specific modifications necessary to meet legal and organizational requirements are described as follows.

To ensure greatest possible flexibility and scalability, a distributed approach following the above introduced paradigm of Medical Data GRIDs was chosen and implemented using widespread Web service technology. Services are implemented in the Java programming language with Tomcat as application server and Apache Axis as Web service framework.

The core architecture consists of independent services responsible for storing documents and corresponding meta data, security features, unique patient identification and service discovery according to the IHE XDS specification. In Figure 1 the IHE-XDS reference architecture is shown along with the services implemented in the prototype architecture. To guarantee a high level of security beyond simple transport layer security, Role Based Access Control as a security concept has been implemented.

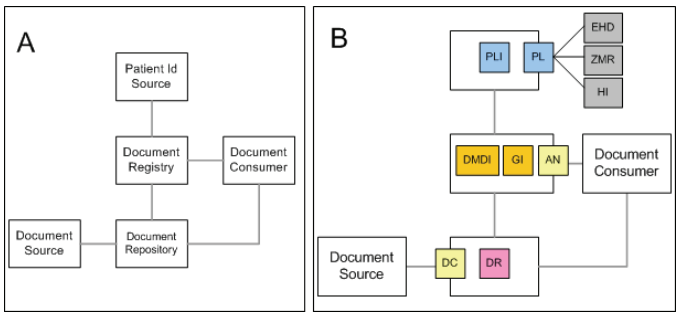

Figure 1: Health@net Architecture based on the IHE-XDS reference architecture. In (A) the IHE-XDS reference architecture is shown. In (B) specific adaptations for the health@net prototype architecture are described. Document Clearing (DC), Document Repository (DR), Document Meta Data Index (DMDI), Global Index (GI), Access Node (AN), Patient Lookup Index (PLI) and Patient Lookup (PL). Governmental services for obtaining patient identification

Core functionality is provided by the three service groups (IHE XDS Actors). Document Repository, Document Registry and PatientID Source. Medical documents remain stored in the organization where they have been produced in the Document Repository (DR). The Document Clearing service (DC) is responsible for converting documents from a proprietary format to the Clinical Document Architecture (CDA) format [9] internally used as data standard for interoperability. Local patient identification is mapped to the internally used unique identification.

The Document Registry service provides functionality for document search, per-document access permissions, a link to the physical location at the Document Repository as well as a service discovery unit. This service group comprises three services: Document Meta Data Index (DMDI), which holds search relevant meta data as well as document based access permissions.

The Global Index (GI) is responsible for finding Meta Data Index services that hold document meta data for a specific patient identified by the unique PatientID. Document consumers are only permitted to access the architecture via a gateway with well defined interfaces, provided by the Access Nodes (AN).

The PatientID Source service group provides for unique patient identification across institutional boundaries, independent form patient's nationality. The Austrian legal situation and the fact that a unique patient identification does no (yet) exist requires different services, partly provided by the Austrian government to be integrated in the architecture.

A Patient Lookup Index (PLI) is used as interface for other services (mostly DC and AN) to obtain a unique patient identification based on demographic data. A Patient

Lookup service (PL) is used to obtain this identifier transparently for the architecture from different governmental person ID sources.

Security Concept: Role Based Access Control (RBAC)

According to functional and technical requirements Shared Electronic Health Records have to fulfill highest possible security and privacy demands. Therefore fine-grained access permissions for all patient related information is required.

Well known information security techniques to ensure confidentiality, integrity, availability and authenticity are mandatory but there are still more domain specific requirements coming from patients, medical professionals or even from both. The following important aspects have been identified and can be found in the list below.

- 4 – eyes – principle (Doctor needs the patients attendance in order to access his health record). Exception: Patient can access and eventually modify his own data. Exception: Emergency access (special logging and informing of the patient).
- Possibility for the owner (patient/citizen) to completely lock/hide certain entries.
- Possibility to delegate time limited access to a doctor and possibility to delegate proxy access to family members.
- Encrypted communication and authentication based on digital certificates (mutual authentication of services).
- Austrian health insurance chip card (e-card) as digital ID-card for authentication with personal health record.

Based on those requirements a hierarchic two level security model has been elaborated as outlined in Figure 2.

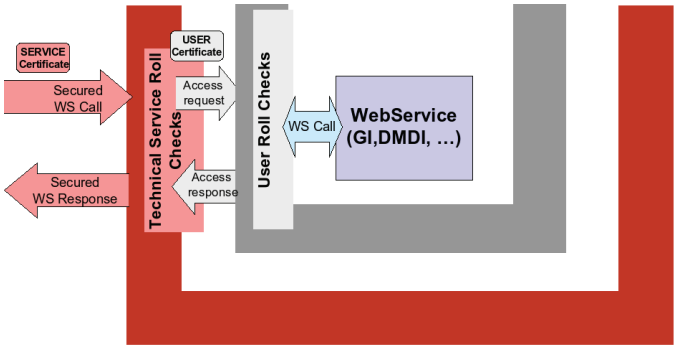

Figure 2 - Two level role check model. In the external level static service roles are checked, in the internal level dynamic user roles. For further details refer to the text.

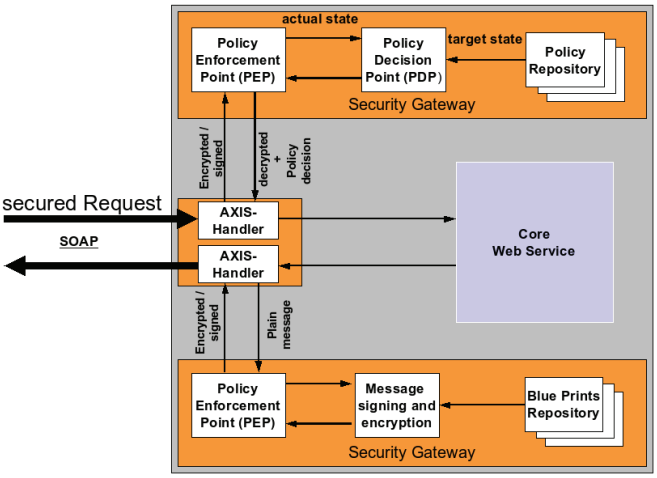

Figure 3 - Policy based security model. The middle part of the figure represents Axis Handler and Core Web Service. Decryption and verification of received messages is shown in the upper part. Encryption and signing of transmitted messages is described in the lower part of the figure. For further details refer to the text.

Level 1: Service role checks:

Each web service has to ensure, that it can only be called by registered and entitled Web services. The calling service has to send a certificate which the called service has to check. Therefore each Web service gets supplied with a service certificate signed by a trusted certification authority and stating out its role. Once a called Web service properly identified the role of the calling service it is compared to the locally configured policies in order to decide whether the call should be permitted or not.

Level 2A: Static user role checks:

After the service role check succeeded, permissions of the user that actually started the request have to be analyzed. As the Electronic Health Record will include different types of documents with different access rules they have to be checked as well. A pharmacist, for example, must not be able to see any discharge letter but, in turn, has to be able to access a patient's prescriptions. Therefore the same role based mechanism as already used in level 1 is applied.

At the time a user account is created, an appropriate user certificate is issued defining the user's profession and effective permissions (assignment procedure of permissions is beyond the scope of this work). When accessing a patient's health record this certificate is checked against the pre-configured policies of the corresponding Web service. For example: In case a user requests access to a patient's prescriptions and the user is assigned the role pharmacists, access will be granted.

Level 2B: Dynamic user role checks:

Furthermore it is important to check dynamic user roles. An authenticated pharmacist, for example, who is correctly trying to access patient's prescriptions should only be permitted to access the information if the consent of the patient is present. Again the same role based check method is applied. In Austria each citizen already has a unique health insurance smart card (e-card) with crypto card functionality. The certificate on this card (and the associated pin-code) can be used to check whether the patient has given his consent while a medical professional is trying to access his health record. Only if the patient's consent can be verified, access will be granted.

In the role based access control mechanism on each level of the security hierarchy actual permissions have to be checked. Therefore each Web service is configured with a set of policies. As the service is called from outside, an inspection is carried out whether the call confirms to the local policies and, only if so, the the requested Web service can be invoked. In case a request does not comply with configured policies the request gets rejected and logged.

For each request a state is extracted which is compared to local policies. If an adequate policy can be found where that the actual state matches the target state, a positive acknowledgment is generated and access is granted.

Implementation using Web Service Security

The security infrastructure is being implemented using Web Service Security Extensions. The Apache Web service framework Axis permits so called “Axis handlers” to be registered with the framework in order to extend it's functionality. In the architecture security functions are integrated via Axis Handlers.

This concept does not require Web services to be designed with security aspects in mind. The RBAC based security infrastructure is pluggable via the Axis handler.

The security gateway depicted in Figure 3 uses policies to map roles to access permissions. The figure describes how received data are decrypted and validated (upper part) and how send data are encrypted and signed (lower part).

Service roles and user roles are defined in the Policy Repository and can be changed dynamically. The procession of a received SOAP message is initially intercepted by the Axis handler and forwarded to the Policy Enforcement Point (PEP).

The actual state (e.g. current role of calling user and requested action) is then extracted and transmitted to the Policy Decision Point (PDP). The PDP searches for a policy in the Policy Repository which defines the requested action as permitted for the respective user. If a corresponding policy is found access is granted, the message decrypted, verified and returned to the Axis handler, which finally forwards the call to the original Web service.

Transmitted messages are processed in a similar workflow. The message is intercepted by the Axis handler and forwarded to the PEP. At this stage the message is signed and encrypted for the receiving service according to the policies in the Blue Print Repository. The Axis handler, as a last step, transmits the secured message to its destination.

The security model described in Figure 3 is the technical implementation of the two level role check model described in Figure 2.

Discussion and outlook

Currently a prototype implementation of the IHE-XDS compliant architecture with the role based access control methodology has started. The development of the network architecture follows an iterative approach which we have chosen to gradually adopt the architecture to evolving requirements of the major players. In this article the first prototype architecture is described including role and context based authorization system to provide for End-to-End security. A prototype is currently being released, which will demonstrate the conformance of the security mechanism to the above mentioned requirements.

The IHE IT Infrastructure Technical Framework [4] does offer Profiles for security, such as the Audit Trail and Node Authentication Profile (ATNA) and the Cross Enterprise User Authentication Profile (XUA). The first covers service authentication only on transport layer (without End-to-End focus), audit and centralized secure logging. The latter covers secure user authentication in trans-institutional context. XUA is not final yet, but the introduced RBAC based approach is expected to be seamlessly integrated in the XUA Profile.

Motivated by the above mentioned drawbacks (XUA is not final and ATNA only provides Point-to-Point and not End-to-End security) the RBAC based security infrastructure has been developed. Point-to-Point security allows secure information to be transferred between precisely two networked nodes. End-to-End security, however allows secure information, dedicated for a specific application, to be transmitted via an arbitrary number of intermediate nodes.

Currently static service role checks (level 1) and static user role checks (level 2A) are implemented. For dynamic user role checks (level 2B) further research concerning the application of attribute certificates is needed. Level 2B checks are expected to be integrated in the next software release, scheduled for the summer 2007.

Although the architecture is based on Medical Data GRIDs, in the prototype phase GRID middleware such as the GLOBUS Toolkit 4 [10] have not been used because requirements for Medical Data GRIDs, as outlined above, are currently not satisfactorily covered. Nevertheless GRID middleware provides interesting features particularly in the field of authentication and distribution of digital certificates. The adaptation of those concepts is planned for the next prototype.

The implementation closely sticks to the IHE XDS specification. Changes concerning the patient identification have become necessary to reflect the requirements of the Austrian federal law for health telematics. However, before IHE XDS based Shared Electronic Health Records can be used in production environment several technical and organizational aspect have to be solved.

Abstract and objective

Medical image data archives have been introduced at Innsbruck University Hospital in 1997 using write-once media (CD-R) for long term storage. Due to increasing data volumes, a migration of the archived data to high capacity magnetic tape storage media was necessary. To fulfil the requirements for guaranteed integrity and non-repudiation of the archived data, an additional data integrity layer was added to the commercial PACS software product to add digital signatures to the archived data and time stamp certificates. A time stamp server software suit had been developed by the hospital IT team for that purpose in 1999, issuing more than 2.4 million certificates since. The data integrity layer proved essential in early detection of a severe hardware malfunction in the tape archive system, which resulted in corruption of archived data in December 2000.

Keywords:

PACS, medical archives, time-stamping, data integrity

Introduction

The guarantee of data integrity in archiving medical data is a prime concern. Usually, this is resolved by using unalterable (write-once) media like WORM, CD-R, DVD-R etc. The first choice of archive media for the PACS introduced at Innsbruck University Hospital in 1997 was CD-R jukeboxes, and image data was only stored in one copy. Due to the fast growing volume of data archived, a decision to change to higher capacity magnetic tape media had to be taken in 1999, also to allow for duplicate archive copies of data to prevent data loss in case of media corruption (actually, in the course of data migration of 1.8 TB of compressed image data in 1999, one CD-R medium - from a total of 4.800 - was found to be corrupt, resulting in the loss of 157 imaging studies). To fulfil the requirements for guaranteed data integrity and eliminate the potential for subsequent alteration of archived data (non-repudiation) when using rewriteable media like magnetic tapes, an additional data integrity layer was added by the hospital IT team to the commercial PACS software product. This data integrity layer is a set of scripts that scan the PACS database for trigger events for archiving and retrieving imaging studies and provide the corresponding fundctionalities by interfacing to the archive management software of the magnetic tape archive. The archiving script scans the database for imaging studies due to be archived, then one by one collects together all image files of this study, and adds a digitally signed "study summary files" to the data set to be archived that allows to validate the integrity of the archive data (in subsequent retrievals) and also requests a time-stamp certificate from a time-stamp server for this archive data set, as a guarantee that the given data set was present at the specified point in time (and not foisted later in a possible fraud attempt).

Methods

To enable the commercial PACS product to use a tape archive system for long term archiving (instead of the CD-R jukeboxes), a software layer was developed by the hospital IT team to connect to the archive management software system. It was decided to archive image data in packages containing one imaging study each (ranging up to Gigabyte size for large CT exams). A study summary file is created for each study, representing an enhanced directory listing of all image files in the study, containing filename, creation date, file size and an MD5 hash of the image file itself (the MD5 hash algorithm was chosen for its fast execution time essential for the hardware available back then). This study summary file is digitally signed with a server specific private key (controlled by hospital IT staff). On retrieval of the archived data set at a later point in time, the signature of the study summary file is verified and the content of the study summary file is cross checked against the retrieved image data – allowing to detect any alteration in the image data files.

This still leaves open the possibility for manipulation by the hospital IT team in control of the signature keys. To eliminate this potential security breach, a digital time-stamping service was developed by a member of the hospi-

tal IT team in early 1999 as a Java application running under Linux. This service has been continuously operational since, issuing more than 2.4 million time-stamp certificates, one for each imaging study archived.

This time-stamping server receives request for issuing a time-stamp certificate via a proprietary TCP/IP socket based network protocol (standards for time-stamp certificate formats and request protocols have only been defined years later [1]). This usually contains an SHA1 hash of the actual data that is to be time-stamped (in our case, an SHA1 hash of the study summary file). The certificate issued is a text data set that is signed by the time-stamping system with its own private key. It is comprised of the data to be time-stamped (the SHA1 hash), the UTC time-stamp, a sequence number, and a hash of the previously issued certificate. This linear linking scheme is the simplest way to guarantee a tamper-prove sequence of time-stamp certificates. It is impossible to alter one of the certificates at a later point in time (even when in control of the signature key), because this would require changing all subsequently issued time-stamp certificates as well. To render even this impossible, once a month, the most recently issued time-stamp is send to a broader group of people to make it publicly known (publishing it in a printed periodical with wider circulation was also considered).

Results

The time-stamping system started operation in May 1999 and was first tested, when 1.8 Terabyte of losslessly compressed image data were migrated from 9 CD-R jukeboxes to the tape archive system in a 2 month effort in the summer of 1999. The dual archiving of data and the digital signature based data integrity layer proved enormously valuable, when a sporadic hardware defect occurred in the tape drives (or rather a SAN fibre channel gateway device) used in the tape archive system, corrupting part of the image data files.

In December 2000, when retrieving imaging studies from the tape archive the data integrity checks comparing data retrieved with the MD5 hash information from the data summary files stored along with the actual image data showed signs of data corruption and caused the hospital IT staff to initiate a problem analysis with the hardware vendor, which proved to be very difficult due to the erratic nature of the hardware defect. After lengthy analysis and due to the fact, that corrupted data sets could be easily identified, the problem could be tracked down and data recovery procedures were initiated.

The time-stamping service has been operating flawlessly since 1999, issuing a total of 2.4 million time-stamp certificates until now. Apart from the incident with data corruption, no data integrity problems ever occurred.

Conclusion

Ensuring data integrity and guaranteeing non-repudiation for magnetic tapes as long term archive medium for large volume medical image data using digital signatures and time-stamp certificates has proved to be a viable and cost effective solution and has been operational at Innsbruck University Hospital from 1999 on. More than 2.4 million imaging studies have been archived and digitally time-stamped. The inhouse development for the time-stamp server proved to be very stable and has been continuous in operation for 8 years. Nevertheless, the linear linking scheme used to generate a tamper-prove sequence of time-stamps has deficits in the verification process [2] and more efficient schemes have been proposed [3]. Due to the absence of standards available at the time of implementation of the time-stamp service, the protocol for requesting time-stamp certificates had been defined in a proprietary way. Subsequently, standards have become available [1]. And open source implementations for time-stamping services are now also available drawing on these standards (see [4] and [5]), which have the additional advantage to be able to utilize commercial Hardware Security Modules (HSM), which guarantee the tamper-prove generation of time-stamp certificates in hardware. Even though the utilization of time-stamps is undisputed, a new standard compliant system with improved security (eg. by using HSM and new secure hash algorithms) can be seen as a requirement for the new medical image and documents archive system, to which the PACS image data has recently been migrated. Anyhow, digital signature legislation limits the validity of digital certificates (the Austrian "Signaturgesetz" sets a maximum of 5 years for the validity for qualified certificates [6]), and thus a renewal of the signatures on the archived data sets has to be considered, best performed along with a periodic active rearchiving on new media to protect against data corruption due to media ageing.

De-Centralized Network System For Sharing Electronic Medical Records

Shinji Kobayashi

CHIHAYA Hospital, Japan

Abstract

Collaboration among medical specialists is necessary. Some regional medical collaboration systems have been developed using centralized models. The centralized model network determines collaboration within the network and cost too much. Therefore, we have preliminary developed a de-centralized medical collaboration system to overcome this barrier to collaboration as sustainable network. This model has some capability to establish sustainable medical network.

Keywords:

de-centralized communication, open source software, electronic medical record, internet, P2P

Introduction

Medical professionals collaborate via referral letters. There are some systems that enable the sharing of electronic medical records (EMR), within a wide area network, using a centralized model[1-5]. However, such models limit the communication and collaboration of EMR to within the network (Figure 1). If we wish to refer a patient to another doctor in such a model, we must confirm whether the doctor belongs to the network or not. Therefore, the centralized model network encloses medical specialist within its network and constitutes a barrier to medical collaboration. Consequently, the centralized model does not match real medical relationships.

Therefore, we preliminary developed a medical-record-sharing system using a de-centralized network to construct de-centralized network which connect every hospital seamlessly (Figure 2).

The aim of this project was to develop collaboration software that seamlessly communicates electronic medical records to other professionals using a de-centralized network.

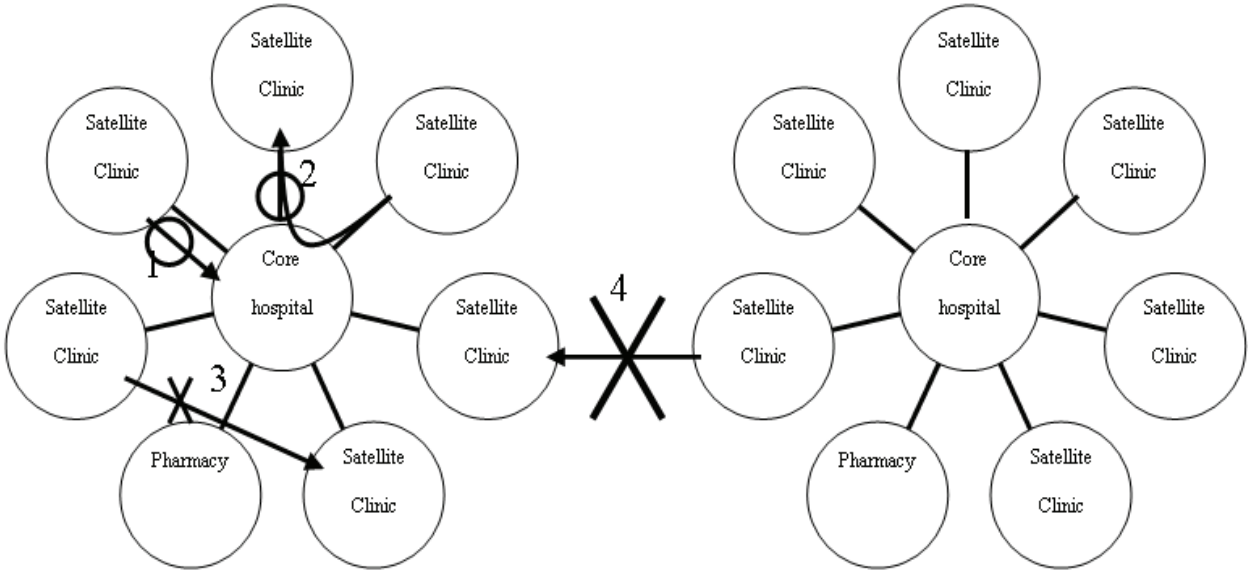

Figure 1 - Typical centralized network model. In this model, a satellite participant can refer a patient from the satellite to the central hospital (arrow 1) or to another satellite via the central hospital (arrow 2). However, a participant cannot refer a patient to another satellite directly, or to another network (arrow 4)

Methods

The system was separated into three modules: the medical referral letter editor, peer-to-peer (P2P) communication, and message management modules. We adopted Java as the development language and developed it using Sun Java 2 Standard Edition Software Development Kit (J2SE SDK) 1.4.2[6]. We used JXTA 2.1[7] as the P2P framework to construct de-centralized network, Eclipse 3.2.1[8] as the integrated development environment (IDE), and Concurrent Versions System (CVS) [9] to administer the source code. The CVS repository is placed on Sourceforge.jp and can be viewed at http://cvs.sourceforge.jp/cgi-bin/viewcvs.cgi/mega-net/.

Medical referral letter editor module

The patient referral letter implements a graphical user interface (GUI) to edit the message. The information in each message is stored as a Java instance and contains the patient's name, birthday, sex, age, diseases, clinical course, past history, family history, medications taken, and notes. After editing the message, it is sent to a medical specialist by the P2P communication module and stored by the message management module.

P2P communication module

For the implementation of this module, refer to the programmer's guide for JXTA[10]. This module includes the following features:

- Create or join PeerGroup with secure authentication.
- Extend PeerAdvertisement with hospital (institute) name, address, doctor's name, doctor's speciality, telephone number, and FAX.
- Publish and discover the extended PeerAdvertisement in real time.
- Connect peer to peer via an encrypted pipe.

The peer discovery algorithm is distributed hash table model implemented with JXTA. A PeerAdvertisement is generated when instantiating a group on a peer, and contains all the necessary parameters, including the participant's medical information in XML format. PeerAdvertisement propagates within PeerGroup, which can connect segments within a secure network cloud, and requires password authentication to join.

Each peer propagates its organization information and doctor's information within this securely protected PeerGroup to be identified. The participant sends an electronic referral letter to the other who could join this network with this authentication, on demand. The PeerGroup provides an encrypted pipe for peer-to-peer connections and sends a ciphered message with patient information using the TLS 1.0 protocol[11] to provide security against Internet sniffing.

When a message is received, this module decrypts the message and stores it on a local hard disk using the message management module.

Message management module

Each electronic medical referral letter is serialised as a Java instance. The serialised instance is saved and loaded on a local disk via a Java stream. This module stores messages that are sent and received via the P2P communication module. The messages are listed in a table and can be viewed as three windows, similar to the layout in MS-OutLook. This module also manages other items to extended PeerAdvertisement described before.

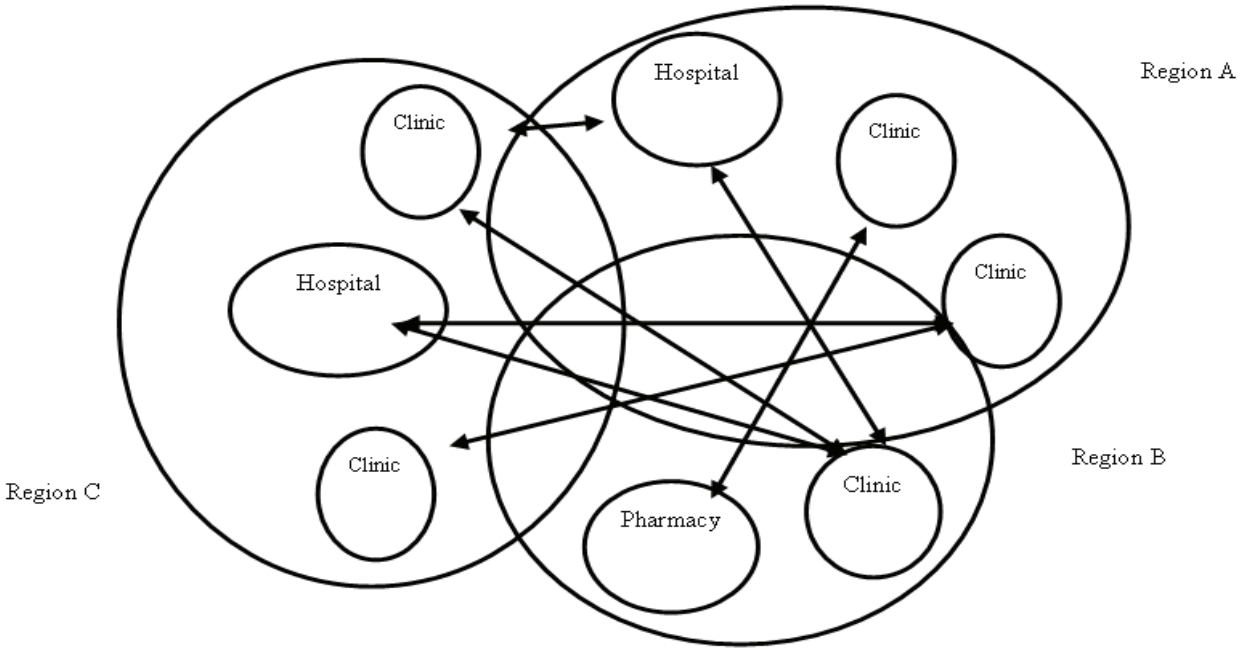

Figure 2 - De-centralized network model. In this model, a participant can make seamless referrals to other participants beyond the region

Results

Our system can successfully transfer encrypted electronic medical referral letters to doctors via a P2P network.

It takes about five minutes to configure this system for use after downloading it. Since there is no server, a client only needs to configure for his / her network. The configuration needs the P2P setting and user information. The only cost to join this network is that of downloading it.

Writing a referral letter

This system finds peers automatically. Information on peers can be viewed in a list window. The list shows the doctor's name, specialty, and organization name. The recipient of the letter can be chosen from this list.

The user can edit a referral letter with a GUI. After editing it, the message is sent to the selected peer instantly and saved on a local hard disk.

Message management

This system receives messages automatically. Messages are saved in two folders: 'sent' and 'received'. The list of messages can be viewed by GUI.

Discussion

As this project is a work in progress, many problems remain to be solved. Nevertheless, this system offers tremendous benefits that can make up for these problems. This paper discusses these problems and invites interested parties to join the project.

The most significant problem in setting up a health care network is that of interconnecting the centres within the network[12]. Each physician should be able to determine which medical specialist to collaborate with, rather than having this decided for him or her by the network architecture. In our de-centralized model, medical professionals can introduce patients to specialists outside the regional network system, as they deem appropriate.

Network model	Development	Maintenance (Server)	Maintenance (Participant)
De-centralized	$60,000	$0	$0
Centralized	$2,000,000	>$100,000/year	>$1,000/year

Table 1 - Cost of the network (Estimate based on other medical record network services which developed by the fund of national funds in our country.)

However, this system has critical problem that cannot send message to off-line participant, although in centralized system, server stores the message for off-line participant. To resolve this problem, we are now refactoring this system for off-line participant by queuing message on local until the participant is on-line to be send message.

In addition, since this system runs on Java VM, it does not depend on a specific operating system (OS). Therefore, this system has few restrictions, not only in terms of medical use, but also in terms of the computer environment.

One remarkable advantage of this system is its total cost (Table 1). In Santa Barbara County, US, P2P based medical system project also reported that it succeeded to reduce total cost of medical communication [13]. There is no cost for a network server with this system. Since we used open source products, we saved development costs. There is, in addition, no cost or fee for participants who wish to join this network. This constitutes a major advantage, as compared to other systems.

As contrast with centralized model, de-centralized network is looser combination with each information system. In general, tight information integration, which shares the same database, is easier to develop than loose one. If chronologically ordered data are needed (laboratory data centre, for example), centralized model is superior to the looser data integration[4]. Therefore, we have to develop some tight information combination interface to the other system that can apply under the open source license.

However, since our source code is open, others can adapt it to the communication module of their hospital information system. Our licence permits the use of our source code in proprietary software.

This system is robust against malicious Internet attack because the target is so widely distributed; this means that an attacker cannot jeopardize the entire system. Even if an attacker cracks the system of one participant, the other participants can still communicate with each other. While it has a lot of merits for medical specialist that EMRs are distributed and available like notorious file sharing systems, patient privacy issue does not allow it. Therefore, we decided security policy that peers can only send EMR to the associated doctor to refer a patient and the documented agreement of patient for transfer is necessary to transfer his / her record, and cannot issue query to the other peer to get unrelated EMRs. Under this policy, the risk of information leakage should be minimal because each participant only stores information on his / her own related patients.

This method does not conflict with inter-network communication, such as IHE-IDX. Peer-to-peer communication system can easily be adapted to organization-to-organization communication.

Although this system has some merits than the other system, legal issues has raised on P2P system. In Japan, P2P file sharing system named Winny caused many security issues that leak significant confidential matters on many personals, companies, and government (such as military matter). The author is accused in a court, whether to develop P2P software is guilt or not. This project is faced in the trouble that we cannot continue our development until this legal issues is clear.

Moreover this system has many technical issues on security and the other field, but we think it is only the technical issue that is able to be resolve. Therefore, we are trying to reconstruct this application over web-based framework, which can disclose electronic medical record to the consumer or the other healthcare provider with strict security for fair use.

Conclusion

We have preliminary developed a de-centralized collaboration system that can transfer electronic medical information seamlessly. As compared to other systems, our system has fewer restrictions, is inexpensive, and can be used to construct a robust network. Furthermore, our open source software has the potential to evolve, which will allow any remaining problems to be overcome in the near future. This system has the capability to enrich medical practice but has been faced to the legal issue.

De-centralized network system for sharing electronic medical records

Shinji KOBAYASHI
CHIHAYA Hospital

Introduction

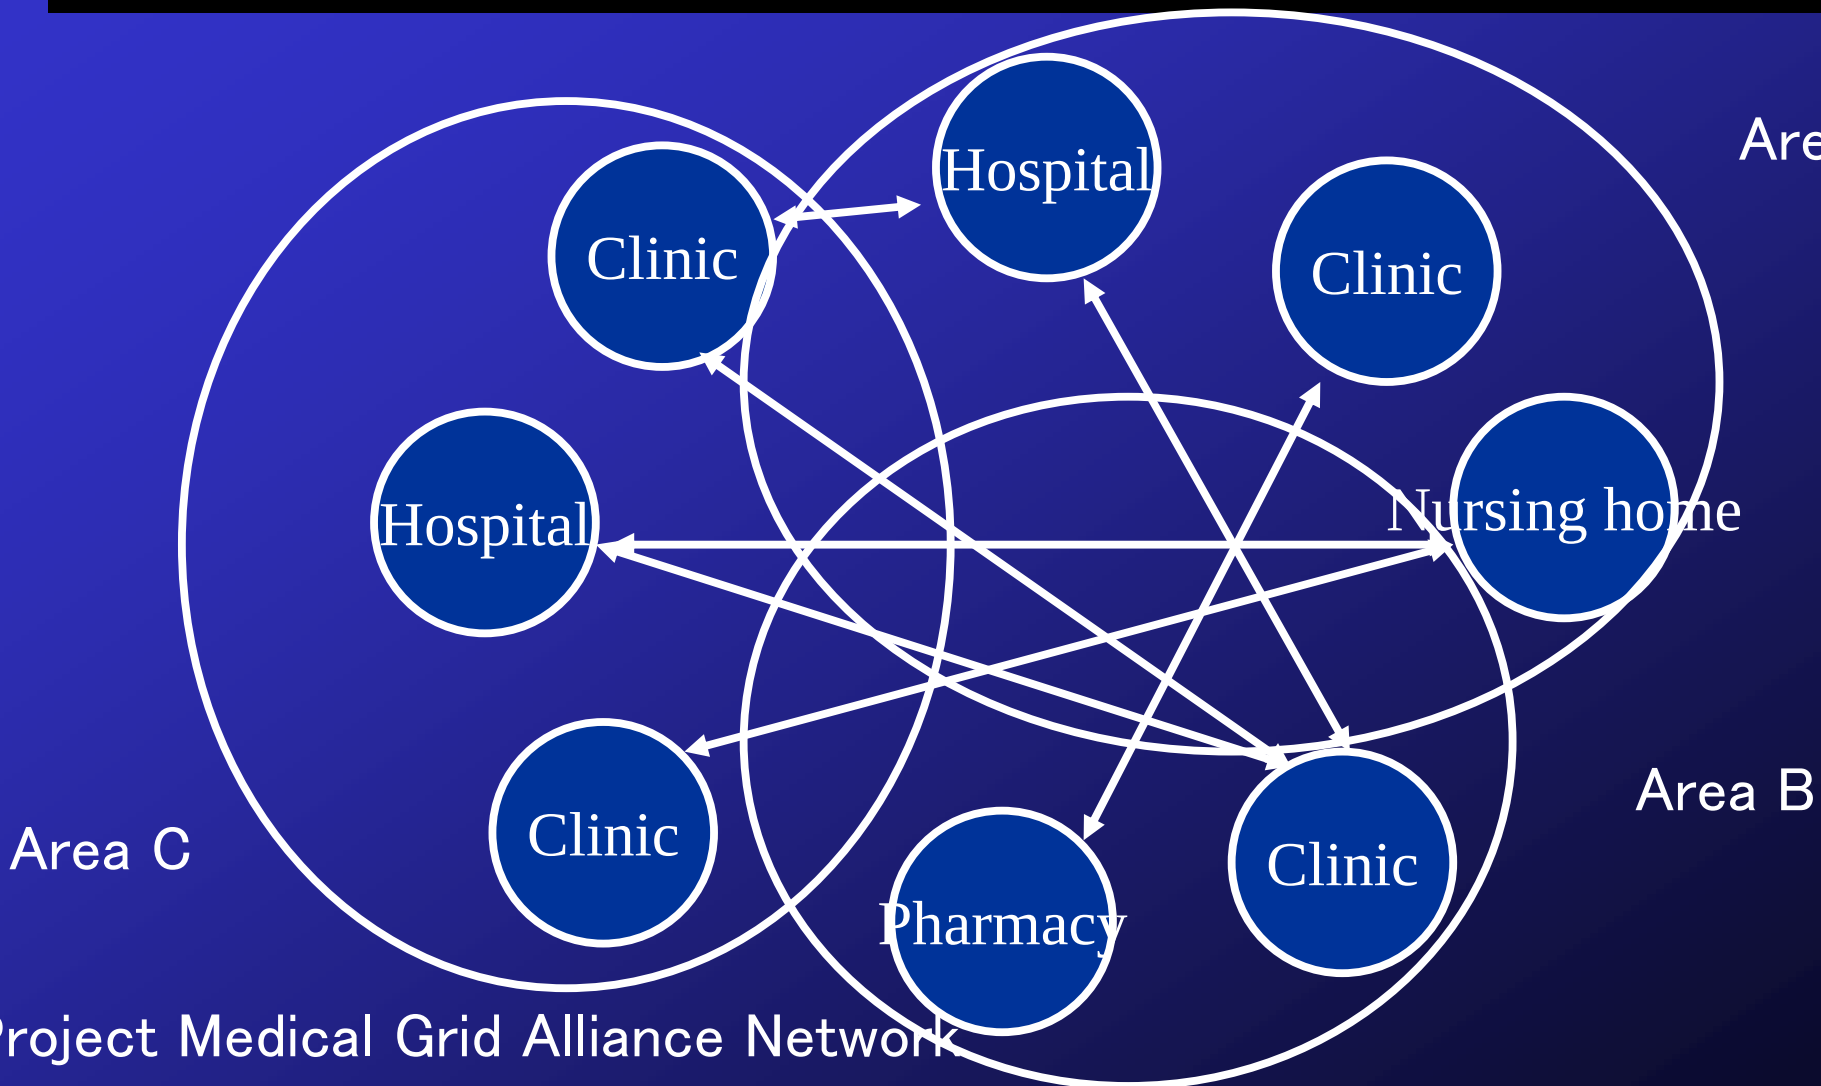
- Inter-hospital relationship
  - –Specialty, intensive care, collaboration
- Share electronic health/medical records
  - –Regional Healthcare Information Organization
  - –EHR
- Is centralized model(Client/Server) suitable?

Regional Healthcare Information Organization(C/S type)

Problem of C/S model

- Mismatch of relationship
  - Relationship is not only limited in organization, but also spread in mutual trust.
- Compatibility among systems
  - Incompatible format
  - Closed architecture
- Administration cost
  - Server, security, software, line
  - How it cost? Is it sustainable?

De-centralized model



Project Medical Grid Alliance Network

Methods

- Development environment

  Java2 SDK 1.4.2, JXTA 2.1, Eclipse 3.2.1, CVS for source code repository
- Software design
  - –Divided three modules, Referral letter editor module, Message management module, P2P communication module
  - –Referral letter editor
    - GUI editor for referral letter
  - –Message management
    - Message saved as Java instance
  - –P2P communication module
    - Search and manage participant healthcare provider by JXTA Framework 2.1, which is open source P2P framework.

Result

- Development
  Total 8547 line, 3packages, 49 classes.
- Software deployment
  Takes about 5 minutes
- Encrypted P2P communication
  - Transfer referral letters to each participant via encrypted pipe, by P2P technology
- Open source
  - We issued software repository on Sourceforge.jp.
    http://cvs.sourceforge.jp/cgi-bin/viewcvs.cgi/mega-net/

Screen snapshots

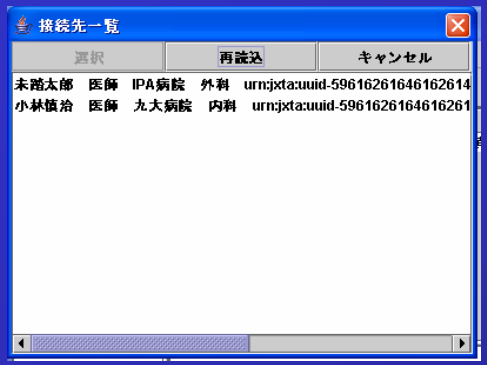


Figure 1. List of healthcare providers

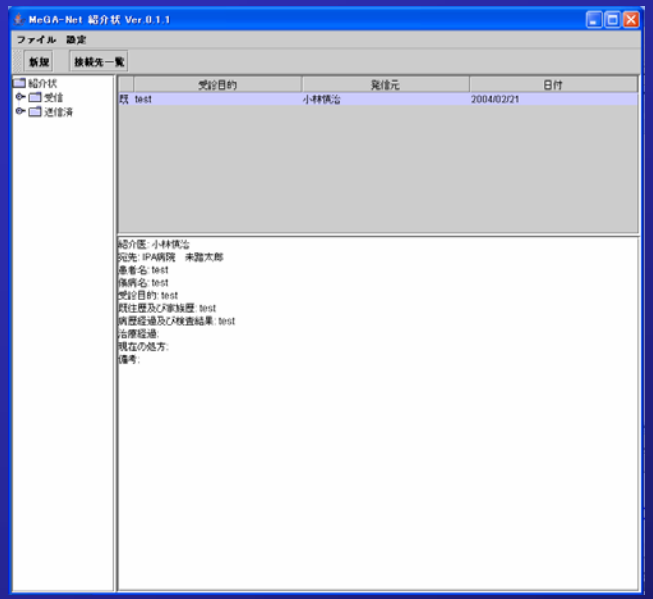

Figure 2. Referral letter management window

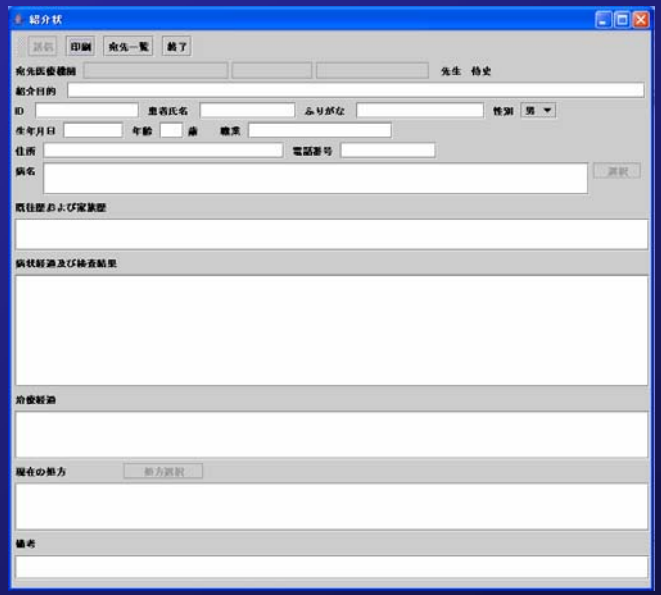

Figure 3. Referral letter editor window

Discussion 1

- Robustness
  - Peer-to-peer communication does not depend on a specified network route, but on duplicated route.
  - Attacker cannot crack entire network. される。
- Information leakage
  - Information is encrypted and transferred directly to each other to protect leakage by the third party
- Authentication
  - JXTA PSE(Personal Security Environment) authentication system implements PKI based authentication.

Discussion 2

- Cost
  - Reduced development cost by using open source software
- Deployment
  - No server setup, client setup only

Model	Development cost	Server maintenance cost	Client maintenance cost
De-centralized	$60,000	$0	$0
Centralized	$2,000,000	>$100,000/year	>$1,000/year

Conclusion

- We have preliminary developed a de-centralized collaboration system.
- As compared to other systems, our system has fewer restrictions, is inexpensive, and can be used to construct a robust network.
- This system has the capability to enrich medical practice but has been faced to the legal issue.

Acknowledgement

- This projected was supported by a grant under the Exploratory Software Project FY2003(IPA, Japan).
- This software has been supported by Sourceforge.jp as development platform.

The Development of Automatic Triage Score Messaging System at Emergency Department: Using Modified Canadian Triage and Acuity Scale (MCTAS)

JaeHo Lee[a], BumJin Oh[a], SangWook Lee[b], SungSook Kim[c], SungWoo Min[b], KyoungSoo Lim[a]

[b] *Medical Information Team, Asan Medical Center, Republic of Korea*
[c] *Nursing Department, Asan Medical Center, Republic of Korea*

Abstract

Triage is an essential component of emergency department (ED) patient management. Canadian Triage and Acuity Scale (CTAS) is a well known triage scale as a reliable tool for rapid patients assessment. The CTAS was modified and implemented to Asan Medical Center through electronic medical record (EMR) systems since April 2006. Automatic PDA messaging system of triage score to emergency medical staff was also developed. Local EMR database, the existing call system, and a new triage messaging interface were integrated. The system was designed as follows: Triage Nurses input modified CTAS score of a patient to nursing information sheet of EMR. If the modified CTAS level is critical, the triage score and other patient important information are instantly transferred to PDA phones of on-call staffs, and if patient's modified CTAS level is not critical, such information is transferred after 2 hours via reservation messaging process. This system is good for emergency communication and can be applied to other critical diseases as well like acute coronary syndrome.

Keywords:

triage, emergency, PDA computer, computerized medical record systems

Introduction

Triage is a critical reference when assigning emergency department (ED) patients' treatment priorities and treatment areas. Also, it is an assessment tool determining the time of stay at ED, and patients' expected outcomes. Canadian Triage and Acuity Scale (CTAS) is a 5-level triage system and is accepted as a more reliable tool than 3 or 4 level triage systems for rapid patient assessment at ED [1].

Asan Medical Center (AMC) is the Korea's largest tertiary referral hospital with 2,200 beds. Every day over 200 patients visit emergency room from all regions of Korea. Overcrowding is always a big threat for a critically-ill patient, because emergency personnel can not contact with him directly and instantly after his visit to ED [2].

AMC has been used other types of triage scale, such as AVPU (Alert, Verbal, Pain, Unresponsive) scale, Glasgow coma scale, Revised triage scale. These scales are simple and easy to use but sometimes inaccurate. These are composed of subjective measurements like blood pressure, mental status, etc.

So, after some modifications of the triage level, CTAS was introduced at AMC. Modified CTAS (MCTAS) scoring system was implemented to EMR system of ED. Automatic PDA messaging system of triage score was implemented for user's convenience and for the rapid triage information transmission. The developmental process and the architecture of the system were reviewed.

Methods

CTAS had been modified by five certified emergency nurses (CENs) and an emergency medical professor since December, 2004. The maximum reassessment time was shortened to one hour from two hour and the CTAS level of trauma patient was elevated a level higher [3]. These modifications were made after discussions of CENs and an emergency medical professor. Before the introduction of MCTAS, CENs had been used MATS (Modified Asan Triage Score) scale as an objective triage scale. The comparison study of the usefulness of two triage scale showed that MCTAS was more reliable than MATS in indicating the severity of condition of ED patients [3]. After then, MCTAS and its basic information were implemented to the EMR system on March 10, 2006. The user interfaces of MCTAS were developed after several times of discussions with the EMR developer team.

The automatic PDA messaging system of MCTAS was implemented with two purposes. The first one was to establish early and direct call system for emergent patients (MCTAS level I, II), the second was to alert on-call emergency staffs the delayed dispatch decision for non-emergent patients. The activation rules, contents of messages, message recipients were decided by emergency medical staffs. Automatic messaging service was started since March 17, 2006 after triage messaging interface was developed. The rules were adjusted twice, and a reservation messaging process was introduced after 3 months of the installation to serve the second purpose.

Results

The instant messaging system was implemented at first for high levels of CTAS: If a CEN inputs patient's triage score into a nursing information sheet window and restores it after other information inputted, the automatic triage messaging process is activated. If a patient's triage score is 1 (resuscitation) or 2 (emergent), EMR server sends it with patient dataset (e.g. patient's ID number, treatment area, chief complaint), and on-call staff's PDA number to SMS (short message service) server instantly through a triage messaging interface. After then, SMS sever sends the whole package of information to a PDA phone of an on-call staff within local wireless network area. If less emergent scores (3-5) are entered, the automatic triage messaging process is not activated. If a triage score of patient is changed to 1 or 2 during ED stay, this information is also automatically transmitted to on-call staff by above process.

The reservation triage score messaging system was implemented 3 months later: If less emergent patient (MCTAS score; 3~5) stays at ED more than 2 hours, reservation call is sent to on-call staff with the same dataset as above. This system was introduced to alert on-call emergency staffs the delayed dispatch decision for non-emergent patients and to solve overcrowding. However, too many messages were transferred to on-call staffs after reservation call system started. Because there are many patients with cancer and cardiovascular problem at AMC, patients could not be discharged easily with laboratory or imaging results only. The process was changed that the reservation call is sent to on-call staffs for only selected patients (fast-track area).

Discussion and conclusion

The overcrowding of ED is a common problem in Korea. This makes it difficult to assign patients proper priority for treatment based on the severity of their condition [3]. Triage is the process of quickly sorting and assigning the right patient to the right resources in the right place at the right time [4]. For this purpose, a comprehensive five-scale triage system has widely been accepted over other scaling systems as the most effective triage tool in ED.

Authors used CTAS for automatic triage messaging system after some modification. This system does not send all triage score of ED patient. The first consideration is a critically-ill patient. For this kind of patient, this system is an excellent communication tool between nurses and emergency medical staffs or between emergency residents and on-call staffs. This messaging system can replace paging system or notifying system in ED, especially for CTAS level 1 patient. Do we need to communicate with a colleague on the phone for the patient on resuscitation?

The reservation messaging system needs more evaluation. Too much PDA messages can be regarded as spam messages. The time limit, patient selection, and triage scores must be considered to change to reduce reservation call messages.

The automatic triage messaging system must be evaluated based on user's satisfaction, (system's) effectiveness, and patients' conditions in future studies. The optimum numbers of messages per day for emergency medical personnel are needed to investigate because more processes can use this automatic paging system. And the regulation of SMS messaging process must be established.

A Sustainable, Multi-Organizational Model for Decision Support During Public Health Emergencies

Julie J. McGowan[a,b], Shaun Grannis[a,b], Margaret W. Richwine[a], J. Marc Overhage[a,b,c]

[a] *School of Medicine, Indiana University, Indiana*
[b] *Regenstrief Institute, Inc., Indiana*
[c] *Indiana Health Information Exchange*

Abstract

In an effort to provide decision support during times of public health emergencies, Regenstrief Institute, Inc. and the Indiana University School of Medicine, in partnership with the county and state health departments, created a sustainable model to deliver information to health care providers and public health personnel. The model leverages extant systems and processes, including active disease monitoring through electronic laboratory reporting and syndromic surveillance, delivery of health information via the Indiana Health Information Exchange, and evidence based utilities and blog technology to create a public health utility with disease-specific information and epidemiologic reporting requirements.

Keywords:

disease outbreaks; bioterrorism; information dissemination; decision support systems, clinical

Introduction

Just-in-time knowledge at the point of decision making is critical to improving health care outcomes. This is especially true when crucial public health decisions must be made in response to a bioterrorist event or an emerging pandemic. However, the ability to access needed information has been extremely problematic because of the different levels of connectivity and training available to public health workers and health care providers across large areas.

To address this issue a partnership was formed among the Indiana State Department of Health and the Marion County Health Department, the Indiana University School of Medicine Libraries (IUSML) and the Indiana Health Information Exchange to establish a cost-effective model for both alerting health care providers and public health workers to developing threats and providing them the needed information for both treatment and reporting.

guidelines and the required reporting of the specified

Methods

The model, predicated on an earlier construct [1], was built on three existing programs. The Regenstrief Institute, Inc. in conjunction with the Indiana Network for Patient Care and the Indiana State Department of Health developed an automated electronic system for reporting notifiable conditions [2] and a state-wide syndromic surveillance system [3]. I3, the Indiana IAIMS (Integrated Advanced Information Management Systems) Initiative, through the Indiana Health Information Exchange and its DOCS4DOCS utility, provided a framework to notify health care providers about real or suspected public health emergencies. [4] The IUSML offered evidence based decision support using Web technologies.

The goals of the project were to insure rapid notification of public health problems to a large yet targeted group of health care providers and to provide access to quality filtered knowledge supporting treatment guidelines and reporting requirements. Because the eventual objective was to operationalize the model for long term adoption, it was essential to develop sustainable methods.

Automated electronic laboratory reporting of notifiable conditions uses LOINC test codes and HL7 messaging to provide timely information to local and state health departments regarding the potential for a public health event. Notifiable conditions from laboratories around the Indianapolis metropolitan statistical area are reported to the health departments. The enhancement model facilitates provider notification and the creation of decision support information.

The Indiana Health Information Exchange maintains a master list of clinical contact information in the central Indiana region. This "master physician index" enables the rapid notification of health care providers about emerging public health threats, and communications can be targeted to specific locations and/or clinical conditions. This insures a higher level of relevance of the warning for the provider. Simultaneously, the IUSML is contacted about the suspected problem and receives information concerning proposed optimum treatment and management condition.

The IUSML is responsible for searching for current evidence about management of the condition and creating a web presence containing this information in a format effective for users. In addition, reporting requirements and links to the health department web sites are included. To insure sustainability, a blog utility was chosen because the technology facilitates document creation and maintenance, is familiar to most users, and provides built-in searching functionality.

In addition to the reporting and management information for health care providers, a listserv is maintained for notification of public health workers. The health departments have their own systems for notifying their affiliated sites, however the notification of access to knowledge-based information is handled by the IUSML once the Blog site has been updated and approved.

While much of the information about emerging public health events comes from the electronic surveillance functionality, the public press also reports events of public health significance. Although press accounts commonly describe incidents in specific locations with little potential to spread, decision support may be beneficial for these events and the web site is updated as the need presents itself.

Results

As of November 2006, there were thirteen public health events that prompted creating knowledge support on the web site. The mechanism for the notification of health care providers has been developed using extant resources but has as yet to gain widespread adoption, not because of the technology but because of organizational issues.

The process for the notification of public health workers was implemented with the second public health event posted and, as a result, the utility has achieved wide spread use. Anecdotal responses to the initiative have indicated that the Web site has provided critical information managing both health care conditions and epidemiologic reporting.

Discussion

By using three extant processes, active surveillance through electronic laboratory reporting, DOCS4DOCS delivery of information to health care providers, and the evidence-based medicine services of the IUSML, a sustainable model was developed to deliver decision support information to targeted health care providers and public health workers during instances of public health events.

The technology and processes were easily adapted to meet the needs of the health departments and system users. However, organizational issues regarding the health care provider notification component have precluded the full operationalization of the system. It is anticipated that these issues will be resolved within the next year and that the system will be fully implemented. However, the public health worker notification and the creation and use of the Blog utility have proven to be an effective means to providing decision support during times of emerging infectious diseases and bioterrorism events.

Conclusion

Emerging public health crises require coordination of information from a variety of sources and targeted provision of quality filtered knowledge to a wide range of health care workers. Access to evidence is critical to the management of the events for both the population and individual patients; collecting information to monitor the impact of the occurrences contributes to the knowledge base and helps mitigate future occurrences. Using extant technology and promoting organizational partnerships can offer a sustainable model to enhance responsiveness to these events.

The Interface Software Design:Information System of Emergency Medical Care For Disaster In Indonesia

Agung Budi Sutiono [a,b], Toshizumi Ohta[a], Tri Wahyu Murni[b], Taufik Hasan[c]

[a]*Graduate School of Information Systems, The University of Electro-Communications, Tokyo, Japan*
[b]*Emergency Department, Hasan Sadikin Hospital, Bandung, Indonesia*
[c]*Research and Development Centre Telkom, Bandung, Indonesia*

Abstract

Information systems have an important impact on emergency situations, especially during disasters and effective connections are required for networking between disaster affected areas, field hospitals and emergency departments. Critically ill patients are the first priority during transport, and in addition, the vital signs should be hemodynamically stable and frequently reported from the disaster affected area and during transportation until arrival in the emergency room. Since the geography of Indonesia includes many mountainous areas, this tends to hamper networking, meaning communication infrastructures have not yet covered all areas and districts of Indonesia.

In this article, we propose the creation of a communication network system using radio VHF (very high frequency) as a wireless connection from disaster affected areas, field hospitals and emergency rooms. The use of this prototype would be relatively cheap for developing countries like Indonesia. During this simulation, we operated the reporting system during a landslide that occurred in Garut County, West Java and which needed to be reported to the Dr. Slamet General Hospital, Garut and also to the Hasan Sadikin General Hospital in Bandung as the medical command control centre in the West Java province. The software interface design was created as required to monitor the report systems of the patient's vital signs, hemodynamically and the wound state while in transit.

Keywords:

information system, vital signs, hemodynamic, disaster, software interface

Introduction

After the landslide occurred in Garut county West Java, Indonesia, the victims had to be evacuated to the nearest hospital emergency department as soon as possible. Initial checks were made for vital signs and hemodynamic stability to ensure it was possible to evacuate them to the emergency department. At the time, despite the numerous patients on the field, we used triage to determine whether the patients had to be evacuated or not. Since geographical conditions also presented obstacles during evacuation, coverage allowing reports to be made via network communications was not possible in the disaster area. Although wireless mobile phones could be used for communication, these tended to function poorly, since the BTS (base transmission stations) in the vicinity had already been damaged due to the natural disaster. Meanwhile, the medical team had to report to the hospital while transporting the critically ill patients.

There were 50 victims at the location, who were classified using green tags (non emergency), yellow tags (emergency but non critical), red tags (critically ill) and black tags (deceased). Approximately 10% of the 50 patients had red tags and needed advanced treatment in the local emergency room (disaster area vicinity) or even evacuation to the top referral hospital. We usually have many problems during transport due to unpredictable patient conditions, and despite hemodynamic stability while going to hospital, conditions sometimes worsen during evacuation.

In the clinical scenarios above, if a health information exchange network were installed within the disaster affected area, with Dr. Slamet General Hospital as the front medical post (the emergency room nearest the disaster area), and Hasan Sadikin General Hospital as the top referral hospital in West Java province, thus enabling data exchange from one to another, and if the hospitals were readily available and ready to receive critically ill patients, this may enhance information systems carrying clinical transfer data and patient consultation and result in a more efficient workflow for the medical and paramedics crews (Fig. 1).

This article will describe the background and motivation for current local health information efforts on the disaster in Indonesia and also how to create an interface design which represents a form of transport for critically ill patients suitable for a developing country like Indonesia.

Discussion of certain issues that may be required can be addressed to the emerging local health service, as well as that concerning some of the specific issues that are likely to affect emergency case management in the referral hospital.

Background

Geographical location and geological condition of Indonesia have made this country one of the most potential countries but at the same time prone to disaster such as earthquake, tsunamis, floods, landslides, cyclones, and volcanic eruptions. In general, disasters occur every year. Even in recently years, disasters have become more frequent and taken place one after another.

No	Type of disaster	Event	People affected
1	Flood	229	416
2	Landslide	106	201
3	Fires	91	26
4	Earthquakes	27	47
5	Typhoon	42	3
6	Volcanic eruption	13	0
	Total	687	2,409

Source: BAKORNAS PBP, 2004

Table 1 - Type and time disaster occurrences in 2003

When earthquake and tsunami disaster happened in Aceh last year, more than 200.000 people died, all of main infrastructure in most of Aceh area was down fall includes telecommunication. Red Cross and army are first institution which arrives in location instantly after information had been validated.

Medical care is normally established at the first opportunity, but limited facilities and support and the lack of adequate facilities in medical care units means victims may perish. In this case, we should have a solution to support the exchange of information between medical care units in disaster areas with the principal hospital and logistic units situated elsewhere.

This project promotes a system for the data communication exchange with a multi-barrier. Where geographic conditions make it particularly difficult to deliver data, and telecommunication networks are especially distant, the courier transmission and synchronized data could represent the best alternative technique to keep the system working. However, the system includes a solution to reduce the time required for courier delivery – namely, to use radio frequency as the data transfer medium.

Material and methods

Emergency medical care information system (EMCIS) is a communication system for emergency situation by using VHF radio technology to deliver low speed data, voice, and image from disaster areas to the center of disaster management system. In this case, the EMCIS Project designed a VHF modem, a protocol communication for the VHF modem, and a software application for delivering medical information.

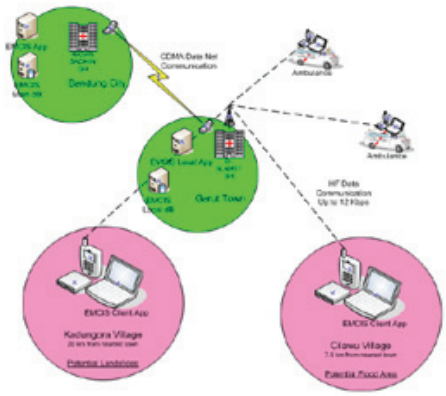

Figure 1 - Network communication and reporting system

Design software interface

On this software interface was designed as needed for critically ill patients. The requirements are user friendly, easy to understand, data entry can be done as quickly as possible, possible for consultation by using instant messenger and must be able to cover patient's conditions reporting whether live threatening or not.

Design input starts by that user needs and translating that data into the engineering terms. Defining design input is not as simple a task as it sounds. The needs itself based on the critical ill patient requirements that can represent the conditions during transporting. Ensuring that adequate safety is built into the interface design and often several trials must be done to reach the best requirements by doing many simulations.

Each patient has their own characteristics of the injury, even if they have the same injury but the problem might be different. There are many parameters for critically ill patient so perhaps need plan for updating design input interface as new information crops up during design.

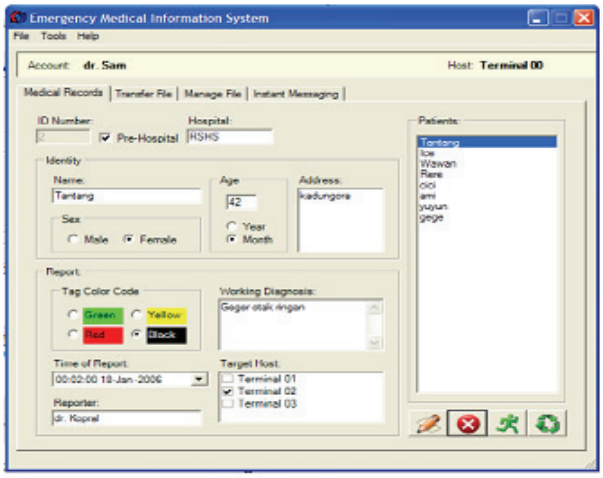

Figure 2 - Main design of EMCIS

In order to focus on how best to support interface design, Westudied the monitoring critical ill patients to find out what kind of parameters that used in emergency room or intensive care unit and suitable for all stages of critical patients. We also collected what is the proper parameter that can be used for live saving and transporting, and what vital sign liked and disliked about critically ill patients. Furthermore we must know when do we have to set the patient in the rest condition of their metabolic system so that the oxygen demand might be in minimum state in order to keep patient a live during evacuation. Using this information, we designed concept to support the core engine for transferring data and making consultation among paramedics in the field and the expert in the hospital. The Clinician that we have discussed has an average of over 10 years experience working with critically ill patient in the intensive care unit or emergency. They work for Hasan Sadikin General Hospital-University of Padjadjaran School of Medicine that focus on areas such as emergency room (ER), intensive care unit (ICU), recovery room (RR), and even operating room (OR). In addition, they have an expert in the critically ill patient caring background.

Almost of the medical staff in that field have the same idea about the parameter for monitoring the patient. The main parameter for the critical patients are chief complaint, level of consciousness, pulse rate, respiration rate, blood pressure (Fig. 4) and location/status of the wound (Fig. 5).

Based on this parameter, the patient will be given tag such as red, yellow, green and black. It is very important because the priority of actions is just depending on this tag. First priority is red tag because this is really critically ill patients and life threatening. Second one is yellow tag where the patient in emergency case but not critical. Green tag is only maybe have a small wound and black is deceased. (Fig. 2).

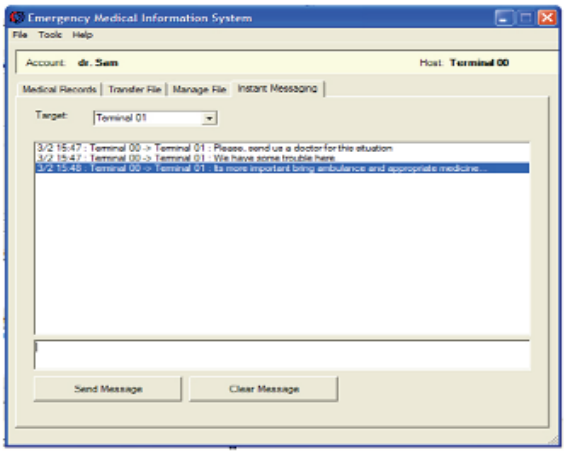

Figure 3 - Instant messaging

During the early stages of interface design we performed the simulation inside the hospital by using radio communication. Some reported that the patient was getting worse hemodynamically or vital sign unstable and then must give the responses and support to the patient. The design that we make based on that simulation so that we made the sketches interface tools, such as multi tab (Fig. 2), and then break down into specific one in every tab. In this part we viewed the general information of the patient (victim) such as identity, report and list of victims. The identity was so simplify in order to make an easy way for data entry during disaster. It only takes a little typing and a click on the box according to the condition. The explanation of interface must be recognized by user as simple as possible and tested with users before building a prototype. In the early stages of design is critical and might be something happen so that simulation must be done as much as possible two or three times a week in emergency room.

A user will interact with the application mostly through forms, so by the simulation hopefully can decrease the error. Whether you are an experienced user or just new comer on using computer, this interface will provide you an easy way for entry data as essential information to the patient, expertise and hospital.

The other facility on this application is instant messaging (Fig. 3). Through this option, paramedics are possible for consultation and transfer file. Even though only small data that can transfer like small size picture but it is very useful on disaster area whereas infrastructure communications collapse.

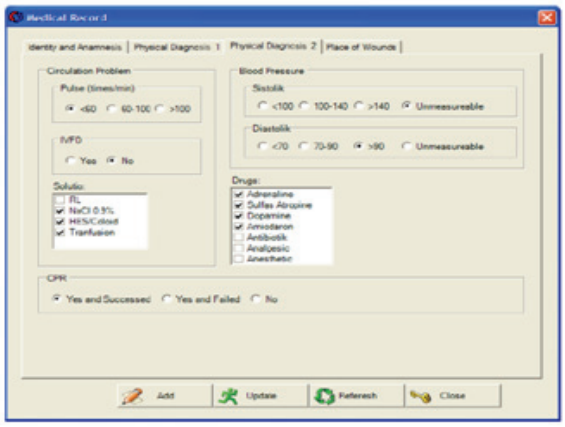

Figure 4 - Physical diagnosis

The other important things are also the actions during the evacuation. After classified into red, yellow and green tag we must do something. For example if the blood pressure decrease, pulse rate increase and location of wound might broken main artery so causing bleeding then we have to give solution and drugs to keep the patient survive. In this case the user is just click the box, what kind of solution and drugs that had been given and then reported to the hospital (Fig. 4). Every patient will have their own data and reported to the referral hospital frequently.

Location of wound in disaster area was needed due to most of the patients are trauma cases. It might have open or closed wound, contusion or fractures, active or occult bleeding so that can describe on the picture by clicking in the box. Every box on the picture represents the main common artery which may cause the active bleeding like on the upper and lower extremities. There is a special case on chest and abdominal trauma because it may cause of massive bleeding even it closed wound. In the chest wound sometimes pneumothorax can happen and it is one of life threatening case so that the paramedics must do something like needle decompression even in the transport (Fig. 5). All organs in the thoracic cavity are related with airway, breathing and circulation which may cause life threatening if we do not do something aggressively.

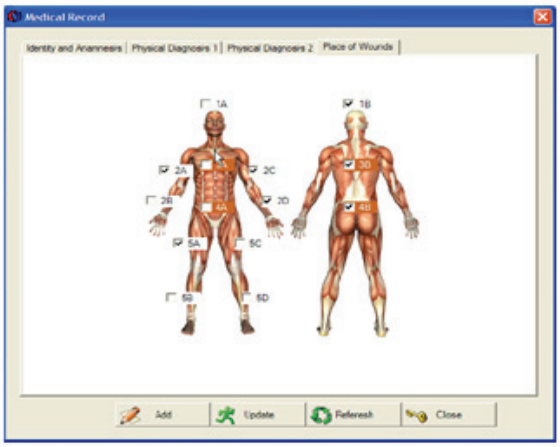

Figure 5 - Place of wound

Discussion

An interface design must reflect both user requirements and a means of communication with the software. A user friendly design is vital as an input maker and each input action will become part of a valued patient database. The interface design component must also be guaranteed to correspond to the bidirectional exchange of communication and data during transport. When interfaces are designed, the composition combines not only user requirements, as the input data maker, but also the environment of critically ill patients. Whatever the patient's condition, they generally have equivalent parameters when life threatening events occur. There are also specific cases, namely head trauma, thoracic cavity trauma and abdominal trauma, where closer attention is vital because if life saving intervention is performed as rapidly as possible, the patient will improve dramatically. For this design feature, a survey was conducted regarding the types of parameter and limitations of the interface design on critically ill patients by performing a simulation evacuation within the hospital. The conclusion was that vital signs, hemodynamic stability and the location of wound/s represent the whole spectrum of patient conditions. The other inputs include therapy while in transit, which can be performed by providing the solutions and/or drugs required in resuscitation. This means a hospital doctor avoids providing over-therapy in solutions or drugs when the patient arrives in the emergency room and will only administer advanced treatment, such as resuscitation surgery, in the event of internal bleeding and/or in an intensive care unit facility. This will allow optimum treatment to be given to patients. Although there are several means of treatment in the hospital, the challenge is how to ensure the patient survives while in transit. With this in mind, the software will be part of pre-hospital care in the field or an medical data information system.

Requirements of Linkage with Triage-Tag Information and Electronic Health Records Available in a Huge Disaster

Takeshi Tanaka[a], Kiyomu Ishikawa[a], Hidehiko Tsukuma[a], Norikazu Iwata[b], Minoru Ikeuchi[a], Yasumasa Iwasaki[a], Nakao Konishi[a]

Abstract and objective

To support transporting victims and patients efficiently in a huge disaster, the authors propose a regional information system sharing real-time acceptance information of hospitals, which is linked with a regional EHR system. Using the simple model of regional EHR with triage-tag information, the authors discuss requirements to distribute real-time acceptance information of hospitals. In the system the flow of triage-tag ID and EHR ID information has a crucial role.

Keywords:

medical records systems, computerized, hospital information systems, disasters, rescue work

Introduction

In a huge disaster, hospitals outside of damaged zone have to accept not only victims but also diseased patients due to destructions of equipments in hospitals and hospital themselves in a damaged zone, as in the case Hanshin-Awaji earthquake on 17 January 1995, by which 64 hundreds people died and 40 thousands injured: In this case the number of transported diseased patients from the damaged zone to outside hospitals was greater than that of victims in the first two weeks [1].

By lessons of Hanshin-Awaji earthquake, a triage-tag standardized by Japanese Fire Defense Agency has been used generally. In the case of leaving the metals in Amagasaki which is the first case of major incident in Japan after the earthquake, nevertheless, the identification and finding location of victims are pointed out as problems. [2]

The authors has been developing the information system in Hiroshima region supporting rescue teams by sharing real-time acceptance information of hospitals of this region with bringing a wide area disaster in view, which nevertheless depends on inputs of hospital administrative [3]. To obtain more correct information of acceptance even in a huge disaster, and to support the identification and finding location of victim, we propose a new model of information system connected with personal information of victims and patients.

Methods

We suppose the model system as following: In one administrative district named region A, a regional EHR system can be used with everyone living there; in which a disaster information center with an information system stands: These systems work under these conditions;

a) Both the EHR system and disaster information center system (DIC) have independently data centers far from this region connected with computer networks each other, which can work in a situation of huge disaster in this region.

b) All (heli)ambulances in the region can communicate with DIC by wireless transmitters, by which they can share acceptance information (maximum and occupation numbers of beds) of each emergency hospital in the region by a network connection between the EHR system and DIC.

c.) All hospitals and clinics in the region have each permanent ID numbers of them on the EHR system.

d.) Computer terminals in all the hospitals and clinics can communicate with the EHR data centers above mentioned without faults of power supplies or computer network.

e.) Every patient in the region has an ID of the EHR system, all of whose hospital records with IDs of hospitals can be retrieved by their ID on EHR.

We next suppose a zone in the region, in which a huge disaster happens: We assume following conditions in this situation:

1.) Computer terminals in all the hospitals outside the zone can communicate to the EHR system.

2.) All the emergency hospitals outside the zone can provide their acceptance information to DIC.

3.) All the victims should be triaged and tagged with permanent IDs: Other information standardized by Japanese Fire Defense Agency than a triage-tag ID should be recorded at each triage steps.

4.) Disaster Medical Association Teams (DMAT) have already been to the zone, and the (heli)ambulances have been ready to transport victims or patients

from the zone. In this situation, victims of disaster could be triaged four times; 1) in tagging a triage-tag at a place he/she rescued; 2) before a medical treatment by DMAT; 3) Before transporting to the outside region; 4) Before a medical treatment in the emergency hospital.

5.) All diseased patients transported from the hospitals or clinics in the zone should be triaged before a medical treatment in the emergency hospital.

Under these assumptions, we organize along a timeline from a rescue to a hospital admission of victim or patient, and consider on requirements of cooperation between the EHR system and DIC to update acceptance information in real-time and to find locations of victims and patients

Results

Primary information in each triage step is shown in the table 1. Since a value of priority on a triage-tag can be varied, acceptance information of the hospital can be determined. In addition, we have to consider patients or victims not transported by (heli)ambulances who can come to a hospital without tagging of triage-tag. Thus, we can obtain most correct information at the fourth triage step before a hospital care. As almost all patients might have EHR-IDs which warrant continuous hospital cares and identifications, it is convenient to input EHR-IDs instead of triage-tag IDs. Since all hospitals have terminals for the EHR system, and since an admission recorded by a triage/EHR-tag ID means an occupation of acceptable bed, the above information can be input from the terminals and used for hospital cares. The locations of them are automatically obtained by input of above information.

Due to these reasons, the requirements are following; 1) the EHR system have to obtain a triage-tag or EHR ID with triage information (priority) of victim or patient and hospital IDs in triage before hospital cares; 2) the EHR system sends the above information; 3) the DIC system can renew acceptance information and locations of victims and patients according to data from the EHR system and distribute to (heli)ambulances (see Fig. 1 and 2).

Discussion and future remarks

Using wireless devices like RFID for identifications [4], hospitals can easily input IDs to renew acceptance information. Mobile devices to input pre-hospital information (symptom, pollution, etc.) and information of transporter (ID of heli/ambulaces) could be helpful for preparations in hospitals and precise trace of victims.

Customized Early Warning System Based on HTN for Home Healthcare Model

Seung-Jin Jang[a], Jip-Min Jung[a], Sung-Oh Hwang[b], Young-Ro Yoon[a]

[a] Department of Biomedical Engineering, Health Science College, Yonsei University, Wonju, South Korea[b]Department of Emergency Medicine, Wonju College of Medicine, Yonsei University, Wonju, South Korea

Abstract and objective

We adopted hierarchical task network (HTN) planning in a customized early warning system for home healthcare model. It is necessary to design a customized early warning system for the patients who were in various health states, because regular or irregular report format and alarm delivery systems were diversified according to severity of health state. HTN planning is suitable for use of constraint programming so as to effectively prune the search space during the search for solution. An efficient and scalable information control is presented by use of HTN. The paper also briefly deals with a process strategy for the early warning system.

Keywords:

Hierarchical Task Network, Emergency Response, Home Healthcare Model

Introduction

As the elderly population and the demand of well-being life increasingly grow, IT-based technology allowing bio-signal measurement and assessment at home have been focused nowadays. The elderly or citizen can be efficiently controlled with respect to health status parameters which act as input features in the early warning system for health status.

Methods and results

The early warning system developed by Home Healthcare Management System Research Center (H2MSRC) in Yonsei University adopted HTN planning in order to efficiently design the planning of emergency response because of extendible, intelligible, and easily communicated properties. Events derived from 7 objective status parameters measured from 4 types of sensor devices and 3 subjective parameters results in customized emergency response according to the formalized I-planning domain model. (Ref. figure 1)

Conclusion

HTN planning was practically adopted in our early warning system for Home healthcare model and revealed the intelligent and collaborative planning ability.

"Toughclinic" – Modern Medical Informatics Under Extremer Conditions

Frank Ueckert

Department of Medical Informatics and Biomathematics, University Hospital, University of Muenster, Germany

Abstract

The care of seriously injured persons or victims of catastrophes in the medical way like in environmental conflict areas or in the administrative way like in a refugee camp often has to be guaranteed under bad conditions. Paper based documentations are easy to implement and to use, but they underlie known disadvantages. With the system "TOUGHCINIC" as an electronic file for exceptional circumstances emergency patients, victims or refugees can be set up very fast. Any facts can be documented in special adapted input and edit mask; digital photos can also be added. The software components are able to be adapted locally.

A wireless cross linking of many individual and extremely robust notebooks without central infrastructure is possible. A breakdown of a laptop or a component does not affect the others. The used applications in reach are automatically adapted with the others and therefore they get always an actual database. After the returning of an employee the data synchronization will be done automatically.

The three principles are the simple handling and the possibility of total configuration by non technical personnel in the case of need, the extremely fast operational readiness as well as the toughness under extreme environmental conditions.

Keywords:

medical records systems, computerized; developing countries; war; disaster help; aid, first

Introduction

The care of seriously injured persons or victims of catastrophes often has to be guaranteed under bad conditions. A save, simple and fast support of the real care is not only medically, e.g. in environmental crisis area, but also administratively necessary for a big amount of affected people in refugee camps.

Paper based documentations can be easily adopted and used, but they underlie significant and also known disadvantages. The material is not resistant, copies are not automatically updated if the original or one of the copies are changed, automatically analysis for example for stock administration (re-order, consumption analysis) or warning notices (immunisation status, dual-physicals) are not implemented and it is in principal only a limited structured documentation possible.

Because of many reasons computer based documentations were in this kind of operation not advisable. The standard hardware is under difficult extremely environmental conditions not reliable. Computer solutions often demand expert-knowledge and cabling on-site additional logistical problems e.g. in camps. Qualified personnel, who has to leave the base for a short time for working, e.g. to accomplish immunisations at nearby locations, could so far badly profit of networked knowledge. Furthermore available software solutions are too complex for the fast and uncomplicated access by international personnel, the features and installations of regular hospital information systems are often unsuitable.

The identification and registration of patients, victims or refugees are often only based on central kept paper lists or on handed out identifier for particular persons (e.g. wristlets). The control and administration of such lists or identifiers is connected with difficulties and time delay especially for searching, because of the typical handling to have either an actual list on a central location or part-actual lists on different locations.

With the planed system TOUGHCLINIC patients, victims and refugees can be registered fast. It supports a medical and/or administrative all-embracing care. The development of this system has started and is described in the following.

HL 7 as a communication standard [1] and communication server as technological middleware platforms are today in many hospitals central components of the hospital computing and from this surrounding hardly to think away [2]. In many hospitals single departments communicate electronically with purchased software products already so called hospital information systems. This is what Waegemann calls as "automized medical record (system)" [3].

If hospital information systems shall conform to the displayed definitions and requirements, it seems apparent that neither hospital information systems nor electronic patient records can be bought as a finished product. Rather the declaration of Van der Velde is true, which calls hospital information systems as a "conceptual bound", in which single appliances develop and can be integrated as an acting whole system [4]. The system TOUGHCLINIC offers such a bound.

Materials and methods

Necessary equipment

About 50 percent of all damages of notebooks go back to transport accidents like falling down or effects of pushing. Screens, cases and hard disc drives are the most affected. Especially the expected environmental conditions like aridity or clamminess, also extreme temperatures and in dealing with technical applications in limited situations let notebooks not appear as adequate equipment in areas of catastrophes or crisis.

Special notebooks e.g. Toughbooks of Panasonic have a special mechanical protection. The cases of these notebooks are manufactured of a magnesium alloy. Warp resistant magnesium alloys at all screens avoid warps or breaks. The hard drives are saved against vibrations. Because of their flexible bearing, connecting plugs resist extreme pressure. Furthermore keyboard and touchpad are sealed against entering fluid. Dust and dirt can not enter. The use of latest touch screen technologies allows although in direct sunlight a high-contrast screen. The specialised notebooks are up to the MIL standard MIL-STD 810F for shock-proof and up to norm IP54 for water and dust protection.

Also the photo industry made progress and offers digital cameras like Olympus µ720SW or Pentax Optio Wpi, which are useful for the project TOUGHCLINIC because of their attributes like waterproofness and resistance for sand and dust by special seals as well as their small dimensions with simultaneous simple usability.

Computer language and architecture

In principal an enlargement of the project is possible, so that the fixed centre in the (first world) home countries always stays well informed about the actual data. This can be useful for automatically ordering or for global forwarded medical consultant requests. In this case, it would be an online available data base. This is not planed in this project, but could be already considered in planning stage. To not eliminate later synergies, a computer language like Java should be used [5]. Java works with the concept Write Once, Run Anywhere. This means that a program programmed in Java has to be compiled theoretically just one time and it runs on all other systems, which has a Java Runtime Environment. This JRE exists for all-around used operating systems like Microsoft Windows, Linus, Solaris, Mac OS X, AIS and many more. In addition there are the JRE not only for server- and desktop operating systems but rather for many other embedded systems like mobile phones, PDAs and also smartcards and other technical platforms, like car and TV. The independence of platforms ends for those systems for which a so called Java Virtual Machine does not exist.

There are many frameworks in uses to achieve an isolation of the systems components and to advance the use of "best-practice" [6].

Java encloses also industry standards for data persistence and network communication. The architecture of TOUGHCLINIC bases on a three-tier-model with the typical tiers: data management, business logic and presentation [7]. Each upper tier can access directly to the underlying tier.

A data base system which uses only a few resources is required for saving the appliance data. This DBS has to be easy to install and to administrate and it also has to support transactions at the same time [8]. HSQLDB and Java DB are two effective and perfected Java data bank systems, which achieve these requirements [9]. Furthermore both systems support the Embedded-Modus in which the DBS is incorporated into the Java appliance so that an exact installation and administration of the data bank system is not necessary anymore. To be transparently for the user it persist only one appliance which has to be started.

One of the central functions of the application is to exchange local data with every reachable co-equipment (unit, implement, and device) and to synchronize one another. One possible method of resolution would be the application of *SyncML* (Synchronization Markup Language), which was defined by the *Open Mobile Alliance* (OMA) to serve exactly this purpose. SyncML-messages are XML-documents, which are exchanged via SyncML-protocol in-between the mobile applications. In doing so there is a difference between the representation protocol and the synchronize protocol. The SyncML representation-protocol defines the message-structure and also the different types of messages e.g. Add, Alert, Atomic, Copy, Delete, Exec, Get, Map, Replace, Search, Sequence and Sync. Furthermore it defines methods for the consistent appellation and identification of dataset, which are synchronized.

The synchronization-protocol focuses on the administration of the particular synchronization-connection. It defines the information flow between the SyncML-client and -server during the synchronization-process as well as the different types of synchronization, like disposable- or non-disposable-synchronization. During the implementation of the SyncML respectively one application takes the role of the Client and another one the role of the Server. The roles are negotiating again for every Synchronization-process. If there is requirement e.g. for a backup, it is possible to synchronize every applications with a central SyncML-Server.

The Java Foundation Classes is a comprehensive collection of GUI-components and Services, which makes the development of demanding graphic user interface possible. More complex components, which are exceeding the

functionalism of the standard components, can be developed via the Java 2D interface. Also three-dimensional issues can be solved with the Java 3D functional-library.

MANET-Radio communication network

So far in a traditional radio-network (Wireless LAN, WLAN) [6, 7, 8] it was only possible to connect one notebook with exactly one central router or exactly one additional notebook. This makes the whole communication very depending on the central architecture and a breakdown of the router would shut down the whole network immediately. Also the bandwidth is limited. More connected notebooks would reduce the flow-rate of data.

Special wireless networks, so called mobile ad-hoc networks (MANET) consider the individual, attending notebooks as a joint, which serve as a repeater to stay in touch with one or more other joints. The result is a network, which can overcome long distances, especially in uneven or challenging terrain. Furthermore MANETs are very reliable, because every node is connected with many other joints. If a joint breaks down out of the network e.g. because of a hardware failure or another reason, the surrounding joints search for an alternative route. Thanks to this still young technology a project like TOUGHCLINIC is practicable.

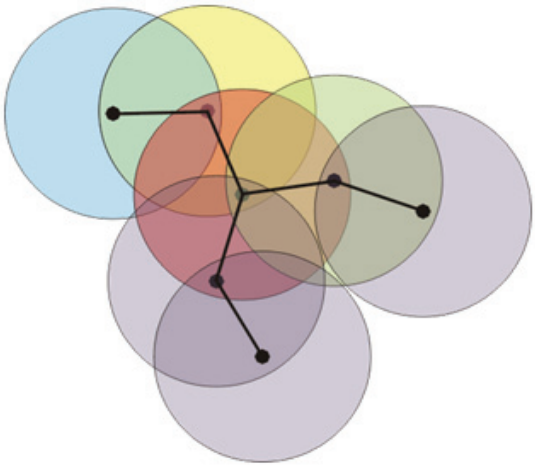

Figure 1- Schematic representation of a MANET-Wireless-Network

To make dynamic routing possible, every application has to send its routing information to every other application, with which one in makes a connection. To do this can be used e.g. the in the meantime fully developed Optimized Link State Routing Protocol (OLSR). At this distributed flexible process of routing, every Router knows the complete net-topology, so that they are able to configure from case to case the shortest way to the destination. Also the data-flow is not lowered because of more applications. It stays constant or even increases.

Structure of the electronic file and the form based additional documentation

Through the provision of a root-appliance and a (constructive) Plug-In-Architecture it is possible that new modules, e.g. (file-rider) in a patient record or also in an administration file, can be added and worked on fast and easy. A special component demonstrates a mechanism for the cognition and administration of Plug-Ins. Every installation of the TOUGHCLINIC can be arranged with a one sentence to Plug-Ins and consequently be arranged by IT-laymen. Because of the experiences of the submitter's institution it's easy to give a reasonable and still basic-documentation for a medicine and an administrative file.

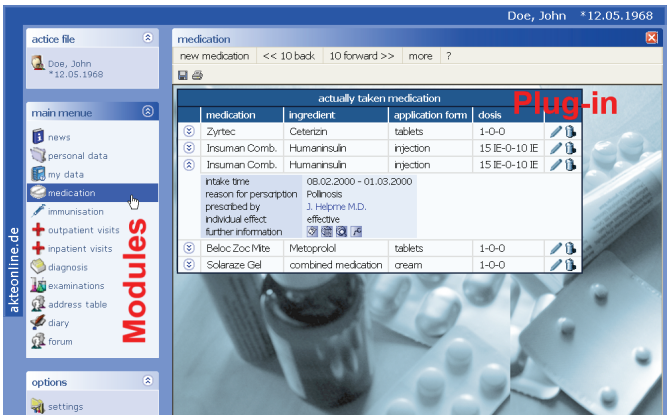

Figure 2- Presentation of modules and Plug-Ins with an example-screenshot of a consistent implementation of software in the system; akteonline.de"

The displayed file structure can include forms as basic modules. This very basic type of mask should be established and worked on by laymen on-site using a form-editor. A special component displays a mechanism for the cognition and administration of forms. Using the forms, the aim is achieved to cover as many as possible intended use, especially to cover the non-planable.

The operation of the system TOUGHCLINIC has to be possible in the English language and with international personnel. The difficulty of the language is not only limited on input and output. It is also included in the understanding and logic of the attendant persons. Some experiences show that for example support staff from different cultures approach problems in a different way than people from our culture. They could use the intended documentation and system functions for our culture, translated from 1:1 in their language, not in the expected way. Because of that preferably a lot of input and output possibilities should be structured in a selection or depend on

pictures. Graphic illustrations of body parts, which can be marked and annotated, could be a good example. These are available for every body part and can be put into the created forms.

Results

Using the system TOUGHCLINIC as here described, any circumstances can be securely documented in special adjusted input and output masks and digital pictures can be added. The software components are due to their modular construction also adjustable for the specific intended use on-site.

Through modern and only now available information technology a wireless networking of many individual, extremely tough and inconspicuous notebook computers without any infrastructure is possible. Breakdown of a notebook or a component does not have any influence on the others. It can be replaced directly by another one (without bothering about manually restoring or copying of data).

The used applications in reach are synchronized automatically with the others and so they receive always an actual dataset. This is also helpful, if notebooks will be launched outside the base. After the returning of the employee the data synchronization will be done automatically. In contrast to the existing W-LAN solutions there is no central hardware-effort necessary. Decoding is so efficient by now to avoid an interception of the content.

Because of the additional decoding of the individual datasets, a losing of one of the high-mobile workstation is limited to a financial loss.

The language barriers between employees from different countries are eliminated through the use of translation-patterns of the data masks, dynamic graphics, e.g. remarkable part of the human body rather than free-text-fields for localization-description.

The three principles of the system TOUGHCLINIC during the support of the medical and administrative care of patients, refugees and victims of catastrophes are very easy handling and the possibility of configuration by non-technical personnel in the case of need, the extremely fast operational readiness as well as the reliable service under extreme environmental conditions.

At the actual early status of development co-operations-partners for processing and use are sought-after, as well as sponsors.

Acknowledgments

Thanks to the potential project-partners Dr. Andreas Fabricius, Missionsärztliches Institut Würzburg (Germany) and Mr. Maurice Mars, University of KwaZulu-Natal (South Africa).

Abstract

As the number of hospitals using Electronic Medical Records (EMR) systems in Japan continues to rise, there is a need to develop an evaluation framework that can allow comparison of EMR effectiveness within and between hospitals.

Principal component analysis (PCA) was used to summarize survey data into a Composite Index (CI). Five constructs –system quality, information quality, service quality, use and user satisfaction were used to develop the CI. The process included formulating items for each constructs, condensing the data into factors relevant to the constructs and calculating the CI by summing up the product of each construct with its respective PCA score.

The preliminary results show that the CI can discriminate between hospitals that are in the same stage of IT maturity and that the ranking of the hospitals using the CI is strongly correlated with hospital's IT maturity.

The CI can be used as a diagnostic tool for hospitals that are implementing EMR systems as well as hospitals that want to benchmark their systems against other hospitals.

Keywords:

Hospital Information Systems, EMR Systems, evaluation, EMR System Composite Index,
Principal Component Analysis

Introduction

Recent research has shown that information technologies and electronic medical records (EMR) systems can improve adherence to clinical guidelines, patient safety, and the delivery of preventive health services, thereby potentially improving health outcomes for patients. Despite these evidences, wider adoption of EMR systems remains limited [1]. However, the government of Japan has initiated several programs that are likely to enhance wider adoption of these systems. For example, the government policy targeting at least 60% of hospitals with 400 beds or more to computerize their records by 2006 [2], the introduction of prospective payment system based on diagnosis procedure combination (DPC) [3] are expected to enhance wider adoption of EMR systems in the coming years.

As the number of hospitals using EMR systems in Japan continues to rise, there is a need to develop an evaluation framework that can allow comparison of EMR systems effectiveness within and between hospitals. In this paper we propose a framework for generating a Composite Index (CI) for evaluating the EMR systems effectiveness within and between hospitals. The framework involves: 1) identification of factors that contribute to the EMR systems effectiveness; 2) development of a set of measures that can be used to quantitatively score the EMR systems effectiveness based on the factors in 1) above; and 3) provision of an overall theoretical framework that incorporates these factors toward developing a CI for EMR systems.

Methods

Factors contributing to EMR systems effectiveness

Researchers from information sciences have long studied various factors that would impact the use of Information Systems (IS). Although there have been no comprehensive studies that would propose a general model for evaluating EMR systems effectiveness, the DeLone & Mclean's model [4] of IS success provides the most extensive and comprehensive framework for identification of factors contributing to the success of EMR systems. We adopted five constructs (Table 1) from the model, guided by the ability of the construct to be measured quantitatively using survey data and can be synthesized into a single composite score (CI) for evaluating EMR systems in a hospital.

Table 1 - Constructs used for CI computation

Constructs: Definition	Example items	# items	User group
System quality: Number of processes / activities that involve the use of computer-based applications	-Inpatient pre-admission -entering patient notes	269	CIO, CMO, CNO
Information quality: The value and usefulness attributed to the output of the EMR system by users	-get the information you need in time -the information content meets your needs?	23	Dr, NS
Service quality: The responsiveness of the systems staffs to users' requests, systems down-time and trouble-shooting of the EMR system.	-can you count on the system to be up and available? -the system subject to frequent system problems and crashes?	4	Dr, NS
Extent of Use: The extent to which users are using the EMR system	-centralized scheduling system for different outpatient clinics -check drug information (such as drug allergy and drug-drug interaction warnings)	68	CIO, Dr, NS
User satisfaction: The extent to which users felt that the EMR system is important in improving the quality of care they provide	-the quality of medicine has improved as a result of the EMR system? -Overall, are you satisfied with the EMR system in your hospital?	31	Dr, NS

[a] CIO = chief Information officer; CMO = chief medical officer; CNO = chief nursing officer; Dr = Doctor; NS = Nurse

Item generation

We compiled items measuring each target construct (Table 1) following an extensive literature review of studies assessing EMR systems effectiveness [5-8]. In order to improve the validity of the CI, multiple sources of evidence on the EMR systems effectiveness was needed. To this end, five user groups, namely, chief information officer (CIO), chief medical officers (CMO), chief nursing officer (CNO), doctors (Dr) and nurses (NS) were surveyed. The users surveyed were the most likely to be knowledgeable about the EMR systems in their hospitals and whose work is the most likely to be affected by the introduction of EMR system. Overall, five instruments targeting each of the five user groups were developed.

Data collection

Data were collected as part of a nationwide longitudinal study evaluating the improvement of quality of healthcare services as a result of the introduction of EMR systems. The present study was conducted during the second phase of the nationwide study and only 71 healthcare institutions (69 hospitals and two clinics) that had responded to the first phase of the study were targeted. In the first phase, 350 healthcare institutions out of 1522 hospital in Japan that had implemented computer-based patient care systems (especially EMR and physician order entry) were randomly selected to participate. The first phase of the study assessed the costs of computerization (both initial investment and running costs). The intention was to build a business model for EMR implementation. In the present study, questionnaires, together with a covering letter, were sent to 71 healthcare institutions. The hospitals were also asked to rank their EMR systems using the hierarchical scale (ranking from 1 as "least computerized" to 5 as "most computerized") developed by the Japanese Association of Healthcare Information Systems Industry (JAHIS) [9], as a measure of IT maturity. Data were collected over a period of six weeks starting the month of February 2006.

Data analysis and CI computation

Overall, 42 institutions (41 hospitals and 1 clinic) responded to the survey. For the purposes of this analysis, we excluded the clinic making the effective response rate to be 59.4% (41/69). The responding hospitals did not differ significantly with the non-responding hospitals on organizational characteristics such as bed size, ownership, age of EMR system and hospital category. We excluded hospitals where the entire user groups were not represented and where only less than 10% of Dr and/or 10% of NS responded. Based on the above criteria, only 20 hospitals could be included in the CI computation.

Data validation and CI computation

In calculating the CI, the process included data transformation, condensing the data into factors relevant to each construct, and calculating the CI by summing up the prod-

uct of each of the five constructs with their corresponding principal component analysis (PCA) scores.

In summary, data preparation involved condensing items that were on a scale of yes/no to distinct sections and recoding the negatively worded items of the Likert scales before carrying out factor analysis. Each of the resultant factors were analyzed for reliability using Cronbach's alpha. Items were deleted where necessary to achieve an alpha of at least .700. Factors with Cronbach's alpha less than .700 were excluded from CI computation. A PCA was conducted on each of the factors with Cronbach's alpha .700. The constructs scores were calculated by summing the product of each of the user groups' scores with the corresponding PCA scores. CI was then calculated by summing up the product of each of the construct scores with the corresponding PCA scores. A detailed description of the CI computation process is available from the first author (Otieno George Ochieng) on request.

Results and discussion

Internal consistency verification

Cronbach's alpha for the 5 constructs revealed an alpha of .717. However, service quality construct was found to be negatively correlated with the corrected Item-totals and suggesting that deleting it could improve the alpha to .843 (Table 2). The lack of positive correlation between service quality and the rest of the constructs could partly be due to the fewer number of items (Table 1) used in measuring it. Since we desired the model to be additive, we dropped the service quality construct from the final CI computation.

The composite CI for evaluating EMR Systems

Table 3 presents the CI for hospitals. The highest CI was recorded in hospital B34 (81.6) and the lowest in D14 (55.4). The average of the CI was 70.7. Dividing the range (81.6-55.4) of the CI into four equal parts reveals that 7 hospitals are in the top quarter and 4 hospitals are in the bottom quarter. The top 7 hospitals can be considered as outstanding performers in the effectiveness of EMR system while the last four hospitals still require concerted efforts to improve the effectiveness of EMR systems as measured by the CI. The table also presents scores for the constructs, which can serve to identify key areas that a hospital is under or over-performing. Generally, hospitals registered lowest score on the information quality construct. The least performing hospital –D14, registered lowest constructs scores in almost all the constructs.

Table 2 - Internal Consistency verification

	Corrected Item-Total Correlation	Squared Multiple Correlation	Cronbach's Alpha if Item Deleted
System	.550	.890	.667
Information	.845	.958	.549
Service	-.281	.224	.843
User satisfaction	.523	.935	.657
Use of EMR	.874	.928	.475

Validation

A literature search revealed no external standard that could be used to assess the criterion validity of the CI. We therefore, assessed only the construct validity of the CI using correlation analyses. The high correlation between the CI and the constructs scores may indeed represent accurate view of the level of EMR systems effectiveness in the surveyed hospitals (Table 4). The CI was also strongly correlated to IT maturity –a scale developed by JAHIS, thus confirming at once the construct validity of the CI.

Conclusion

This is the first study that attempts to develop a CI for evaluating EMR systems effectiveness. It proposes a framework for evaluating the EMR systems effectiveness of a hospital and identifies five constructs and surrogate measures that can be used in quantifying them. It then describes a procedure for calculating the CI for evaluating EMR systems effectiveness in hospitals. The CI is important because its level can be used as a strong predictor of how well a hospital can perform in the new healthcare environment. The CI can also provide policy makers with a detailed scorecard of their EMR systems relative to its peer counterparts. Further, a breakdown of the constructs' scores allow policy analyst to pinpoint areas of strengths and weakness, thus providing a balanced perspective in guiding a hospital through the computerization. The framework developed here should be viewed as both descriptive and diagnostic: Descriptive because it tends to explain the state of EMR system and diagnostic because it identifies problems areas.

Table 3 - The CI for EMR systems in the surveyed hospitals

No	Hospital Code	System quality	Information quality	Use	User satisfaction	CI	IT maturity
1	B34	86.9	60.3	73.8	62.1	81.6	4.0
2	D11	64.4	64.5	67.8	72.5	77.9	3.0
3	D23	84.5	55.9	70.8	57.0	77.2	5.0
4	D29	82.0	58.3	69.9	56.3	76.9	3.0
5	D40	86.1	54.0	71.7	53.2	76.4	4.0
6	C35	85.6	55.0	68.2	56.9	76.3	3.0
7	D20	79.3	55.3	68.4	58.3	75.3	3.0
8	B10	76.2	56.2	67.0	55.9	73.7	3.0
9	D24	72.8	56.2	64.5	60.6	73.2	3.0
10	D33	77.1	53.9	65.0	56.6	72.7	3.0
11	D37	80.6	51.7	67.1	51.7	72.3	3.0
12	D16	73.4	52.5	65.7	55.2	71.2	3.0
13	B43	75.9	51.3	65.5	52.6	70.7	3.0
14	D28	72.7	51.6	64.7	51.7	69.5	3.0
15	C22	73.4	51.2	59.1	51.8	67.7	3.0
16	D17	55.2	51.4	55.9	57.5	63.6	2.5
17	C38	61.1	48.4	51.1	53.2	61.5	2.5
18	C12	64.4	42.8	57.1	46.7	60.8	2.0
19	A27	66.7	44.1	51.4	46.9	60.0	2.5
20	D14	53.2	42.7	47.1	49.5	55.4	2.5

Table 4 - Correlation coefficients between the constructs, IT maturity scale and the CI

Constructs & IT maturity Scale	CI
System quality	.955(**)
Information quality	.893(**)
Use	.991(**)
User satisfaction	.802(**)
IT Maturity	.897(**)

** P-value<0.01 level (2-tailed)

We acknowledge some of the methodological limitations related to the computation of the CI. First, the hospitals selected are too few. Secondly, PCA technique based on correlation matrix was used, which tends to be unstable given the rapid pace of change in EMR implementation. However, PCA was the most scientific and credible method of combining data from different users with items on different scales.

Further work to validate the index is currently in progress.

Acknowledgement

This research was partly supported by the research grant from the Ministry of Health, Labour and Welfare, Government of Japan, number H17-Med-038. We are indebted to Prof. Hasegawa and Prof. Hosoi for their support in this study.

A Composite Index for Evaluating Electronic Medical Records Systems: Work in Progress

Otieno George Ochieng[a], Toyama Hinako[a], Asonuma Motohiro[a], Koide Daisuke[b], Naitoh Keiko[c]

[a] Health and Welfare Information System, Division of Health Service Management, Graduate School, International University of Health and Welfare, Japan

[b] Clinical Bioinformatics Research Unit, Graduate School of Medicine, The University of Tokyo, Japan

[c] Center of Preventive Medicine, Takagi Hospital, Japan

2. Background of the study

- As the number of hospitals using electronic medical records (EMR) systems
  - continues to rise, there is
  - A need for evaluation framework that
  - Allow comparison of effectiveness of EMR systems within and between hospitals

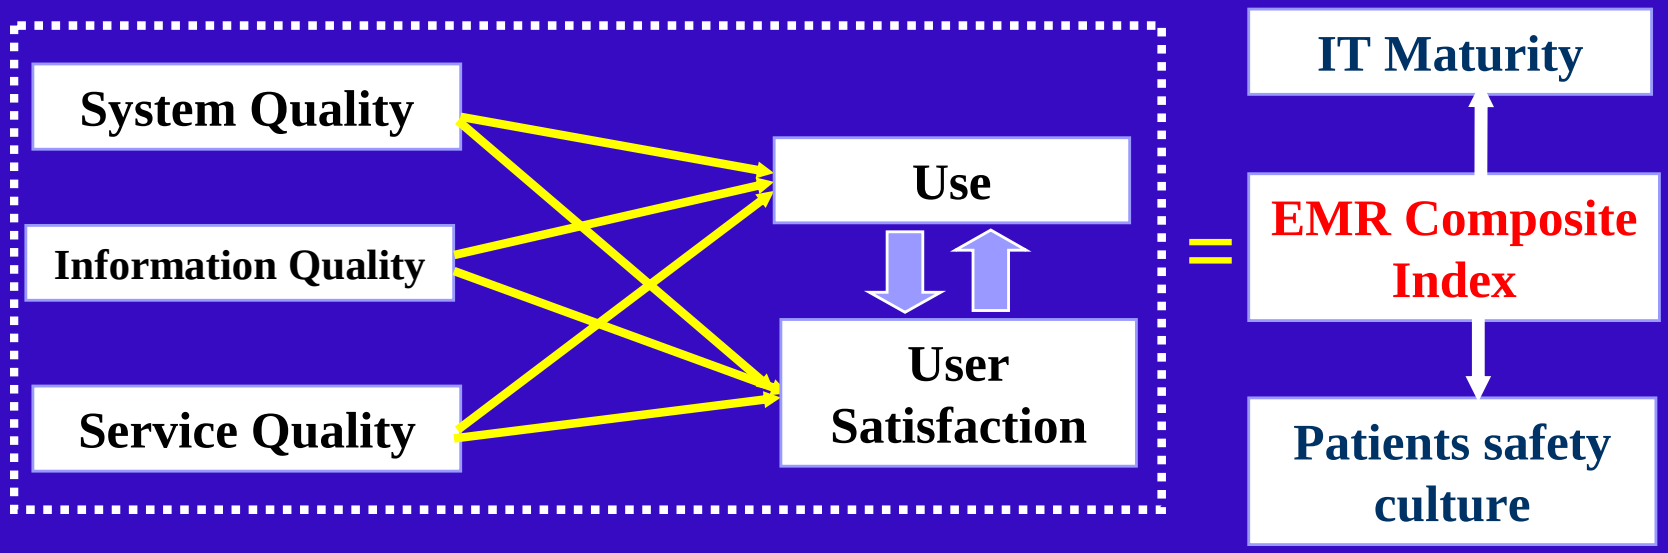
- Objective:

  To propose a framework for generating a Composite Index (C.I) for evaluating the effectiveness of EMR systems

3. The Framework:

- **Involves:**
  - Identification Constructs for EMR systems effectiveness
  - Identification of Items to measure the constructs
  - Calculating the Composite Index (C.I) for EMR systems effectiveness
  - Validation of the C.I

The Model



4. Methods I: Data collection

- 41from a total 69 (59.4%) hospitals returned questionnaires
- Data on IT maturity of EMR systems based on the JAHIS 5-level scale ("1" least computerized and "5" most computerized) and Patient safety culture were also collected
- 20 hospitals were selected for Composite Index (CI) calculation

  based on:

  - Whether all the 5 Target Group of users were represented
  - Whether at least 10% of doctors and /or 10% of nurses participated

5. Methods II: CI calculation

- **Principal component analysis (PCA) was the main analysis procedure because;**
  - **Items in the survey were not on the same scale**
  - **Different respondents were surveyed**
- **PCA was also used as a Data reduction and weighting process**

Benchmarking of hospitals

- **Data for the Composite Index was transformed using the "best performer" and "worst performer" approach**
- **To transform the data the following formula was used:**

$$r = 1-((Max-x) / Max) * F)$$

Where F = max / (max-min); x = original value; r = transformed value.

Thus for x = max, r = 1-0 = 1

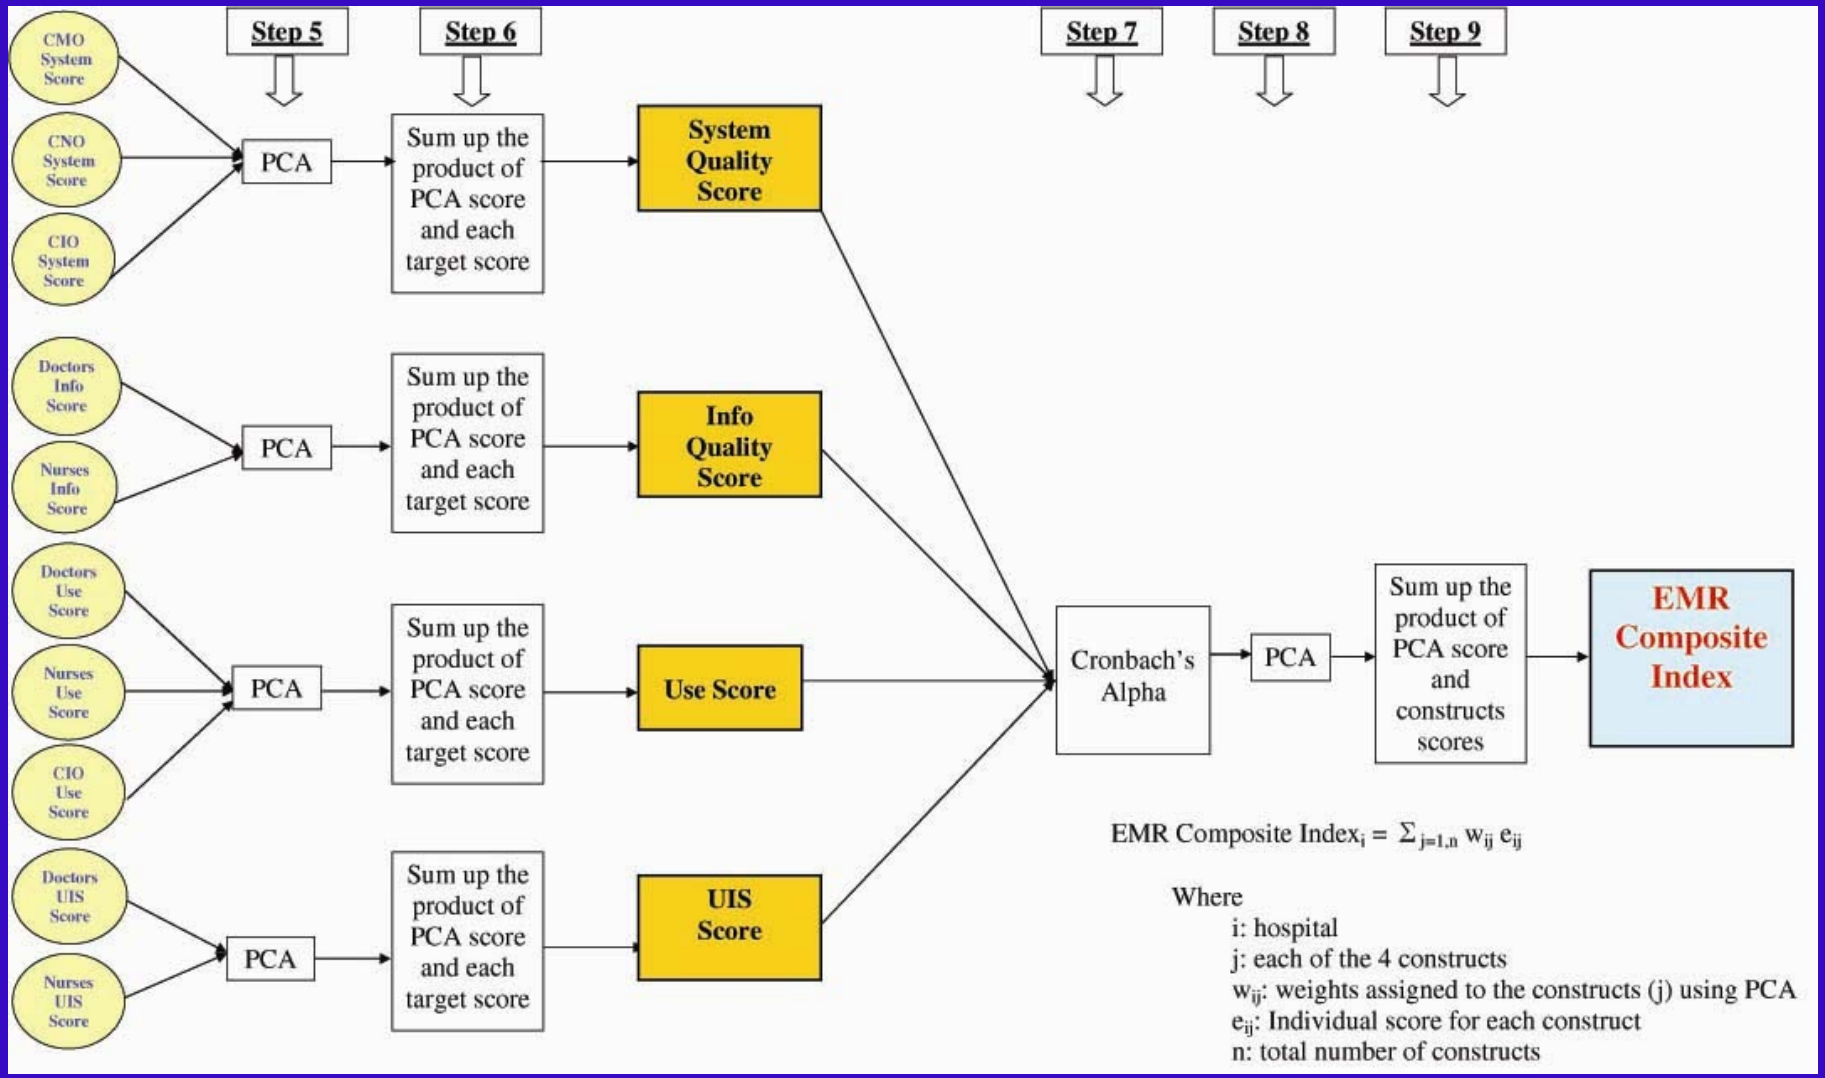
x = min, r = 1-1 = 0

6. EMR Composite Index Construction process

Constructs	No. Items	Scale	1st step	2nd step	3rd step	User group Scores
System quality Is checking drug allergy computerized?	269	Yes/no	Average	Cronbach's alpha	PCA	CIO, CMO, CNO
Information quality does the information content meet your needs?	23	5-point Likert	Factor analysis	Cronbach's alpha	PCA	Dr, NS
Service quality Is the system always up and running?	4	5-point Likert	Factor analysis	Cronbach's alpha	PCA	Dr, NS
Use How often do you use the system to check drug information?	68	5-point Likert	Factor analysis	Cronbach's alpha	PCA	Dr, NS
User satisfaction Overall, are you satisfied with the EMR system in your hospital?	31	5-point Likert	Factor analysis	Cronbach's alpha	PCA	Dr, NS

CIO-Chief Info Officer; CMO-Chief Medical Officer; CNO-Chief Nursing Officer; Dr-Doctor; NS-Nurse

7. EMR composite Index Calculation



Info=information; use=extent of use of EMR system; UIS=user of information satisfaction

8. Results: EMR Composite Index (CI)

No.	Hospital code	System quality	Information quality	Use	User satisfaction	CI	IT maturity	Patient safety
1	B34	86.9	60.3	73.8	62.1	81.6	4.0	71.0
2	D11	64.4	64.5	67.8	72.5	77.9	3.0	75.1
3	D23	84.5	55.9	70.8	57.0	77.2	5.0	64.6
4	D29	82.0	58.3	69.9	56.3	76.9	3.0	76.4
5	D40	86.1	54.0	71.7	53.2	76.4	4.0	69.7
6	C35	85.6	55.0	68.2	56.9	76.3	3.0	67.7
7	D20	79.3	55.3	68.4	58.3	75.3	3.0	55.8
8	B10	76.2	56.2	67.0	55.9	73.7	3.0	72.5

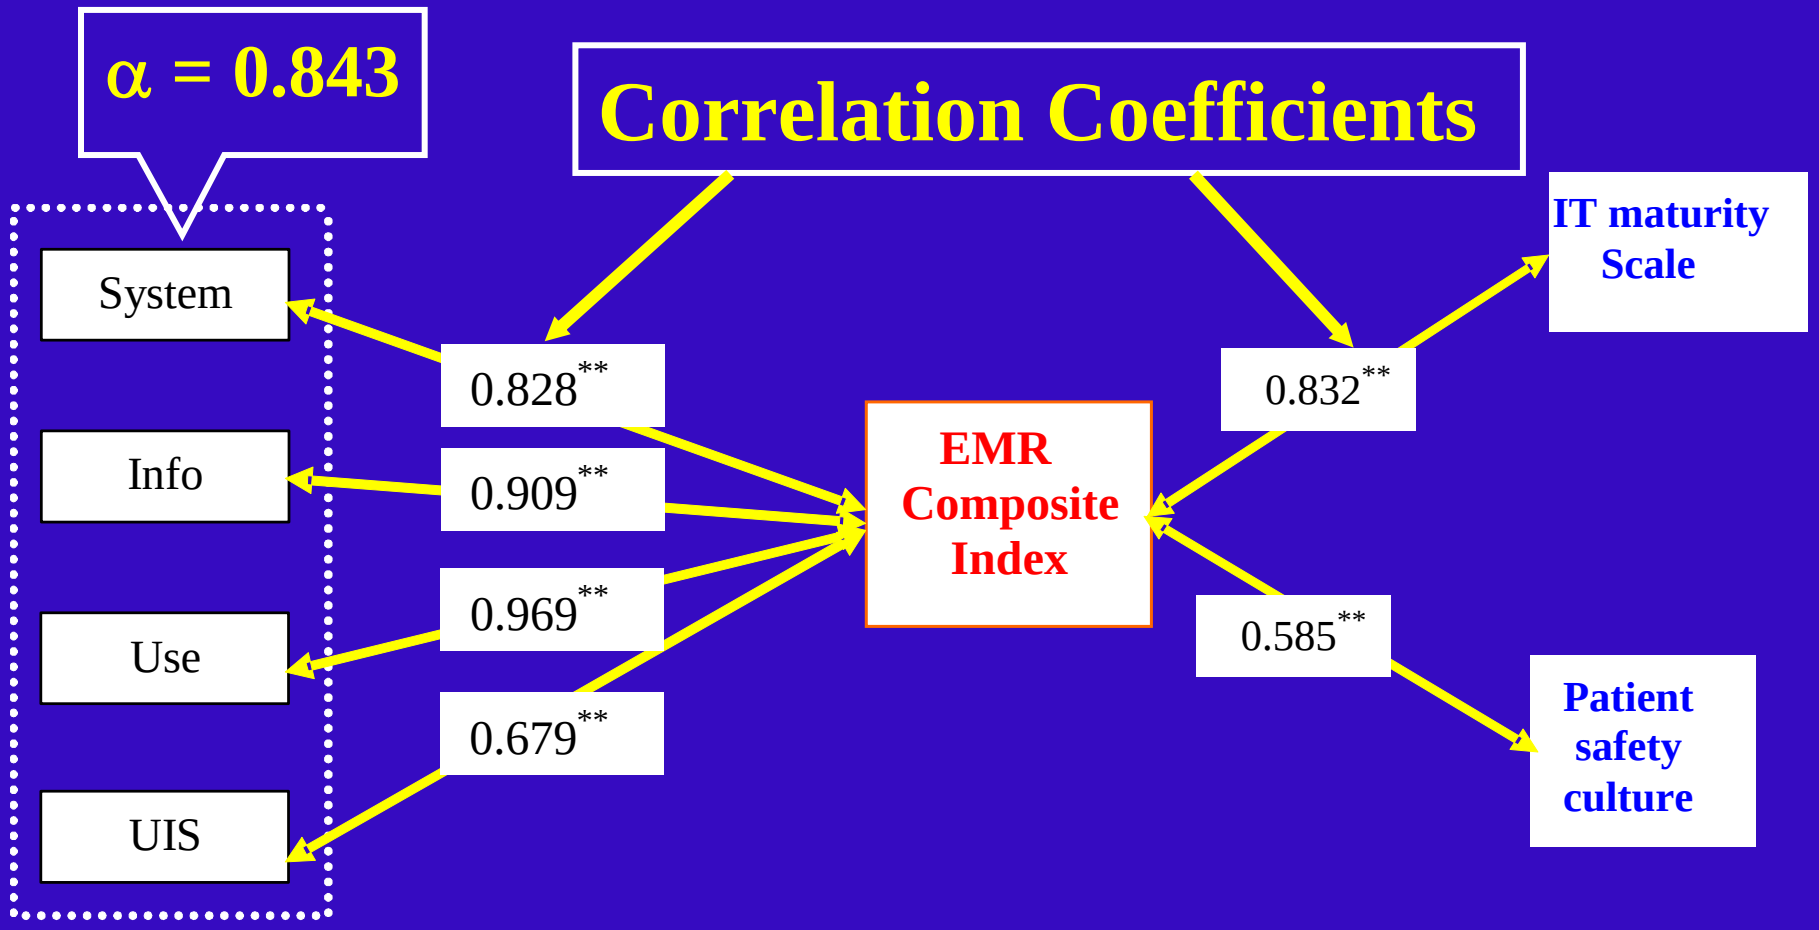
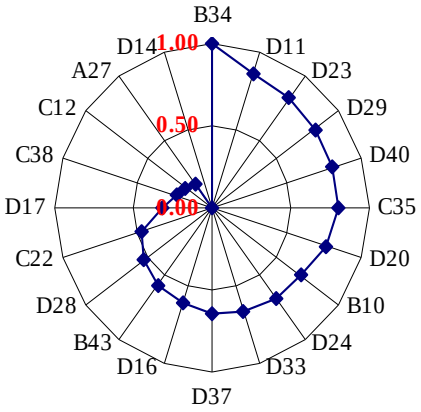
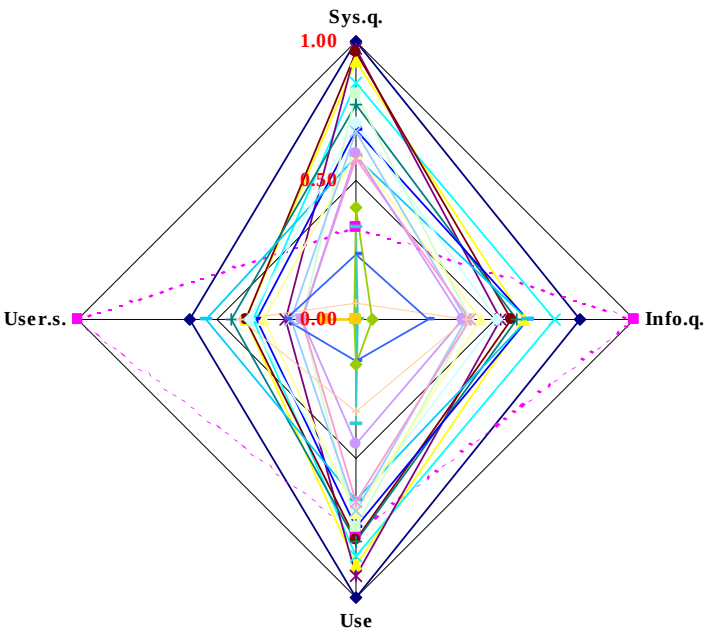
9. Validation of the CI



**p-value < 0.01 level (2-tailed Pearson correlation)

10. Benchmarking of the hospitals using CI





Sys.q=system quality; info.q=information quality; user s=user satisfaction

11. Discussion and conclusion

- These initial results show that:
  - The CI is internally consistent
  - has good construct validity, and
  - is sensitive to differences between hospitals

- Proposed a framework for evaluating effectiveness of EMR systems by;
  - Identifying relevant constructs, and
  - Describing a procedure for CI generation
- The CI can:
  - Provide a detailed scorecard for EMR systems, and
  - Allow analyst to pinpoint areas of strengths and weakness to guide computerization

Collective Intelligence and a Sustainable Healthcare System

Farhad Adam Abar

Chief Architect, IBA Health, USA

Abstract

Collective Intelligence is Mother Nature's way of cooping with evolving complexities. For a sustainable healthcare system, we must cast a critical look at our traditional episodic based healthcare delivery model and focus more on disease prevention and chronic disease management. This in part is possible by way of having access to timely and accurate lifetime patient medical information. A National Health Information Infrastructure initiative is the catalyst needed for such dramatic changes in our healthcare system.

Keywords:

national health information network

Unsustainable healthcare system

The Centers for Medicare and Medicaid Services (CMS) recently released projected health care expenditures for the 2005 through 2015 period. [1] Total health expenditures are estimated to be $2.16 trillion in 2006, and are projected to rise to over $4 trillion in 2015. Per person health spending is $7,110 this year and is projected to increase to $12,320 by the end of the period.

Health spending continues to increase much faster than the overall economy (i.e., gross domestic product, or GDP). Since 1970, health care spending has grown at an average annual rate of 9.9%, or about 2.5 percentage points faster than GDP. [2] In recent decades, the growth rates for health spending and GDP have slowed, but health spending growth remains consistently above GDP growth. As a share of the economy, health care has risen from 7.2% of GDP in 1965 to over 16% of GDP today, and it is projected to be 20% of GDP just 10 years from now.

Despite such overwhelming expenditure:

- Medical errors is the third leading cause of death in the United States. [3]
- 250,000 people die in the U.S. each year due to surgical errors, mistaken diagnostics, incorrect prescribing, hospital-acquired infections and inadequate care.
- There are over 46 million uninsured persons in US. [4]

Clearly this is not a sustainable healthcare system. The time has come to take a few fundamental steps away from our traditional business and clinical models.

Business model

The current financial incentives in healthcare system undermine efforts to improve preventive and primary care, manage chronic conditions, and coordinate care. It is based on claim-based transaction model which forces providers to focus more on patient volume and less on healthy patients. Revamped payment models should reward more effective and efficient care, with focus on value. Indeed US government, health plans, employers, and "watch dog" groups are all moving towards the implementation of quality measures, public reporting of both hospital and physician performance, and the tying of those outcomes to reimbursement.

Clinical model

In a sustainable healthcare system healthy population is as important as individual patient treatment. More often, in the present hospital-based systems:

- Physicians and other clinicians sometimes provide patient care while lacking knowledge of previous medical history, resulting in both wasteful duplication and clinical decisions that do not take into account critical data related to patient health. In fact, studies show that paper hospital records are unavailable when needed approximately one-third of the time.
- Hospitals and physicians are often unable to obtain usable information that is essential to research breakthroughs in confusing particularities of individual patients or in avoiding preventable medical errors and malpractices.
- Public health agencies and providers are unable to exchange information critical to identifying, tracking, and responding to public health threats ranging from traditional epidemics to deliberate bio-terrorist attacks.
- Health services researchers do not have ready access to data required to develop improved processes of care, which would lead to improved health outcomes.
- Patients who wish to collaborate with their doctors in managing their own health have little information to work with. Meanwhile, private and governmental payers, as well as individual workers, and consumers, continue to bear the financial burden of clinical inefficiency.

Higher quality of care and efficiency is achieved when up-to-date best practice information is universally available replacing opinion-based decision-making to evidence-based decision-making. The constraining tunnel vision created by the present silos of clinical information must give way to a bird's-eye view of patient lifetime medical encounters.

Collective intelligence

By definition Collective Intelligence is an intelligence that emerges from the collaboration and competition of many individuals, an intelligence that seemingly has a mind of its own.

The field of collective intelligence is seen by many as primarily a human enterprise in which mind-sets, a willingness to share, and openness to the value of distributed intelligence for the common good are paramount. Participants are confident of their own abilities and recognize that the whole is indeed greater than the sum of any individual parts.

As complexity and crises increase, more people and institutions are recognizing that our collective intelligence - at every level and especially in its wiser forms - has tremendous potential to produce positive change and even turn major breakdowns and crises into evolutionary breakthroughs. [5]

Thus collective intelligence is a holy grail of social change and social creativity. If we could better understand how to support it, increase it and facilitate it, we would be more able to effectively co-create a better world. Doing that, of course, involves significant political, economic, social, cultural, organizational and spiritual challenges. But the rewards, when these challenges are successfully engaged, are tremendous.

Harnessing collective intelligence

As patients move through various episodes of care, it becomes evident that to enhance quality of care various stakeholders' business processes must be woven together into an integrative delivery mechanism. National Health Information Infrastructure (NHII) is a new paradigm for the achievement of real-time information integration. It is a platform for sharing information and knowledge appropriately so it is available to people when they need it to make the best possible health decision.

NHII includes not just technologies but, more importantly, values, practices, relationships, laws, standards, systems, and applications that support all facets of individual health, health care, and public health. It encompasses tools such as clinical practice guidelines, educational resources for the public and health professionals, geographic information systems, and health statistics at all levels of government, and many forms of communication among users. [6]

Concisely, National Health Information Infrastructure:

- is an initiative set forth to improve the effectiveness, efficiency and overall quality of health and health care,
- is a comprehensive knowledge-based network of interoperable systems of clinical, public health, and personal health information that would improve decision-making by making health information available when and where it is needed,
- is the set of technologies, standards, applications, systems, values, and laws that support all facets of individual health, health care, and public health,
- improves public health through advanced bio-surveillance methods,
- streamlines collection of data for quality measurement and research,
- is voluntary,
- is NOT a centralized database of medical records or a government regulation,
- is an information infrastructure, not information system,
- sits beside the legacy systems of providers, payers, etc,
- reduces local implementation barriers while making the meaning of content in local systems increasingly explicit with time,
- facilitates direct access to external information if permitted by patient consent,
- facilitates incorporation of practice guides,
- decouples the management of information about patients from the systems that automate practice.

To meet the Nation's health needs, the NHII must serve all individuals and communities equitably. The interconnections made possible by the NHII would allow information capacities that now exist or are developing in the health field to be put to fuller use.

Ready access to relevant, reliable information and secure modes of communication would enable consumers, patients, healthcare and public health professionals, public agencies, and others to address personal and community health concerns far more effectively.

NHII architecture

A successful NHII architecture must address three fundamental layers of (1) Systems Integration which is concerned with publication, description, and translation, (2) Organizational integration which deals with consensus, and credentialing, and finally (3) Semantic Integration which handles integration at business process level.

The overarching goal of adopting NHII is to achieve progressive homogeneity across the nation healthcare delivery system, respecting the federated environment, and a balance between what is common and what is decentralized.

Federated model

The interweaving fabric is based on an integrated but decentralized/federated delivery system, which maintains each organization's brand and identity. Its objective is not to impose uniformity throughout the System: instead it recognizes that the agility and autonomy are significant contributing factors to system's overall success.

Conversely, it also recognizes that more synergy needs to be leveraged across entities and that critical functions exist (such as common patient identification, providers registry, referral network etc.) where nation-wide consistency/commonality must be implemented to achieve a holistic healthcare system.

Therefore, NHII federated architecture is about relations between system parts, and between people. It recognizes organizational politics and admits conflict would better reflect reality than a model of unstinting cooperation and unfettered exchange of information. Federalism is preferred archetype, where potentially competing or non-cooperating parties are brought together by negotiation.

NHII federated architecture identifies closely related (people and supporting systems) activities in an organization, along geographical, process, or functional lines. It divides the organization into clusters (domains) with their own administrative and control mechanisms, and supporting systems. The internals of a domain are to be opaque to other domains. It lets domains communicate exclusively via messages to be placed on a federal nation-wide information highway guaranteeing message delivery. Data flow is only by a domain publishing, and other domains subscribing to, specified agreed upon information. A domain itself can consist of a federation; therefore, in this sense, this federation pattern is recursive.

NHII federated architecture is a direct response to the healthcare market challenges associated with fragmented provider structure and rapid changes of affiliation among providers. Independent clinics are constantly bought out or are forming to be more competitive. Physicians' affiliation to hospitals and health plans are constantly evolving. The overall framework supports a complex, adaptive system, which aims to create a global healthcare community by the physicians for their patients.

Governance model

NHII Governance Model defines the policies and practices all services should follow. With no clear guidelines on how an enterprise would govern its services, national initiatives would fail to deliver the results.

Governance is determined by the policies, rules, and regulations under which an organization functions, as well as the processes ensure compliance. While design-time governance deals with capturing information about services and policies, run-time governance enforces those policies during service discovery, management, and execution. For effective governance, a federated control within the NHII infrastructure is needed to ensure that organizational policies are consistently applied.

NHII governance model supports:

- Central registry to store all services, associated metadata, plus business and technical policies.
- Directory services that accurately certify, identify, and categorize clients and providers of health care services.
- Federated identity, verification, and authorization.
- Local, regional, and federal access control mechanism with fine-grain granularity.
- Audits and logging

Trusted third party

Following the successful Model of Internet's Domain Name System, there needs to be regional central authorities which facilitate interactions between stakeholders who both trust the third party. They need to use this trust to secure their own interactions.

Core services provided by the trusted authority include:

- PKI services for distributed authentication, identification, and verification of engaging partners.
- Registry and directory services that accurately identify clients (white pages) and providers (yellow pages) of healthcare services.
- Person meta-data object repository which keeps track of individual's lifetime encounters with the nation's healthcare system.
- Transactional queuing system to support asynchronous nature of healthcare processes.

Conclusion

The NHII would serve important national interests. *Implementation of the NHII will have a dramatic impact on the effectiveness, efficiency, and overall quality of health and health care.* Serious problems such as public health emergencies, medical errors, and health disparities could be addressed in a more timely and comprehensive fashion. Furthermore, even though NHII itself will deliver huge benefits, much like other public infrastructures such as roads, communications, electricity, etc. main outcomes will be derived by additional services. It will spawn new business activities that would otherwise be economically unfeasible.

Online vs. Offline Quality Management in Diabetes Care: Impact On Process Quality

Ivo Rakovac[a,b], Peter Beck[a], Bruno Cadonna[a], Thomas Truskaller[a], Thomas R Pieber[a,b]

[a] *Institute of Medical Technologies and Health Management, JOANNEUM RESEARCH Forschungsgesellschaft mbH, Austria*
[b] *Department of Internal Medicine, Diabetes and Metabolism, Medical University Graz, Austria*

Abstract

Process quality measures were compared between centers that perform quality management only offline, by means of paper based quarterly benchmarking reports, with centers that additionally performed online benchmarking with a web based application. In this observational study (164 centers with documented 60,859 patient visits) no differences in the rates of 9 recommended process quality indicators in diabetes care were observed between the two groups of centers.

Keywords:

Quality Assurance, Health Care, Internet, Diabetes Mellitus

Introduction

Number of persons suffering from Diabetes Mellitus is rising worldwide, mainly due to sedentary lifestyle and aging populations. Although effective treatments for Diabetes Mellitus are available, substantial proportion of patients does not receive recommended care.

Feedback of medical performance and benchmarking are considered to be effective methods of quality improvement [1, 2]. We developed and deployed BARS, a web-based system for data collection and benchmarking in diabetes care [3] in year 2002. Data can be collected either online, on paper forms or imported from EMRs. Using this software, paper based quality of care reports are produced quarterly and sent to all participants via ground mail.

In this poster, the impact of additional online benchmarking on process quality is examined.

Methods

Forum for Quality Systems in Diabetes Care (FQSD) is a voluntary quality improvement initiative active in Germany and Austria. FQSD members document pseudo-anonymized patient data annually on structured data entry forms, either on paper sheets or online. All centers (general practitioners and hospitals) that collected data receive quarterly non anonymized (with identifiable centers) quality of care reports. Additionally, benchmarking can be performed anytime online using BARS, a web based application [3]. Screenshot of an executed benchmarking query is given in Figure 1. FQSD members participate in continuous medical education meetings with workshop character, which are organized twice a year in Austria and once yearly in Germany.

Improvements in process quality and intermediate outcomes achieved by Austrian FQSD members have been described elsewhere [4].

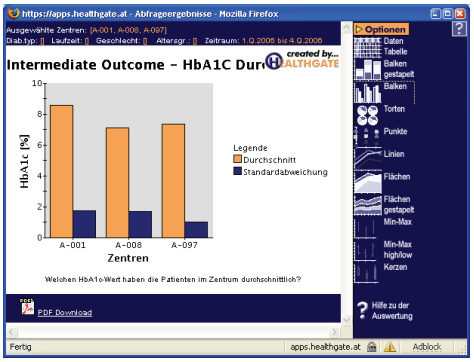

Figure 1 - Screenshot of executed query

For each center process quality measures (percentages of visits with recommended examinations or prescriptions) were calculated for the baseline and follow up period of 2 years before and after the deployment of the web application. During this time, all considered process measures were included in the reports, and for some of them, evidence has been reviewed in continuous medical education meetings.

If center personnel performed at least one additional online benchmark monthly during follow up period, this center was considered an online center. In order to adjust for the potential imbalance between online and offline groups of centers, analysis of covariance (ANCOVA) was used to assess the impact of additional online benchmarking. Centers that collected less than 10 yearly documentations during either baseline or follow up period were excluded from the analysis.

Results

147 and 17 centers have been classified as offline and online centers, respectively. Offline centers documented on average (mean ± SD) 137 ± 192 and 164 ± 288 visits during baseline and follow up period, respectively. Online centers documented 376 ± 400 and 604 ± 544 visits during baseline and follow up period, respectively, resulting in on average 179 (95% CI 65 – 292, p<0.001) more documented visits in the online group. Process quality results are shown in Table 1.

Table 1 - Process quality indicators. Data are means ± SD. Data are percentage of patients per center receiving recommended examination or medication

	Offline centers		**Online centers**		**p**
	Baseline	**Follow up**	**Baseline**	**Follow up**	
HbA1c recorded	89±19	91±16	94±5	95±5	0.761
RR recorded	95±6	96±6	97±3	95±5	0.195
Full lipid profile	32±41	74±28	31±39	78±18	0.497
Microalbumin recorded	55±34	54±38	65±22	60±25	0.652
Feet exam	64±31	63±28	76±21	70±22	0.896
Eye exam	58±25	54±24	58±20	52±24	0.652
RR> 140/90 treated	70±24	76±23	81±10	83±11	0.992
Statins prescribed**	49±30	53±29	51±18	52±17	0.810
Aspirin prescribed*	61±30	62±28	61±17	64±20	0.760

* Apply only to patients with myocardial infraction or stroke.

Discussion

In our study, online centers increased the number of documented patient visits, but did not improve process quality compared to offline centers. To our knowledge, this is the first study that evaluated the impact of additional online benchmarking on process quality measures.

In our study, only a low proportion (10%) of centers performed online benchmarking.

Alternatively, results of this study can be used to answer the question if more frequent feedback improves process quality. Results of the Cochrane review [2], in which no evidence of feedback frequency on process quality could be seen, is inline with our data.

There are several limitations of our study. Firstly, due to its non randomized design, results should be viewed with caution. Although we adjusted the results for the difference in the baseline performances, there are several other possible sources of bias we could not adjust for (dedication to quality improvement, resources available in centers …). Secondly, centers had relatively high baseline performance, which, according to the literature [2], leaves fewer opportunities for further quality improvement.

Reminders, which can be effective in improving process quality, especially if they provide timely information with actionable recommendations [5], were implemented after follow up period and their effect will be evaluated separately.

Conclusion

In our study, additional online benchmarking did not further improve process quality beyond improvements observed with the use of paper based benchmarking. Additional studies, preferably randomized controlled trials, are needed in order to objectively assess the impact of additional online benchmarking on process quality.

Barriers to Interdisciplinary Use of Patient Problem Lists across an Integrated Health Care Delivery System

Patricia C. Dykes, Matvey B. Palchuk, Qi Li, Victoria Doroshenko, Howard Goldberg

Partners HealthCare Clinical Informatics Research & Development, Boston, USA

Abstract

While the benefits of a dynamic patient problem list have been recognized for decades, evidence suggests that the practice of generating and maintaining problem lists is inconsistent, occurs in silos and is frequently not patient-centric. This poster includes a brief review of the literature on patient problem lists and then describes the process, tools and findings from an evaluation of interdisciplinary use of patient problem lists across levels of care in an integrated health care delivery system in the northeastern United States. Recommendations for building systems and processes that are supportive of enterprise wide use of patient problem lists are discussed.

Keywords:

problem-oriented medical record, problem list, patient-centered care, documentation

Introduction

The significance of the patient problem list as a key component of the medical record is well established. In 1968, Lawrence Weed described the value of the problem list with regard to its ability to enable the physician to systematically address patient problems. Weed viewed the problem list as the organizing feature of the medical record and in his seminal paper entitled, *Medical Records That Guide and Teach,* Weed (1968) described the problem list as the "dynamic 'table of contents' of the patient's chart, which can be updated at any time" (p. 597)[1]. Weed coined the phrase "problem oriented medical record" (POMR) to describe a patient record characterized by the presence of a complete and dynamic problem list that is informed by a structured, systematically collected database.

An important premise of the POMR is that the structure of the record (e.g. chronologically by problem) is more patient-centric than the traditional approach of structuring the medical record chronologically by discipline. The POMR facilitates integration of data entered by the interdisciplines and ubiquitous access to data, goals, orders, plans, and progress notes related to a particular problem. However, to achieve generalizable integration, a standardized taxonomy and approach to coding problems is needed. Significant barriers exist to capturing patient problem data in a structured, coded format. At present, a clinically useful, controlled medical terminology that adequately represents the range of problems encountered in clinical settings does not exist. Evaluation studies testing the adequacy of existing controlled vocabularies for representing clinician-generated problem statements found that that they are inadequate and require enhancement with additional terms to meet the needs of providers at the point of care.[1-3] An additional barrier to the use of an interdisciplinary patient problem list is the variability in approaches to design and function of the patient problem list that lead to lack of interoperability and preclude data reuse and sharing.

Data collection

An interview guide was developed from a review of the literature and the work of Campbell (1998) and Warren (1998) and was made available to participants prior to site visits. The interview guide standardized data collection across sessions and sites. Interviews were conducted using one-on-one and interdisciplinary focus group formats and centered on the following: 1) information and administrative attributes; 2) benefits and facilitators to existing problem list documentation processes; 3) barriers to enterprise-wide use of interdisciplinary patient problem lists. Participants were identified by hospital leadership due to their clinical leadership roles, expertise with local documentation systems and familiarity with use of patient problem lists.

Results

The degree to which include the features and achieve the benefits of a well-designed and well executed problem list (as defined by Campbell et. al (1998)) is reported in **Table 1**.[4] Vendor functionality is summarized on the left side of **Table 1** under the heading, "Vendor Functionality". The degree to which users perceive key attributes and benefits to be present in inpatient and outpatient settings are summarized by level of care and vendor product versus paper documentation systems on the right side of **Table 1**. Findings indicate that vendor products include many key problem list attributes. However, the degree to which users perceive the attributes and associated benefits to be present varies by site and by user. Of note is the variability of user perception of problem list attributes and benefits even when the vendor product in place is the same.

The primary barriers to use of a common patient problem list across disciplines and levels of care were identified in this evaluation and classified under the following categories: 1) Tools, 2) People and 3) Processes. In this context, tools are defined as the systems in place (e.g. electronic or paper documentation systems) designed to facilitate the use of an interdisciplinary patient problem list. The concept of people includes the attitudes and behaviors of users, patients and characteristics of the organizational culture that are facilitators or barriers to interdisciplinary use of a patient problem list. Processes include operations or events within a hospital or healthcare system that facilitate or prevent adoption of common patient problem list (e.g. organizational policy or implementation strategies).

Tool-related barriers include: 1) Lack of interoperability between systems. 2) The inability of outside vendors to employ web-based services. 3) Differences in structure and coding schemes that exist across vendor products limits the ability to execute a sharable list and assure that updates and changes to a patient problem list are reflected across the system.

People-related barriers include: 1) Attitudes or beliefs related to existing problem list functionality were inconsistent and in some cases inaccurate. 2) Cultural resistance to "patient-centric" problem lists rather than "discipline-centric" problem lists.

Process-related barriers include: 1) Institutional policies and implementation strategies and 2) dual electronic and paper documentation systems.

Conclusion

Barriers to use of a common patient problem list noted in this evaluation include the use of paper-based documentation systems, the execution and functionality of vendor products, and local documentation policy and practices. As organizations continue the transition from paper to electronic systems, it is important that careful consideration is given to EHR design so that systems include key information and administrative attributes of well designed problem lists and the problem list functionality is usable within the context of busy patient care workflows.

Barriers to Interdisciplinary Use of Patient Problem Lists Across an Integrated Health Care Delivery System

Partners HealthCare Clinical Informatics Research & Development, Boston, USA

Patricia C. Dykes, Matvey B. Palchuk, Qi Li, Victoria Doroshenko, Howard Goldberg

Abstract

- While the benefits of a dynamic patient problem list have been recognized for decades, evidence suggests that the practice of generating and maintaining problem lists is inconsistent, occurs in silos and is frequently not patient-centric. This paper includes a brief review of the literature on patient problem lists and then describes the process, tools and findings from an evaluation of interdisciplinary use of patient problem lists across levels of care in an integrated health care delivery system in the northeastern United States. Recommendations for building systems and processes that are supportive of enterprise wide use of patient problem lists are discussed.

- **Keywords: Problem-Oriented Medical Record, Problem list, Patient-Centered Care, Documentation**

Project Goals

- The goal of the project was to describe “current state” with regard to interdisciplinary use of patient problem lists across Partners’ sites and levels of care and to evaluate the degree to which users perceive that key problem list attributes and benefits are present in existing vendor products.
- An additional goal was to identify barriers and facilitators to an enterprise-wide solution to a common electronic patient problem list.

Study Institutions

- Partners is an integrated health care delivery system located in Northeastern United States and includes academic medical centers, community and specialty hospitals and a network of providers and specialists across the healthcare continuum. Partners' has an enterprise patient problem list that has been a component of legacy ambulatory systems since 1990 (Kuperman et. al, 1995) and as part of the ambulatory Longitudinal Medical Record (LMR) since 2000 (Spurr et. al. 2001). Coded concepts in the Partners problem list dictionary were developed based on evaluation and synthesis of free text terms entered by physicians in the ambulatory setting.21 A paper-based patient record is employed on inpatient units in the Academic Medical Centers (AMCs) and vendor solutions at inpatient community and specialty sites.

Data Collection Methods

- An interview guide was developed from a review of the literature and the work of Campbell (1998) and Warren (1998) and was made available to participants prior to site visits. The interview guide standardized data collection across sessions and sites. Interviews were conducted using one-on-one and interdisciplinary focus group formats and centered on the following:
  1. Information and administrative attributes;
  2. Benefits and facilitators to existing problem list documentation processes;
  3. Barriers to enterprise-wide use of interdisciplinary patient problem lists.
- Participants were identified by hospital leadership due to their clinical leadership roles, expertise with local documentation systems and familiarity with use of patient problem lists.

Results

- Findings indicate that vendor products include many key problem list attributes. However, the degree to which users perceive the attributes and associated benefits to be present varies by site and by user. Of note is the variability of user perception of problem list attributes and benefits even when the vendor product in place is the same.
  - The degree to which problem list functionality and processes across Partners sites include the features and achieve the benefits of a well-designed and well executed problem list (as defined by Campbell et. al (1998)) is reported in **Table 1.**
  - Vendor functionality is summarized on the left side of **Table 1** under the heading, “Vendor Functionality”.
  - The degree to which users perceive key attributes and benefits to be present in inpatient and outpatient settings are summarized by level of care and vendor product versus paper documentation systems on the right side of **Table 1.**

PCP=Primary Care Provider; **SP**=Specialist; **NPP**=Non-Physician Provider; **V**=Vendor

Table 1: Key problem list attributes by vendor, setting and provider

Results

- The primary barriers to use of a common patient problem list across disciplines and levels of care were identified in this evaluation and classified under the following categories: 1) tools, 2) people and 3) processes.
  1. **Tools:** The systems in place (e.g. electronic or paper documentation systems) designed to facilitate the use of an interdisciplinary patient problem list.
  - Primary Tool-related Barriers:
    1. Lack of interoperability between systems
    2. The inability of outside vendors to employ web-based services
    3. Differences in structure and coding schemes that exist across vendor products limits the ability to execute a sharable list and assure that updates and changes to a patient problem list are reflected across the system.

Results

2. **People:** Include the attitudes and behaviors of users, patients and characteristics of the organizational culture that are facilitators or barriers to interdisciplinary use of a patient problem list.

- **Primary People-related Barriers:**
  1. Attitudes or beliefs related to existing problem list functionality were inconsistent and in some cases inaccurate.
  2. Cultural resistance to “patient-centric” problem lists rather than “discipline-centric” problem lists.

Results

3. **Processes:** Include operations or events within a hospital or healthcare system that facilitate or prevent adoption of common patient problem list (e.g. organizational policy or implementation strategies).

- **Primary Process-related Barriers:**
  1. Institutional policies and implementation strategies
  2. Dual electronic and paper documentation systems

Discussion

- The technical capacity of electronic systems to support key attributes of patient problem list functionality exists in many vendor systems. However, this evaluation suggests that access to advanced functionality does not guarantee that key problem list attributes and associated benefits will be recognized by providers or that problem list functionality will be used enterprise-wide in ways that are patient-centric.

Abstract

The age-related decline in kidney (renal) function is poorly recognised by doctors prescribing renally cleared drugs in the elderly. This causes inadvertent overdosing of renally cleared drugs, increasing the incidence of adverse drug events. A clinical decision support system (GFR+) was developed for calculation of renal function and doses of key drugs adjusted for both weight and renal function. We examined the rate of appropriate prescribing for key renally cleared drugs before and after GFR+ implementation.

Improvements were seen in appropriate dosing of enoxaparin (from 68% to 86%, p=0.03), gentamicin (63% to 87%, p=0.01) and vancomycin (47% to 87%, p=0.07). More appropriate use of therapeutic drug monitoring for gentamicin (70% to 90%, p=0.0)3 and vancomycin (61% to 84%, p=0.17 was noted. With-holding renally cleared drugs during episodes of acute renal failure (43% to 64%, p=0.13) in creased, as did the frequency that frusemide was held (19% versus 31%, p<0.01). GFR+ improved prescribing habits of key renally cleared drugs in an elderly hospitalised population. This is expected to improve patient safety and outcomes in this susceptible group.

Keywords:

dosing, clinical decision support, drug safety, adverse drug reaction

Introduction

Adjusting doses of renally cleared drugs for renal function is an essential element of prescribing. Renal function declines slowly with age, but this is poorly recognised by doctors. The subsequent lack of dose adjustment leads to inadvertent overdosing in older patients, and an excess of adverse drug events, some of which are life-threatening[1]. The occurrence of an adverse drug event is associated with a two-fold increase in mortality rate, increased length of hospital stay of 1.91 days, and an extra US$2262 per patient[6]. Non-compliance for renal drug dosing within the hospital setting is common, with inappropriate prescribing in 19-67% of patients and this is often driven by over-reliance of serum creatinine as a marker of renal function, which is misleading in the elderly[2].

Renal function estimation, with a view to drug dosing, is not a reflex part of clinical practice for most clinicians. Lack of recognition of those drugs that are renally cleared may contribute to poor prescribing, along with the continuing reliance by some clinicians on serum creatinine as a quick guide to renal function in the elderly. Clinicians can easily be misled by normal-range serum creatinine measurements for elderly patients, which can mask significant renal decline. A serum creatinine of 100micromol/l is generally considered to be in the normal range, but results in vastly lower renal function estimations when applied to elderly patients. An 80 year old, 160cm, 45kg female with a serum creatinine of 100micromol/L has an estimated renal function of only 28ml/min, clearly necessitating adjustment of renally cleared drugs.

Methods

An integrated clinical decision support system (GFR+) was developed for the hospital inpatient setting (Figure 1). Functions included automatic renal function estimates, and development and incorporation of sophisticated dosing algorithms, including dose adjustment for renal function, weight and obesity. The module was linked through local databases to enable automatic input of required variables. Serum creatinine values were updated automatically as they became available. GFR+ was designed as a stand-alone module, outside of normal workflow, as electronic prescribing is not available at this hospital. Prescribers were under no obligation to utilize GFR+. Data were collected for 5 months pre- and post-intervention to assess the impact of GFR+ on appropriate prescribing of renally cleared drugs within the hospital setting. The focus was on several critical drugs with a low therapeutic index (gentamicin, enoxaparin and vancomycin), and whether appropriate drug management action was taken during episodes of acute renal failure. GFR+, along with key messages on prescribing issues surrounding renally cleared drugs was introduced using an academic detailing approach.

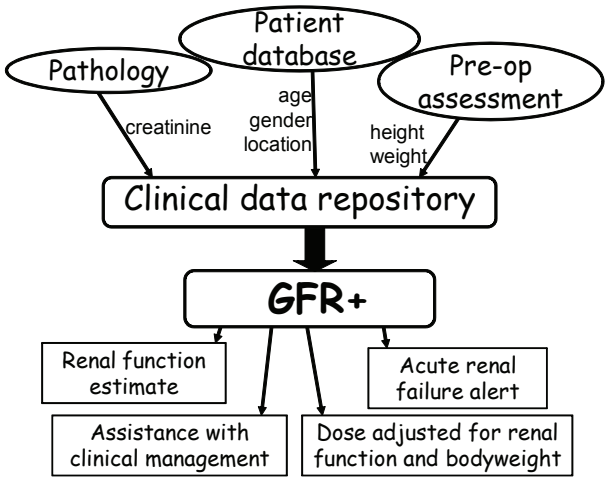

Figure 1

Results

Patient characteristics across the two groups were similar with the following exceptions: pre-intervention patients had better renal function, were less likely to be on frusemide as part of drug management, and more likely to receive gentamicin or vancomycin as part of their drug management during hospitalisation.

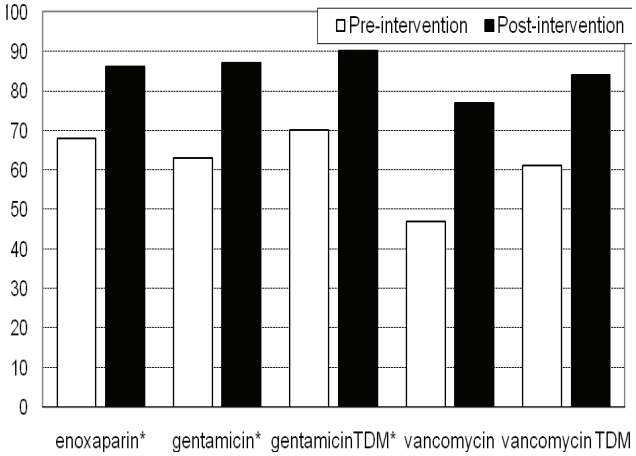
Table 1

	Pre-intervention	Post-intervention
N	509	492
No. of males	292	300
Age (y)	77.9 ± 11.2	78.6 ± 12.4
Weight (kg)	73.9 ± 17.8	72.7 ± 19.9
Length of stay (d)	7 (1-154)	7 (1-84)
Co-morbidities (median, range)	3 (0-12)	3 (0-9)
Renal function * (ml/min)	47.4 + 24.1	43.3 + 22.7
Acute renal failure	24	16
ACE Inhibitors	258	252
Allopurinol	50	54
Digoxin	98	80
Enoxaparin	44	58
Frusemide*	204	233
Gentamicin*	77	38
Lithium	1	1
Metformin	64	60
Vancomycin*	37	17

*p<0.05

Improvements occurred in targeted key drugs commenced during the hospital admission, as well as appropriate therapeutic drug monitoring for gentamicin and vancomycin (see Figure 2).

*Figure 2 - (*p<0.05)*



During the pre-intervention period 38% of renally cleared drugs were held in patients experiencing acute renal failure, improving to 62% after GFR+ (p=0.01).

Frusemide was held in 18.6% of patients at some time during an admission for the pre-intervention phase compared to 30.9% of patients after GFR+ (p=0.003). There was no impact on drug dosing in cases were the patient had previously been commenced outside the hospital on too high a dose (15% vs. 20%, p=0.49).

*p<0.05 for difference between groups

In the pre-intervention period where either an ACE I, allpurinol, digoxin or metformin were initiated during the course of the admission, the starting dose was too high on 11% of occasions, compared to 6% of occasions during the post-intervention phase (p=0.34).

Discussion

The implementation of GFR+ using an academic detailing approach significantly improved a number of aspects of the management of renally cleared drugs. Prescribing of key renally cleared drugs were successfully targeted. Two drugs of particular concern in our patient population were enoxaparin and gentamicin. These two drugs are used for potentially life-threatening conditions, have a low therapeutic index, require adjustment for impaired renal function, and commonly cause serious adverse drug events in the elderly. The dosing accuracy of both these drugs improved significantly. An unexpected benefit for gentamicin management was the improvement in therapeutic drug monitoring, driven by the presence of the monitoring recommendation given with the dose. Vancomycin prescribing also improved markedly (47% to 77%), as was the use of vancomycin therapeutic drug monitoring, but

the smaller patient numbers recruited failed to reach statistical significance (p=0.07 and p=0.17 respectively).

The combination of GFR+ and academic detailing resulted in a better understanding by prescribers of those drugs needing to be held when renal function decreased. This was reflected in an improvement from 38% to 62% for renally cleared drugs held during episodes of acute renal failure. There number of instances where patients on frusemide had this drug held or ceased at some point during an admission increased after the introduction of GFR+. A key message in the academic detailing process focused on frusemide use, and we feel this change reflected a better understanding by clinicians of the potential for frusemide to cause or exacerbate declining renal function.

GFR+ allowed use of sophisticated and better suited dosing algorithms that would not be possible outside this setting. This is expected to lead to decreased rates of adverse drug events for these drugs, especially in elderly patients.

There was a high impact on prescribing, despite GFR+ not being a part of the prescribers normal workflow. GFR+ was readily sustainable across the hospital. Formal user feedback was extremely positive.

Conclusion

GFR+ significantly improves prescribing and understanding of renally cleared drugs, in the hospital setting, which should translate into a decreased rate of adverse drug events.

Mr. Steve Govis[3]

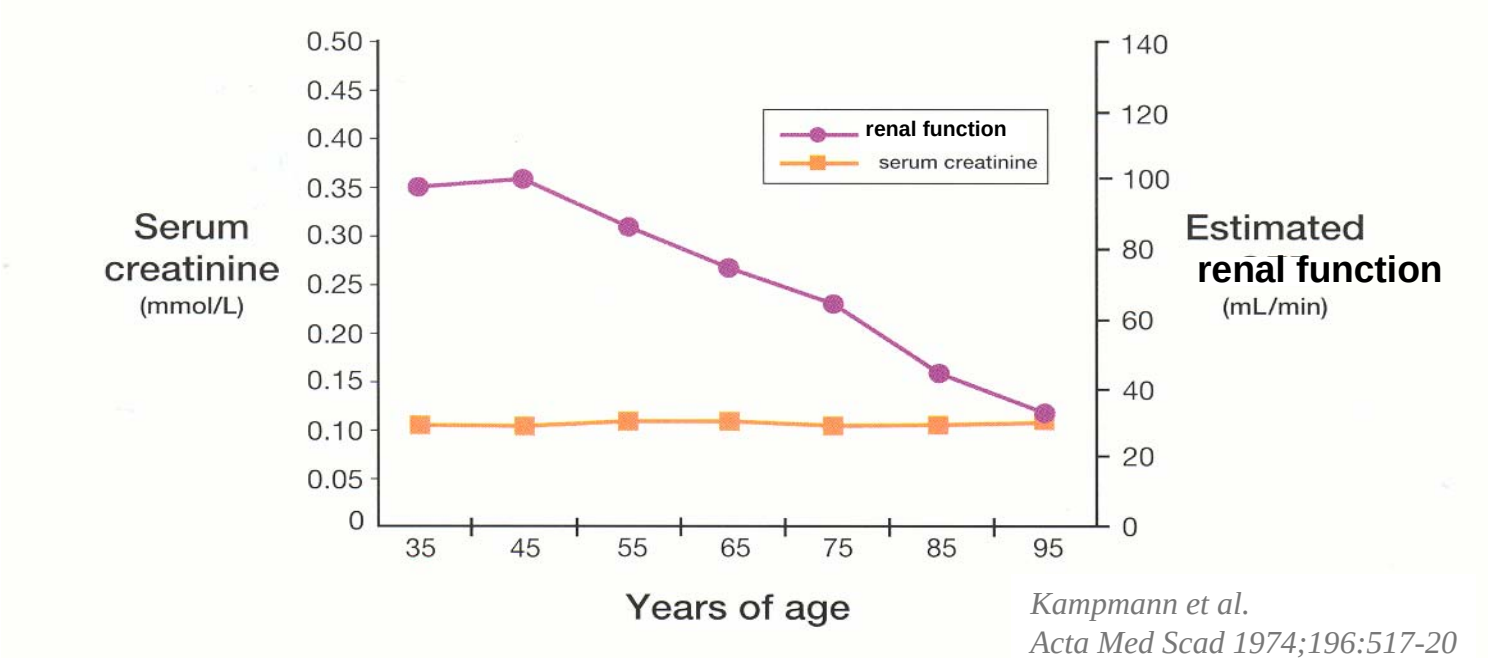
Mr. Tom Belcher[3]

Government of South Australia

1. Repatriation General Hospital
2. University of Adelaide
3. rL-Solutions

The Problem.

• lack of recognition of age-related decline in kidney (renal) function in hospital patients
• clinical culture revolves around using serum creatinine as a marker of renal function, which is very misleading in the elderly

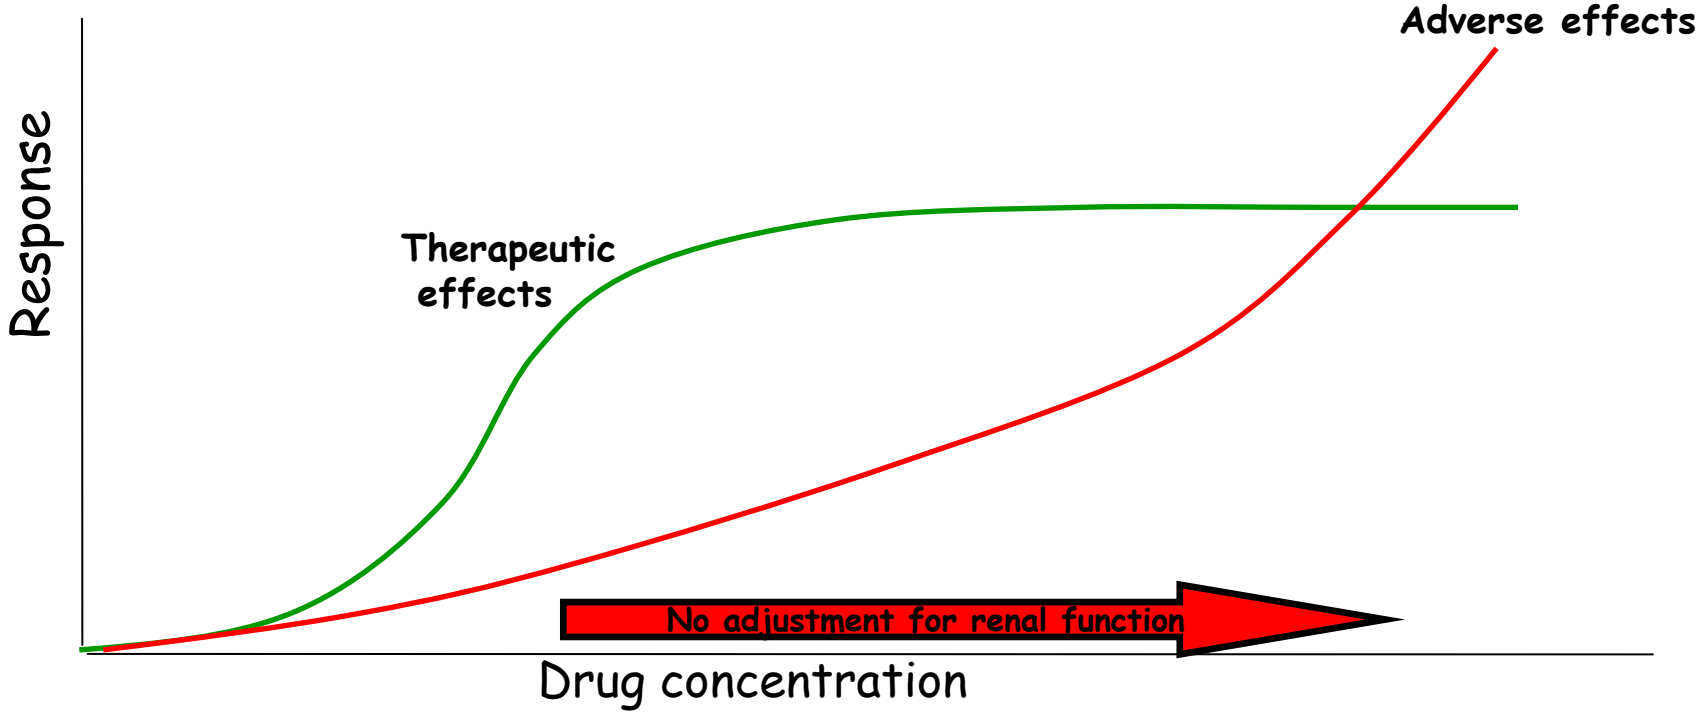


Kampmann et al.
Acta Med Scad 1974;196:517-20

• many key drugs excreted from the body via kidneys (renally cleared)
•the dose of these drugs needs to be decreased according to the decreasing renal function
•not being done in older patients with key drugs in particular (enoxaparin, gentamicin) - identified via death review audit process

The Problem.

•by not appropriately decreasing the dose when renal function is impaired, the patient inadvertently receives an overdose. The drug concentrations build up in the body, increasing the likelihood of adverse drug events.



•this causes a 2-fold increase in the rate of adverse drug events

Corsonello A et al. Arch Int Med 2005; 165: 790-5.

•adverse drug events are associated with a two-fold increase in mortality rate, increased length of hospital stay of 1.91 days, and an extra US$2262 per patient

Classen DC et al. JAMA 1997; 277: 301-6

Existing literature: Dosage adjustment in patients with renal impairment

Cantu et al. Am J Hosp Pharm 1992;49:2944-8.

- 169 inpatients with GFR<40 of which 60 patients were prescribed a renally cleared drug requiring dose adjustment
- 45% of renally cleared drugs too high
- on average 2.5 times higher than recommended dose
- prescribers notified of excessive dosing changed the dose 80% of the time

Formula required for estimation of patients renal function

- modified version of the Cockroft-Gault formula, using the lesser of ideal or actual weight, serum creatinine capped at a minimum of 60 mmol/l.

$$\textbf{Renal function (ml/min)} = \frac{(140 - \textbf{age}) \times \textbf{weight} \times k \ (\times 0.85 \text{ if female})}{\text{serum } \textbf{creatinine}}$$

Methodology

- clinical decision support module developed (GFR+). See next slide
- dosing guidelines developed with adjustment incorporated for renal function and body weight
- drugs included enoxaparin, gentamicin, metformin, ACE inhibitors, digoxin, vancomycin
- dosing and drug management data collected on 500 patients on renally cleared drugs before introduction of GFR+ to assess baseline
- GFR+ introduced to prescribers via academic detailing
- a further 500 patients were assessed and prescribing accuracy compared to baseline as well as drug management during episodes of acute renal failure

Enoxaparin Treatment Doses

Dosing Frequency

Dosing frequency is maintained at twice daily for all patients. Once daily dosing is generally discouraged in order to avoid peaks that may be associated with bleeding, although it may be a necessary option for patients receiving home based therapy being administered by RDNS nurses.

Doses are rounded up to the nearest 5mg in order to accomodate the commercially available pre-filled syringes (Clexane©). For doses lower than 60mg the 60 mg syringe will have to be used for all doses except 20mg and 40mg. The 20mg and 40mg pre-packed syringes do not have markings that allow their use for any other doses.

Commencing Warfarin

Continue enoxaparin treatment for at least 24 hours after the patients returns their first therapeutic INR.

Anti-Xa Monitoring

Severe Renal Impairment

The estimated GFR is less than 30ml/min

The following drugs should only be used with caution, if at all:

- Acyclovir
- Allopurinol
- Gabapentin
- Lithium
- Metformin
- Morphine
- Spironolactone (pending potassium)
- Venlafaxine

Highlights drugs to be avoided if patient has severe renal impairment

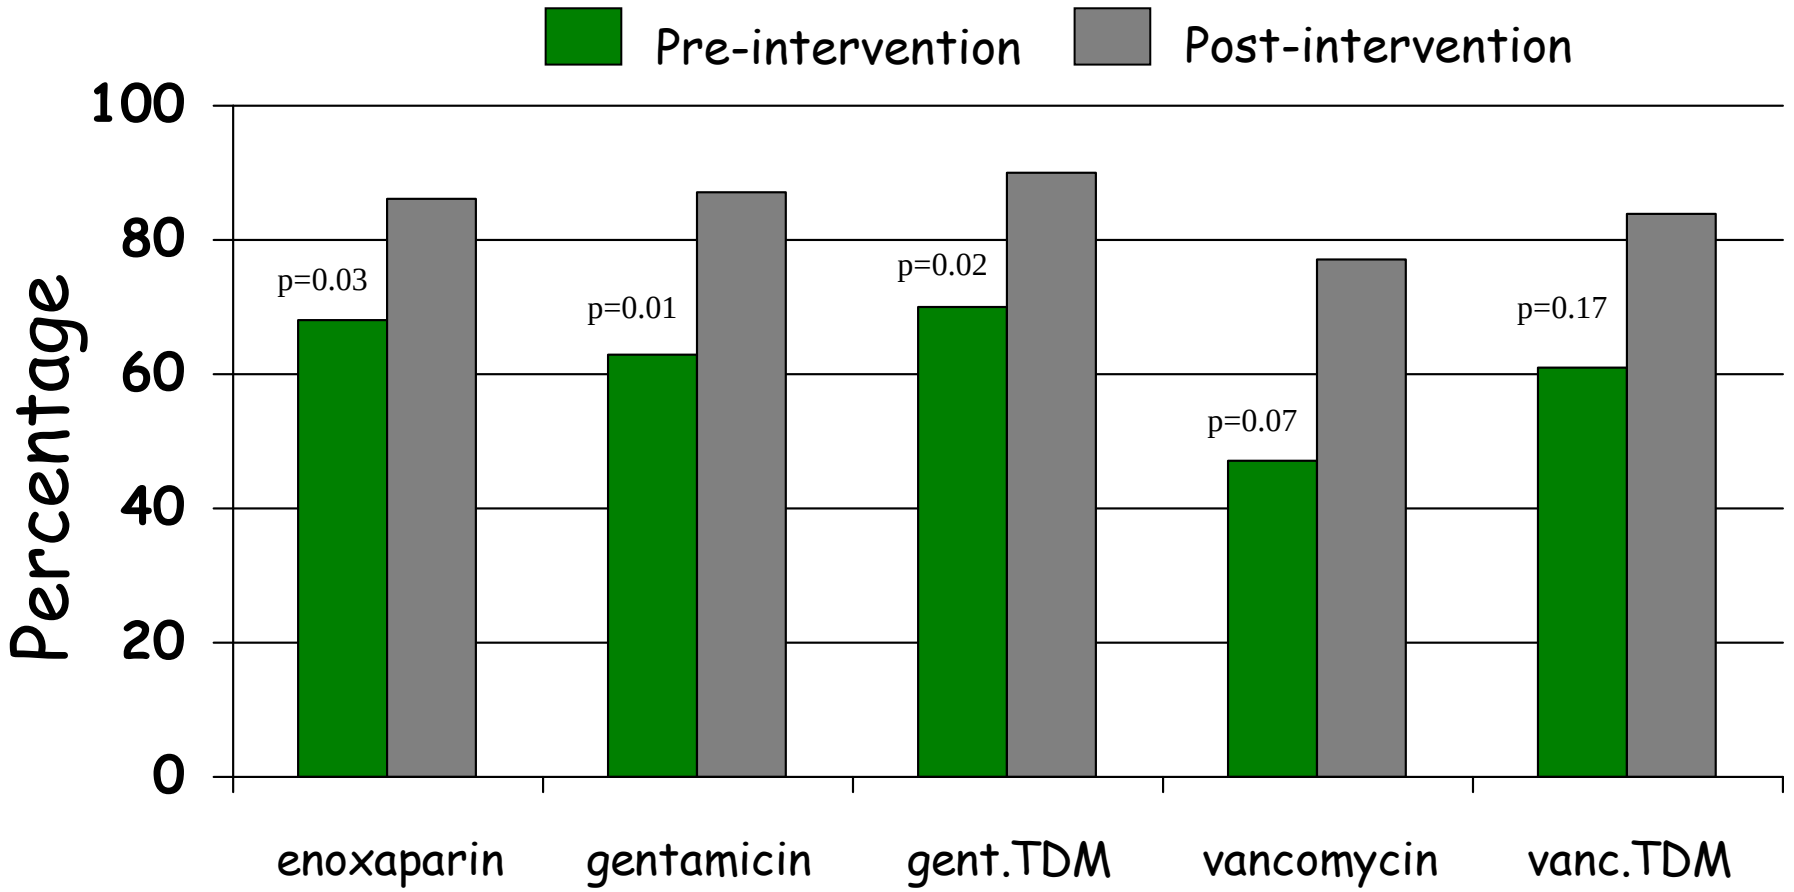
Improvement in prescribing of renally cleared drugs.



- frusemide was more likely to be held after the intervention (19% versus 31%, p<0.01).
- during episodes of acute renal failure, renally cleared drugs (ACE inhibitors, metformin, digoxin, frusemide) were held on 38% of instances in the pre-intervention period versus 62% post-intervention (p=0.01).

Discussion

- likely to lead to improved patient safety and outcomes
- extremely positive reception from medical staff
- apart from dose adjustment for renal clearance and weight, also possible to focus on different issues for different drugs:

✓ improving gentamicin dosing by extending the dosing interval during renal impairment rather than decreasing the dose

✓ encouraging appropriate drug monitoring

✓ encouraging maximisation of ACE inhibitor doses for heart failure

✓ building a general awareness of drug issues related to renal function

[c] *Department of Nursing, Hiroshima University Hospital, Hiroshima, Japan*
[d] *Information Media Center, Hiroshima University, Hiroshima, Japan*

Abstract

It is evaluated how the consistent management of information of the clinical process on injection is useful to the improvement of patients' safety. As a result of the evaluation, when the information from the order entry to the execution could be consistently managed, it was found that the system was a sufficiently useful.

Keywords:

safety management, EHR, team practice,
adverse event report

Introduction

The necessary condition of patients' safety management in team practice is to be correctly shared the progress of process of order, acceptance of order, preparation, execution and recording on the clinical treatment among all members of a medical team.

For that purpose, the authors designed and developed the new EHR system which was able to support grasping and sharing the progress of clinical process among medical professions concerned, and check on correctness of combination of medical practice and patient with bar codes, even when the order was frequently changed [1][2]. The system has been operating at the inpatient ward of Hiroshima University hospital since December of 2004. We qualitatively evaluated the system by the questionnaire survey to the system users (medical professions) from the viewpoint of usefulness in team medical practice, and obtained the results that about 65 % of the respondent (88 % when limiting to the nursing staff) answered the consistent management of information was useful for team practice[2].

In this paper, in order to evaluate the effect of consistent management of medical information on the clinical process to patients' safety management quantitatively, injection business which is one of the most complex medical practices is studied.

Methods

We evaluated contribution of the injection system to patients' safety by the hand-written type adverse event reports which were submitted to the department of medical safety management of our hospital.

The procedure of analysis was as follows.

- First of all, we collected the adverse event reports submitted for half a year before and after the injection system introduction.
- Next, the collected reports were classified into four categories by the cause of the adverse event. Four categories are as follows:

  The first is an event that occurs due to description mistake of injection order by a doctor.

  The second is an event that occurs because those who prepare or execute the injection could not receive doctor's order and/or order change in appropriate timing. For instance, this category includes a case that a nurse did not recognize cancellation of the injection order by the doctor and executed it.

  The third case is that those who prepare the injection make a mistake in the kind and/or the dosage of medicine, etc.

  The fourth case is that the doer makes a mistake in confirmation of the target patient.
- Finally, the numbers of adverse events of each of the four categories are compared before and after the injection system introduction.

Results

The result is shown in Fig. 1. Fig. 1 shows that the numbers of reports of adverse events decrease for the 1st, 2nd, and 4th categories after introducing the system. On the other hand, it is understood that the third category doesn't decrease from fig. 1. In the first category, the checking system to the injection order is one of the reasons for decrease in the adverse event.

The effect of this system is especially expected for the event of the second category. Actually, the adverse event concerning the second category did not occur after having been introduced the system. The system should be able to prevent the adverse event of the 4th category in principle. However, two events happened because of violation of the rule, that is, the doer skipped the procedure of confirming the patient with the barcode reader near the bed side. On the other hand, from the result of the category 3, it is clear that the consistent management of the information on the process of injection doesn't contribute to the decrease of human mistakes too much.

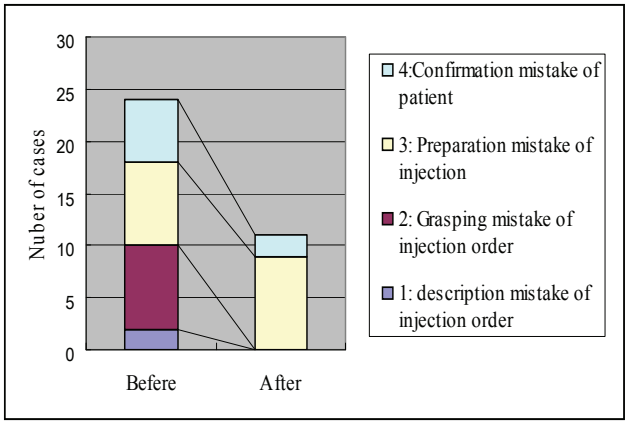

Figure 1 - Comparison of number according to the cause of the adverse event before and after the system introduction

Discussion

After analyzing adverse event reports in detail, we found the following features.

(A) There were few adverse events when the process of injection can be consistently managed by the system from an order entry to an execution. So it is possible to judge that the consistent management of information on medical treatment process contributes sufficiently to the patients' safety.

(B) The adverse event reports were classified into the following six types: (B-1) The doer obtained correct information, but didn't keep the working procedure, (B-2) The doer obtained correct information, but didn't carefully confirm it, and made a mistake when preparing, for instance, misunderstanding in the schedule time of injection, dosage of medicine, (B-3) The user mistook the usage of the system for understanding shortage,

For the problem (B-1) and (B-3), it is considered that a complex business procedure disturbs a decrease in risk factors. Therefore, it becomes more and more important to research a simple and intuitive business flow. For the problem (B-2), it might be a basic solution that the medical professions act carefully based on correct information that the system offers.

However, in one side, it is necessary to examine the improvement of the system. For instance, is it easy to understand the display and the size of the character? In this sense, we should pay attention to the fact that a lot of users pointed out that information displayed by computers didn't understand important points easily. Improvement of this viewpoint is one of the important problems for the safety management with a computer.

Conclusion

It became clear that the system consistently managed the process information from the order to execution was useful for the patient safety in team practice. However, it was suggested to have to improve the expression of the emphasis point etc. Moreover, it will be necessary to consider patients' safe in the emergency case that cannot input the order beforehand. These are next subjects.

[d] *Department of Health Policy and Management, Seoul National University College of Medicine, Korea*

Abstract and objective

Medication error prevention using computerized physician order entry (CPOE) with clinical decision support system (CDSS) is known effective to reduce the incidence of adverse drug events (ADEs). In 2006, a renal dosing system was developed and implemented in Seoul National University Bundang Hospital (SNUBH) with a full electronic medical record (EMR) system. To assess the performance of the renal dosing system at the early stage and to analyze the system effects, alerts generated for one month were reviewed by clinical pharmacists retrospectively. Alerting rate was 5.4% and inappropriate alerts were 17.7%. Antihistamine and antimicrobials were mainly needed to adjust dosage. Users' acceptance and overriding rates were 32.4 % and 67.6% respectively. Despite of false-positive and overriding alerts, the renal dosing system adjusted considerable numbers of excess dosing in renally impaired patients and aroused physician's attention for safety.

Keywords:

Clinical Decision Support Systems (CDSS),
Renal Dosing System, Adverse Drug Events (ADEs),
alerts

Introduction

As the awareness of patient safety is increased, ADEs are considered as one of the most important problems to solve. CPOE with CDSS enables to reduce preventable ADEs by alerting at the time of prescribing. For the purpose of patient safety, we developed renal dosing knowledge base and implemented the renal dosing system in SNUBH. This study was designed to evaluate the first phase performance of the system and to identify physician's reaction patterns to alerts.

Methods

SNUBH is a 909-bed, secondary and academic hospital affiliated with Seoul National University of Medicine in Gyeonggi-do, Korea. Since the opening, it has adopted a full EMR system, BESTcare. After loading the renal dosing system in the prescribing environment, data of generated alerts during one month (September, 2006) was collected and reviewed retrospectively. Clinical pharmacists evaluated performance of the system by comparing prescribing dose with individual renal function and assessed physician's feedback patterns.

Results

The number of alerts generated during one month was 5,723 cases and 5.4% of total inpatients' prescriptions, and false-positive alert rate which didn't match criteria was 17.7%. Antihistamine (45.5%) and antimicrobial (17.0%) were main drug categories need to adjust dosage. Units occurred frequent alerts were Joint disease and Reconstruction Center and General Surgery; 18.8% and 14.2% respectively. Physicians' immediate and actual acceptance rates to alerts were 17.7% and 32.4%.

Conclusions

Alert rate of the renal dosing system (50%) was much higher than other types of medication-related alerts in terms of clinical decision support. False-positive alerts were mainly due to errors of study criteria and patient's information recorded in EMR. Considerable drug dosage adjusted within a few days after alerting, but many physicians still ignored alerts. It was accounted for insufficient applying of each medical unit's practice and medication used in procedure or operation. Despite of many limitations, the renal dosing system was meaningful in respect of trying preventable care in practice and beneficial effect of increasing physician's adoption of safer prescribing pattern. In conclusion, application of the renal dosing system adjusted inappropriate doses in many patients and affected physician's prescribing patterns. And further revision of the system and evaluation will be needed.

Center for Interoperable EHR

Introduction

- Patient Safety
  - One of the most important challenges facing health care today
  - An increasingly recognized opportunity for stakeholders in improving quality of health care delivery
- Key solution of adverse events related to inappropriate prescribing: CPOE linked to CDSS
- Effect of CDSS for patients with renal insufficiency
  - NEPHROS study
    - Improvements in appropriateness of dosing(54→67%) and frequency (35→59%)
    - LOS 0.5 days shorter

Methods (1/3)

- Study sites
  - Seoul National University Bundang Hospital
    - 909-bed, secondary, teaching hospital
    - Geriatric patients oriented
  - Operating full electronic medical record system with medication-related decision support systems

- Implementation of renal dosing system
  - Development of renal dosing knowledge base
    - Pilot-test
    - Expert panel review
  - Put into operation of renal dosing system at August 24, 2006
    - Adult (age $\geq$ 12) inpatients only
    - 2 renal function categories: moderate & severe renal impairment (GFR $\leq$ 50 mL/min)

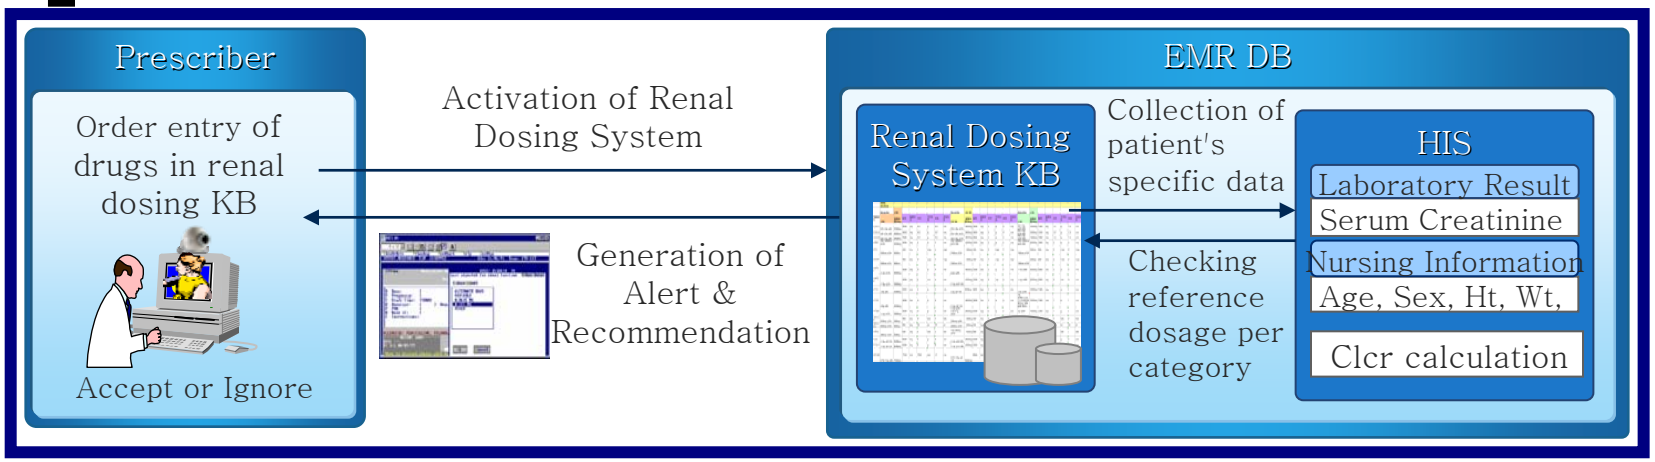
CiEHR
Center for Interoperable EHR

Methods (2/3)

- Data collection
  - Study period: September 1~30, 2006
  - Study population: 4,159 inpatients of September
  - Electronically collected logs data whether generated alerts by the renal dosing system
- Evaluation
  - Patient's chart review by clinical pharmacists
  - Performance
    - Appropriateness of renal dosing alerts
  - Clinical impact
    - Acceptance rate of renal dosing alerts
    - Cause of ignorance

CiEHR
Center for Interoperable EHR

Methods – Study Flow (3/3)



Data Collection and Chart Review
Appropriateness of alert, Prescriber's Acceptance

Outcome Evaluation
Performance and Clinical Impact
of Renal Dosing System

Renal dosing system Evaluation and Revision

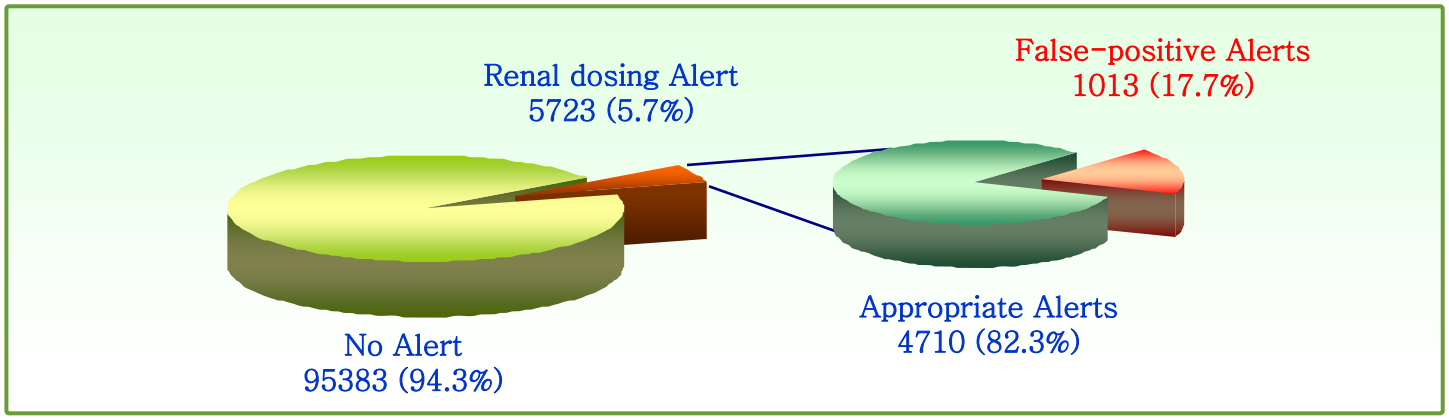
CiEHR
Center for Interoperable EHR

Results (1/3)

- Alert rate of renal dosing system - 5.7%
  - 5,723 alerts/101,106 inpatients' prescription for a 1-month

- Analysis of system performance
  - False-positive rate which didn't match criteria – 1,013 alerts
  - Error rate of renal dosing alerts – 17.7%

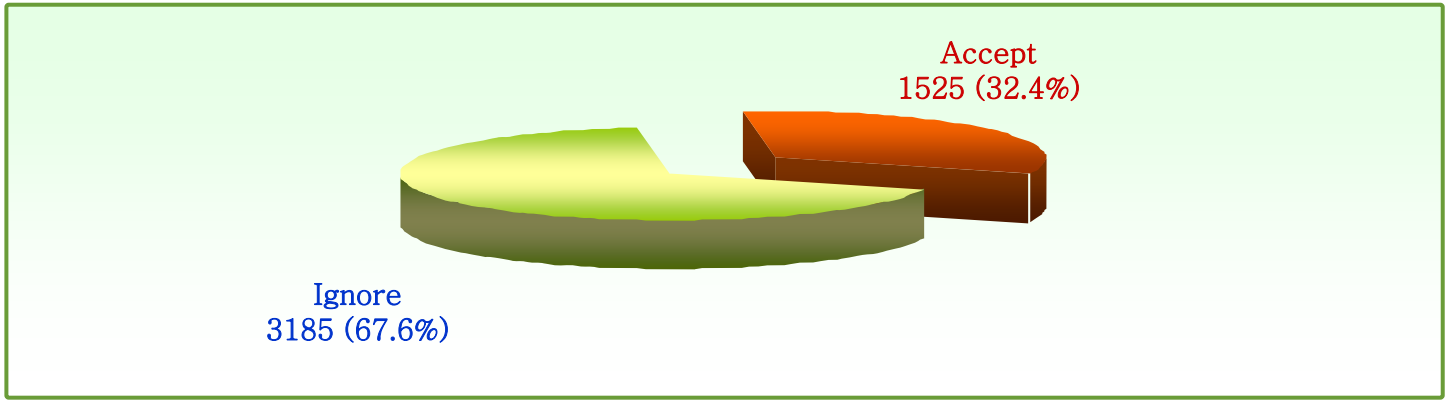
Renal dosing appropriateness alert rates



Results (2/3)

- Analysis of clinical effect
  - Chart review of 4,710 appropriate alerts/385 patients
  - Immediate accept rate (by computer logged data) – 17.7%
  - Ultimate accept rate (by chart review) – 32.4%
- Reason of ignore to alert
  - Therapeutic/temporal use, Don't know why
  - Just below borderline case & Set order

Accept rate of renal dosing alerts



CiEHR
Center for Interoperable EHR

Results (3/3)

- Main drug categories need to adjust dosage
  - Antihistamine – 2, 124 case (45.5%)
  - Antimicrobials – 803 case (17.0%)
  - Hypoglycemic agents – 410 case (8.7%)

- Units occurred frequent alerts
  - Joint disease and Reconstruction Center – 18.8%
  - General Surgery – 14.2%
  - Urology – 12.3%

Discussion (1/2)

- Low alert rate of renal dosing system (5.7%)
  - Application of strict alerting rule: GFR ≤ 50 ml/min
  - Existence of several medication-related CDSS

- High error rate of alerts (17.7%)
  - Mainly due to error of GFR calculation based on confusion of selection patients' weight
  - Logic: If Actual body weight > Ideal body weight, then take ideal body weight

Discussion (2/2)

- Matters of low acceptance rate
  - Carry out re-test of patients' old renal function
  - Increment of consulting to specialist

  → Meaningful changes of physicians' prescribing behaviors and educational effect

- Issues of considerable ignorance rate of alerts
  - Insufficient applying of each medical unit's practice
  - Medication used in procedure or operation

- Main drug categories occurred alerts
  - Add specialized recommendation by specialist's consultation
  - Expectation of clinically valuable information for patient safety

CiEHR
Center for Interoperable EHR

Conclusions

- Application of the renal dosing system
  - Adjusted inappropriate doses in many patients
  - Made a beneficial effect to physician's prescribing patterns

  → Meaningful tool with respect to try for preventable health care

- Future research issues
  - Revision of the system
  - Evaluation of economical effect

Co-Construction of eHealth Services and Technology: Challenges and Solutions

Hannele Hyppönen

STAKES Unit of eHealth and eWelfare
National Research and Development Centre for welfare and health (STAKES), Finland

Abstract

Health care is a challenging context for ICT applications. There is no lack of studies reporting failed projects due to failure to merge professional, bureaucratic and technological missions, interests and focus. How could the experiences of these projects be structured and offered to others to support further health ICT projects? This paper describes a conceptualization of co-construction of a health service and information processing tools as a possible answer. It was created by structuring empirical findings of a case study with help of theoretical concepts. The conceptualization was further applied in two case studies as a framework to generate data for formative evaluation. The conceptualization helped in detecting the questions that the projects were failing to answer during the development. Co-construction requires multidiciplinary knowledge, and networking with experts already in the planning stage is beneficial in order to manage the complex parallel change process of services and ICT.

Keywords:

medical informatics applications, organizational innovation, technology assessment

Introduction

ICT is regarded as the key driver of economic growth in western as well as in transition economies. Due to increases in national spending on health care, the governments in welfare societies have increasingly turned to ICT in search of solutions for meeting the increasing demand without increasing the costs. Evidence supporting positive return on investments or the improved quality of the ICT enhanced health services is, however, shown to be still scarce (1, 2). Studies of eHealth projects report problems in merging technical and service orientations, interests and field-specific tools, finding the common language and tools for collaboration. A misalignment of interests, roles and communication of social and technical partners, poor management of the entity of sociotechnical change and a lack of usability and utility of the implemented technologies are also reported (3-5). The paper is based in a study that asks, how the experiences gained in these projects could be structured and offered for others to support future health ICT projects to develop systems in a more appropriate way? (6).

Methods

In an attempt to answer this question, empirical data was collected from an eHealth project. It was structured with help of three concepts that have been used in activity theoretical analyses of work as well as in the fields of ICT, CSCW and HCI studies (3, 7-10): a model of network of activity systems, the concept of developmental contradiction and a model of cycle of expansive learning (11-13). The model of network of activity systems was used for structuring the social and health care service activity in ex ante and ex post situation. The developmental contradictions were used to structure the needs and possible directions for development. The cycle of expansive learning was used to structure the process of solving the contradictions by generating and implementing a new eService concept in the eHealth project. (6).

This conceptualization was applied as a framework for structuring the results in Case Study I (for details, see 14). The data included statistics, annual reports, documents and interviews of the ex ante situation of the service, project plans and reports, meeting minutes, letters and other documents, and interviews of the stakeholders who had participated in the ICT project. Ethnographic participatory observation, interviews of the service providers and clients and documents of the ex post situation were collected. (6).

The empirical findings from Case I were reflected against theoretical concepts in an academic dissertation in order to create a preliminary, abstracted understanding of the findings. It was then applied in the second Case to study its potential in a context of formative and summative evaluation - providing information about an ongoing case and feeding the results back to the project managers for corrective action (see also 15). The data collected from the project and the service in transition was structured with helps of the conceptualization to study the project process quality. The analyses with conclusions were frequently fed back to the project for corrective action. The approach is likened to that of Constructive Technology Assessment (16). (cf.6).

In Case study III the conceptualization was applied to study, how the lessons learned in the previous cases could be used to support a project from early on. The conceptualization was used to generate questions for the project concerning the information that the project had collected

or planned to collect to extract and solve the developmental contradictions.

Results

Case study I: Elaborating the conceptualization

Case Study (14) structured the co-development of service and its tools in an eHealth project with theoretical concepts described above. The network of activity systems was used as a tool to structure data collection about the service prior to and after the intervention. The concept of contradiction and the model of expansive learning were used in structuring the change of the service. One cycle of expansive learning was not enough to depict the development of the service and ICT designed to support it. These remained as two separate foci of development with separate networks constructing them. Two parallel cycles of development - that of the service and that of the technology - were needed to depict the totality. How these two cycles interacted became the main focus of interest in Case Study I. The resulting conceptualization is presented in Figure 1.

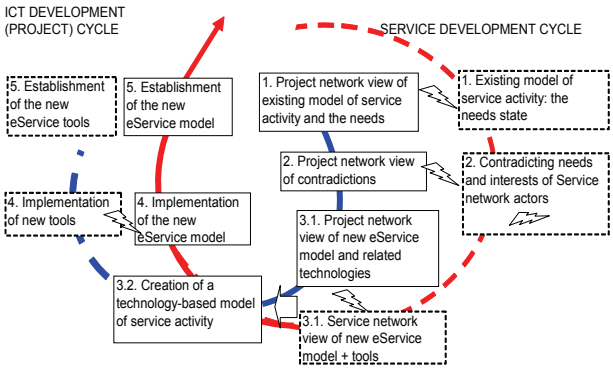

Figure 1 - Case I structured with help of the elaborated conceptual tools depicting the development cycle of the service activity (larger cycle), the development cycle of the ICT tools and the interaction of these two developments (6, 14)

The larger cycle in Figure 1 depicts the phases of service development. The smaller cycle depicts the phases of the ICT development. The cycles start with a conception of the service to be developed. This was different in the two networks. The ICT project view prevailed, leading to generation of an eHealth service concept that could not be implemented. The service concept was redesigned and implemented, but the ICT was not, leading to its abandonment after the pilot. The new eService model remained in use, supported by old technologies (telephone and fax).

Case studies II and II: The conceptualisation as a framework for formative evaluation

The conceptualization was used in consequent two case studies to assess its applicability in the context of formative project evaluation. In Case II, the ex ante and ex post service situation were delineated with help of the network model, the co-evolution of the eService and technology leading from ex ante to ex post situation with the elaborated expansive cycle model. Since the pilot was still ongoing, feedback could be provided to developers of the problems found in defining the developmental contradictions, as well as in the process of solving them. The project had, however, already developed the eService concept and its piloting was about to start when the study began. There was no time to redesign the system to solve the problems. There was a strong political will to get the piloting started quickly.

The implementation was not a great success. Of the four pilot areas, only three implemented the system, two stopped later, and the pilot use was minimal. Information of the ex post situation with unsolved developmental contradictions was collected and mediated to the project, to be used on a basis of preparing a new legislation. Some impact of the results can be seen in the consequent legislation that was issued to regulate the particular eService activity, and the related bill.

In Case Study III, the conceptualization was used to support the project which was in concept creation phase, to define the developmental contradictions and to solve them. The structured analysis of the project and the developmental contradictions, which the project was not addressing, were presented to the project actors. This led the project to go "back to basics", analysing the service activity, detecting bottlenecks and drafting of new eService processes where these would be solved. Information processes related to the service processes were delineated to produce the ICT requirements of different actors in different process phases. The project plans to spread the system to other health centres in the city as soon as the technology is redesigned according to the feedback.

Discussion and conclusions

As part of Case Study III, a workshop was arranged to collect feedback of the relevance of the conceptualization to the project participants. The initial results show that on a scale of 1-3 (1=no significance, 3=major significance), the city as well as the university regarded the support of "major significance" in 3 of 5 phases of development, and of "some significance" in the remaining two phases of development. The three most significant areas where the conceptualisation was regarded as important were: 1) structuring data collection from ex-ante and ex-post service situation 2) managing the co-development of the

service and technology 3) evaluation of the change in order to spread the system.

The results indicate that eHealth projects need better understanding of the multiple foci and objects of development. The two ongoing case studies (II and III) show some evidence of the usefulness of the conceptualisation for helping the future practitioners in the field to understand the challenges in ICT-enhanced service change, and find solutions to them. The network of activity systems proved as a useful concept to structure requirements from the ex ante service activity, and for planning the ex post service activity where the contradictions are solved. The model of expansive learnning with two parallel cycles can help manage the change and to evaluate the change process. The projects need to build a balanced network of actors who have adequate knowledge and the required skills for supporting the project in the required data collection and analysis as well as management of the entity. Further studies are needed for evaluating the impact of the conceptualization.

Co-Construction of eHealth Services and Technology: Challenges and Solutions

Hannele Hyppönen

STAKES *Unit for eHealth and eWelfare, National Research and Development Centre for Welfare and Health (STAKES), Finland*

Introduction

Health care is a challenging context for ICT applications. There is no lack of studies reporting failures to merge professional, bureaucratic and technological missions, interests and focus. (1-2).

Evidence to support positive return on investments or improved quality of ICT enhanced health services is still scarce (3-4).

How could the experiences gained in various projects be structured and offered for others to support future health ICT projects to develop systems in a more appropriate way?

Methods

a) Methodology

Data from an in-depth case study on process and effects of an eHealth project were structured with theoretical concepts

The theoretical concepts were elaborated into a model of co-construction of service and technology

The model was implmented in two consequent case studies to assess its potential for formative (constructive) assessment of the eHealth projects

Evidence was collected on impacts of the model.

b) Data collected

Case study I

•Historical data (documents, interviews) on ex-ante service activity and on construction and implementation of the eService model. Empirical data (observation, interviews,documents, statistics) on the established (ex post) eService activity

Case study II

•Historical data (documents, interviews) on the early phases of the construction of the eService model. Empirical data (observation, interviews, documents, statistics) on ex-ante and ex post service activity. Empirical data (participatory observation, interviews, documents) on later phases of the eService model construction and implementation

Case study III

•Historical data (documents, interviews) on the early phases of the eService model construction. Empirical data (participatory observation, group sessions) on later process phases and implementation of the eService model

Results

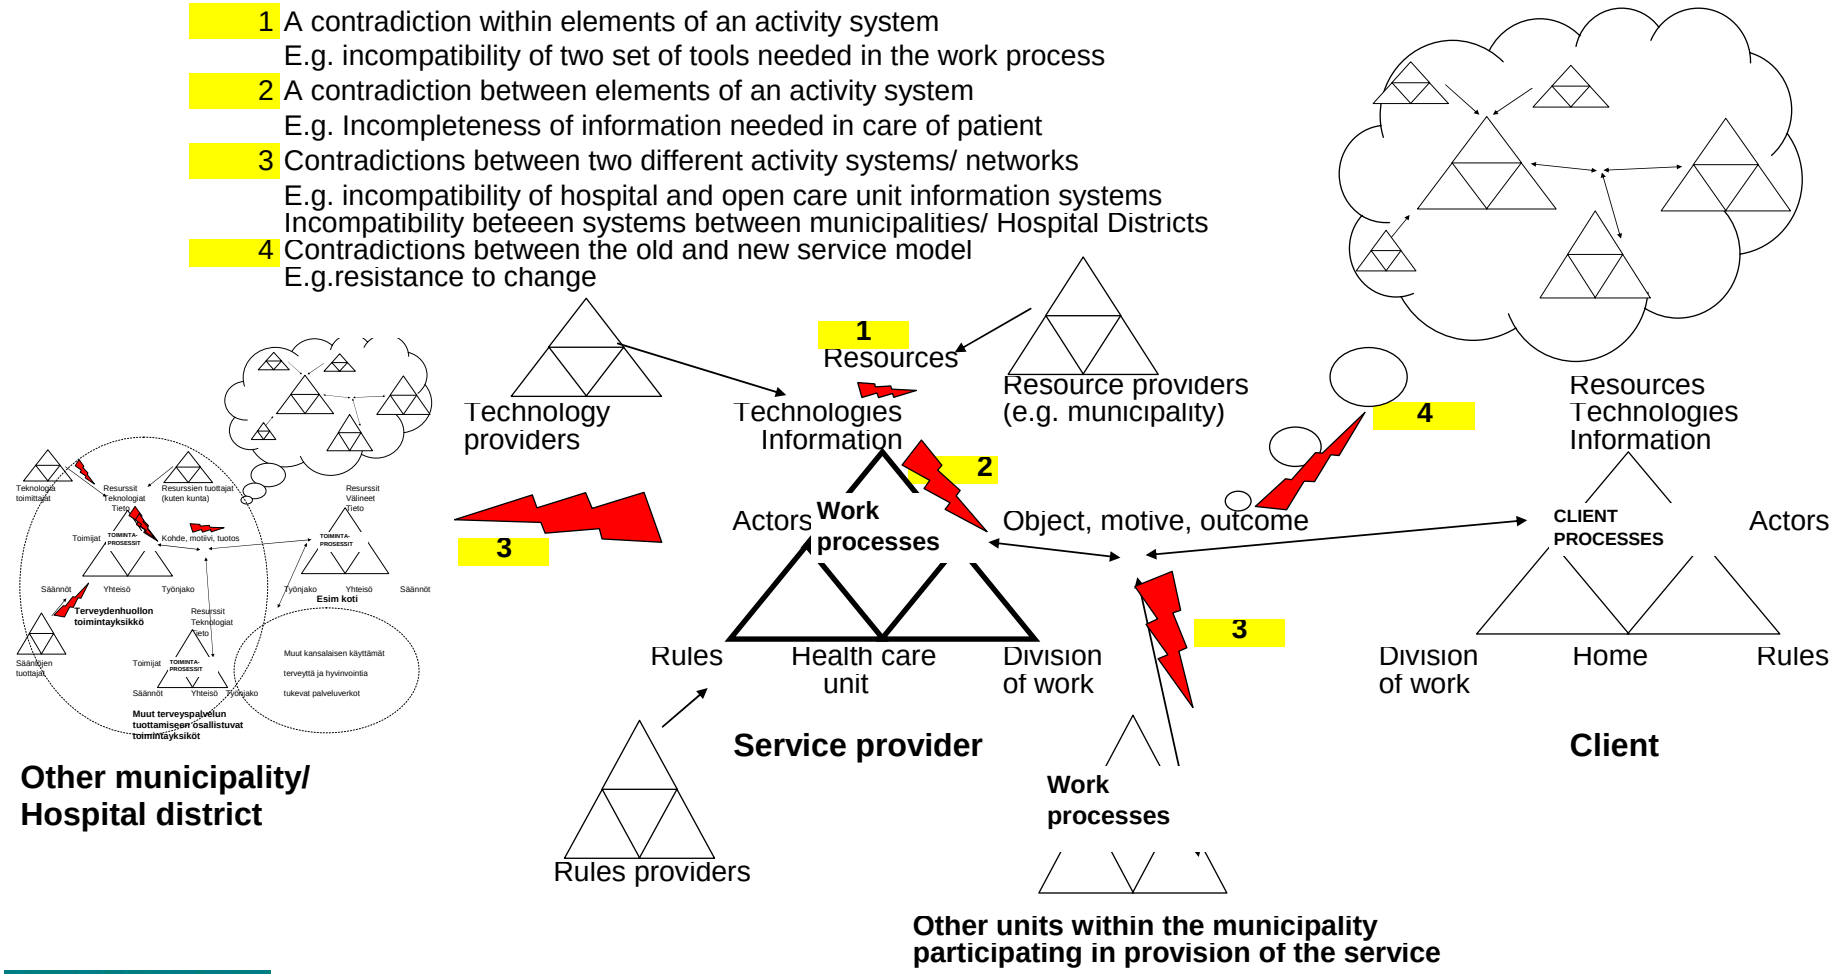
Case I: a retrospective study of construction, implementation and impacts of an innovation award-winning eService for Home Health Care (7; 1)

- Impacts of the eHealth project:
  - The new eHealth model helped to outsource part of the home health care service, did not save any money compared to the old, reduced availability and quality of the service
- The construction process:
  - No analysis of the ex ante work and information processes, their developmental contradictions to be solved or indicators of change.
  - The construction process concentrated on ICT, no simultaneous re-engineering of work processes in collaboration with service providers
- Conclusions of case study I:
  - There is a need to elaborate the existing conceptual tools. Conceptualization to structure the co-construction of eService and technology and related challenges was created:

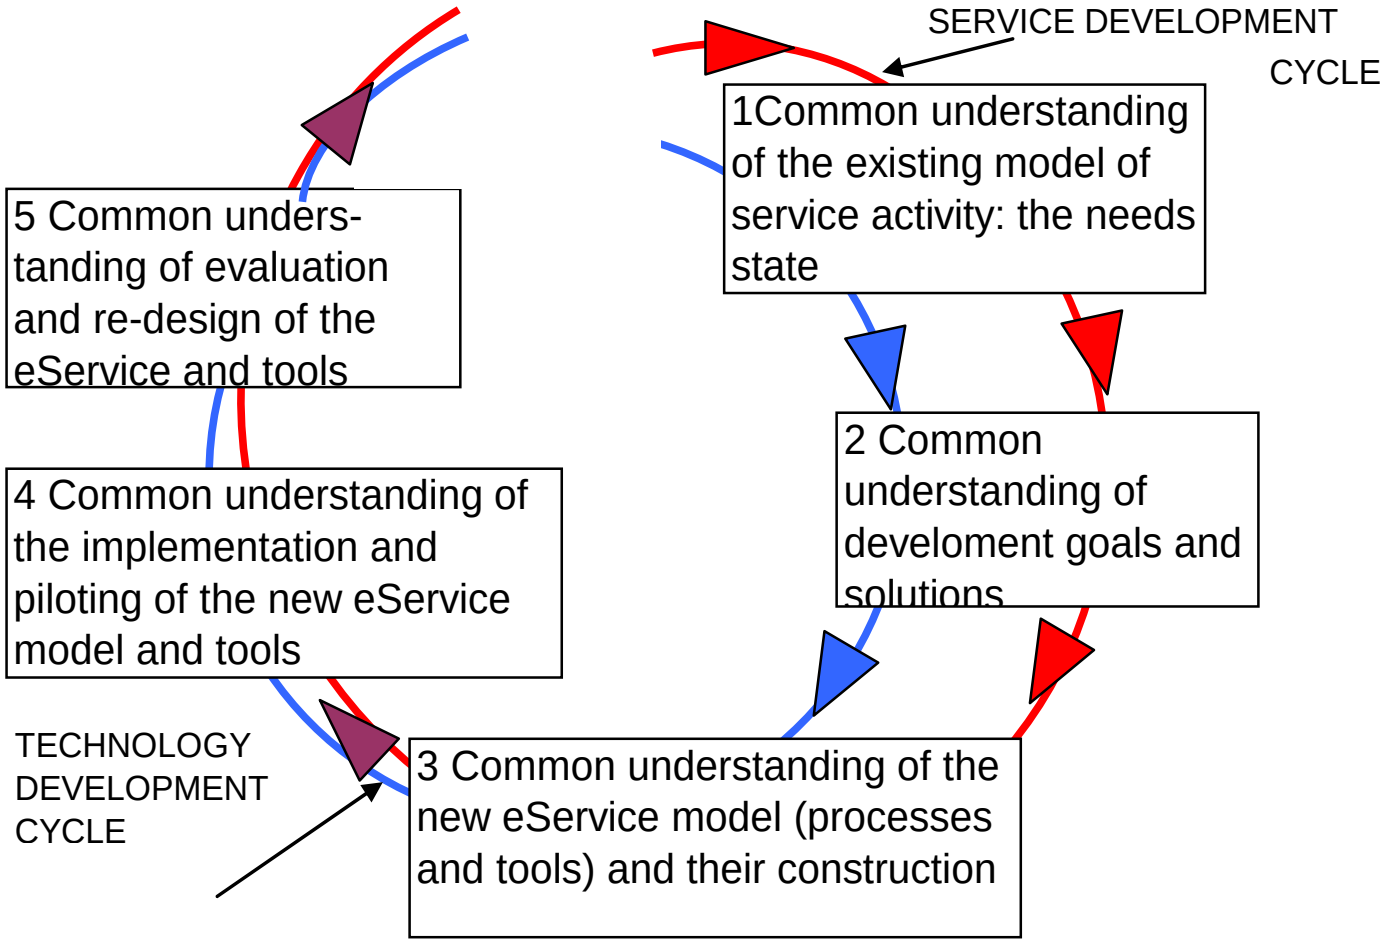
The created conceptualization to structure a service activity and its ICT-enhanced change

1) Network of activity systems and categories of problems triggering the change (7;1 cf. 5; 6)

1 A contradiction within elements of an activity system
E.g. incompatibility of two set of tools needed in the work process
2 A contradiction between elements of an activity system
E.g. Incompleteness of information needed in care of patient
3 Contradictions between two different activity systems/ networks
E.g. incompatibility of hospital and open care unit information systems
Incompatibility beteeen systems between municipalities/ Hospital Districts
4 Contradictions between the old and new service model
E.g.resistance to change



2) A cycle of expansive learning to co-construct the service and its tools (solving the developmental contradictions) (7; 1).



Case II: Implementation of the theoretical tools to structure formative and summative evaluation of the development and piloting of a national ePrescribing system (8;1)

- The construction process
  - The project was based on a comprehensive but superficial study of prescribing service and its problems in ex ante situation. No in-depth analysis of the local service network and developmental contradictions were done.
  - There was a common understanding of the overall development goals and solutions. The construction process, however, focused on ICT and regulations, the service processes were not re-engineered
- Implementation and piloting:
  - Three out of four piloting health care organizations implemented the system, two stopped due to technical, usability and utility problems; Less than 1000 ePrescriptions were written in 2 years
  - The system did not bring short term added value to the doctors, limited value to pharmasists, no short term value to the clients due to the problems
  - ePrescribing legislation was prepared on the basis of the experiences
- Conclusions of case study II:
  - Conceptualization was used to detect problems in the co-construction phases 1-3. Feedback came too late to have an impact on the project (implementation was about to start). The system functioning, utility and usability problems were classified as contradictions within and between the network activity systems. The data was used in preparation of the ePrescribing legislation.

Case III: Implementation of the theoretical tools to support construction of a citizens eHealth service

Intervention:

Two "mirrors" offered to the project:

A structured image of the development process as co-construction

A structured literature review of concrete tools to answer the problems

The construction process:

- The project was based on technology providers' idea, supported by municipal strategies
- Different studies of the ex ante work and information processes were conducted. The developmental contradictions to be solved or indicators of change were not extracted in the project planning phase
- Technology providers started to construct the ICT solutions, service providers the envisioned work processes. Little concrete collaboration between them
- "Return to the basics": service providers analysed the ex ante work and information processes, problems to be solved, indicators of change to steer the re-engineering of work processes and ICT development
- The implemented new eService model was well accepted, technologies still require re-engineering
- Diffusion of the system is planned with re-engineered technologies

Conclusions of case study III

- Problems pointed out in the co-construction phases 1-3 caused the service provider to analyse the old work and information processes, problems to be solved, to select indicators of change and to steer the re-engineering of work processes and ICT development. The technology provider did not re-engineer the technology that they had developed prior to the intervention
- The conceptual tools provided a tool for the project manager to structure the overall change and evaluation and information required in the process. The literature review offered some concrete tools for data collection.
- More detailed tools and support from different sciences (especially management, work and information sciences, economics, evaluation) would have been needed to direct informed data collection and analysis
- The project manager would also have required support for using the conceptual tools to structure the overall change and information required.

Discussion and conclusions

- The created conceptualization proved useful for classifying problems in the co-development and piloting of eHealth solutions. It also showed promise in classifying types of information that are required to answer the problems.
- eHealth projects would benefit from early adoption of a commonly agreed, adequately detailed and structured understanding of:
  - the multiple objects, interests and foci of development.
  - the context where the new tools, rules and practices will be implemented,
  - the development contradictions in the context, estimates of cost benefits of technology as a solution to them
  - the process and methods of co-construction.
- Management and execution of the co-construction requires a lot of cross-diciplinary information and methods. The projects need to build a balanced network of actors who have adequate knowledge and the required skills for supporting the project in the required data collection and analysis as well as management of the entity.
- More cross-diciplinary studies are required to elaborate the essential questions to ask and necessary information to be collected in different phases of different eHealth projects in order for the projects to succeed.

What Kinds of Intangible are Important to Identify and Measure?

Bahlol Rahimi

Department of Computer and Information Science, Linköping University, Sweden (PhD Candidate)
Department of Social Medicine, Urmia University of Medical Sciences, Iran

Abstract

Information technology has the power to increase the quality of work creating accurate and update data, but gives the organization the capacity reduce cost of coordination, communications, and information processing.

In this poster we identify a number of intangible outputs that can be important to measure in medical informatics area. Three categories of outputs, namely technical, individual and organizational, are suggested to specially give attention to and to consider when discussing the intangible effects of the implementation and use of IS.

Keywords:

information systems, intangibles, healthcare

Introduction

Information technology, defined as computers as well as related digital communication technology, has the power to increase quality of work creating accurate and update data, but also to give organizations the possibility to reduce cost of coordination, communications, and information processing. (1)

The increased need and pressure for implementing information technology in all healthcare domains increased also the need to evaluate IT-applications. This is because evaluations can give decision makers knowledge about the benefits, effects and impacts of IT. Evaluation can also gives key information about which areas are specially influenced and about which kind of outputs, both tangibles and intangibles, are important to valuate and evaluate. According to Devaraj and Kohli (2002), intangible outputs play important role in organizational success. They also state that investing in IT make organizations profitable. (2) However, despite the importance of the intangibles, evaluation of them have not yet been justified or accounted. In this poster we identify categories their intangibles are important for organizational effectiveness and thus important to measure, account and justified, especially in the area of medical informatics.

Definition of intangible

Kaplan and Norton (2004) have described intangibles as "knowledge that exists in an organization to create differential advantage" or "the capability of the company's employees to satisfy customer needs". Some examples from their point of view are: workforce knowledge, leadership, high quality products and services, motivated and skilled employees, responsive and predictable internal processes, and customer satisfaction.(3) Intangibles assets according the new International Accounting Standard IAS 38 are defined as an identifiable non-monetary asset without physical substance held for use in the production or supply of goods or services, for rental to others, or for administrative purposes such as skills, information systems, and satisfied customers.(4)

Methods

A literature review of current studies on the area of evaluation of intangible outputs both at the industry and healthcare areas has been done. The review covers scientific publication like journals, books, Internet. Literature was reviewed using the terms and combinations of terms such as intangible evaluation, information system, and medical informatics from 1990 upward. Journals like Journal of American medical informatics association, the proceeding of AMIA and Medinfo conferences, Journal of Management Information system, and The Electronic Journal of Information Systems Evaluation was reviewed.

Result

Ruland et al (2003) in their study entitled "Usefulness and effects on costs and staff management of a nursing resource management information system" showed that a significant improvement in information management after four months of implementation of the new system. It was also observed that it became easier to analyze the relationship between patient activities, staffing, as well as the cost of care. The positive results were revealed regarding the ease of use and user satisfaction. (5) Vontetsianos et al (2005) indicated that with introducing the new system, the user (nurse, physician, and other staff) satisfaction has improved. (6)

Zhang et al (2004) showed that by introduction of computerized patient record, improved hospital administration (with 80% positive response) and better presentation of information (with 75% positive responses); the overall optimistic attitude were found to be evident.(7) Breslow et al (2004) showed that management or administration of

hospital/ward/department as well as information management has been improved as a result of introducing the new information system. (8) Jonathan et al (2005) showed that accuracy and readability as well as uniformity and availability of data have increased after the new system implementation. (9) Pizziferri et al (2005) as results of their evaluation indicated that, the physician believed that the input of the new system on communication, access, efficiency, workload, and quality of care indicated that the new system resulted in an improvement in many domains. (10) Robert et al (2005) affirmed that the new e-health improved efficiency and safety of delivering cares in their studies. (11)

Identifying three categories their intangibles are important for organizational effectiveness and example of intangibles

Category 1, examples of Technical intangibles	Category 2, examples of Individual intangibles	Category 3, examples of organizational intangibles
-Accuracy of data -Access and availability of data -Readability and uniformity of data	-IT proficiency for employee -Improving of decision-making -Clearer understanding of problem -Increasing of user satisfaction	-Improvement in communication (improved organizational teamwork) -Better organizational planning and control -Utilization of management time -Improved organizational learning

Discussion and conclusion

Managers or decision makers become more cautious about approving new investment, particularly investment in information system. It might be due to their less knowledge about the benefits arising by information system, especially the intangible one. They are often familiar with tangible output measurement like cost-benefit analysis that illustrates everything in numerical data, which are more defendable to executive board but it seems that considering intangible benefits is not common when decision maker going to justify.

The identification of categories of intangible outputs can make clearer the payoff mechanism and help decision makers and managers to know more about the impact of medical information system both at individuals and organization level.

It could be conclude that developing methods and models to evaluate intangible is a challenge that medical informatics will need to continue to improve and discus.

What kinds of intangible are important to identify and measure?

Bahlol Rahimi

Dept. of Computer and Information Science (IDA)
Linköpings universitet, Sweden

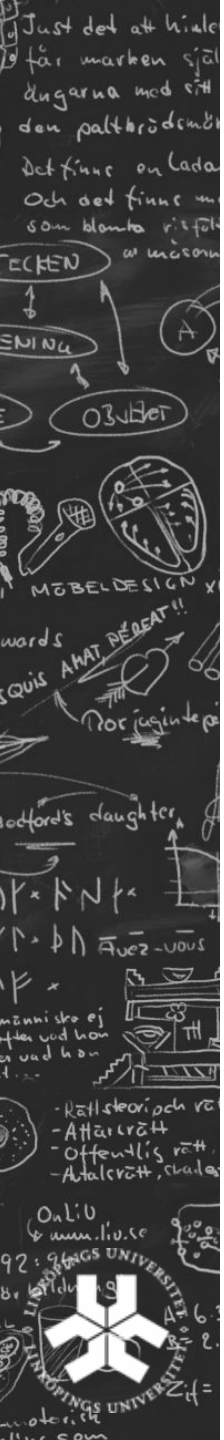
LiU expanding reality

Introduction

- Increased need and pressure for implementing information technology in all healthcare domains
- Increased need to evaluate IT-applications.
- Knowledge about the benefits, effects and impacts of IT
- Information about which areas are specially influenced and about which kind of outputs
- Both tangibles and intangibles, are important to valuate and evaluate.

Introduction (count..)

- Both tangibles and intangibles, are important to valuate and evaluate
- Intangible outputs play important role in organizational success
- Investing in IT make organizations profitable
- Despite the importance of the intangibles, evaluation of them have not yet been justified or accounted



Aim:

In this poster we identify categories their intangibles are important for organizational effectiveness and thus important to measure, account and justified, especially in the area of medical informatics.

Intangible:

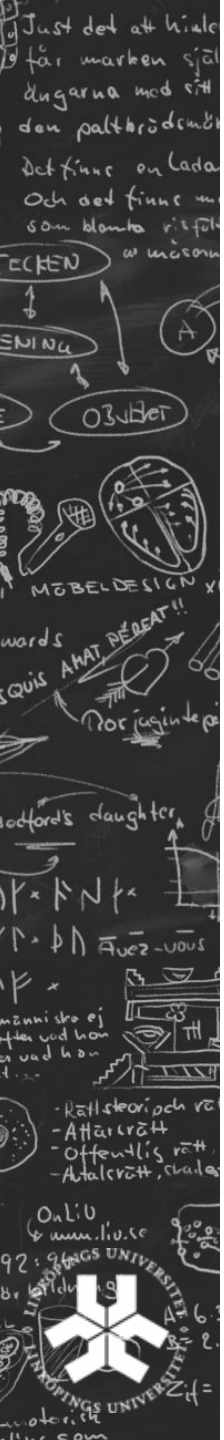
- Kaplan and Norton (2004) have described intangibles as “knowledge that exists in an organization to create differential advantage” or “the capability of the company’s employees to satisfy customer needs”.
  - ✓ Some examples from their point of view are: workforce knowledge, leadership, high quality products and services, motivated and skilled employees, responsive and predictable internal processes, and customer satisfaction.
- Intangibles assets according the new International Accounting Standard IAS 38 are defined as an identifiable non-monetary asset without physical substance held for use in the production or supply of goods or services, for rental to others, or for administrative purposes such as skills, information systems, and satisfied customers.

Methods:

- literature review of current studies on the area of evaluation of intangible outputs both at the industry and healthcare areas
- The review covers scientific publication like journals, books, Internet.
- Literature was reviewed using the terms and combinations of terms such as intangible evaluation, information system, and medical informatics from 1990 upward.
- Journals like Journal of American medical informatics association, the proceeding of AMIA and Medinfo conferences, Journal of Management Information system, and The Electronic Journal of Information Systems Evaluation was reviewed.

Result:

- **Identifying three categories their intangibles are important for organizational effectiveness and example of intangibles**
  - **Technical intangibles**
  - **Individual intangibles**
  - **Organizational intangibles**



Examples of “Technical Intangibles”

- **Accuracy of data**
- **Accessibility of data**
- **Availability of data**
- **Readability of data**
- **Uniformity of data**

Examples of Individual Intangibles

- ✓ **IT proficiency for employee**
- ✓ **Improving of decision-making**
- ✓ **Clearer understanding of problem**
- ✓ **Increasing of user satisfaction**

Examples of Organizational Intangibles

- ✓ **Improvement in communication**
- ✓ **Improved organizational teamwork**
- ✓ **Better organizational planning and control**
- ✓ **Utilization of management time**
- ✓ **Improved organizational learning**

Discussion & Conclusion

- The identification of categories of intangible outputs can make clearer the payoff mechanism and help decision makers and managers to know more about the impact of medical information system both at individuals and organization level.

- To develop methods and models to evaluate intangible is a challenge that medical informatics will need to continue to improve and discus.

Heuristic Evaluation of a Web-based Prototype for a Personal Digital Assistant-Decision Support System for the Management of Obesity

Nam-Ju Lee[a], Leanne Currie[a], Ritamarie John[a], Elizabeth Chen[b], Myra Joyce[a], Suzanne Bakken[a,b]

[a] *Columbia University School of Nursing, New York, New York*
[b] *Department of Biomedical Informatics, Columbia University, New York, New York*

Abstract

This study used heuristic evaluation to identify usability issues of a Web-based prototype for a personal digital assistant -based decision support system (PDA-DSS) for the management of obesity. Three usability experts evaluated the prototype using heuristics, scenarios, and an evaluation survey form. In a usability laboratory, evaluators were asked to think aloud and their verbalizations were audio and video recorded. The overall severity scores of each heuristic were between 0 (No usability problem) and 2 (Minor usability problem). Generally, the experts agreed that the navigation, terminologies, options, and abbreviations were clear and consistent.

Keywords:

decision support systems, clinical, heuristic evaluation, computers, handheld

Introduction

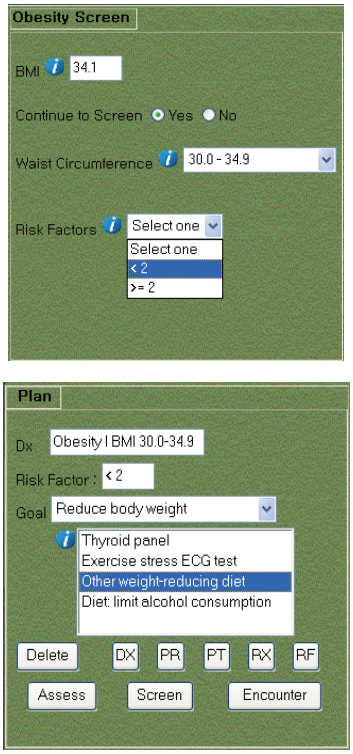
Handheld devices raise special interface design issues that do not occur with desktop applications, and this results in a formidable challenge for design and evaluation. In a systemic review of usability issues that involved the design and implementation of PDA-DSSs, user interface issues were classified as display, security, memory, Web browser, and communication issues [1]. Despite these obvious challenges, few studies have examined the special challenges of employing health care information systems on handheld devices, especially in health care settings. Therefore, studies are needed not only to assess user interface issues in the design and implementation of PDA-based information systems in a health care setting, but also to evaluate them through usability engineering methods. The purpose of this study was to identify usability problems in the Web-based prototype user interface for the PDA-DSS for the management of obesity through heuristic evaluation.

MODS-APN

The development and evaluation of a prototype PDA-DSS based on a clinical practice guideline (CPG) for the management of obesity is part of the Mobile Decision Support for Advanced Practice Nursing (MODS-APN) project. The goal of MODS-APN is to improve APN students' adherence to CPGs in three areas – obesity management, tobacco cessation, and depression screening. The DSS for the management of obesity is based on decision-rules and documentation templates, which remind APN students to document specific data for screening obesity and guide them to perform CPG recommendations. The system provides APN students with the appropriate obesity diagnosis based on the results of screening and a tailored plan of care based upon the patient's goal and the results of screening.

The development and evaluation of a Web-based user interface (Figure 1) of the PDA-DSS for the management of obesity was intended to get usability experts' quick feedback on the user interface (e.g., navigation, button labels, and drop down lists) before the full implementation on the PDA.

Figure 1 - Screen shots of the web-based prototype



Heuristic evaluation

Heuristic evaluation is a usability engineering method for finding usability problems in a user interface design and for structuring the critique of a system using a set of relatively simple and general heuristics [2]. Skillful experts can capture many system usability problems using heuristic evaluation, and this technique is effective, easy to learn, and relatively inexpensive [3].

Materials and methods

First, three experts who have experience related to the development of PDA-DSSs, heuristic evaluation, interface design or cognitive science and a doctorate in informatics or a related field were invited to participate via email. They were then given a general introduction to the heuristic evaluation protocol with five scenarios and a form for evaluating the application. The scenarios reflected all functions of the application and included the tasks to be tested. The evaluation survey form included seven principles of usability (Table 1) of relevance to the Web-based prototype user interface for the PDA-DSS for the management of obesity. These were derived from Nielsen's 10 heuristics and include sub-questions, yes or no questions to each sub-question addressing the adherence to heuristic principles, open-ended comments, and a severity rating (0-4) to rate the severity of usability problems for each heuristic.

The experts tested the Web-based prototype user interface independently with the scenarios for approximately 30-90 minutes in a usability laboratory. They were asked to verbalize what they were thinking, seeing, and trying to do while they were evaluating the application. During the evaluation, the experts were asked to identify the problems in the interface (e.g., navigation and labels of buttons or drop down lists), to rate the problems' severity using a severity rating scale, and to write additional comments on the heuristic evaluation survey form. The evaluation sessions were audio and video recorded.

The frequencies of adherence to usability principles were calculated according to the sub-questions of the seven usability principles. Total severity scores and mean severity scores were calculated for each heuristic principle. Evaluators' comments about usability problems were grouped and content-analyzed according to the usability principles.

Results

Experts responded that the usability principle was not violated in 14 of 19 sub-questions related to the seven usability principles. The overall severity scores of each heuristic ranged from 0 (No usability problem) for 2 of 7 heuristics to 2 (Minor usability problem) for 5 of 7 heuristics. Generally, the experts agreed that the navigation, terminologies, options, and abbreviations were clear and consistent, and that the system was easy to use.

Table 1 - Usability problems and mean severity scores

2. User Control and Freedom Not to cancel, Radio button	.67
3. Consistency and Standards Less specified label/ instruction, Inconsistency in decimal points	.67
4. Help Users Recognize, Diagnose, and Recover from Errors Implicit warning message	.67
5. Recognition Rather Than Recall Long text in information, Necessary information display, Long lists in a pop-up list, More information	0
6. Aesthetic and Minimalist Design Too much text	.67
7. Error Prevention (mean severity score=.67) Small font, Unpreventable user's mistake in entering, Double negative statement	.67

Table 1 lists the sub-categories of the problems identified in the experts' narrative comments and the mean severity scores. The first and second experts mentioned seven problems each, and the third expert identified 11 problems. Most problems were related to detailed or less specific instructions or the information linked by Infobuttons, which provided users with information related to the screening of and planning for the treatment of obesity. Due to a lack of screen space, the information or instructions needed to be concise, and the display order of information was important. To resolve this issue, experts recommended specifying the labels and button names on some screens, as well as the titles of pop-up messages. User training was also an essential recommendation for improving usability problems.

Another problem that was identified for 'User Control and Freedom' was the irreversibility of the user interface once users decided whether or not to perform obesity screening. Not allowing users to reverse their responses can result in frustration, especially considering a PDA's interface constraints. The usability issues that were identified by the experts and potential design solutions were discussed with the project team members during the next step, the implementation of a PDA-DSS.

Conclusion

Heuristic evaluation using the scenarios was a useful method to find usability problems in the early phase prototyping a PDA-DSS. The findings of this study provided iterative feedback regarding the design and implementation of the PDA-DSS for the management of obesity. This approach had an important impact on making the system easier to use and more useful from the perspective of design and content in the proceeding iterations.

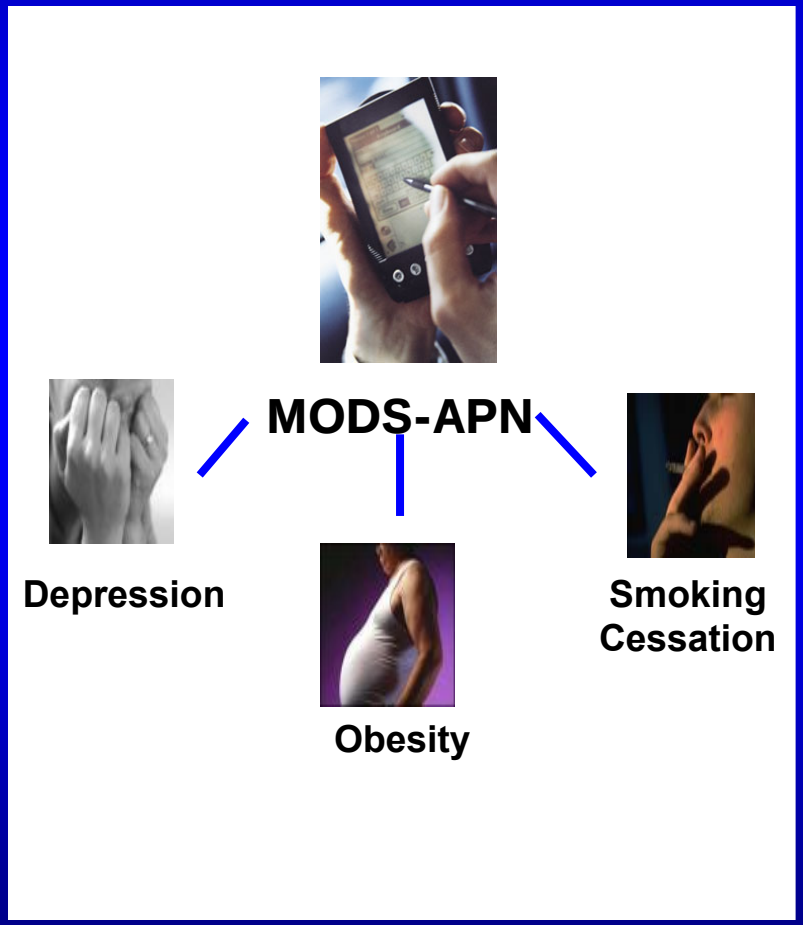
Introduction

- Handheld devices raise special interface design issues that do not occur with desktop applications
- This results in formidable challenges for design and evaluation
- Few studies have examined the special challenges of employing health care information systems on handheld devices in health care settings

Purpose of Study

The purpose of the study was to identify usability problems in the Web-based prototype user interface for the PDA-DSS for the management of obesity through heuristic evaluation

Mobile Decision Support for Advanced Practice Nursing (MODS-APN)



- Template-based approach to decision support for three guidelines on personal digital assistant (PDA)
- Randomized controlled trial is underway to compare APN students' adherence to guideline screening and treatment recommendations

Web-based Prototype of the PDA-DSS for the Management of Obesity

- The PDA-DSS for the management of obesity provides APN students with appropriate obesity diagnoses based on the results of screening and tailored plans.
- The Web-based prototype of the PDA-DSS was intended to get usability experts' quick feedback on the user interface

Materials and Methods

- Three experts in heuristic evaluation, interface design or cognitive science
- Usability laboratory at Columbia University School of Nursing
- Evaluation forms including 5 scenarios, 7 usability principles, sub-questions, a severity rating to rate the severity of usability problems, and open-ended comments
- Think aloud technique
- Audio and video recording
- Content analysis

Results: Overall Severity Score by Each Usability Factor

Usability Factors	Severity Score by Each Evaluator			Total Score	Mean Severity Score

Infobuttons: A Study of Usability

Lily Gutnik[a], Sarah Collins[b], Leanne M. Currie[a,b], James J. Cimino[a], and Vimla L. Patel[a]

[a]*Department of Biomedical Informatics, Columbia University, USA*
[b]*School of Nursing, Columbia University, USA*

Abstract and objective

Studies of clinician's information needs while treating patients have shown that the resolution of these needs is often deferred or fails, which may lead to medical errors. The Infobutton Manager was developed to help improve the resolution of information needs by providing users with links to on-line health information resources. The aim of this study was to determine the usability of the Infobutton interface to resolve clinicians' information needs. We provided clinicians with typical case scenarios using a computerized order entry system (CPOE) and Infobuttons and asked them to verbalize their thought processes as they were using the CPOE. We video-recorded the computer screens as the users worked, conducted brief exit interviews, and analyzed these data. Results indicated that the participants found the resources provided by Infobutton helpful and easy to use.

Keywords:

usability testing, clinical information needs, information retrieval decision support

Introduction

Though technology for clinical care is created to facilitate the clinician's workload and enhance patient care, tools that are inadequately designed can actually have adverse effects [1]. Inadequate design can result from a disconnect between the design process and the needs of the end-users [2]. Infobutton is a tool designed to provide clinicians with access to on-line health information resources to quickly resolve their information needs [3]. This study explored the usability of a new user Infobutton interface which was designed to be easier to read, more concise, and have more consistent navigation.

Methods

We conducted the present laboratory study to seek in-depth feedback from clinicians about the design and usability of Infobuttons within a CPOE system. Each participant was given three typical scenarios to be interpreted using the CPOE system and Infobutton. The computer screen was video recorded using Morae™ software. Participants were asked to "think aloud," that is to verbalize their thoughts. At the end of the session, the researcher conducted a brief exit interview. A previously established coding framework was applied to the data to characterize information needs.

Results

Two nurses, one physician, and one physician's assistant took part in the study, yielding a total of 79 information needs. Twenty-three of these needs (29%) were related to drug information, 28 (35%) concerned institutional procedures or policies, and the remainder were related to patient care and the treatment plan. Forty-eight information needs (60%) were successfully resolved using Infobuttons, 15 were deferred, and 14 needs failed to be resolved. Fifty-one needs (65%) were from an external source (e.g., Micromedex) and 26 (33%) were from an internal source (e.g., the local intranet). Exit interviews revealed an overall satisfaction with the resources provided by and the usability of Infobuttons. Excess information making navigation difficult was one of the problems identified.

Conclusion

Although clinicians show a high occurrence of information needs as they treat their patients, many of these needs can be met with Infobuttons All participants agreed that the information resources provided by Infobutton were valuable and easy to understand. This study imparted us with insight on the questions clinicians need to have answered for effective decision-making, and accentuated the need to be mindful of information overload.

Department of Communication, E-Learning Lab – center for user driven innovation, leaning and design, Aalborg University, Aalborg, Denmark
Virtual Center for Health Informatics (V-CHI), Aalborg University, Aalborg, Denmark

Abstract

The paper develops a language for addressing transformations of communication and workflow in health care from implementing IT. Introducing categories for identifying distorted communication; different levels of IT-interactions are discerned into a framework for identifying IT initiated problems in health care. The categories evolved from synthesizing three studies of IT-implementation in healthcare arrangements, i.e. on IT-implementation for supporting communication across different health care institutions, across wards in a University Hospital and for internal communication at a medical ward and major empirical usability studies in health care. The studies are based on qualitative interviews and observation. The analysis of the studies is inspired from theoretical work on IT-infrastructure. The conceptual framework of identifying distorted communication and collaboration mediated by IT is discussed and additional strengthened in a metaanalysize with recent research on unintended adverse consequences from implementing CPOE, computer order entry systems in health care practices.

Keywords:

HCI, socio-technical, infrastructure, communication, IT

Introduction

Along the line of many other western countries the Danish society is facing new challenges in organizing Health Care. An aging population, rising demands and possibilities of treatment and care, lack of clinical staff among other issues are pressing new national politics onto health care practices, management and organization. Information technology is given a central role as change agent of health care infrastructure towards visions of more quality, safety and continuity in and across healthcare settings [1, 2]. This paper questions the nature of infrastructure as some'thing' that can be deliberately planned for by authorities and vendors. IT-systems in health care have often enough failed to fulfill the desired hopes designed for, leaving the health care organizations with systems that nobody use and at great financial expenses. Building project organizations within the health care institutions to support an ongoing process of implementation and customization of systems to living clinical practices have become an answer to the unpredictable nature of IT-systems on health care infrastructure. The project organization not only have to train the vast amount of users in clinical settings in the functionalities of the specific system, but also to offer continuous support on both system demands and user demands, both running or working 24 hours a day, seven days a week, 365 days a year. The 'working relation' [3] of users and system depends highly on the degree of stability, of usability and of utility of the concrete artifact in the specific care domain and practice. This less predictable evolvement of infrastructure from IT-implementation, also termed risk management [4] put emphasis on screening, evaluation and learning from unintended consequences of implementing IT system into health care. The project organization is thereby also facing additional implementation challenges of becoming aware of new kinds of possible 'errors' arising from putting IT-system into clinical use. The categories and framework presented in the following, hope to facilitate the identification, articulation and negotiation of undesirable changes of health care infrastructures.

Materials and methods

Implementation of ICT in health care have shown to have unintended consequences for the organization of health care work [5]. Some of the communicational inadequacies can not be reduced to neither technical nor usability problems but rather utility inconsistencies in the social and technical relations of system and user. Therefore such socio-technical problems following IT-implementation are characterized in framing the relation between the main actors in the health care system differently. These differences make infrastructural questions visible and prepare the ground for negotiation and redesign.

Three qualitative studies of IT-implementation in Health Care have been conducted. The studies are of IT-implementations 1. across different health care institutions, 2. across wards in a University Hospital and 3. for internal communication at a medical ward.

The first study is about implementation of electronic exchange of information between the municipality and the hospital [6, 7]. The aim was to gain a more correct exchange of information and also a faster and more holis-

tic treatment of the citizen involved by switching from communicating through telephone and letters to electronic information exchange. A well known standard, EDI messages by ways of Vans technology, was chosen for exchange of information, but a more complicated and demanding infrastructure evolved. Some of the problems were due to complicated interaction style by an old patient administrative system (PAS) at the hospital and to computer inexperience among the staff. It was a highly time demanding task so send and receive messages and doubtfulness arose concerning the rules for exchange of information and to some extend questioned the rationale of using the system. The agreements that should solve the problems got rather complicated in order to cover all situations. This implied that the staff had to double communicate, i.e. more work instead of less work, to secure the communication. Adding to this, and coming from societal context, there were the whole issue of patient consent, which questioned the legality of the basic intensions and goals behind the project.

The second study is about new tasks of the project organization in a university hospital implementing electronic order-entry-system, CPOE. The aims of the system are among other to improve patient safety and continuity of patient treatment and care. In relation to a new health law clinicians have been reporting on unintended consequences in clinical work. Within a 6-month period 97 unintended consequences from using the CPOE-system in the University Hospital have been reported to the County, the Hospitals owners. These are in an Audit Report from the County [8] categorized as 45 unintended consequences of technical nature, due to an instable system and inadequate user interface and 52 unintended consequences of organizational nature, expressed as a lack of correspondence between electronically documentation of medication and other registration of data. The responsible implementer of the project organization experienced though that the so called 'technical errors' and 'organizational errors' were mutual dependent. They even feed each other in practice and affected the infrastructure of health care as well.

The third study [9, 10] points to central situation of enacting medication with CPOE at two internal medical wards at a middle-sized Danish hospital. The program of action for medication consists of minimum seven core acts or 'subprograms of action': 1) the indication of treatment, initiated by the patient's problem/diagnose, 2) the 'prescription' (recommendation of treatment and patient's consent of choice), 3)'requisition', i.e. 'registration', i.e. order in CPOE-system, 4) 'dosage', i.e. making drug ready for consumption, 5) 'administration' (patient is given the drug), 6) 'assessment' of drug effect on the patient, and 7) 'considerations on how to proceed', i.e. whether to continue or withdraw the drug. This process takes place within a different temporal rhythm, and located at different places, for example at the patient's bedside, in the hallway, in different offices and the drug storage. Global access from other wards or institutions is possible. The CPOE interacted with four of the seven subprograms in the medication process, 2) the prescription, 3) the requisition (order entry), 4) dosage and 7) withdrawal or continuity of treatment. The study identifies transformation of ordination with the CPOE, of the registration of clinical collaboration and possibly transformation of patient trajectories with CPOE. Core relations between patients and clinicians are touched upon by these transformations of the local medication practice.

The above mentioned studies were analyzed according to the usability of the system when 'entering and receiving messages' [5:106], i.e. in the direct interaction between user and system. And in relation to the 'communication and coordination Process' [5:107], i.e. the mediated collaboration with the system between users at different locations. Finally infrastructural changes are cybernectically understood as 'trans-contextual syndromes' or 'double bind' [11] in the case of paradoxes between the organizational purpose of the system and the utility in use [3]. Systemic experiences of double binds point to 'socio-technical problems' that open up for 'politics of design' [12] and a 'Parliament of Things' [13] in the responsible organization.

Results

The findings of the studies can be summed up at different analytical levels of interacting with the IT. At one level there were interruptions in the direct interaction between user and system, entering or receiving data. At another level or shift in the meaning of interaction there were discontinuity in the mediated interaction and collaboration of the users with the system. Transformations of infrastructures were disclosed as socio-technical problems (double binds or paradoxes) as the organizational structure enacted with the IT dis-cohered with the intentions of implementing the system. The findings of the studies can be summed up accordingly.

IT communication across institutions: municipality and hospital

The first study showed the complexity of the problems related to achieve the aims of implementation of a new infrastructure with the EDI standard. Doubtfulness and double communication was some of the unintended consequences and the findings of the study can be summed up as follows:

1. Level of interaction with the EDI standard: the communication between municipality and hospital where interrupted as their existing PAS was difficult and time consuming to use

2. Level of IT-mediated interaction among users: the users needed to establish new procedures for sending and receiving messages to each other, dividing them into urgent/complicated messages and un-urgent messages where only the latter could be sent electronically, and additionally to set rules for who was responsible for reading and acting upon the electronic information.
3. Infrastructural level: In contrast to the expected vision of optimizing communication the information exchange expanded, double communication including IT and telephone were necessary to secure quality of collaboration. The exchange of electronic patient data also collided with the law on data security, where by a whole new infrastructural problem arose at national level.

IT communication across wards in university hospital

The second study showed that IT-implementation gives new communication problems in the health care organization, and thus that intentions of more patient safety and less continuity problems are not automatically a result of a CPOE system, but a new challenge to health care and project organizations that cannot be reduced to neither technical nor organizational errors. The two studies can be summed up as problems at the following levels of interacting with IT.

'Technical error' of patient safety

1. Level of interaction: the technical error in the CPOE-system of showing wrong patient identification numbers, CPR interrupted the patient safety through out the organization, leaving the responsible management with the communication problem: *But how do you communicate to 3000 end-users?*
2. Level of mediated interaction: warning the end-users by a telephone-chain informing all wards failed, as sudden emergency patients toke the attention of the clinicians at the medical ward. The clinical collaboration with the CPOE became more risky for patients as well as for users as the last ward in the telephone chain never received the warning.
3. Infrastructural level points to the possible arousal of new medication errors and to socio-technical problems in taking responsibility for individual patients' safety as a clinical user, and as responsible manager of the reliability of the system to all patients and users.

'Organizational error' of patient continuity across wards

1. Level of interacting: the ward of intensive care lack information in the CPOE on patient transferred from the ward of surgery.
2. Level of IT-mediated interaction between the wards: as the surgeons do not need the CPOE for their work discontinuity appeared in the collaboration between the wards with the replacement of paper with the CPOE.
3. At the infrastructural level the problem of re-creating patient continuity between the wards with CPOE became a new socio-technical problem, also pushing the question: *Who is responsible for things to flow?*

Communication on medication across clinicians using a CPOE System at two medical wards

The study points to that more 'global access' to patients' medication data with CPOE-system might locally give more difficult access. New, physical and social distance of prescribing and coordinating medication work with the CPOE arose, alongside with new tasks of and divisions of work.

Transformation of ordination with CPOE

1. Level of interaction: the physical distance between the patient's bed, the CPOE and other artifacts interrupts the physician's prescription and requisition of drugs in the CPOE on doctors rounds
2. Level of IT-mediated interaction: the physician would reduce the walking by memorize tree and four patients at a time and order their prescriptions in the CPOE after dictating to the patient record in the hallway.
3. Level of infrastructure: socio-technical double binds arose as the doctor-patient relation transformed into collective e-patient, when entering 'mass-orders' several patients at a time. Cognitive pressure is put on the individual doctor in order not to mix up the patients, the patients' prescriptions and orders up with each other. Mistakes are likely to be difficult to trace in the CPOE as they happen before the orders are prescribed.

Transformation of user rights and clinical teamwork

1. Level of interaction: the users are interrupted in their workflow by an inflexible system for entering and retrieving information.
2. Level of IT-mediated interaction: discontinuity between the rationality of medication work inscribed in the software, the numbers and location of PC made the clinicians work-around their personal user-rights in order to coordinate teamwork and continue workflow.
3. Level of infrastructure: tensions are created with the CPOE between the formal right and duties of nurses and physicians, inscribed in their different user-rights with their actual collaboration. As an outcome a collective e-clinician came into being for team working under seemingly, strictly individualized user-rights.

Possible transformation of patient trajectories with CPOE

1. Level of interaction: discharging patients with CPOE interrupt the clinicians practice, as withdrawn

medication unlike the limited time-span and contextual use of the prior paper medication scheme - has to be actively withdrawn in the electronic system.

2. Level of IT-mediated interaction with future users: a discontinuity in patient's medical treatment might happen when the patient reenters the health care system, unless the users envision future users and also withdrawn orders in the system
3. Level of infrastructure: transformation of patient continuity across different health care sites with the risk of wrong medication.

The analytical findings of the three studies of disclosure of infrastructures by IT-implementation can be summed up as *situations and moments of interruption, discontinuity and sociotechnical tensions in the users' communication with the system.* These spatial and temporal points of departure for infrastructural changes can be framed in the following matrix:

Table 1 - Infrastructural relations in HCI

Categories of HCI relations	Interruption	Discontinuity	Socio-technical tensions
Direct interaction			
IT-mediated interaction			
Infrastructures			

The framework can afford the identification and articulation of IT-implementation problems in relation to usability and utility of the system - as experienced by the individual user interacting directly with the system entering or retrieving data, from experiencing the social collaboration in mediating clinical task with IT, and how these work relations are cultivated by the IT-system and identities are folded and molded into the organizational infrastructure:

Examples of (easier recognizable) computer experiences from our studies can highlight the blanks of the matrix in following way:

Table 2 - Problems in healthcare infrastructures

Categories of HCI relations	Interruption	Discontinuity	Socio-technical problems
Level 1 Direct interaction of user and interface	"Receiving and entering data" <=> User-rights, accessibility, training	Performance loss <=> 'deskilling'	'cognitive overload' <=> Stress
Level 2 IT-mediated interaction/ collaboration	Stability of system, software design, GUI <=> 'Entfremdung'	Coordination problems <=> Work-around, Arbitrary or double communication	Conflicts, indifference, delegation of work 'Unsafe', risky

Discussion

The presented studies of infrastructural chances in and cross different health care institutions underline that the intended effects and visions of implementing IT into their infrastructures are not easily realized. Instead the complexity of implementing IT into existing health care practices draw attention to the established relations of coordinating and mediating work, including other techniques, and the material surroundings of always enacting health care locally.

The categories of HCI relations and framework developed in this paper to identify interruptions, discontinuities and socio-technical problems in the health care infrastructure from implementing IT are not valid by the frequency and similarity of the problems identified. This paper does not build on large, quantitative data collections, across many hospital and many informants. In stead in depth analysis of local experiences and settings have prevailed. The results and research purpose of the studies are therefore not to generalize infrastructural changes from IT-implementations, but to develop a language for informaticians and project organizations to address future infrastructural changes as situations and moments that are sensitive to adjustments and renegotiation of the IT-system (artifact) and the work practices in question. In order to falsify, and possibly strength the synthesis of the studies, the categories of human-computer relations (table 1) can be tested by other studies.

Cambell, Sittig, Ash, Guappone and Dykstra [14] identify nine types of unintended consequences related to CPOE. The types are the outcome of a major qualitative study over 9 month, 390 hours of observation, 43 hours of interview, transcripts and field notes of approximate 1900 pages at five US-hospitals using either homegrown and vender built COPE-systems. The nine major categories are in order of decreasing frequency: 1) more/new work for clinicians; 2) unfavorable workflow issues; 3) never ending system demands; 4) problems related to paper persistence; 5) untoward changes in communication patterns and practices; 6) negative emotions; 7) generation of new kinds of errors; 8) unexpected changes of power structure; and 9) overdependence on the technology. A metaanalysis of the nine types of unintended consequences with the categories of HCI relations reflects the following

relations between the types and the human-computer interactions:

Table 3 - Types of UC from Health care infrastructures with CPOE, ranged by frequency

Categories of HCI - relations	Interruption in usability	Discontinuity in utility	Socio-technical tensions/problems
Direct interaction of user and interface	'Negative emotions' (6)	'Problems related to paper persistence' (4)	'More/new work for clinicians' (1)
IT-mediated interaction/ collaboration	'Never ending system demands' (3)	'Unfavourable workflow issues' (2)	Untoward changes in communication patterns and practices (5)
Infrastructures	'Overdependency of the technology' (9)	'Generation of new kinds of errors' (7)	'Unexpected changes in power structure' (8)

The outcome of this metaanalysis of the types and of the test of the categories on the more generalizable studies of CPOE is twofold. The categories of HCI relations can be said to *anchorage* the nine types of UC from a more generalized, decontextualized knowledge on IT-implementation to the framework's more concrete, spatial and temporal relations of enacting health care within socio-technical infrastructures. The nine types of UC *verify* the categories of HCI relations as far as the relations in the framework for identifying transformation in working relations between users and computers are confirmed.

Using Participatory Action Research to Evaluate and Improve Change: Pilot Implementation of an Electronic Health Record in Rural Tanzania

Nicole A. Grimm, Nicola T. Shaw

Department of Medicine, University of Alberta, Canada
Integrated Centre for Care Advancement through Research (iCARE),University of Alberta and Capital Health, Canada

Abstract

The purpose of this study is to use a Participatory Action Research (PAR) approach to facilitate the implementation of a new electronic Health Information System (HIS) in rural Tanzania. Health care funding to Africa has increased the electronic tracking of patients. There is a gap, however in HIS implementation and evaluation research in Sub-Saharan Africa. The implementation process can be considered a mutual transformation between the organization and the technology, best served by iterative feedback from users. Hence, we will use a PAR approach to build local capacity to evaluate the impact of the new HIS within a local context. Stakeholders will be empowered to participate in the identification, collection, and analysis of issues related to the implementation and to build and evaluate shared plans for change. This will be an iterative process. This collaborative study will contribute to knowledge of the PAR approach in health informatics and will fill a gap in the knowledge of HIS implementation and evaluation research in Sub-Saharan Africa.

Keywords:

Sub-Saharan Africa, technology, healthcare, evaluation, action research

Introduction

Health Information Systems (HIS) have increasingly become part of healthcare management and delivery in low- and high-income countries. The implementation of HIS involves the set-up and adoption of electronic systems in varied care settings. The implementation process can be considered a mutual transformation of the organization and the technology in tandem, best served by utilization of users' perspectives being fed back into a constantly evolving system. Evaluation of the HIS is considered imperative to provide information that could enable ongoing adjustments to be made to the implementation process [1]. There is a gap, however, in HIS implementation and evaluation research in Sub-Saharan Africa [2].

Theoretical approach

In designing this study we recognized that summative assessment does not build capacity within the research environment. As most theoretical frameworks are summative and based on Western (or high-income) countries [2] they are usually not transferable to low-income countries. Likewise, adapting evaluation studies from high-income countries can be problematic. Integrating HIS into clinical environments has context specific conditions and limitations in low-income countries particularly in rural areas [3]. It is therefore important to take the local context and culture into consideration.

PAR is a way of "knowing" about a phenomena that is driven by stakeholders "living" the phenomena. Our approach will thus be both formative and summative in nature which will enable us to continuously refine and adapt as we explore emerging trends and use iterative data collection and analysis to guide future steps. PAR involves three basic actions: data collection ("look"), data analysis and theorization ("think"), and planning, implementation, and evaluation ("act"). These actions are guided by a facilitator [4]. PAR builds capacity by empowering local stakeholders to participate in the identification, collection, and analysis of issues directly related to the implementation process. This can help drive the sustainability of the study and identify cost-effective solutions to iterative quality improvement [5].

The research question is: "How can Participatory Action Research be used to facilitate the implementation of a new electronic Health Information System within a rural Tanzanian clinical environment?

Research methodology

Research Locus

Field research began in April 2007 and will occur over a 12 – 18 month period at Haydom Lutheran Hospital (HLH), Mbulu, Manyara, Tanzania. HLH is located approximately 300km southwest of Arusha in the Mbulu District, and borders 4 other districts which it also serves, a population of approximately 580,000. HLH has roughly 12,000 inpatients and 60,000 outpatients each year. The hospital currently works over capacity with an average of 370 inpatients/day assigned to 350 beds. HLH is a pilot site for the implementation of the Care2X HIS, an open-source software application introduced to collect and store administrative and clinical data.

Participatory action research

We will engage local stakeholders to work through the iterative Participatory Action Research approach to evaluate the implementation of the Care2X system, and build and implement shared plans for change. It is anticipated that one full cycle of the action research stages (look, think, act) will take approximately 8 weeks. There will be 6 cycles over the course of a year. Stakeholders are identified as those who are or will be using and/or making decisions about the new electronic Health Information System and include employees and administrators.

Data collection will consist of interviews, meetings, observation and document review, and will occur on site at HLH in Haydom and ELCT Health in Arusha. Data analysis is also an iterative process in which findings are summarized into reports for participant review and feedback. The research results will be widely disseminated in a manner that is accessible to local stakeholders, as well as national and international audiences.

Results

Progress to date

Grimm visited Haydom Lutheran Hospital and ELCT Health in January 2006, at which time the research project was identified. Ethical approval, and ethical and research clearance have been obtained from the University of Alberta, the National Institute of Medical Research Tanzania, and the Tanzania Commission for Science and Technology respectively. Grimm moved to Haydom, Tanzania in March 2007 in order to conduct the field research.

Discussion

Unlike hypothesis-driven orthodox research, or researcher-driven social science research, PAR is stakeholder-driven and drives social change. Local stakeholders will provide essential and ongoing input to the iterative evaluation and improvement of the Care2X HIS implementation. The use of a PAR approach will build capacity at HLH and the Evangelical Lutheran Church of Tanzania Health to identify issues related to the implementation of the Care2X system, and to build and evaluate shared plans for change. The PAR approach is scalable and can be used by our study partners to build capacity for HIS implementation initiatives at other sites. This, in turn, contributes to the sustainability of the initiative.

Conclusions

This collaborative study has the potential for the advancement of excellent research by filling a gap in the knowledge about HIS implementation and evaluation in Sub-Saharan Africa. This research contributes to knowledge of the PAR approach in health informatics and of HIS implementation in a low-income country. It also provides insights into the modification and use of the Care2X system for administrative and clinical management in Sub-Saharan Africa. Our research is exceptionally timely as the need for knowledge about evaluating the impact of HIS is increasing exponentially as electronic HIS implementation rates increase internationally. The case study within a resource-poor country will be used to inform HIS studies in resource-rich countries, specifically rural and remote health care environments.

Acknowledgments

This research would not be possible without the support of our research team: Dr. Shoo Lee, iCARE; Dr. Richard Scott, University of Calgary; Dr. Thorkild Tylleskär, University of Bergen; Dr. Alan Gillies, University of Central Lancashire; and Tanzanian Collaborators: Dr. Mauri Niemi, Evangelical Lutheran Church of Tanzania (ELCT) Health; Dr. Øystein Olsen, Haydom Lutheran Hospital; Ms. Neema Mgana, African Regional Youth Initiative; and Mr. Oscar Mukasa, Ifakara Health Research and Development Centre.

INTRODUCTION

- Electronic Health Information Systems increasingly part of health care management & delivery
- Funding has increased electronic tracking of patients, drug inventory and order planning
- Change management issues at organizational & individual levels
- Gap in Health Information System evaluation research for Sub-Saharan Africa and internationally
- High-income countries can learn from Health Information System implementations

EVALUATION OF HEALTH INFORMATION SYSTEMS - SOCIAL RESEARCH

- Health Information Systems are part of a larger system
- Social, contextual, and technological influences
- Multiple methods (quantitative and qualitative)
- Formative and summative
- Most theoretical frameworks are based on high-income countries
- Adapting evaluation studies can be problematic

PARTICIPATORY ACTION RESEARCH

- An approach not a method
- Hypothesis-generating
- Build capacity to evaluate implementation within local context
- Mixed methods case study
- Social interactionism, socio-technical paradigms
- Iterative Quality Improvement
- Drives social change

CONTEXT

- The Opportunity
  - ELCT Health of Tanzania implementing Care2X Health Information System
  - Haydom Lutheran Hospital pilot site (commenced January 2007)
- Research question
  - How can Participatory Action Research be used to facilitate the implementation of a new electronic Health Information System within a rural Tanzanian clinical environment?

PURPOSE AND OBJECTIVES

- Purpose
  - To facilitate the implementation of a new Health Information System in rural Tanzania using a Participatory Action Research approach.

- Objectives
  - Identify opportunities to improve
  - Create, implement and evaluate shared plans
  - Build local capacity
  - Provide local information
  - Disseminate results broadly

METHODOLOGY

- Research Locus
  - Haydom Lutheran Hospital, Mbulu, Manyara, Tanzania
  - 12-18 months field research
- Stakeholder Recruitment
  - Administrators, employees, contractors

path paving the way
AHFMR Alberta Heritage Foundation for Medical Research
University of Alberta
Capital Health Edmonton Area
IDRC CRDI
iCARE about health Integrated Centre for Care Advancement through Research

METHODOLOGY

- Participatory Action Research
  - Stakeholder-driven
  - Researcher as facilitator
  - Formative, summative, iterative
  - Drives social change
- “Look”, “Think”, ”Act”
  - Identify issues of importance and build shared plans for change
  - Interviews, focus groups, meetings, observations, literature and document review
  - 8 week cycles (6 cycles in one year)

METHODOLOGY

- Construct validity
  - Multiple perspectives and sources of evidence
  - Member-checking
  - Journaling
  - Action research is modifiable
- External validity
  - Incorporation of general theory
  - Explore rival explanations
- Reliability
  - Protocol will be systematically documented

SIGNIFICANCE

- Contributes to knowledge of the Participatory Action Research approach in health informatics
- Insights into the modification and use of the Care2X system in Sub-Saharan Africa
- Fill a gap in knowledge about Health Information System evaluation research in Sub-Saharan Africa and internationally
- Case study will be used to inform Health Information System evaluation research in resource-rich countries, specifically rural and remote health care environments

TO DATE…

- January 2006 site visit to ELCT Health and Haydom Lutheran Hospital
- Ethical approval from University of Alberta

- Research and ethical clearance from the Tanzania Commission for Science and Technology and the Tanzania National Institute for Medical Research
- Field research commenced April 2007

Evaluation Framework for the Electronic Transmission and Processing of Prescriptions Project in the Iranian Social Security Organization

Ramin Moghaddam

Director, Medical Informatics Department, Social Security Organization, Tehran , IRAN

Abstract

Fifty to seventy percent of information system projects fail. [1] Most of the failures are not the victims of flawed technology, but rather organizational and people related issues. According to a long term plan, Iranian Social Security Organization(ISSO) is going to enable the sharing of health related information in a secure environment by means of reliable data in the right time to improve health of insured people throughout the country. Electronic Transmission & Processing of Prescriptions (ETPP) project in this organization deals with the prescribed medicaments related information from around 7000 pharmacies throughout the country that ISSO contracted with them in order to deliver seamless services to 30 million insured people .It was crucial to define an evaluation framewrok for this nationwide project in order to apply formative and summative evaluation . [1][2][3] This framework facilitates scientific and practical multidimentional judgment about success or faliure of this project. [2][3]

Keywords:

evaluation framework, electronic transmission, processing prescriptions, ETPP, success, failure

Introduction

Introducing an innovation into a big organization such as ISSO evokes changes . In some cases these changes will be minor ones that hardly affect the organization and the people working in it. [3] In other cases, those having to use the innovation might experienece major changes. ISSO is responsible for delivering direct & indirect medical services to thirty million insured people through the ISSO's health care network in the country . In the ISSO healthcare network , there are more than 350 owned medical centers in addition to 40000(including 7000 pharmacies) contracted healthcare institutions. ETPP project has been designed in order to enable sharing of valuable prescription information using a secure electronic environment to improve health and safety of insured people based on scientific approach alongside the facilitation of tracking the financial loads & risks. This electronic environment brings facilities for different stakeholders in the ISSO by means of reducing chances of abuse and redundant inspections, simplification of outpatient procedures, increasing the accuracy of medical expenses report information, holding the reimbursement information, medical records, etc. However, only a thorough evaluation study can show whether or not a specific system was successful in a specific setting. [3] With having this insight, a wide range of attributes shall be measured in evaluation of the ETPP project. These attributes vary from purely technical factors to outcome measures such as quality of services and from end user evaluation to extent of diffusion into the organization. It is likely that no single criterion can account for success or failure of the project. [2][3]

Methods

After a robust literature review, the ETPP evaluation framework has been developed mainly based on Delone and McLean multidimensional success model. [3][4] Delone and McLean proposed to subdivide success measures of management information systems into six distinct categories: 1) system quality, 2) information quality, 3) usage, 4) user satisfaction, 5) individual impact, and 6) organizational impact. Within each category several attributes could contribute to success. [3] Delone and McLean concluded that success was a multidimensional construct that should be measured as such. [4] In addition, they argued that the focus of an evaluation depended on factors such as objectives of the study and the organizational context. [4] The comprehensive evaluation information could be emerged from each entity by different qualitative and quantitative data collection methods such as questionnaire, chart review, interview, time sampling, work sampling, focus group and observations. [3]

Results

The system development, system quality, implementation, information quality, system usage, user perspective, individual impact and organizational impact are entities of ETPP evaluation framework. The attributes of each entity have been customized. The system development entity has several attributes as: system design, system architecture, development methodology, data modeling and normalization, extent of user group involvement. The system quality entity has several attributes as: ease of use, response time, timesavings, creating extra works, perceived ease of use, usability, up-time, ease of learning, complicated built in business rules, reliability, security, help, data accuracy.

The implementation entity has several attributes as: user group ownership, training efficacy, time delay for maintenance. The information quality entity has several attributes as: completeness, accuracy of data, legibility, timeliness, perceived usefulness, availability, comprehensiveness, consistency, reliability and format. The system usage entity has several attributes as: frequency of use, number of entries, duration of use, location of data, frequency of use of specific functions, frequency of report generation. The user perspective entity has several attributes as: user satisfaction, user attitude, user friendliness, expectations, competence. The individual impact entity has several attributes as: direct benefits, changed documentation habits, information use, efficiency and effectiveness of work, job satisfaction. The organizational impact entity has several attributes as : communication and collaboration, social accountability, time savings, cost, reduction of staff, number of procedures reduced . [3]

Discussion

The framework can be circulated between different parties and is a perfect evaluation tool from different perspectives when a large scale information system as ETPP is designed, developed and implemented. A good evaluation should include multiple, carefully selected periods of data collection and should include all stakeholders' points of view. [3] Kaplan suggested the following methodological guidelines for evaluations: 1) focus on a variety of concerns, 2) choose a longitudinal study design, 3) use multiple methods, 4) choose a study design that can be adapted to the study findings whenever necessary, and 5) be both formative and summative. [3][5]

Conclusion

Among healthcare professionals, new innovations are predominantly judged by their direct value for patient care. Information systems with a practical utility for patient care or diagnostic procedures are relatively easily accepted, sometimes even without any scientific evidence of their value. [3] However, systems like ETPP that support the process of healthcare without being directly relevant to patient care are less easily accepted. [3] To address a blending approach to formative and summative information systems evaluation, it should start before system development and should have no fixed end. [3] This is the nature of evaluation which is a dynamic process in information systems life cycle.

Medical Informed Consent in the Digital Age: Usability of a Computerized Informed Consent Application among Cardiology and Ophthalmology Patients and Clinician Users

Julito Uy[a]

[a]*Masters in Biomedical Informatics Program OHSU, Portland Oregon. Thomas E. Creek Department of Veterans Affairs Medical Center and Texas Tech University Health Science Center, Amarillo Texas*

Abstract

The study evaluated the usability of a computerized informed consent software product, iMedConsent by analyzing the trend in satisfaction ratings using Likert scale to survey questions. Cardiology and Ophthalmology patients and clinician users in a Veterans Affairs Hospital in southwestern United States were provided questionnaires to describe levels of satisfaction upon using the software. Data analysis of satisfaction ratings demonstrated that, iMedConsent is highly usable to patients and clinicians alike. However, patients with less computer knowledge and experience may be less satisfied with using the computer to learn about an upcoming procedure. These differences merit further consideration in the future widespread implementation of computerized consent software.

Keywords:

informed consent, ethics, medical malpractice, Veterans Affair

Introduction

In the US, lack of proper informed consent is listed as a factor in 40%-60% of all malpractice cases. Indeed, failure to obtain proper consent itself ranks among the top ten reasons for malpractice claims [1]. State medical boards investigate patients' allegations of violations involving informed consent. Physicians found to be in violation can face fines, suspensions, or revocation of their professional licenses.

The current standard of obtaining informed consent is a paper-based form. Nonetheless, different studies echoed the need to improve the paper based consent process [2]. In 2003, the Department of Veterans Affairs system adopted computerized informed consent software, iMedConsent based on Department of Veterans Affairs and Joint Commission on Accreditation of Healthcare Organizations standards [3]. It is being positioned for full implementation after undergoing successful pilot studies.

Materials and methods

A questionnaire form was made available to patients who consented to a procedure using iMedConsent in the Cardiology and Ophthalmology Outpatient clinics from May 20, 2005 to Dec 30, 2005 and clinicians who actively use iMedConsent. The level of satisfaction was rated on a Likert scale: 5 – very satisfied, 4 – somewhat satisfied, 3 – neither dissatisfied nor satisfied, 2 – somewhat dissatisfied, 1- very dissatisfied. Each participant was asked to state perceived level of computer knowledge: none (N), beginner (B), average (Av), above average (AA) and advanced (Ad). A space was provided for comments not covered by survey questions.

Frequency distribution was used to identify statistical trends on patients' and clinicians' data. SPSS's nonparametric Kruskall-Wallis test was used to establish statistically significant similarity ($p=0.01$) of satisfaction ratings among different patient groups. To improve statistical power, patients were divided into two major groups. Unskilled computer users (UCUs), consisted of N and B groups and skilled computer users (SCUs), consisted of Av, AA and Ad groups.

Results

Clinicians' comments encompassed software implementation concerns (downtime, does not always load up), design issues (inability to edit, the need for physician's availability, procedures selection) and knowledge problems (related to finding the right procedure).

Table 1 - Percentage of patients (N = 152) who were somewhat satisfied and very satisfied

Survey question	N	B	Av	AA	Ad
Understanding of the procedure	90	92	100	100	100
Understanding of a) risks	83	92	100	100	100
b) benefits	86	92	100	100	100
c) alternatives	75	92	95	100	100
Addressing patient concerns	86	97	98	100	94
Ease on signing	83	91	100	96	100
Computer as learning medium	67	81	95	96	100
Computer- based versus paper-based consent	74	81	98	100	100
Overall satisfaction	86	97	100	100	100

Table 2 - Percentage of clinician users (N =8) who were somewhat satisfied and very satisfied

Amount of time/training needed/spent learning iMedConsent	75
Amount of time needed to complete an informed consent document	75
The information presented to the patient	
a. Indications of a procedure	63
b. Risks/Benefits of a procedure	75
c. Alternatives of a procedure	63
Do you feel that the patient concerns about the procedure have been addressed?	50
Computer as medium for discussion and documentation of an informed consent	63
Anatomical images and diagrams, patient educationmaterialsanddruginformation.	37
Overall satisfaction with the process	63

Discussion

Using a p value of 0.01, there were no statistically significant differences in the satisfaction ratings among different patient subgroups (p range: .03-.166) on overall satisfaction with the process, overall understanding of procedure, understanding of risks, benefits and alternatives involved (Table 1). However, use of iMedConsent as a learning medium and comparison of paper-based versus computer based consent process were met with mixed responses. There were statistically significant differences noted on the low ratings among N and B users (p = .001, .006 respectively) which was demonstrated also by comparison of the UCUs and SCUs (p = .000 and .002).

Five out of eight clinician users expressed satisfaction with using the software. However, only 4 out of 8 clinician users surveyed felt that patient concerns were addressed and only 3 out of 8 were satisfied with the educational support features (Table 2).

Conclusion

Overall, iMedConsent software is a highly usable digital tool for obtaining a patient's informed consent in the outpatient Ophthalmology and Cardiology clinics for patients of all levels of computer knowledge and among early clinician users. However, iMedConsent as an educational tool, showed significant differences in the satisfaction ratings of patients with varying levels of computer skills. This was mirrored in the clinician arm of the study. This finding needs consideration in the future widespread implementation of the software.

Medical Informed Consent in the Digital Age: Usability of a Computerized Informed Consent Application Among Cardiology and Ophthalmology Patients and Clinician Users

Julito Uy, MD

Masters in Biomedical Informatics Program
OHSU, Portland Oregon. Thomas E. Creek Department of Veterans Affairs Medical Center and Texas Tech University Health Science Center, Amarillo Texas USA

Objective

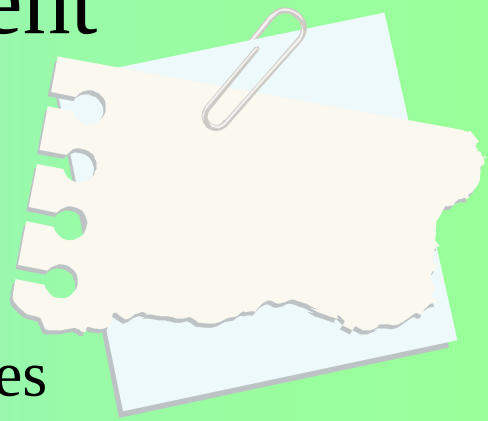
- To evaluate the usability of a computerized informed consent software product, iMedConsent, by analyzing trend in satisfaction ratings to survey questions among Cardiology and Ophthalmology patients and clinician users in a Veterans Affairs Hospital in southwestern United States .

- Specifically, this study attempts to demonstrate that positive rating is observed in all levels of computer knowledge.

Background

- In the US, lack of proper informed consent is listed as a factor in 40%-60% of all malpractice cases.
- Failure to obtain proper consent itself ranks among the top ten reasons for malpractice claims with median award of $500,000 from 1994-2003 [1].
- State medical boards investigate patients' allegations of violations involving informed consent. Physicians found to be in violation can face fines, suspensions, or revocations of their professional licenses.

The Paper-based Informed Consent

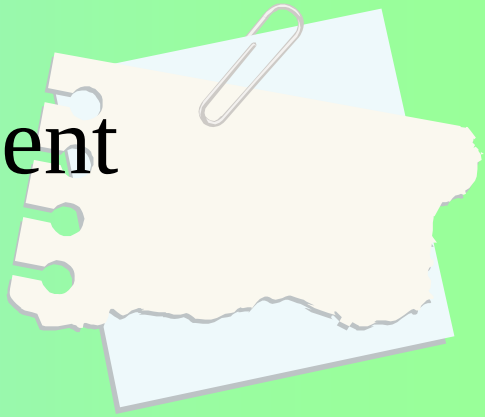


- The Veteran's Health Administration (VHA) National Center for Ethics in Health Care reported that the paper based consent process does not completely comply with the VA policy on informed consent.[2]

Content analysis of 540 paper-based informed consent forms for procedures from members of the American Hospital Association showed [3]:

- **26%** of the forms studied had complete documentation of all four essential elements of a valid informed consent,
- **35%** had only three, **23%** had only two and **14%** had only one.
- Only **14%** of the forms were useful in helping patients in their decision-making.

The Paper-Based Informed Consent



- Only **10.2%** of encounters with surgeons and **7.7%** of encounters with primary care physicians out of 1,057 encounters studied showed inclusion of all elements of informed consent [4].

- Significant majority (**59.5%**) of patients had difficulty understanding the standard informed consent documents in a study on health literacy among public hospital patients [5].

Materials and Methods

- iMedConsent simplifies and standardizes the process of obtaining informed consent by using templates constructed based on US Department of Veteran Affairs and Joint Commission on Accreditation of Healthcare Organizations standards [6].

- Presents a comprehensive discussion of nature of procedure, risks, benefits, and alternatives in a time-efficient way.
- Contains illustrations depicting anatomical structures with patient education materials in 4th grade readability levels.
- Contains a drug information library.
- Comes with a signature capture device ePad.
- Creates a legal document that is legible, retrievable, verifiable and complete, a defense against medical liability claims arising from failure to inform.

- The software versions used were v3.81 patch 347 and 3.81 389b.

Materials and Methods

- Questionnaires provided to Ophthalmology and Cardiology patients and clinician users who use iMedConsent software.

- Level of satisfaction was rated on a Likert scale:

5 – very satisfied,

4 – somewhat satisfied,

3 – neither dissatisfied nor satisfied,

2 – somewhat dissatisfied,

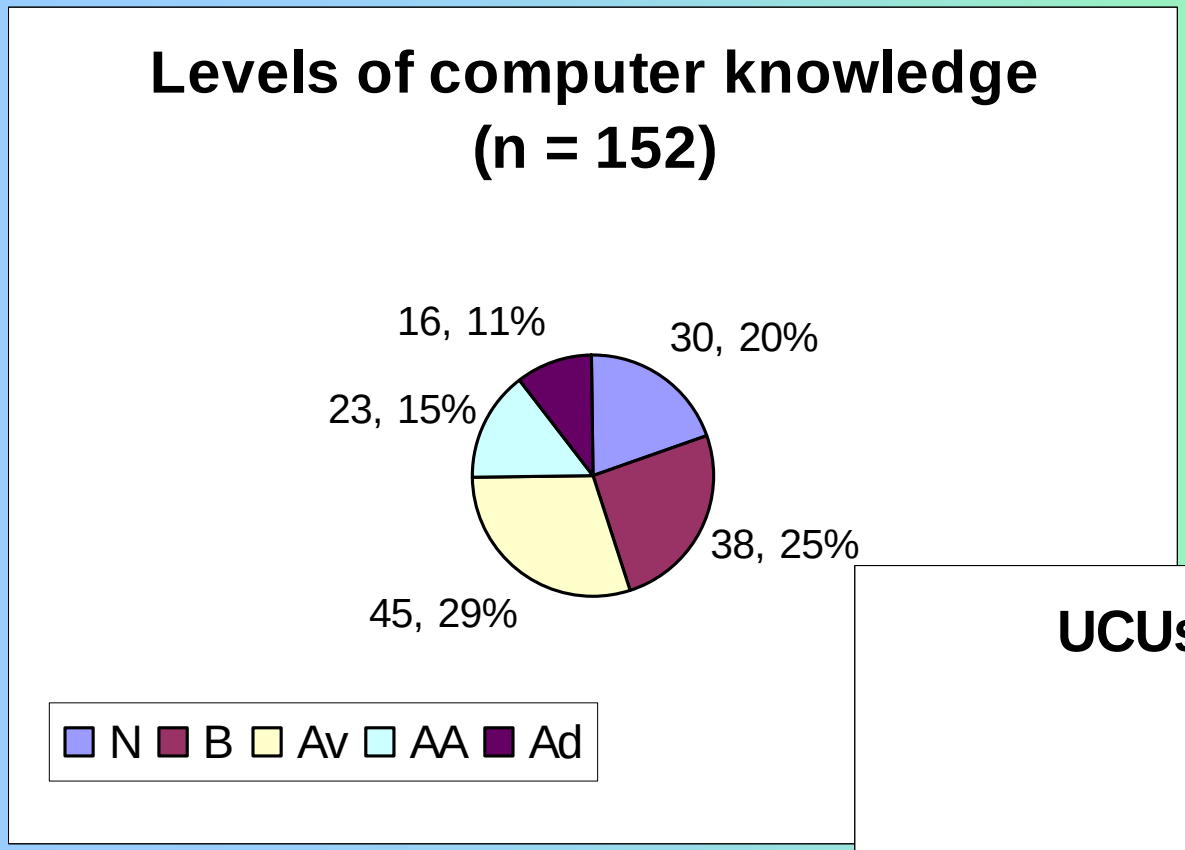
1- very dissatisfied.

- Levels of computer knowledge were: none (N), beginner (B) , average (Av), above average (AA) and advanced (Ad).

- To improve statistical power, N and B users were grouped as “Unskilled Computer Users” or UCUs and Av, AA and Ad were grouped as “Skilled Computer Users” or SCUs.

- Comments and recommendations

Results



Levels of computer knowledge
(n = 152)
16, 11%

UCUs (n = 84) and SCUs
(n = 68)
68, 45%
84, 55%
UCUs
SCUs

Percentage of patients who were somewhat satisfied and very satisfied.

Using $p < 0.01$, No statistically significant differences among patient subgroups (p range: .030-.166) on

- understanding of procedure,
- understanding of risks, benefits and alternatives involved,
- overall satisfaction with process

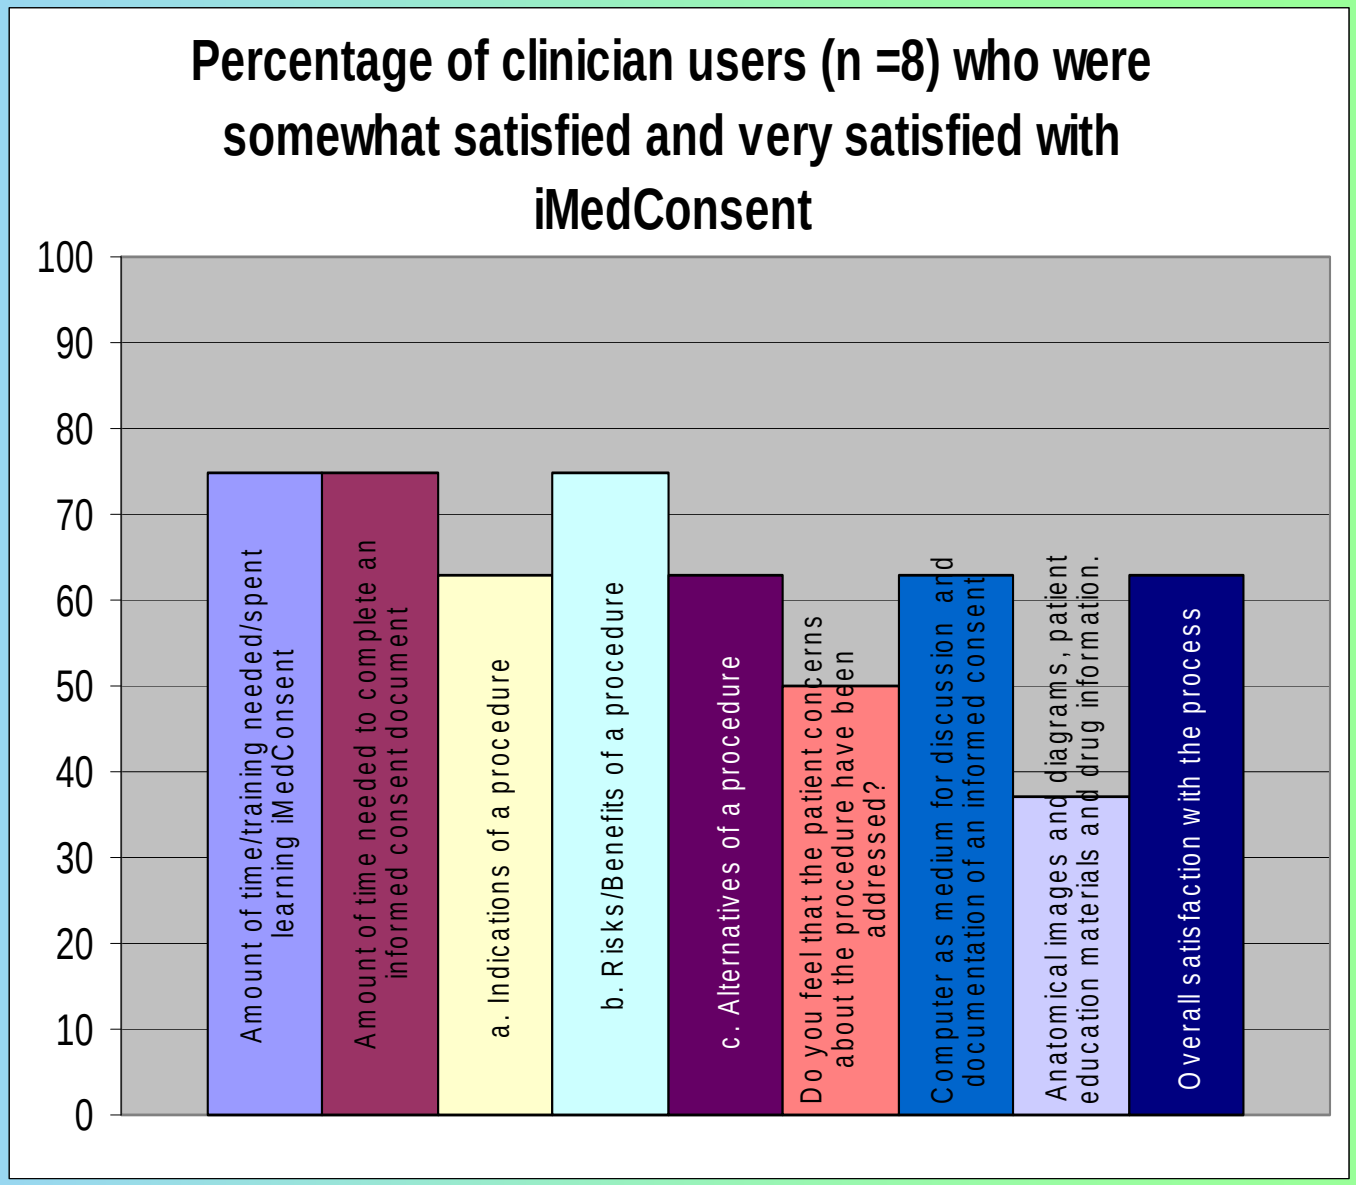
Statistically significant differences observed among patient subgroups on:

- Computer as a medium for learning ($p = .001$)
- Comparison of paper-based versus computer-based consent process ($p = .006$)
- Statistically significant differences were also demonstrated by comparison of UCUs and SCUs ($p = .000$ and $.002$).

Survey questions	N	B	Av	AA	Ad
Understanding of procedure	90	92	100	100	100
Understanding of a) risks	83	92	100	100	100
b) benefits	86	92	100	100	100
c) alternatives	75	92	95	100	100
Addressing patient concerns	86	97	98	100	94
Ease on signing	83	91	100	96	100
Computer for learning	67	81	95	96	100
Computer based versus paper based consent	74	81	98	100	100
Overall satisfaction	86	97	100	100	100

- Majority expressed overall satisfaction with using iMedConsent.
- 4/8 of clinician users surveyed felt that patient concerns were addressed.
- 3/8 were satisfied with the educational support features.
- Comments:

a. software implementation concerns
b. design issues
c. knowledge problems



The number of returned questionnaires is small from the clinician users arm to attain statistical significance.

Conclusion

- Overall, iMedConsent software is a highly usable digital tool for obtaining a patient's informed consent in outpatient Ophthalmology and Cardiology clinics for patients of all levels of computer knowledge and among clinician users.

- However, as an educational tool, there are significant differences in satisfaction ratings of patients with different computer skills.

- This finding needs consideration in future widespread adoption of iMedConsent software.

Assessing Clinical Processes – Lessons Learned

Samrend Saboor, Elske Ammenwerth

Institute for Health Information Systems, UMIT, Hall in Tyrol, Austria

Abstract

Introduction: This paper deals with the systematic assessment of clinical processes. In this context, an own assessment approach is introduced. It was developed during a two year lasting cooperative project. Aim: The aim of this paper is to share the experiences that were made with the selected approach. Method: Processes are assessed with the help of "views" and "rule-sets": Within a view selected elements of a clinical process are combined in a matrix. The analysis determines which details are needed. Specific flaws are then detected by applying rule-sets on these views. Results: The strengths and limitations which were observed during the evaluation of the approach are summarised in a structured way. Conclusion: The experiences in this paper contribute to future developments in process assessment. The approach itself could support the process oriented information management in hospitals.

Keywords:

process assessment (health care), process measure, public health informatics, information system

Introduction

Clinical processes can be seen as complex interactions between several hospital departments. Each department has its own objectives that lead to specialised workflows, role definitions and proprietary tools. This cooperative environment with its high demand on communication (e.g., [1]) is often seen as a main reason for the weaknesses clinical processes show, e.g. regarding their efficiency [2-4]. Similar problems are already known outside of the health care domain. Thus it seems feasible to adopt concepts like the well established Business Process Reengineering (BPR). One of its main principles says that companies can only improve their efficiency by focusing on their main processes [5]. The successful application of the BPR in turn depends on adequate process descriptions [6] which are analysed for possible weaknesses, in order to derive improvements (according to Deming's Plan-Do-Check-Act cycle, [7]). In fact, there are established tools which are meant to model and assess processes regardless of their professional context (e.g. the ARIS toolset [8]). Hence, their application on clinical processes basically seems possible. Based on the understanding of authors like Harrington who named in [9] measurements as the keys to improvement, BPR tools often equate assessment with measuring discrete process attributes (e.g. temporal or monetary details). But measurements themselves have no value without a context in which their results are judged [10]. This context is explicit process knowledge that guides measurements and helps to interpret results. In case of clinical processes this kind of context is missing. Thus, the degree in which the versatile capabilities of the BPR tools contribute to a feasible process assessment strongly depends on the subjective viewpoint of the person who uses these functions. A possible conclusion is therefore, that a systematic assessment of clinical processes is still missing [11].

The MedFlow project

Motivated by these drawbacks, the MedFlow project was initiated together with partners from the Leopold-Franzens-University of Innsbruck and the health care IT company ITH (Information Technology for Healthcare). The project lasted from 2004 until 2006 and aimed to develop a practical method and appropriate tools that support the systematic assessment of clinical processes. In this context, processes were regarded as interrelated actions that were augmented by descriptions of involved tools, roles and information objects. The resulting method takes this into account by declaring a core model that integrates sub-models for each of these four process aspects. The developed concept for assessing clinical processes bases on the application of so called "views" and "rule-sets": Within a view selected elements of at least two sub-models are combined in a matrix. Here, the kind of analysis determines which sub-models are combined. Specific flaws are then detected by applying rule-sets on these views. Each rule-set represents a pattern which is searched for in the view-matrix. The combination of a view with a corresponding rule-set is referred to as a "quality check".

The idea of the quality checks is further explained with an example in the following method section. However, the focus of the paper lies on summarising the strengths and limitations of the newly developed approach (i.e., applying rule-sets on views). These were gathered by applying the method on the process of ordering radiological examinations.

Aim of this paper

This paper is meant to share the experiences that were made with an assessment approach which uses rule-sets on appropriate extractions of process models.

Materials and methods

Preconditions for process assessment

Dealing with proper process assessment, the following open issues or rather conditions were identified:

- Important quality criteria for the regarded process must be determined in advance. On the basis of these criteria the relevant process details are identified.
  1. The model must adequately describe all details of the examined process which have been identified as relevant in 1.
  2. The model details must be organized in a way that they are accessible for the assessment.
  3. In order to avoid that criteria are skipped during the assessment, all criteria must be collected and arranged in a structured way.
  4. There must be a practical way to test the process for each criterion.

In the MedFlow project, the first condition was met by using methods like system analysis and literature research (e.g. [12, 13]). In this way quality criteria like "Number of distinct input information objects" or "Existence of media breaks" were gathered for the example process of ordering radiological examinations. Necessary process details are determined by deriving weak points from each criterion.

In order to meet the second and third precondition, a new core model which uses an own meta-model was developed: This core-model consists of four sub-models (process model, information model, tool model, organisational model) with each concentrating on distinct aspects of a process (i.e., control flow, data flow, tool usage, organisational information) – they are realised for instance on top of UML Activity Diagrams [14] and the Three Layer Graph-Based Meta-Model (3LGM², [15]). Additionally, own elements were introduced. Details can be found in [16].

The fourth condition was fulfilled by sorting the found criteria into a catalogue. In accordance to the basic quality aspects that are provided in [13] the catalogue was structured as follows:

- Quality of structures: This aspect can be further divided into the quality of documentation, logical and physical tools and finally the quality of integration between those tools.
- Quality of the processes
- Quality of the outcome (i.e., the degree the process contributes to achieve the hospital's strategic goals)

Thus, the above mentioned criteria "Existence of media breaks" can be found in the catalogue under the aspect "Quality of documentation" (which is part of "Quality of structures").

The fifth precondition was considered by developing a generally applicable assessment concept: In this concept the assessment is regarded as a series of questions. Each question scrutinises the existence of one process weak point. Because every weak point pertains to only one certain quality criterion, each question is answered on the basis of a specific subset of the details within a process model. This subset can either just list the elements of one sub-model or combine the elements of two sub-models. Because of this selective view on the process model the subsets are also called "views". In order to test a process model for a weak point, a specific pattern is searched within the appropriate view. Every pattern is expressed as a "rule-set". The combination of view and rule-set is also stored in the structured catalogue. Table 1 illustrates the structure of the catalogue entries using the example of media breaks.

Table 1 – Excerpt from the criteria catalogue

Quality Criteria	Quality Check		Possible weak point
	View	Rule-set	
Existence of Media breaks	Information-Model x Media Info	All information objects which are stored electronically and paper-based	Media cracks potentially cause inconsistencies in information objects.

Example for the detection of weak points

This section provides a small example on how the assessment method is used to detect media breaks. According to the appropriate catalogue entry (shown in Table 1), this criterion is assessed on basis of a view that combines the logical sub-model with the info.

An extraction of such a view is shown in Table 2: The lines of the matrix contain the information objects (e.g., a CT image, report) which are created, read, written or copied in the process. The columns contain the possible media states in which information objects can reside (e.g., in Table 2 "persistent (digital)" means that the information object is stored permanently on a server or a PC where it is available for distributed access). An information object can reside in only one media state at a time. If copies exist these copies should be stored at least on the same media type (i.e., paper-based or digitally). A common weak point in this context is that an information object is stored on different media types which is also called media break.

Media breaks are detected by selecting all lines (i.e., information objects) of the view which have multiple cross points. A cross point means that an information object is represented at least once in this state. Thus, multiple cross points in one line with different media type indicate media breaks. This is the case for the information object "Order form" in Table 2.

Table 2 – Excerpt of the view for detecting media breaks (see highlighting)

Media Information / Inform. object	…	persistent (digital)	persistent (paper-based)	…
CT image		X		
Order form		X	X	
Report	…	…	…	

Results

This section first shortly summarises the major achievements of the MedFlow-project in terms of its aim. After that, the second part explains the experiences regarding strengths and especially limitations of this approach.

Results of the MedFlow project

The aim of the MedFlow project was the development of a method that supports the systematic assessment of clinical processes. As explained in the methods section, the approach assesses process models by applying specific rule-sets on appropriately selected details. Considering this, the significant results can be resumed as follows:

- The development of the core model with its integrative meta-model: It allows to model processes with those details which were identified as relevant for process assessment. The organisation of the details into the specialised sub-models allows the access to those details for the assessment.
- The compilation of the structured catalogue: It contains essential quality criteria – not only with respect to processes but also the documentation and the involved tools. A first version of the catalogue comprised 38 useful quality criteria (see Table 3). However, it was not possible to develop checks for all criteria. The limitations, their reasons and the further efforts are explained in more detail in the succeeding section
- The implementation of a prototypic software: Making use of the newly developed meta-model this software is able to assess process models which were described in the MedFlow-notation. It has interfaces for established modeling suites like Microsoft's Visio. Elements are stored in a repository which can be queried for assessing the process model. The output is provided in a web front-end. The result of a check is presented in a view which is similar to that shown in Table 2.

Table 3 - The quality aspects and the related criteria

Quality Aspect	Sub-aspect	Quality criteria
Quality of structures	Quality of documentation	Correctness, integrity, reliability, completeness, accuracy, relevance, authenticity, availability, confidentiality & security, backup
	Quality of logical tools	Functionality, reliability, usability, efficiency, maintainability, portability
	Quality of physical tools	Adequacy, availability / accessibility, versatility, efficiency, adaptability, stability & reliability, security, harmlessness, usability, degree of standardisation
	Quality of integration	Adaptability & extensibility, controlled redundancy of data
Quality of processes	-	Efficient information logistic, adequate number of tools, information acquisition & usage, controlled data transmission, patient-centered information management
Outcome quality	-	Efficient communication, availability of all relevant patient data, comprehensive (electr.) patient record, increased usage of mobile information processing tools, optimised user interfaces, patient access on the own record, availability of medical data for research

Strengths and limitations of the developed approach

As already explained in the previous sections, the MedFlow project introduced an own approach for assessing clinical processes (i.e., "views" and "rule-sets"). In order to evaluate this approach a typical and sufficient complex clinical process was selected – the ordering of radiological examinations, and the communication of the related findings. Those processes were described based on a system analysis performed at the University Hospitals of Innsbruck, Austria. Here, the following strengths and limitations could be experienced:

Regarding the strengths:

- The concept of view/rule-set is flexible in configuration and generally applicable. New quality checks can be defined very quickly on the basis of details available in the core model.

- Assessment results just include those details which are essential for the certain quality check and the underlying question. Thus, the results can be anticipated more easily.
- Because of its structured and methodical way this approach guarantees that none of the registered process aspects (which are identified as relevant) are skipped.
- Including also descriptions about which information is needed to answer the checks and how to use them properly, the catalogue is applicable on all kinds of BPR tools.
- The resulting catalogue itself could be used as a collection of requirements which helps to improve BPR tools or as a guideline for the development of new assessment software.

Regarding the limitations:

The limitations must be separated into two groups: The first group contains general limitations which are common to all model-based process assessment methods. The second is made up of limitations specific to the new approach.

General limitations:

- The feasibility of the assessment is directly dependant on the quality of the process model. Aspects of this quality are for instance the correctness, consistency and completeness of the model. In order to avoid poor model quality, additionally acquisition guidelines must be defined in advance and used during the modelling stage.
- Even if the assessment is applied on adequate process models, it showed that the found results can be just regarded as hints on possible weak points. Found weaknesses like redundant information objects can be already known and even intended.

Specific limitations:

According to their reasons, the limitations in this group can be further divided into the following sub-groups:

- Limitations due to the implementation-specific meta-model: The meta-model describes the relationships between the elements of one sub-model and also between the elements of different sub-models. It defines details like directions of associations and cardinalities. However, the meta-model must be translated into a machine-useable form before it can be used to build a model repository which can be queried for assessing its details.
- It showed that the implementation puts strict restrictions on the associations within the meta-model. In consequence, not all necessary views could be generated by the latter prototype. Although improvements were applied relatively easy on the theoretic meta-model, several views could not be generated because the required associations could not be implemented.

Limitations due to the expressiveness of views:

- In contrast to the previous one, this limitation is not caused by missing elements or associations. It rather means that some quality checks require process details that cannot be represented in form of a view (i.e., combining independent details in a matrix). An example for this limitation is for instance the criterion “adaptability & extensibility” which belongs to the aspect “quality of integrations”.
- Limitations due to the validity or rather adaptability of the used criteria: This is one of the most essential limitations to probably any assessment method. In case of the MedFlow approach especially those criteria that deal with the quality of documentation point to this kind of limitation (e.g., “accuracy” or “reliability”). Their checks mostly require the utilisation of the content of model elements. An implementation of methods for assessing these checks is hardly possible.
- On the other hand, the contribution of these checks to a meaningful assessment of the process quality is vague. It must be further examined in more detail for each of the affected criteria.

The approach is suitable for assessing aspects dealing with the quality of processes. Further, the media type information and the defined storage states within the information model support the basic assessment of the information object life cycle. In contrast, the approach lacks in the assessment of content-related or organisational issues. These include criteria like efficient staff employment, efficient communication or accuracy of information objects.

Discussion and conclusion

This paper deals with a newly developed method which is meant to supports the structured assessment of clinical processes. However, the main focus lies on the strengths and limitations of this approach: An own core model is used to integrate four sub-models with each concentrating on distinct aspects of a process (i.e., control flow, data flow, tool usage, organisational information). In order to assess the quality of a process, selected elements of at least two sub-models are combined in a matrix. Weak points are then detected by applying specific rule-sets on these views. Each rule-set represents a pattern of critical cross-points which are searched for in the appropriate view-matrix. A main component of this assessment approach is the structured catalogue. It contains essential quality criteria, according weak points and appropriate quality checks (see Table 3 in result section for a list of quality aspects and criteria).

The experiences presented in this paper result from the evaluation of the new method. In this evaluation the method was applied on the sufficient complex process of ordering radiological examinations (as observed in the University Hospitals of Innsbruck, Austria).

The limitations of the approach can be separated into general and approach-specific: The general limitations are common to all model-based assessment approaches. The feasibility of this kind of assessment directly depends on the quality of the process model. Thus, poor model quality aggravates the detection of possible weak points.

Limitations specific to the selected approach can be summarised as follows: The underlying architecture of the new assessment method (i.e., the core-model) is based on an integrative meta-model. The implementation of this meta-model has put restrictions on the possible associations. Therefore, not all quality checks could be implemented. Further, some quality checks required process details which cannot be represented in form of a view. In turn, other quality criteria within the structured catalogue required the examination of the content of process elements (e.g., content of information objects). Their implementation – as far as possible – would mean big efforts. However, the degree of contribution of these checks is still to determine.

The strengths of the presented approach can be summarised as follows: It is flexible in usage - new quality checks can be defined easily on the basis of available process details. It provides a structured way to assess clinical processes - all relevant quality checks are registered in the structured catalogue. Thus, none of the checks are skipped during assessment. Overlooking and understanding the results is facilitated - the assessment results just contain those details that are relevant for the specific quality check. Because the structured catalogue also defines which details are needed to check the existence of weak points it can be also used as a guideline for the process assessment with other BPR tools. Moreover, it can be seen as a set of requirements for the development of new BPR tools.

It turned out that the presented approach is best used to assess clinical processes regarding their control flow (i.e., the sequence of involved activities - including control elements like associations, conjunctions and disjunctions) and information handling. The latter represents criteria like “efficient information processing”, “appropriate amount of tools”, “controlled data transmission within processes” or “availability of information objects”. The information-handling deals with the acquisition of new information objects (e.g., final report or ordering of examination), their manipulation and storage. The correct handling of information objects directly influences the quality of communication between involved actors or hospital departments. This in turn is essential for good treatment processes.

The presented approach could help to improve the documentation and communication within clinical processes. This also includes the involved infrastructure in terms of logical tools (e.g., software applications) and physical tools (e.g., server). Therefore, further developments should concentrate on these aspects. After this, the resulting method could be used to derive performance indicators, e.g. by analysing the result-sets for critical patterns. Tools which will be implemented on the basis of this approach could be used in scope of the strategic and tactical information management.

Acknowledgment

The MedFlow project was supported by the Austrian Ministry for Economy and Labour. It was realised in close cooperation with the Institute of Computer Science (University of Innsbruck), the Department for Information & Software Engineering (UMIT) and the Information Technologies for Healthcare GmbH.

Applications of Data Mining in Healthcare

Richi Nayak

School of Information Systems, Queensland University of Technology, Brisbane, Australia

Abstract

In this paper we discuss the use of data mining in many areas of Healthcare such as the treatment effectiveness, healthcare management, customer relationship management and the fraud and abuse detection.

Keywords:

data mining, healthcare informatics

Introduction

Healthcare is one of the world fastest growing industries and profession [7]. One of the main objectives of a healthcare organisation is its ability to obtain, store, analyse and be able to utilise data across the whole organisation effectively. The growth of databases in healthcare practices and researches are evident in the large number of claims databases, registries, electronic medical record databases, disease surveillance systems, and ad hoc research database systems. Pattern-identification tasks such as detecting associations between certain risk factors and outcomes, ascertaining trends in healthcare utilisation, or discovering new models of disease in certain population rapidly becoming striking. As Healthcares emphasise on high level decision making from the collected current and historical data for identifying useful trends and creating summaries of the data, query languages written for databases alone are not able to handle that. In order to effectively use the available data, advanced data analysis techniques such as data mining are required. Data mining (DM), also known as knowledge discovery in databases, has been successfully deployed to find trends and patterns of interest in many domains [8]. This paper explores applications of data mining to Healthcare in areas such as the evaluation of treatment effectiveness, management of healthcare, customer relationship management and the detection of fraud and abuse.

Data mining in clinical care and customer services areas

Data mining is increasingly being used to determine the diagnosis and the most suitable treatments that should be prescribed. It assists (1) to study what factors may interfere with a drug, for example high-fiber foods can interfere with the absorption of certain antidepressants and heart medicines [3], (2) to examine between allergies and a disease to find most effective treatment [10], (3) to correlate the presence of one set of symptoms with another set of symptoms in a diagnosis by analyzing the outcome [12], (4) to find common symptoms to aid diagnosis of an outbreak so that prevention can occur before the outbreaks, and (5) to identify chronic diseases such as who are the high risk patients and how to reduce their number of hospital stay and claims [5]. Data mining techniques can establish the behaviour patterns relevant to a disease. This helps administrators to determine the optimal lengths of hospital stay for specific diseases and to establish best practices for treating diseases [6].

Predictive modeling is immensely useful in predicting the cause of a disease and determining effective treatments based on many known inputs. For example to analyze what symptoms are responsible for thrombosis attacks (blood clots in the heart), a data mining algorithm examines the conditions pre and post the attacks of many patients. Information like: changes in lab results over time, patient demographics, thrombosis diagnosis symptoms leading to thrombosis and other collagen diseases; are extracted from clinical databases. The extracted patterns such as “high APPT levels are 80% responsible for thrombosis” help in interpretation of the patient profile. The accuracy for these kinds of predictions is reported as being above eighty percent [2].

Health Geomatics helps decision makers and service planners to understand the relationship between location and healthcare services [1]. Data mining can be used to evaluate the geography of diseases and healthcare resource utilization. The geography of diseases covers exploration, modeling spatiotemporal incidences of diseases and generating hypotheses of new disease. It helps to identify diseases that occur in a particular area. Health care institutions can then use this information to implement preventative schemes to reduce an outbreak. The information provided to health care officials is more powerful than any spreadsheet database table because it helps to discover new knowledge. Additionally, various information can be integrated to aid health related analysis, this includes: population (census and socioeconomic data), environmental and ecological data, topography, hydrology and climate data, health infrastructure (data on mortality, morbidity, disease distribution and health care facilities) and data needed to perform different types of health related analysis.

Data mining is also been used in modelling and analysis of complex data sets such as genome to understand the human genetic structure [4]. The pattern recognition of a cancer cell based on the genes with the use of predictive data mining technique helps physicians to build more precise treatments. Data mining programs can analyse data at a rate and level of complexity that is impossible to do with other methods. For health care professionals, disease progression is an example where sequence based data mining algorithms may be used. Attributes such as how the viruses or cancer cells spread, the different stages, symptoms etc are taken into consideration while analyzing the path of progression. The sequential patterns helped to determine which organ the disease is likely to spread to or confined to an organ according to the endpoint in the sequence generated.

To improve the clinical and management decision support, the health care industry is increasingly using data mining to determine health policies and priority areas, to coordinate care trials and in improving customer relationship management. Many hospitals have been applying DM techniques to the patients' survey collected. The results give hospitals the knowledge on patient requirements so that they can tailor services to suit patients' needs [9]. Predictive DM is also being used to match the clients' need with a suitably qualified staff member in a home-based health care environment by a health care agency where the coordinator had to match manually otherwise after receiving the request [11].

Application of DM techniques has also been used in financial areas of the healthcare organisation such as fraud detection and monitoring of cost and resources. Association rules are used for analysing the relationships among people, departments and organizations in health informatics A Health insurance organization can benefit from applying association rules to analyze their patient claims, in particular with the steady rise in health-care costs and the growing urgency to control these costs. For example, association rules can be used to detect patterns in ordering pathology services and the claims made by the patients. For example if a patient claims "test-B with test-C, there will be a 92.8% chance that a test-A would also be claimed". The Insurance company can use association rules to prevent fraud and inappropriate practices of requesting or providing services which are unreasonable, unnecessary or excessive (e.g., indiscriminate ordering of blood tests).

Conclusion and future trends

Over the past decade, data mining has been increasingly utilised by many major health institutes. Healthcare organisations have come to realisation that data, stored in the form of databases, are not being used to their maximum capability. Data mining methods are required for decision-making thus assuring quality healthcare. Data mining helps healthcare insurers to detect fraud and abuse; healthcare organisations in customer relationship management decisions; physicians to identify effective treatments and best practices; and patients to receive better and more affordable healthcare services.

The future of data mining in the field of healthcare is still an emerging process. Many aspects of data mining need to be introduced. One cannot depend entirely on a data mining output because its incorrect interpretation of the data can be a matter of life and death. The post-processing in which the outcomes are evaluated should be in depth. Alternative measures such as sensitivity, specificity, post-test probability and misclassification cost should also be considered when evaluating the quality of data mining outcome in a medical domain.

Dealing with more comprehensive data such as ultrasound images, temporal data and mixed data types, is a key direction for the future. In particular, when we have large datasets that contain rare events (temporal sequences), it is due to the risk factors that a straightforward application of data mining might not be able to identify frequent patterns of discovery such as low occurrence rate of adverse drug reactions or biomedical fluid flows during respiration.

Incorporating any associated knowledge from multiple locations significantly increases the efficiency of the mining process and the quality of the knowledge discovered. In particular, there is a wealth of information exists on Internet for medical domain. The mining process should take advantage of existing information in real time while making decision. A standard format for communication also needs to be devised such as XML. Research has shown that the better and improved results are achieved when combined the results of many DM algorithms and operations. Currently, each algorithm produces output in its own format. The integration takes extra processing. When the inputs to and outputs from a model uses the same expression language such as XML, the integration process will be easier.

Applications of Data Mining in Healthcare

Richi Nayak

School of Information Systems, Queensland University of Technology, Brisbane, Australia

Introduction

- Healthcare is one of the world fastest growing industries and profession [7].
- One of the main objectives of a healthcare organisation is its ability to obtain, store, analyse and be able to utilise data across the whole organisation effectively.
- The growth of databases in healthcare practices and researches are evident lately.
- Pattern-identification tasks such as detecting associations between certain risk factors and outcomes, ascertaining trends in healthcare utilisation, or discovering new models of disease in certain population rapidly becoming striking.
- Healthcares emphasise on high level decision making from the collected current and historical data for identifying useful trends and creating summaries of the data, query languages written for databases alone are not able to handle that.

Introduction

- In order to effectively use the available data, advanced data analysis techniques such as data mining are required.
- Data mining (DM), also known as knowledge discovery in databases, has been successfully deployed to find trends and patterns of interest in many domains.
- This paper explores applications of data mining to Healthcare in areas such as the evaluation of treatment effectiveness, management of healthcare, customer relationship management and the detection of fraud and abuse.

Data mining in clinical care

- Data mining is increasingly being used to determine the diagnosis and the most suitable treatments that should be prescribed.
- It assists
- (1) to study what factors may interfere with a drug, for example high-fiber foods can interfere with the absorption of certain antidepressants and heart medicines,
- (2) to examine between allergies and a disease to find most effective treatment,
- (3) to correlate the presence of one set of symptoms with another set of symptoms in a diagnosis by analyzing the outcome,

Data mining in clinical care

- (4) to find common symptoms to aid diagnosis of an outbreak so that prevention can occur before the outbreaks
- (5) to identify chronic diseases such as who are the high risk patients and how to reduce their number of hospital stay and claims.
- (6) to establish the behavior patterns relevant to a disease. This helps administrators to determine the optimal lengths of hospital stay for specific diseases and to establish best practices for treating diseases.

Data mining in customer services areas

- To improve the clinical and management decision support, the health care industry is increasingly using data mining to determine health policies and priority areas, to coordinate care trials and in improving customer relationship management.
- Many hospitals have been applying DM techniques to the patients' survey collected. The results give hospitals the knowledge on patient requirements so that they can tailor services to suit patients' needs.
- Predictive DM is also being used to match the clients' need with a suitably qualified staff member in a home-based health care environment by a health care agency where the coordinator had to match manually otherwise after receiving the request.

Data mining in customer services areas

Billing claims and fraud detection

- Application of DM techniques has also been used in financial areas of the healthcare organisation such as fraud detection and monitoring of cost and resources.
- Association rules are used for analysing the relationships among people, departments and organizations in health informatics.
- A Health insurance organization can benefit from applying association rules to analyze their patient claims, in particular with the steady rise in health-care costs and the growing urgency to control these costs.

Data mining in customer services areas

Billing claims and fraud detection

- Association rules can be used to detect patterns in ordering pathology services and the claims made by the patients.
- For example if a patient claims “test-B with test-C, there will be a 92.8% chance that a test-A would also be claimed”.
- The Insurance company can use association rules to prevent fraud and inappropriate practices of requesting or providing services which are unreasonable, unnecessary or excessive (e.g., indiscriminate ordering of blood tests).

Summary

- Over the past decade, data mining has been increasingly utilised by many major health institutes.
- Healthcare organisations have come to realisation that data, stored in the form of databases, are not being used to their maximum capability.
- Data mining methods are required for decision-making thus assuring quality healthcare.
- Data mining helps
  - healthcare insurers to detect fraud and abuse;
  - healthcare organisations in customer relationship management decisions;
  - physicians to identify effective treatments and best practices;
  - and patients to receive better and more affordable healthcare services.

Reality

- The future of data mining in the field of healthcare is still an emerging process.
- One cannot depend entirely on a data mining output because its incorrect interpretation of the data can be a matter of life and death.
- The post-processing in which the outcomes are evaluated should be in depth.
- Alternative measures such as sensitivity, specificity, post-test probability and misclassification cost should also be considered when evaluating the quality of data mining outcome in a medical domain.

Future

- Dealing with more comprehensive data such as ultrasound images, temporal data and mixed data types, is a key direction for the future.
- In particular, when we have large datasets that contain rare events (temporal sequences), it is due to the risk factors that a straightforward application of data mining might not be able to identify frequent patterns of discovery such as low occurrence rate of adverse drug reactions or biomedical fluid flows during respiration.
- Incorporating any associated knowledge from multiple locations significantly increases the efficiency of the mining process and the quality of the knowledge discovered.
- In particular, there is a wealth of information exists on Internet for medical domain. The mining process should take advantage of existing information in real time while making decision.
- A standard format for communication also needs to be devised such as XML. Research has shown that the better and improved results are achieved when combined the results of many DM algorithms and operations. Currently, each algorithm produces output in its own format. The integration takes extra processing. When the inputs to and outputs from a model uses the same expression language such as XML, the integration process will be easier.

Efficiency and Safety of New Radiofrequency Identification System in Japanese Hospital

Yuichiro Saito[a], Takashi Hasegawa[b], Tetsuo Sakamaki[c]

[a]*Division of Cardiovascular Medicine, Gunma University Hospital, Maebashi, Japan*
[b]*Informatics Education Center , International University of Health and Welfare, Tokyo, Japan*
[c] *Medical Informatics and Decision Sciences,Gunma University Hospital, Maebashi, Japan*

Abstract and objective

Radiofrequency identification (RFID) uses radio-frequency tags attached to people or objects to provide identification, tracking, and security under the general heading of automatic identification. New RFID system (UHF band, 953 MHz) has been available since April, 2005 in Japan. We tested efficiency and safety of new RFID system in our hospital. Electric fields produced by new RFID had no significant effects on cardiac pacemakers, implantable cardioverter defibrillators (ICD), and other medical devices(ex. Electrocardiogram recorder, cardiac monitor, intra-aortic balloon pumping, infusion pump, and respirator) in our hospital. New radiofrequency tags seemed to provide extensive patient identification and to track capital equipments within our hospitals. Healthcare systems today are increasingly complex and interrelated processes, while new RFID technologies will provide opportunities for enhanced patient care and safety in Japanese hospital.

Keywords:

cardiac pacemaker, implantable cardioverter defibrillators, healthcare, patient safety

Introduction

Radiofrequency identification (RFID) has recently begun to receive increased interest in supply chain, in order to increase the efficiency and visibility of material and information flows. RFID may address to improve safety and increase in productivity. New RFID system (UHF band, 953 MHz) has been available since April, 2005 in Japan. However, there has been no attempt to determine whether electric fields produced by new RFID can influence cardiac pacemakers, implantable cardioverter defibrillators (ICD), and other medical devices in our hospital. We further examined to track new IC tags attached to people and medical equipments in hospitals.

Our data may provide the potential benefits, the area of applications, and the corresponding strategies of RFID in hospital environments.

Methods

We examined effects of RFID system on 7cardiac pacemakers and 5 ICDs in 0.18 % salt solution, similar electric condition to human body. The experimental conditions for interference induced by RFID were between a homogeneous electric field perpendicular to the area formed by the antenna and radio-frequency tags.

We next tested whether Electrocardiogram (ECG) recorder, ECG monitor, intra-aortic balloon pumping (IABP), infusion pump, and respirator in our hospital could work normally under new RFID system.

Furthermore, we evaluated to track new IC tags attached to people and medical equipments in our hospital.

Results

Electric fields produced by RFID had no significant effects on cardiac pacemakers. The RFID systems did not interfere with ICDs.

ECG recorder, ECG monitor, IABP, infusion pump, and respirator were worked normally under operation of RFID systems.

Radiofrequency tags attached to people and capital equipments within our hospitals provide more extensive identification than traditional bar coding can. New RFID tags increased read accuracy, even with the tag placed on metallic objects. However, the read range seemed to be reduced from an average of 2.5m.

Conclusion

RFID may be ultimately used for many of the functions currently carried out using bar coding if the cost of RFID comes down. Healthcare systems today are increasingly complex. RFID is a technology that will have a profound impact on effective and safe patient care in Japanese hospitals in near future.

A Comprehensive Health Information System to Support Health Promotion and Disease Prevention in Japan

Machi Suka[1], Katsumi Yoshida[1], Takeshi Kubodera[2], Keiko Ogawa[3], Fumiyoshi Katayama[4], Jitsuzo Yamazaki[5]

[1] Department of Preventive Medicine, St. Marianna University School of Medicine, Japan
[2] NTT DATA Corporation, Japan
[3] T.T.T. Kabushikikaisya, Japan
[4] Next Ware Corporation, Japan
[5] Top Business System Corporation, Japan

Abstract

The Japanese Ministry of Health, Labour, and Welfare intends to reform the health promotion and disease prevention system in 2008. We are developing a comprehensive health information system that will support health examination, health education, and outcome assessment in compliance with the newly-proposed national guidelines. The system adopts a state-of-the art secure communication protocol - TCP2, which will enable information sharing based on personal identification and hardware- and software-independent security.

Keywords:

health information system, internet, health examination, health education, outcome assessment, Japan

Introduction

In order to promote the prevention of cardiovascular diseases, the Japanese Ministry of Health, Labour, and Welfare intends to reform the health promotion and disease prevention system in 2008. Under the new system, medical insurance organizations will be responsible for providing annual health examination and health education for every insured person aged 40 years and implementing outcome assessment. They fervently hope for a comprehensive health information system because they will have to deal with health information that is collected from various sources (Figure 1).

In 2006, we established a university-industry collaboration project with the aim of developing a comprehensive health information system to support health promotion and disease prevention in Japan (J-CHIS).

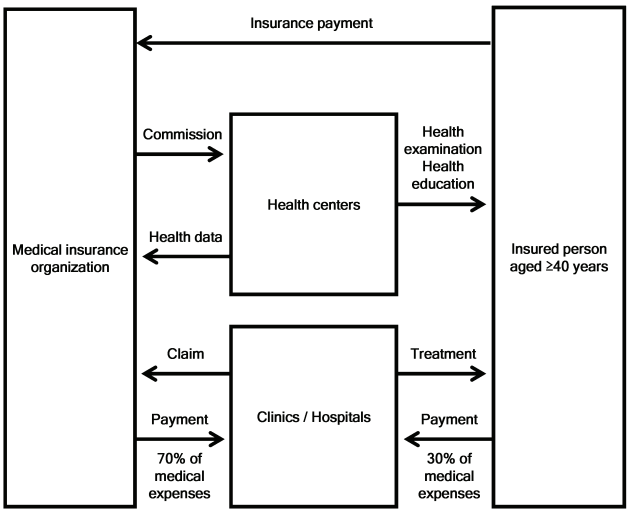

Figure 1 - Overview of the public health system in Japan

Methods

The J-CHIS is designed to support health examination, health education, and outcome assessment in compliance with the newly-proposed national guidelines (available for download at http://www.mhlw.go.jp/bunya/kenkou/seikatsu/index.html).

Results and discussion

The J-CHIS consists of three components - health data, health education resources, and medical insurance data (Figure 2). Health data shown in Table 1 are collected from health centers where the insured people receive health examination and health education. Notice that each medical insurance organization will commission more than one health center to provide health examination and health education for the insured people, and health examination and health education for each insured person will possibly be conducted at different health centers. Health education resources include information about health promotion and

disease prevention and instruction materials that are useful for health education at health centers or at home. Medical insurance data are collected from clinics and hospitals where insured people receive medical treatment, as part of the procedures for payment of medical expenses.

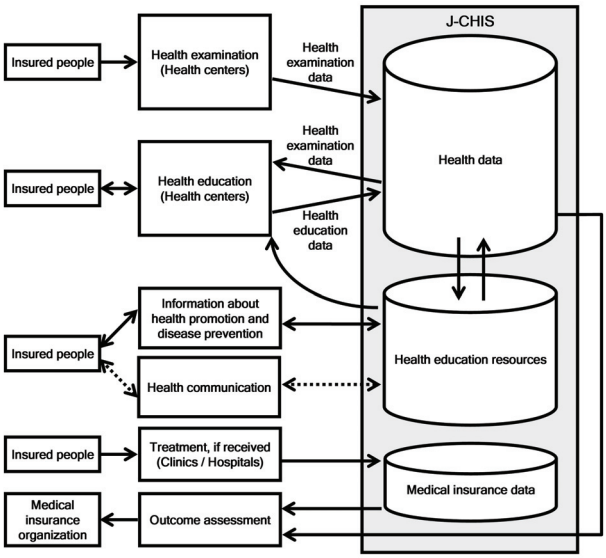

Figure 2 - Overview of the J-CHIS

Table 1 - Health data

Health examination
Height, Weight, BMI, Waist circumference, Blood pressure, Blood glucose, HbA1c, LDL, HDL, Triglyceride, AST, ALT, GT, Urinalysis, Smoking habit, Medication
Health education
Participation in health education sessions, Goal setting

The users will access each component through the Internet. Communication on the Internet is timely and easily accessible, but data on the Internet is vulnerable. The J-CHIS requires vigorous security measures to preserve strict privacy. Moreover, the components of health data and health education resources will be accessed by various people from various places using various computer hardware; insured people will check their own health data and seek information about health promotion and disease prevention; health center staff will input and check their clients' health data and use instruction materials for health education at health centers. It is difficult to prepare specific software that is usable under such wide variety of circumstances. In order to deal with these problems, the J-CHIS adopts a state-of-the-art secure communication protocol - TCP2 (developed by T.T.T. kabushikikaisya, Tokyo, Japan; available for download at http://www.tttnet.ne.jp/tcp2.html). TCP2 performs encryption, certification, key switch, and firewall on the fourth (transport) layer of the Open System Interconnection (OSI) reference model (Figure 3). The use of TCP2 makes it possible 1) to identify the person who accesses the system, 2) to establish secure communication independent of hardware and software, and 3) to build strict privacy and security measures into the system. Information sharing based on personal identification and hardware- and software-independent security will be realized in the J-CHIS.

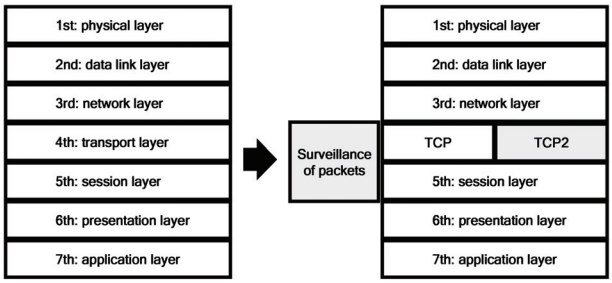

Figure 3 - TCP2

Conclusion

The J-CHIS will support health examination, health education, and outcome assessment in compliance with the newly-proposed national guidelines. It will contribute to promoting the Japanese health promotion and disease prevention system by information sharing based on personal identification and hardware- and software-independent security.

A Comprehensive Health Information System to Support Health Promotion and Disease Prevention in Japan

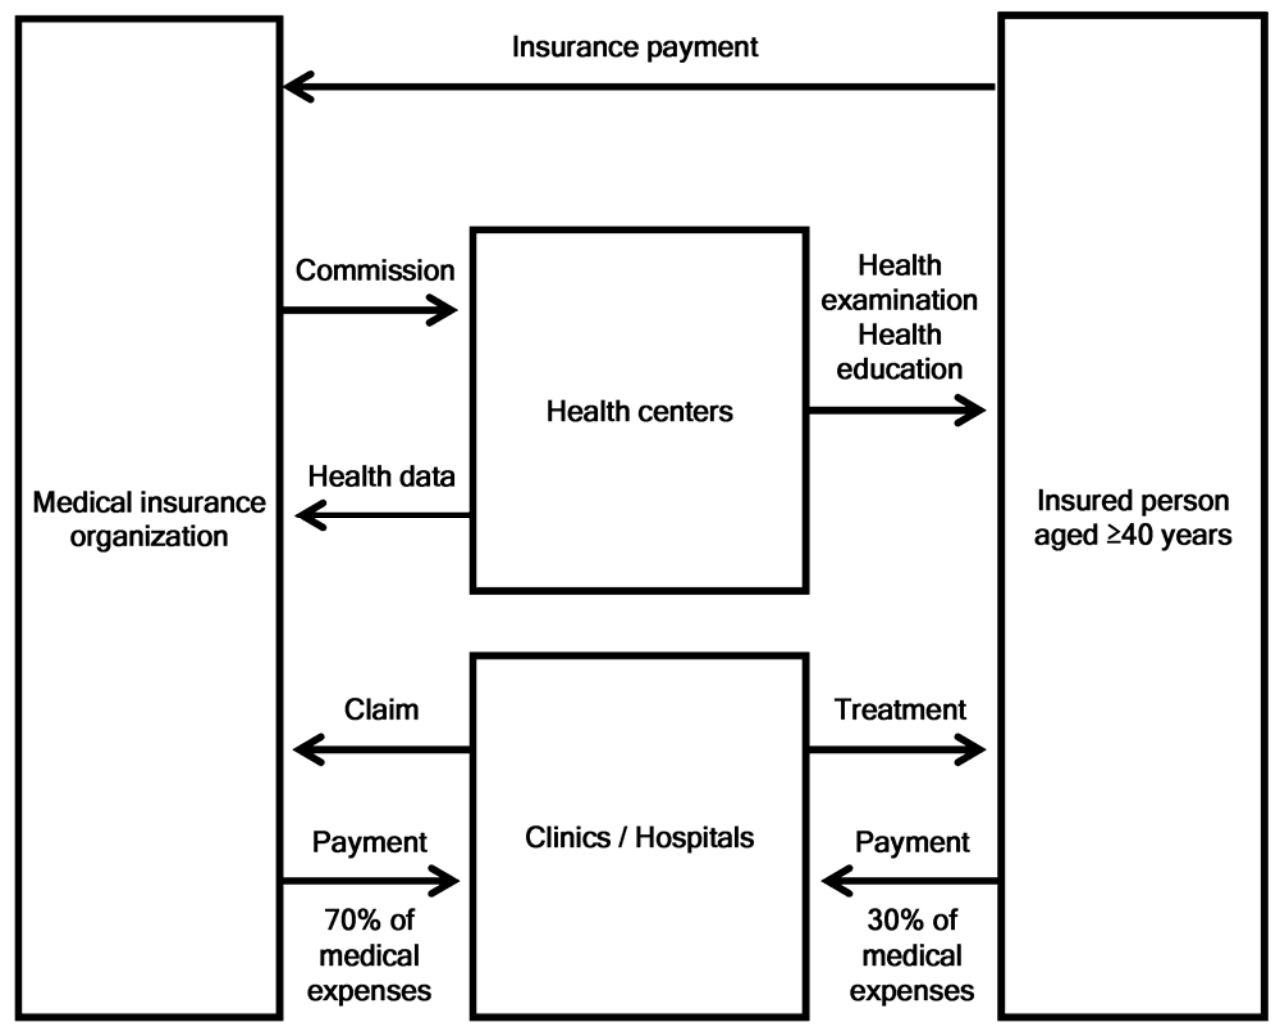
Suka M[1], Yoshida K[1], Kubodera T[2], Ogawa K[3], Katayama F[4], Yamazaki J[5]

[1] *St. Marianna University School of Medicine, Japan*
[2] *NTT DATA Corporation, Japan*
[3] *T.T.T. Kabushikikaisya, Japan*
[4] *Next Ware Corporation, Japan*
[5] *Top Business System Corporation, Japan*

Background

- The Japanese Ministry of Health, Labour, and Welfare intends to reform the health promotion and disease prevention system in 2008.
- After the introduction of the system, medical insurance organizations will be responsible for providing annual health examination and health education for every insured person aged ≥40 yrs and implementing outcome assessment.
- And they will have to deal with health information that is collected from various sources (Figure 1).

Figure 1 – Public health system in Japan



Objective

- In 2006, we established a university-industry collaboration project with the aim of developing a comprehensive health information system to support health promotion and disease prevention in Japan (J-CHIS).

Methods

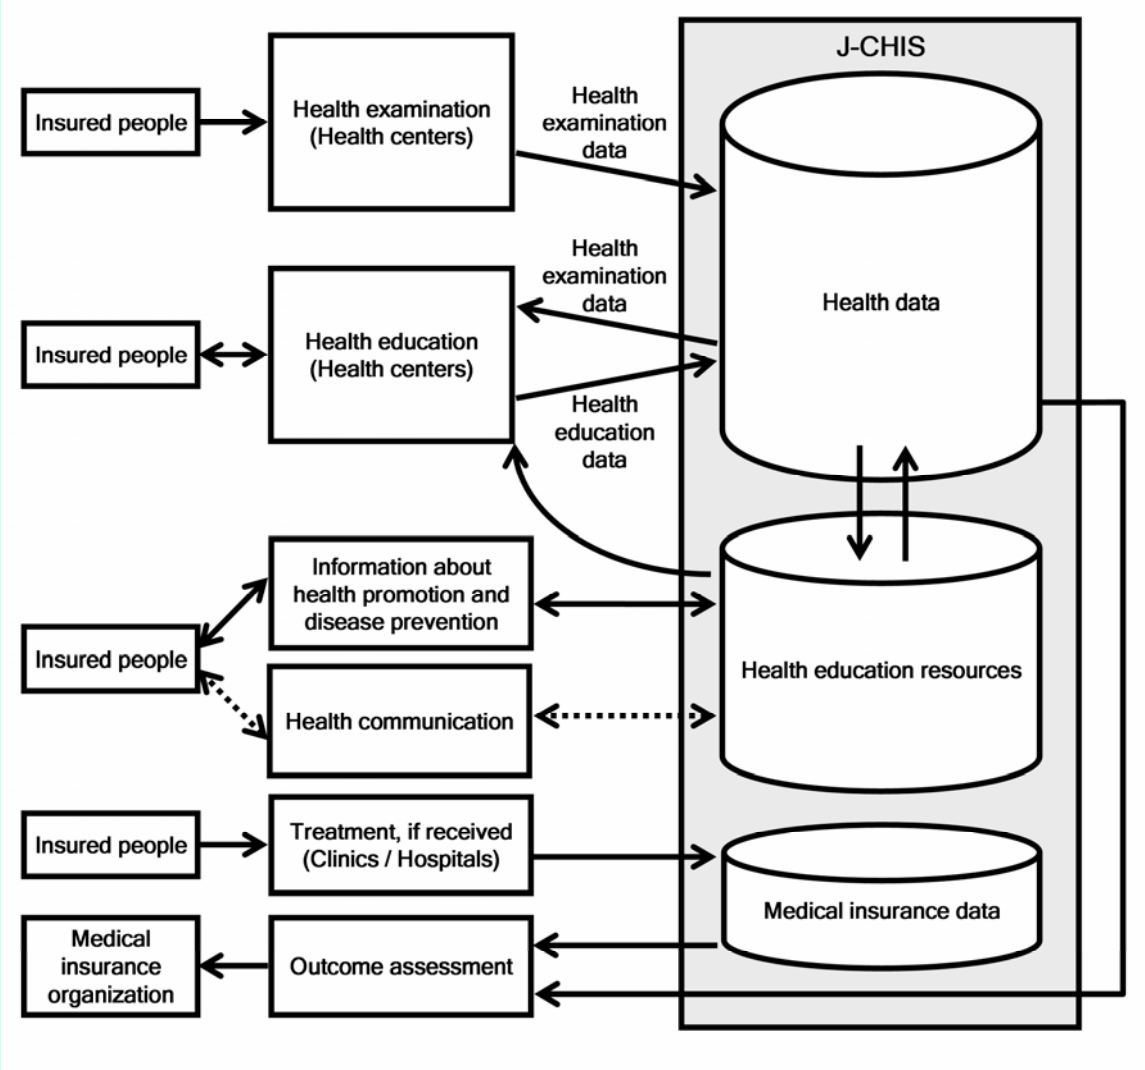
- The J-CHIS is designed to support
  - health examination
  - health education
  - outcome assessment

  in compliance with the newly-proposed national guidelines (available at http://www.mhlw.go.jp/bunya/kenkou/seikatsu/index.html).

Overview of the J-CHIS

- The J-CHIS consists of 3 components (Figure 2):
  - “Health data” are collected from health centers where the insured people receive health examination and health education.
  - “Health education resources” include information about health promotion and disease prevention and instruction materials.
  - “Medical insurance data” are collected from clinics and hospitals where insured people receive medical treatment.

Figure 2 - The J-CHIS



Problems to be solved

- The users will access each component through the Internet.
  - Communication on the Internet is timely and easily accessible, but data on the Internet is vulnerable.
- The components of health data and health education resources will be accessed by various people from various places using various computer hardware.
  - It is difficult to prepare specific software that is usable under such wide variety of circumstances.

Breakthrough

- The J-CHIS adopts a state-of-the-art secure communication protocol - TCP2 (developed by T.T.T. kabushikikaisya, Tokyo, Japan; available at http://www.tttnet.ne.jp/tcp2.html).
- TCP2 performs encryption, certification, key switch, and firewall on the 4th (transport) layer of the Open System Interconnection (OSI) reference model.

Effectiveness of TCP2

1) to identify the person who accesses the system
2) to establish secure communication independent of hardware and software
3) to build strict privacy and security measures into the system

Information sharing based on personal identification and hardware- and software-independent security will be realized in the J-CHIS.

Conclusion

- The J-CHIS will support health examination, health education, and outcome assessment in compliance with the newly-proposed national guidelines.
- And it will contribute to promoting the Japanese health promotion and disease prevention system by information sharing based on personal identification and hardware- and software-independent security.

A Web-based Data Visualization System to Present Infectious Disease Surveillance Data

Masashi Inoue[a], Shinsaku Hasegawa[b], Akihiko Suyama[c]

[a] *Information Media Center, Tottori University, Yonago, Japan*
[b] *Hokkaido Institute of Public Health, Sapporo, Japan*
[c] *Department of Epidemiology, Radiation Effects Research Foundation, Nagasaki, Japan*

Abstract

Based on the Japanese infectious disease surveillance scheme, weekly or monthly reports on infectious diseases are collected from all over the country. We have developed a Web-based data visualization system to make the infectious disease surveillance data more comprehensible for medical personnel. The main feature of the system is that it automatically generates Flash animation by using the collected numerical data which visualizes the time series and spatial shift of the case incidents of disease simultaneously on the home page. This system can provide support for medical personnel to grasp the trend of infectious diseases morbidity and to warn them of any impending outbreak of the diseases.

Keywords:

web-based system, infectious diseases, flash animation

Introduction

The Japanese infectious disease surveillance scheme has been established to detect infectious disease outbreak in early stage, to identify the causative viral strains and to rapidly assess related morbidity and mortality. Based on this schemes, information gathered weekly or monthly on infectious diseases are collected from assigned hospitals or clinics and distributed by print or by home page through the Internet. Because the information reported on the home page is usually numerical data or simple graphic chart, it is difficult for medical personnel to grasp the trend of infectious disease morbidity all over the country. To make a scheme function well, it must provide a good representation of the results of the surveillance [1]. We thought that an animated representation of the data would be a useful way to visualize the time series and spatial shifts of the case incidents of disease simultaneously. However, it is time consuming task to generate animation based on the numerical data gathered weekly or monthly. So, we have developed a web-based data visualization system which can automatically generate Flash animations or graphic images and can visualize time series and spatial shifts of case incidents of disease simultaneously according to the numerical data collected on the home page.

Methods

The operating system used is a Windows2000 Server with Apache 2.0 and MySQL 4.1 as the Web server software and the database management system, respectively. PHP4 was used as a server-side script language and Flash Action Script (FAS) was also used to create animation. The hardware in use for the server is an IBM PC compatible computer with Pentium 4 processor, 512MB of RAM, 80 GB hard discs and 100 base-T network interfaces. Figure 1 shows a block diagram of the server computer setup.

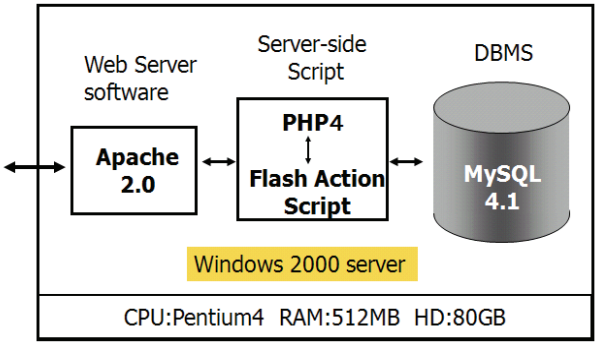

Figure 1 - A block diagram of the server computer setup

The procedure for presenting the animation or graphic image is as follows:

1) the PHP4 server-side script interprets the query keys' input in the request form and retrieves suitable data from the database;
2) the server-side script then passes the data to FAS and FAS automatically generates Flash animation according to the data passed;
3) besides the animation, the PHP4 server-side script automatically generates graphic image file, such as PNG format file, using the data retrieved;
4) Apache sends the Flash animation or image file to the client computer;
5) and the clients' browser displays the animation or image.

A pilot version of this system is usable as a hyperlink at http:// infectsrv2.med.tottori-u.ac.jp/infectious/itis3.html.

Results

At this time, the information stored in the database system is 1) data related to 47 prefectures in Japan and 2) 21 administrative medical districts on the island of Hokkaido, the largest prefecture in Japan located off the northernmost tip of the main island. In case 1), epidemic parotitis data from January 1990 to October 2006 was collected and reflects about 80,000 cases. Case 2) represents epidemic parotitis and measles data collected from January 1990 to February 2007 and reflects about 18,000 cases. This system can present the following three kinds of animation or graphic image:

1) Flash animation simultaneously showing geographical and progressive changes in morbidity throughout the country (Fig. 2): as soon as the start button is clicked, the animation starts and each prefecture is classified into five color coded levels, showing the intensity of the epidemic, which change accordingly as the time progress;
2) A three dimensional bar chart showing annual weekly series rates of occurrence in each prefecture (Fig. 3): The x-axis and y-axis reveal annual weekly periods (1 year is shown as 52 weeks) and rates of occurrence in each prefecture, respectively;
3) A map chart showing the morbidity of any arbitrary 4 consecutive weeks in Hokkaido (Fig. 4): the map shows the intensity of the epidemic of each 21 administrative medical districts by color coding.

Discussion

To make the surveillance scheme function well, it is important to provide a good representation of the data collected in compliance with users' requests. It has also been mentioned that two kinds of output are useful for monitoring the morbidity of epidemic disease: time series of incidents of cases and spatial spread of infectious disease incidents [2]. Our system can visualize time series and spatial shifts of the case incidents of disease simultaneously as images or animations on the home page. Because the animation generated is in Flash movie format, almost any browser can show it. The system can provide support for medical personnel to quickly grasp the trend of infectious diseases morbidity and to warn the general population of any impending outbreak of diseases. We believe this makes infectious disease surveillance data more easily comprehensible for medical personnel.

Abstract

Information retrieval (IR) is a technology to help people find information, however it is hard to formulate information need into just a few words. In order to solve this problem, we adopted knowledge ontology in the IR process to design a query expansion. We implemented three IR models, Vector Space Model (VSM), Hidden Markov Model (HMM), and Topical Mixture Model (TMM) and evaluated these models with and without ontology-based query expansion. In conclusion, TMM has the best performance and people who are not familiar with specific domain knowledge, the ontology-based query expansion can help them generate queries and obtain relevant information.

Keywords:

ontology, information retrieval, Vector Space Model, Hidden Markov Model, Topical Mixture Model

Introduction

Due to the advancement of computer technologies, tremendous volumes of biomedical data have been digitized. In order to retrieve useful information from these data, the development of intelligent information retrieval (IR) methods becomes more important. In most IR systems, term matching is a common approach; however no searching result can be obtained if query terms are not found in the system lexicon. For biomedical professionals, they know what keywords can be used to find correct information; for people who don't have enough knowledge, it is difficult to obtain accurate information by using inappropriate keywords. Thus, we developed an ontology-based query expansion adopted in three IR models, Vector Space Model (VSM), Hidden Markov Model (HMM), and Topical Mixture Model (TMM) and evaluated the performance of these IR models with and without ontology-based query expansion.

Methods

Information Retrieval Model

Vector Space Model

Each document, D_i, is represented by a feature vector, $\overrightarrow{D_i}$; each component, $g(t)$, in the vector is associated with the statistics of a specific index term, t,

$$g(t) = \left(1 + \ln\left(c(t)\right)\right)\ln\left(N / N_t\right) \tag{1}$$

where $c(t)$ denotes the occurrence count of term t within document D_i, and the logarithmic operation is used to compress its distribution. The term weighting scheme, $1+ln(c(t))$, is a variation of conventional schemes. N_t is the total number of documents in the collection in which the specific indexing term t appears, and N is the total number of documents in the collection. A query, Q, is also represented by a vector, $\vec{Q}$, in which every component is a word in the query. The cosine measure is used to estimate the relevance between query Q and document D:

$$R(Q,D) = \cos(\vec{Q},\vec{D}) = \left(\vec{Q} \bullet \vec{D}\right) \Big/ \left(\left\|\vec{Q}\right\| \cdot \left\|\vec{D}\right\|\right) \tag{2}$$

HMM/N-gram Model

In our implementation of the HMM/N-gram model, each document is composed of a mixture of N-gram distributions, which can be represented as a special case of HMM. The N-gram distributions are estimated on the basis of frequency of words or word pairs occurring in documents and are smoothed using linear interpolation with background unigram or bigram language models estimated from a large outside text corpus. In this study, we only implemented HMM/Unigram model. For example, given a query Q and a document D, the relevance measure for the HMM/Unigram model can be expressed as:

$$P\left(Q|D\right) = \prod_{n=1}^{N}\left[m_1 P\left(q_n|D\right) + m_2 P\left(q_n|Corpus\right)\right] \tag{3}$$

where $P(q_n|D)$ is the unigram probability of a index term q_n within the document D and $P(q_n|Corpus)$ is the probability of an index term q_n within the large corpus. Weighting parameters, m_1 and m_2 are summed to one and tied among the entire document collection. They are opti-

mized using the expectation-maximization (EM) algorithm.

Topical Mixture Model

Each document D_i is interpreted as a mixture model and a set of k latent topical distributions characterized with unigram language modeling are used to predict the input query words and each of the latent topics is associated with a document-specific weighting parameter.

$$P(Q|D_i) \approx \prod_{n=1}^{N} \sum_{k=1}^{K} P(q_n|T_k) P(T_k|D_i) \quad (4)$$

where $P(q_n|T_k)$ is the probability of the query word q_n occurring in a specific latent topic T_k, and $P(T_k|D_i)$ is the posterior probability of the topic T_k conditioned on the document D_i, with the constraint $\sum_{k=1}^{K} P(T_k|D_i) = 1$. The key idea of TMM is that the relevance measure of a query word q_n and a document D_i is not calculated directly based on the frequency of q_n occurring in D_i, but instead based on the frequency of q_n in the latent topic T_k as well as the likelihood that D_i generates the respective topic T_k.

Query expansion based on the ontological structure

The SARS ontology, which was developed by referring to biomedical literatures, medical textbooks, and MeSH was used to designed an ontology-based query expansion: First, synonyms of query words are extracted from a synonym database as additional query words. Then if a query word is matched in the ontological term, its precedent parent node terms, its sibling node terms, and its descendant child node terms are also extracted as additional query words. In addition, the synonym extraction procedure is carried out again to find synonyms of the extracted ontological terms. Finally, the original query is expanded to a vector that includes SARS related words and corresponding weightings.

$$\{(q_1, W_1), (q_2, W_2), ..., (q_k, W_k), ...(q_n, W_n)\} \quad (8)$$

Results

We defined two retrieval modes, ontology-based mode and keyword-based mode for evaluation of IR model with and without ontology-based query expansion. The values of precision for the three IR models are shown in Table 1. In both retrieval modes, TMM has the best performance than the other IR models. In general, the values of precision of ontology-based mode are always lower than the keyword-based mode.

Table 1 - Values of precision of three IR models

IR Model	VSM	HMM	TMM
Keyword-based	0.5047	0.4896	0.7346
Ontology-based	0.4798	0.3631	0.6544

The interpolated recall-precision curves of three IR models in the ontology-based mode are shown in Figure 1. Except for recall level 0, the precisions of TMM are much higher than those of VSM and HMM. The patterns of the recall-precision curves of these models are different: TMM curve is concave downward and VSM and HMM curves are concave upward. This means the acceleration of decrease in precision with increase in recall of TMM is negative and those of the other two models are positive. Usually, the models are operated in the range of low recall values; therefore, TMM is the best model we should choose for the reason that it's curve slope in that range is the lowest among the three models.

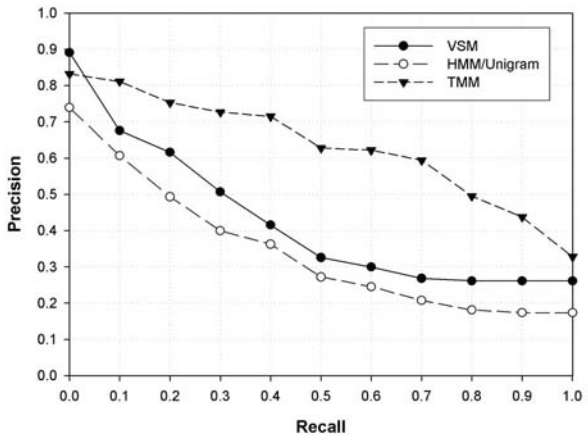

Figure 1 – Interpolated recall-precision curves of VSM, HMM/Unigram model, and TMM with ontology-based mode

Discussion

The value of precision of TMM in both keyword-based and ontology-based retrieval mode is much higher than other IR models. In Figure 1, the interpolated recall-precision curve of TMM is more stable than others. Thus the performance of the ontology-based query expansion is the best when it is applied to TMM. Relevant information is required to train TMM, however it is usually unavailable at beginning of building an IR system. An alternative way is that using VSM or HMM to develop the IR system and logging user's queries and reviewed documents. Then we can establish relevant information according to searching logs for training and updating model parameters. In addition, people usually review only top 10 or 20 records from searching results. For VSM and HMM, precision at recall level 0 is greater than 0.7 in the ontology-based mode. Therefore the performances of VSM and HMM are good enough when people only review preceding retrieval results.

Conclusion

We used ontological structure to design query expansion and applied it to three IR models. The evaluation results showed that the performance of TMM is better than other two IR models in both keyword-based and ontology-based retrieval mode. In practical use, we conclude that for users who are familiar with specific knowledge, using keyword-based method to obtain more precise information; otherwise, using ontology-based query expansion to generate queries and find relevant information.

IT Strategies for Sustainable Healthcare Systems: Case Studies

György Kozmann, István Vassányi, Balázs Végs

University of Pannonia, Department of Information Systems

Abstract

In this paper the challenge of sustainable healthcare has been addressed by examples of intelligent cost-effective IT solutions multiplying human capabilities in three different directions. Intelligent monitoring improves the frequency and depth of patient surveillance without any hotelling expenses. The NEUROWEB project is promising an accelerated knowledge acquisition at the frontline of neurology and genomics, hopefully leading to personalized and optimal treatments. Brvain bioelectrical imaging provides a novel low-cost, high spatio-temporal resolution technology of brain studies which directly address the physical phenomena behind the neural activity. Case studies outlined emphasize specific features essentially contributing to sustainability.

Keywords:

brain mapping, patient-monitoring, telemedicine, information distribution, genomics

Introduction

It is generally agreed that the steadily growing expenses of healthcare cannot be stopped without intelligent solutions saving manpower in routine procedures of care or without well organized knowledge centers efficiently disseminating validated information between specialists, or without equipments with improved diagnostic capabilities. A further aspect of the design of sustainable systems is the involvement of new technologies like mobile phones, internet, etc. The case studies shown below provide examples with obvious benefits in this direction.

Materials and methods

In sustainable healthcare systems patients and medical doctors should benefit for a long run from the application of Information Technology. Improved diagnostic procedures, easy and continuously updated knowledge management,, solutions for home care are just some examples. In the followings, we briefly discuss three example projects applying state-of-art IT.

General frame of a cardiovascular tele-monitoring system

Telemedicine provides a cost-effective and comfortable means of medical care [1, 2]. There are several Tele-Monitoring Systems (TMS) that can receive ECG and other signals via various telecommunication connections. In the usual setup, a portable device records and stores the measured electrical signals which are transmitted via modem-based digital links [3], fax [4], or phone [5] to a workstation. After signal processing, the results can be displayed, or printed for human evaluation.

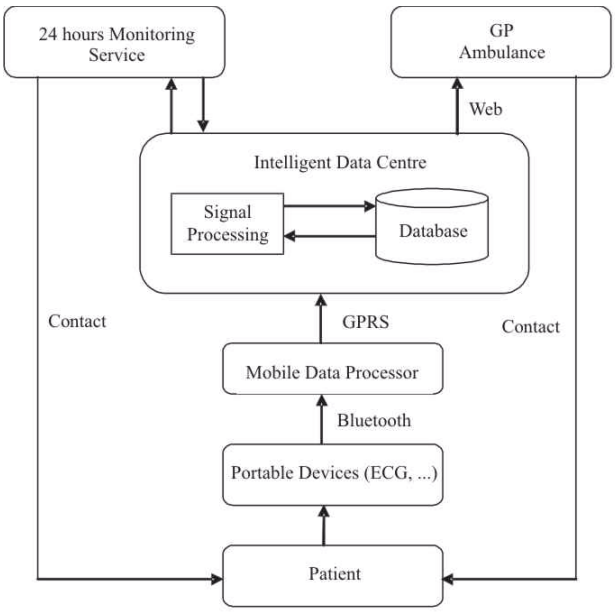

Figure 1 - The TMS architecture

The architecture of our TMS is shown in Fig 1. The monitoring procedure starts at the Monitoring Service by recording a sample of 12-lead ECG measurements. Our methods use these ECGs as baseline measurements. Later on, a portable 3-lead ECG (I, II, V2) device is used to monitor the patients in their home and to transmit the ECG results via Bluetooth to a mobile phone, which forwards them to a data centre. The ECG sampling rate of the device (300Hz, 600Hz) and duration (30 sec., 60 sec.) can be changed remotely from the Monitoring Centre at any time. The portable ECG recorder is shown in Fig 2. If needed (e.g. in the case of electrode reversal), an automatically generated warning SMS and/or e-mail is sent to the patient. Then an AI expert system evaluates the results, and if needed an alarm signal and the related actual and the previously collected trend data are sent to the 24-hour

Monitoring Service. An alarm signal is an indicator of a significant change in a clinical parameter (or parameter vector). The final medical diagnosis is to be drawn by the cardiologist at the Monitoring Centre. To avoid frequent false alarms, special attention was paid to the personalized analysis of significant and malignant changes in the monitored parameters.

Figure 2 - The mobile ECG device

Intelligent solutions

We added three intelligent features to enhance the TMS, electrode reversal detection, personalized evaluation and lead reconstruction (not detailed in the paper).

Electrode reversal detection. The 3 signal electrodes and the fourth ground electrode can be placed in distinct 24 configurations, out of which only one is correct. This error is often made by inexperienced users. The correlation between reversed and normal (correctly placed) signal morphology is examined in all the 24 cases. We use linear discriminant analysis to decide whether the electrodes were reversed or not. If there is an incoming home measurement in the Intelligent Data Center, the algorithm systematically generates the 18-element vector based on the incoming recent measurement and the baseline measurement stored in the database. In case of interchange the patient will be notified with a warning SMS or/and email to check the placement of the electrodes.

To test the method, we used a training sample of 598 ECG records (60 sec., 1KHz, 3-lead) in each group. The testing sample included 65 ECGs in each reversal group (60 sec., 600Hz, 3- lead) and a single baseline measurement (60 sec., 600Hz, 12-lead) for each subject. The linear discriminant analysis revealed that out of the 65 properly placed ECGs 64 were correctly classified, which means 98.4% sensitivity. In 14 reversed groups the sensitivity was at least 90%, in 4 group the sensitivity was between 80% and 90% and in 3 groups the sensitivity was lower than 80% (51% worst case). Out of the 1495 interchanged ECGs 1316 were classified correctly, which means 88% specificity.

Personalized evaluation. A new learning type interpretation algorithm was developed to make the evaluation system personalized. The method calculates the personalized decision thresholds for several P, Q, R, S, T wave-parameters of the patient. If any of the ECG parameters of the incoming measurements exceeds the decision threshold, then a significant change in that ECG parameter is assumed to be present. At first threshold calculation is based on published standard deviations representative on the whole population. Based on home/monitored signals the thresholds are gradually adapted to the patient monitored.. After 100 home measurements the threshold is calculated exclusively from the patients' own measurements. This algorithm automatically considers both long term ECG variability and small, habitual electrode misplacement errors

The Tele-Monitoring System is currently being implemented as an application for monitoring persons under extreme working conditions. The implementation supports further monitored signals like temperature, blood oxygen level and acceleration.

Advanced knowledge dissemination: The NEUROWEB project

NEUROWEB is a startup European research project in the Sixth Framework Program of the European Community, aiming to integrate and share knowledge and information in neurology and neurosciences. The project is led by the National Neurological Institute "Carlo Besta" of Milano, Italy. The consortium has four IT companies, five academic institutions, one governmental body and four neurological/stroke clinics in Italy, Hungary, Netherlands and Greece. The project runs from mid-2006 to 2008 and the expected outcome is an internet-based software framework that allows:

- the integration into a single virtual database the clinical and genetic databases of the 4 participating clinical centres, which are different in structure, language, territorial area and pathologies of interest;
- to query also the databanks present on the web containing human polymorphism profiles in normal and pathological populations.

For the professional user, the system provides the following main functions:

- Clinical diagnosis validation based on Clinical Protocol Paths. This means that the system will search for cases with a similar anamnesis and medical data using a pre-defined set of clinical protocols. Similarity analysis will be based on standard data mining tools and on a reference ontology that connects the various databases. of the clinical partners (ontology driven reasoning). See Clinical Engine and Semantic Engine in Fig. XX..

- Genomic Polymorphic Analysis. It will be possible to inspect a patient's genomic status against the state-of-art in Genomic Research to contrast genomic and clinical data. (Genomic Engine in Fig. XX) The genomic engine will mine public genomic databases in order to extract (and continuously update) a collection of polymorphisms related to the pathologies of interest; then it will cross-check these polymorphisms against the available genomic information concerning specific patients.

Special system components will automatically search available public databases and other resources and offer new scientific results that bear importance for a given case.

We plan to support "learn by search and example": an IT architecture which will remember users experience and offer the capability to verify existing Patient Records (Clinical and/or Genomic data) by new experimental Clinical Protocol Paths.

The architecture of the planned system with the Semantic, Clinical and Genomic Engines is shown in Fig. 3.

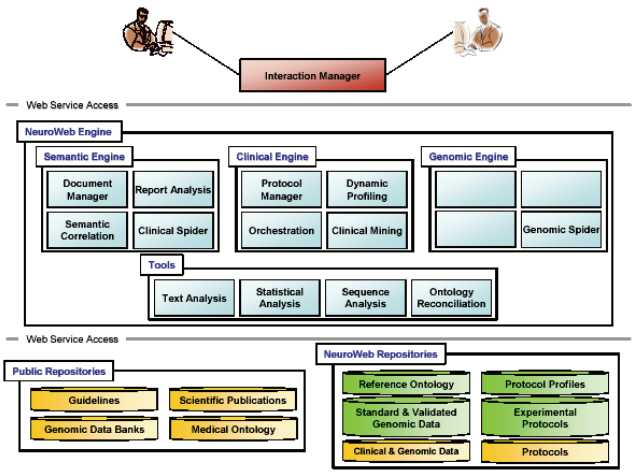

Figure 3 - The NEUROWEB architecture

The protocol manager will enable users to define, modify, store, retrieve according to criteria defined by clinicians and execute clinical protocols. Moreover, it will support the definition of new experimental protocols that can be defined and statistically validated by the NEUROWEB system. Protocol execution will rely on a protocol enacter that orchestrates and invokes remote web services, and a clinical miner that supplies the functionalities to extract data from the clinic databases involved in the project.

The Semantic Navigator, joined to a Text Miner, will support intelligent searches on distributed databases of clinical cases, with direct reference to the information stored in the Patient Records, through a unified interface shielding the user from the details of organization specific implementation. The Clinical Miner will learn the issued meta-queries and also rank them.

The whole system will also include:

- A tele-consulting system based on discussion forums. Each thread in discussion forms should be linked to a case, a query (several cases) or to a protocol. Users should be able to retrieve past discussion on the basis of queries, cases, and protocols.
- A front-end for the MEDLINE database, enabling to associate clinical papers to queries. Users should be able to navigate from cases and workflows to relevant literature, and vice versa. Associations should be established in a manual manner by clinicians.

The first results of the project are expected by mid-2007.

Elaborating new modalities: The BEM project

The BEM project's (Brain Electro-Mapping) aim is to create a system that with the modeling involved takes the challenge of creating a high-resolution mapping method that is able to show the possible changes in brain function after a stoke incident at the level of bioelectric equivalent sources. The investigation of brain plasticity requires the highest possible resolution available. The main goal is to create a cost-effective alternative to current solutions (fMRI, PET) that is comparable to those in spatial resolution, while significantly better in temporal resolution, allowing a rather accurate characterization of within brain communications. This project if financed by the Government of Hungary, runs from mid-2004 to mid-2007.

A high percentage of the stroke affected patients (over 70%) tend to recover from their state through a healing, functional regeneration process (this property of the brain is called plasticity). To understand this process and extend our current knowledge we develop a brain source mapping and imaging modality which could intensely help doctors at supporting and accelerating the process by therapy, and could validate drug effects promising this speed-up. The system presented herein solves the inverse EEG problem taking EEG measurements to calculate bio-electric activity at cortical level. The problem is solved using the mathematical description of bio-physical processes. Figure 4 presents the tasks of such a system, the process of EEG-based brain mapping.

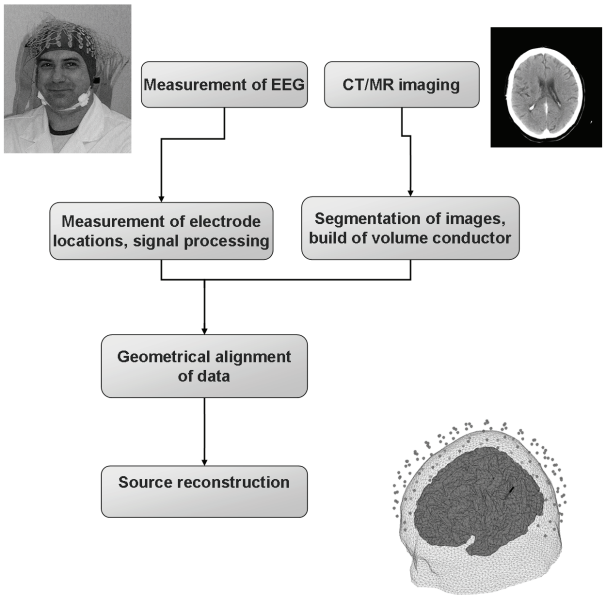

Figure 4 - The BEM architecture

Surface Laplacian maps One of the other methods the project is to utilize is the surface Laplacian maps. This method calculates cortical radial currents based on the EEG (scalp recorded potential-distribution). This method has high importance and tradition in medical analysis of brain activity, therefore this was the first stage of our modeling. Figure 5 presents images created by the linear Laplacian operator.

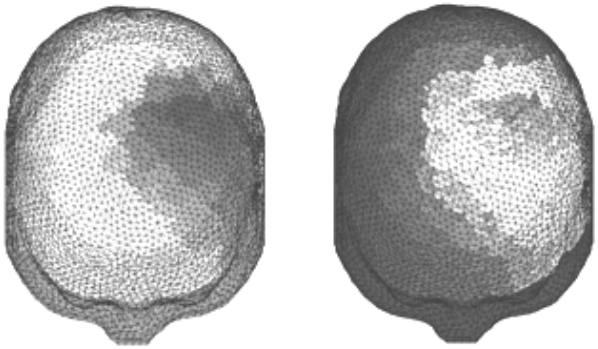

Figure 5 - Potential (left) and Surface Laplacian (right) maps in a finger tapping experiment

Analysis of error As currently there exist no study that investigates plasticity in these matters, it is only presumed that it requires the millimeter-precise recovery of neural brain activity. Similar studies involving the estimation of brain activation casuality underline this thesis [7, 8, 9, 10, 11]. The effectiveness of such a system is dependent of the resolution it is able to reach, therefore it is important to investigate the factors that affect it. In this analysis the following factors are considered:

- parameters describing the geometry of the volume conductor (the model representing the head and the brain)
- conductivity parameters of the volume conductor
- noise arising at EEG measurements
- possible errors entering the system at electrode positioning.

According to results of analysis a source localization error of under 2mm for near cortical sources would need an EEG measurement SNR of 20dB or higher and uncertainties of at most 1mm rms in electrode placement. Tests revealed, that localization error reacts sensitively to changes in conductor geometry parameters, but allows for an under 1mm localization error with errors of 5% in conductivity parameters.

Results

The paper briefly described three projects currently being implemented at the University of Pannonia, Veszprem, Hungary. Results achieved so far were discussed above, new results are expected particularly from the startup projects. We believe that the application of such IT based intelligent solutions is the only way of making our healthcare systems in the long run sustainable.

Acknowledgments

The iAccess Handbook: A Methodology for Access Control Integration

Per Håkon Meland[a], Lillian Røstad[b], Inger Anne Tøndel[a], Øystein Nytrø[b]

[a] *SINTEF, Software Engineering, Safety and Security, Norway*
[b] *Department of Computer and Information Science, NTNU, Norway*

Abstract

Health care information about a patient is usually scattered among several clinical systems - potentially more than a hundred separate systems just within one hospital. System integration and interoperability is difficult to achieve, and various strategies for integration exist. However, one topic that has not received much attention is how to integrate system specific security mechanisms such as access control. This paper presents the iAccess handbook, which is a tool to aid this process. It consists of a repository of reference information and a set of methods for collecting information and presenting results, and concerns the legal, organizational and technological aspects of integrated access control for health information systems. The methods have been applied on two separate integration efforts in Norway.

Keywords:

access to information, information protection, computer security, medical records

Introduction

In this paper we present the iAccess (*Integrated Access Control for Health Care Information Systems*) handbook which is a tool to be used during planning, designing and describing access control for integrated health care solutions. The handbook consists of a repository of reference information and a set of methods for collecting information and presenting results.

The methods have been applied on two separate integration efforts in Norway.

Methods and results

The iAccess handbook

The purpose of the iAccess handbook is to serve as a collection of information and methods that are useful and appropriate when integrating the access control of heterogeneous health care information systems. The handbook itself is web-based, and both readable and editable for registered users, such as people from health care organizations, researchers and students (doctoral fellows primarily). The handbook has been created using the free MediaWiki software package[1], which allows easy publication and development of content in a collaborative setting. The following sections will briefly explain the main contents from each of the three parts of the handbook.

Handbook part 1: Reference information

For the reference part of the iAccess handbook, we have borrowed the concept of viewpoints from the software architecture field - specifically from *IEEE 1471-2000 Recommended Practice for Architectural Description of Software-Intensive Systems* [1]. We have defined three viewpoints; *legal, organizational and technical*. These viewpoints were selected in recognition of the fact that access control is not merely a technical issue. Organizational measures are important in enforcing access control and ensuring patient privacy. The legislation defines *if*, *how* and *when* sharing of sensitive health information can take place.

Handbook part 2: Survey methods

This part of the handbook defines a set of survey methods, and we will here briefly present the main ones and discuss our experiences with them.

Study of documentation

From studying documentation you can learn a lot about an organization and/or a system that will be useful when working with access control integration, and also for planning workshops and interviews (see the following sections). There are certain kinds of documentation with relevance for access control, which should be present in a health care organization, and we recommend focusing on the following: organizational information security policies, organizational structure - including roles and responsibilities for information security, organization-level access control policy, strategies - for instance integration strategy, high-level system documentation, description of implementation and use of access control mechanisms, requirements with respect to identification, authentication and authorization, risk analysis based on system security and patient safety.

Different organizations have different types of documentation. The results from a documentation study greatly depend on the organizations studied. It can be just as interesting to see what kind of documentation exists, as to study

1 MediaWiki is a free software wiki package originally written for Wikipedia, see http://www.mediawiki.org.

the actual content. If the anticipated documentation does not exist, asking for it still serves a purpose by making the organization aware of what information could be expected to be present.

Process workshops

Our process workshop is based on the methodology defined by Dingsøyr et al in [2]. The purpose of the process workshop is to get input from a heterogeneous group of people that are involved in a given process. In other words: While documentation can provide information about how something is supposed to be done - the process workshop conveys information about how it is actually done.

During a process workshop, the participants are presented a scenario, and then each one writes down keywords related to activities, participating roles, documentation and tools that are used to solve the scenario. This is done in the same way as a traditional brainstorming session. After this, the workshop participants gather around a process map and eliminate/add/reorganize the notes on the map until they have reached a version of the process description that they can all agree upon, as shown in Figure 1.

Semi-structured interviews

Semi-structured interviews [3] are used to gather detailed information to complement and elaborate the process descriptions obtained in the workshops. This is be done by using a set of pre-defined questions (an interview guide), but allowing the interviewees to answer freely - there are no categories to select from and the interviewees are allowed to ask questions. An interview guide should start by explaining the interview motivation, and briefly explain the relevant terms. The interview guide should be based on the process maps.

Handbook part 3: Combining and presenting results

This part of the handbook describes how to combine and present the results from the survey methods. The most promising technique is the use of an extended version of UML[2] activity diagrams for modeling the process descriptions and information related to processes. An UML activity diagrams is well suited for describing processes and activities, both related to human and system behavior, because of a visual organization that is easily understandable by most people.

Discussion

The original reason for creating the iAccess handbook was to have an instrument for surveying and documenting real-life access control integration efforts of health care systems in Norway.

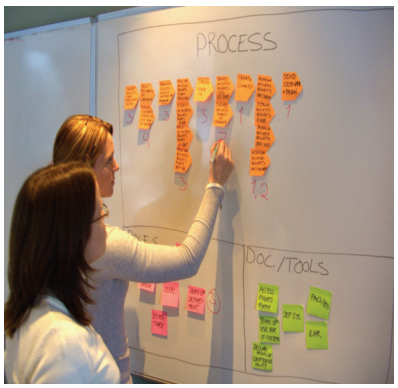

Figure 1 - Creating the process map by using sticky notes and active discussions

The results so far have mainly been used by the health care organizations themselves and by doctoral fellows researching how technical, legal and organization challenges should be solved. A survey gives a snapshot of today's situation, what has improved from the past and what is planned in the near and distant future. Just as interesting, some improvements may be negative for the majority of the users, and it is important to share that kind of information with the rest of the community in order to avoid reoccurrence.

Conclusion

We have presented the iAccess handbook, which consists of three parts relevant for analyzing planned or existing efforts for access control integration for health care systems. Representing multiple views from various stakeholders in unified diagrams eases the understanding on how things are and what should be done. The methods in this paper are first and foremost qualitative, and our future work will add methods that provide more quantitative results.

An Concern-Oriented and Ontology-Based Approach to Constructing Informational Facets of Clinical Trials

Crengua Bogdan[a], Daniela Luzi[b], Fabrizio L. Ricci[b], Luca D. Serbanati[c]

[a]*Ovidius University, Constanta, Romania,* [b]*CNR-IRPPS, Rome, Italy,* [c] *Politehnica University, Bucharest, Romania*

Abstract

The complexity of the clinical trial (CT) process involves high investments in the research of a new drug or procedure. To reduce costs and enhance the research quality more and more activities in the CT process need an IT support. To develop efficient automated solution first a conceptual modeling step should be carried out. To model the CT research partitioning criteria of the CT conceptual domain are required.

The main objective of our research is to identify effective partitioning criteria for modeling the CT research.

A concern-oriented analysis method for developing information systems is applied. The method uses the concerns of various stakeholders of the CT research for partitioning the CT conceptual domain in stakeholder-oriented subdomains. Mental representations description of stakeholder's beliefs and knowledge related to each concern are identified and on their basis, a concern-oriented ontology of the CT can be created.

Facets of the CT future information system are created based on the CT domain ontology. In this paper, an example of how such facets can be constructed for the subject selection section of the CT protocol is presented.

Keywords:

clinical trial, selection criteria, ontology, modeling, concerns

Introduction

The complexity of the clinical trial (CT) process involves high investments in the research of a new drug or procedure. The great amount of workload required to carry out a CT research as well as the request of high quality in data gathering and processing have led to increase the ICT support. To reduce costs and enhance the research quality many software products are available on the market (for example, CRF (Case Report Form) gathering and processing, electronic data capturing, Clinical Trial Management, Clinical Data Management, etc.). The current trend is to expand the ICT support and automatize as many as possible activities in the CT process. But some CT activities as protocol authoring [1], [2] remain largely manual because are highly creative and intensely knowledge-based.

The paper presents a method to interpret CT protocols which allows us a more systematic approach for automatizing of the protocol writing process.

Our solution is founded on the assumption that any automatization is based on an accurate conceptual model of the reality to be automatized. In the CT case many efforts were done to model the CT universe [3]. Generally, conceptual modeling requires partitioning the reality domain under study in loosely coupled parts and for each part a successive partitioning to be carried out until the resulting parts can be easily described. Finding suitable partitioning criteria is a challenge for any system analyst especially when the system under study is a complex one, as in the case of clinical trial.

Our method claims that the partitioning criteria are tightly related to the stakeholders' concerns in developing, operating or evolution of the information system (IS).

In the paper [4] we identify four perspectives from which an IS can be developed: social, functional, informational and technological. In this paper, we present the result obtained from the informational perspective. In this perspective, an IS is viewed as a distributed repository of data, information and knowledge that is used by the business agents.

Our concern-based approach allows us to divide the conceptual universe of the CT in a systematic manner. In this way an ontology of CTs information system can be constructed [5] and on its base we may construct facets of the IS of the future clinical trial, as we defined and exemplified in this paper.

Ontologies

An ontology is a formal specification of the intent of concepts and the intensional relationships that can exist between concepts. Using logical axioms, it is a declarative model of a domain. As a formal system, an ontology allows us to build proofs of assertions viewed as theorems or conclusions. In respect to other models, ontologies allow accurate expression of meaning of models.

According to Guarino's definition, "An ontology is a logical theory accounting for the intended meaning of a formal vocabulary, i.e. its ontological commitment to a particular conceptualization of the world" [6]. A conceptualization is

a set of conceptual (intensional) relations defined on a domain space [6].

In our research we use DOLCE (Descriptive Ontology for Linguistic and Cognitive Engineering) [7] with its extension D&S (Descriptions and Situations) [8] as a "foundational"[1] ontology where we "plug in" our ontology. DOLCE is an ontology of particulars, in the sense that its domain of discourse is restricted to particulars[2]. We adhered to the DOLCE+D&S ontology because: a) DOLCE captures the ontological categories belonging to natural languages and human commonsense; b) being a formal ontology [6], DOLCE and D&S precisely define its notions and relations used; and c) DOLCE and D&S contain all categories and relations we need for writing our ontology.

Concerns

In [9] we defined the concept of *concern of a stakeholder* (briefly *concern*) as a problem-related care of one or more stakeholders involved in the construction or operation of an information system in its natural environment.

Ontologically, a concern is a state of mind arising from preoccupation or interest in a problem that the stakeholder identified in the real world. In our case the stakeholder's interest derives frequently from a need or from his/her responsibility in the IS evolution process, but can also originate in a desire or another interest.

As it is known, on the one hand, in the process of development of an IS, the stakeholders are people who are directly or indirectly affected by it. On the other hand, they influence the system development and/or use. Examples of such stakeholders are direct users, managers of users, management staff members, customers, suppliers, internal departments that support the project, financial departments, and so on.

The problem specification is the pair: a) initial state description (of the current situation, as the stakeholder perceives it) and b) final state description (of the situation that matches expectations, interests, or desires of the stakeholder). These two elements are respectively considered as hypothesis and conclusion of the problem specification. If grouped with the role of the stakeholder who manifests interest or preoccupation about the problem, this pair becomes the high-level specification of a concern that the stakeholder will try to solve. We consider a problem's initial state containing all data, information, and knowledge necessary to obtain the final state of the problem.

In the case of CTs, applying the informational perspective with the objective of identification of subjects' selection criteria, the writing committee has nine concerns. For instance, the high-level specification of one of these concerns is presented in the Table 1.

Tabel 1 - The high-level specification of a concern

C4	*Name*: Care to find how the clinical manifestation of the disease is related to the objectives attainment and the selection criteria identification	
	Problem	*Hypothesis*: Following information is available: trial objectives, trial design, statistical considerations; previous CT projects and their scientific results
		Conclusion: How the disease in the stage treated in the study will be tested in order to get the diagnostic?
		What basic characteristics (gender, race, life expectancy, performance status) have the study population affected by the disease?
		How the clinical manifestation of the disease might affect the safety of the subjects and the attainment of the objectives?
		What particularities of the disease are important for the identifying the selection criteria?
		How the pathogenesis of the disease might affect the general clinical state of the subjects and the inferring of the selection criteria?
	Stakeholders: Writing committee	

In our approach, each concern has associated a rationale that we explain it in the next subsection.

Concern rationales

We define the concern's rationale a cluster of concepts and their conceptual relations used for the concern solving. In other words, the concern's rationale describes the semantic domain which the stakeholder should manage in order to solve the concern.

The concepts of such a rationale come from informal descriptions of the mental representations of the beliefs of the stakeholder (-s) during the concern's life cycle. The beliefs represent convictions a stakeholder holds for true in a given situation, independently of the nature of the source

1 A foundational ontology characterizes general terms (e.g. entity, event, process, spatial and temporal location) and basic relations (e.g. part-of, qua-lity-of, participation, dependence).

2 Particulars are entities that cannot have instances that are individuals, whereas universals represent ideas or abstract entities which can have instances.

of the conviction: either from perception or an inference from previous knowledge, or a verbally transmitted knowledge. Of course, a belief may be true for one or more stakeholders (thus a piece of knowledge for them), but false for others. When it is accepted as true by all of us (or in all possible worlds), it is a piece of general knowledge.

Regarding a concern, the beliefs to be considered are those associated to the concern's hypothesis and conclusion, but also those which represent milestones in the concern solving process, mainly the hypothesizes and conclusions of concerns the concern depends of. For instance, due to limited space, a belief and a piece of knowledge of the concern C4 are showed in the Table 2.

Table 2 - Mental representation descriptions of a piece of knowledge and a belief of C4

Code	Mental representation description in natural language
K1	The persons who have the disease in the stage considered by the study may be eligible
B10	The existence of the disease and its stage affect the life expectancy of a person

Methods

To obtain a multi-facetted ontology of an IS a concern-oriented method based on stakeholder analysis was proposed in [4] and [5]. The method has 12 steps: 1) identification of stakeholders; 2) identification of concerns; 3) concern classification; 4) identification of relations between concerns; 5) concern prioritization; 6) identification of rationales in concern specifications; 7) identification of the concepts used in the rationales; 8) ontological analysis of the intension of the concepts; 9) choosing a foundational ontology to be extended by our ontology; 10) classification of the concepts conforming the foundational ontology; 11) identification of conceptual relations in concepts' rationales; and 12) definition of the ontology using a formal logic language. The ontology we obtain with this method is structured according to stakeholders' concerns. Its components are vocabularies. In these vocabularies we find either specific and shared concepts. [5] presents how this method ws used to construct a domain ontology for CT subject selection criteria.

The method also includes guidelines for designing informational views of the IS under study from the obtained ontology. For this, other 3 steps should be added to the basic method: 13) construction of the UML ontological model of each piece of knowledge or belief; 14) construction of facets for each concern rationale; and 15) constructon of the informational view by grouping facets of some related concens.

Results

Views and facets

In our approach, a view is a model of an IS related to a particular, homogeneous from a logical point of view, set of concerns. The particularity is due to the fact that the concerns emerge from a particular perspective of the IS developing process: social, functional, informational, or technological. Therefore, depending on the perspective applied, we obtain social, functional, informational, or technological views. We consider the views as simplified models of the future or existing informational system. In this paper, we consider only the informational views.

In our approach an informational view is the structural model of the system to be modeled, basically a UML class diagram [10]. It contains the categories in the system's conceptual domain, their relations, as well as the constraints regarding the model interpretation. An informational view is a cluster of *facets*. Each facet is a simplified model of the informational view and represents a concern-driven projection of the informational view according to a stakeholder's point of view [11]. This point of view is shaped by the stakeholder's role or responsibilities in the future system, in this case, the CT information system. We can say that a facet describes the rationale of a concern. Technically, it is constructed according to a template that contains the following fields: the codes of the facet and concern, the dependency graph of beliefs and knowledge of the concern and the structure of the facet. The later is a UML class diagram that contains the concepts from CT conceptual domain and their ontological relations. In our approach, the structure of a facet is constructed on the basis of the UML ontological models of the knowledge and beliefs of a concern. In the followings, the UML ontological model is defined and some examples of such models are given.

UML ontological model

A UML ontological model is a class diagram that semi-formally describes the semantics of a piece of knowledge or belief of a concern's rationale. Such a model is constructed from the domain ontology of a CT information system by preserving its semantics. It uses concepts of the UML metamodel [10] like class, datatype, association, and dependence. In our research, we found that the correspondence between these concepts and the categories and conceptual relations of the domain ontology are expressed in the following rules:

- all categories of the domain ontology, excepting the abstracts, are mapped to classes; for instance, in the figures 1 and 2, all the categories from the CT domain ontology are mapped to classes.
- categories subsumed abstract category are eventually mapped to the datatype UML concept. As we know, a

data type is a type whose values have no identity [10]. For instance, in the Figure 3 the class AgeValue is a subclass of the AbstractRegion marked by the stereotype datatype, because the property doesn't carry an identity criterion, as it was defined by the methodology OntoClean [12]. In other words, knowing two occurrence of the same value of age they cannot be differentiated. But the time intervals can be differentiated after their duration and the time in which they occurred. That is why the TimeInterval class isn't marked with the stereotype datatype. In addition, TimeInterval is an association class is due to the fact that the corresponding ontological category participates in temporal ontological relations like *participateIn, sequences*, etc.

- all ontological relations, excepting parthood and constitution, are mapped in associations in UML ontological models. As it is known, an association is a relation that describes semantic connections between individuals that are instances of the given classes [10]. For instance, the *refer* association (Figure 1) between the classes DiseaseDescription and DiseaseState maps the ontological relation with the same name which denotes that the DiseaseDescription category, which is subsumed by the Description category, uses the course DiseaseStage, which sequences the referred perdurant DiseaseState.
- temporal and temporary parthood, also constitution relations are mapped in UML aggregation relations. For instance, the instances of the DiseaseDescription class contains as temporary part an instance of the DiseaseName class, but the later can appear in the CT objectives and also in the selection criteria of subject. As it is known, in the case in which the aggregate class has the responsibilities to manage its parts, the aggregation relation becomes a composition one [10].

In order to construct an UML ontological model of a piece of knowledge or belief, our approach proposes the applying of the abstraction mechanism and the following rules on its mental representation description in the natural language:

- if a concept from the mental representation corresponds to a category from the CTs domain ontology, we map this category and the category or categories from the foundational ontology which subsume it into the classes or datatypes. For instance, in order to construct the UML ontological model of the K1 (Figure 1), we applied this rule in the case of the categories Person, Disease, DiseaseStage, NewAdmissibleDiseaseStage and we add to the model the classes AgentivePhysicalObject, Process, Value.
- if a concept corresponds to a quality from foundational or CTs domain ontology, the model contains corresponding class and in addition the class or classes that map the category or categories in which the quality inheres in, because according to DOLCE, each quality is specifically and constantly dependent on the entity it inheres in [7]. For instance, in order to construct the UML ontological model of the B10 (Figure 2), we applied this rule in the case of quality LifeExpectancy and its quale, a value of Abstract Region category.
- in the case of a relation between two concepts, we check if it is an ontological relation. If so, we transform the relation into an UML one, according to the rules above enumerated.
- if the relation between two concepts, excepting the causality one, is not an ontological one, the CT domain ontology is traversed on the basis of the subsumption relation of the corresponding categories of concepts and, on the basis of the reasoning supplied by the ontology, we search the ontological relation that has the same meaning with the initial relation. For instance, in the K1 the relation *have* between Person and Disease is ontologically interpreted by the DOLCE relation of participation ("*x participates in y*" [7]) between those categories. That is why, in the UML ontological model of K1 the name of association between two classes is *participateIn*.
- the causal relation between two concepts is described in model by the dependence relation. For instance, the belief B10 supplies the meaning that the value of the life expectancy of a person depends on the stage of his/her disease. We show this semantics in the UML ontological model from the Figure 2.

In addition, in the UML ontological models of K1 and B10 we observe that these may contain incomplete information, namely those that are particular to the future CT. This information is described by subclasses whose names are prefixed by "New" or map categories from foundational or domain ontology, like AbstractRegion, Activity, and so on.

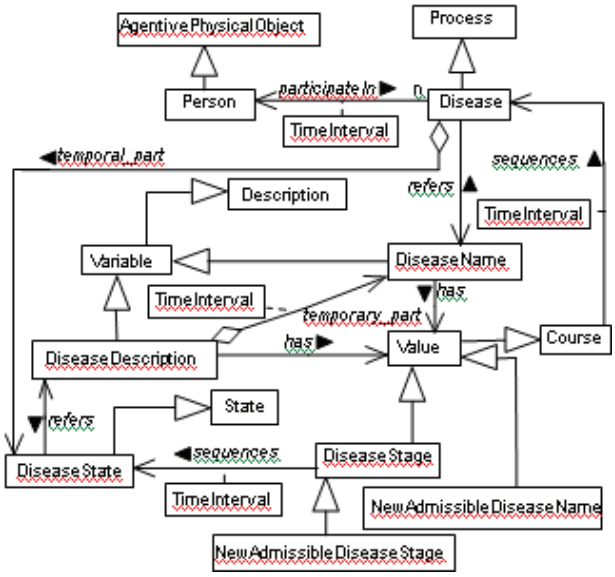

Figure 1 - The UML ontological model of K1

After we constructed the UML ontological models of beliefs and knowledge of a concern, we may construct its facet. In order to construct the facet structure, we again apply the abstraction mechanism on the UML ontological models and we take only the classes that will be part from the future informational system and the ontological relations between them. That is why the facet structure of the concern C4 (Figure 3) doesn't contain the classes that map the categories from the foundational ontology or other like Variable, Value, and so on, that is those have no direct correspondent in the future IS.

Discussion

In this paper, we showed the application in the case of CTs of a concern-oriented analysis method for developing information systems. The method uses the concerns of the writing committee for partitioning the CT conceptual domain in stakeholder-oriented sub-domains. Mental representations of stakeholder's beliefs and knowledge related to each concern are identified and on their basis, a concern-oriented ontology of the CT can be created.

Having the CT domain ontology, we showed how facets of the CT future information system could be created. In this paper, we give examples for a concern emerged from the need of identification of the subject selection criteria.

Some of the advantages supplied of our approach are: a) being a concern-oriented method, it allows to the system analyst to step by step resolve himself or with help of other stakeholders the concerns manifested by the stakeholders and identified from the perspectives of the IS developing. These facts also imply that the concerns of each stakeholder can be resolved in an independent way; b) by definition, the CT domain ontology can be reused in automatized constructing of the CT protocol; c) being constructed based on domain ontology, we think that facets can be automatically constructed using a software tool. In this way, the facets could be used as a verifying and validation tool of the beliefs and knowledge declared by the stakeholders of the future IS.

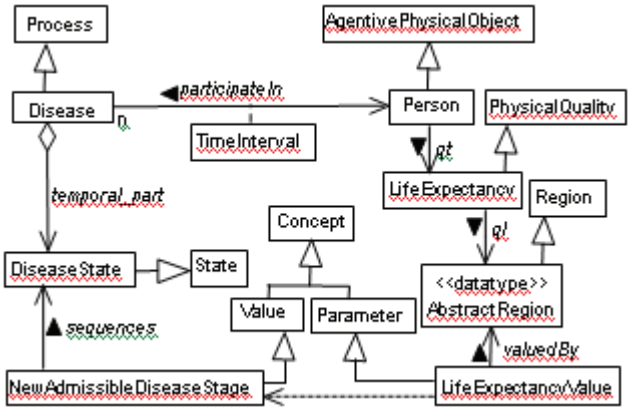

Figure 2 - The UML ontological model of B10

As future research we intend to identify the needed composition rules to construct the views of the information system, and in particular, of clinical trials.

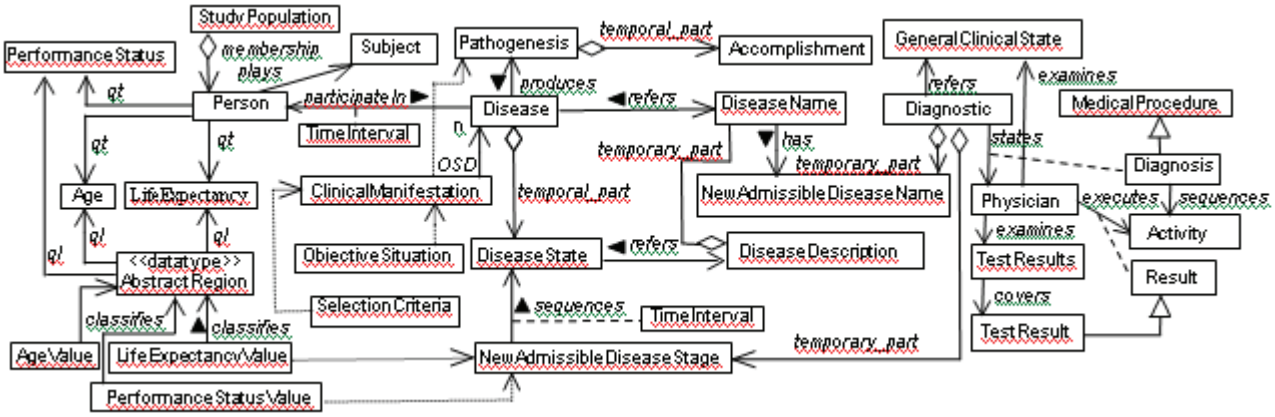

Figure 3 - The facet structure of the concern C4

Cards in Health Telematics Applications – Tool or Token

Peter Pharow, Bernd Blobel

eHealth Competence Center, Regensburg, Germany

Abstract

Health Information Systems and Applications depend on the acceptance-based empowerment and involvement of all parties requiring secure and trustworthy communication and co-operation. Separating security services from medical information management allows for benefiting from different technologies including independent evolvement without ignoring their weaknesses. Using cards in healthcare raises the important question on whether a card shall be considered a token -a key to access functionality- or a tool with its own application functionality and data. The presented paper analyzes cards with regard to their usage in health information systems. The preferred way to deal with challenges of modern healthcare requirements shall be a balanced combination of cards as tokens and networks for information and functionality provision.

Keywords:

health card, patient card, security token, health network, health information system

Introduction

Healthcare is turning towards the shared care paradigm providing an integrated care approach. The paradigm change is bound to largely extended communication and co-operation between all healthcare providers involved in the patient's care as the challenge of increasing quality and efficiency requirements in the respective domains needs to be met. Thus, new ways for defining, designing, developing, and integrating future-proof and component-based health information systems are required. In that context, patient involvement and patient empowerment as well as education and training of health professionals are important pre-requisites for overcoming traditional ways of organization-centered treatment towards a person-centered approach called "Personal Health". Using token technology in general achieves an increasing importance. The present paper deals with specific benefits and weaknesses using cards either as a token or as real part of the application in healthcare [1].

Methods

Regardless whether using up-to-date card-related technology for identification, verification, and access purposes -the token functionality- or adding application-related functionality including data storage in terms of tools, both approaches have their specific benefits and weaknesses. For characterizing card usage in modern integrated information systems and networks, different aspects and views on tokens and tools need to be analyzed. Apart from awareness, confidence, acceptance, accessibility, and usability the scope of such an analysis ranges from interoperability, technical and organizational issues up to security, safety, privacy, usefulness, and reliability. At least a part of information stored in modern health information systems is intended to be possessed and used by human beings. Appropriate technical means and media are needed for reliable and liable storage of identity-related information, respective cryptographic keys, administrative and business data structures and even applications providing the functionality required including a directed exchange of data to the respective communication partners. Ranging from implementation of simple hardware tokens for restricted functions such as an identity-related service up to portable information systems carried by the information subject, requirements generally apply [2].

There are a number of basic security requirements which will allow the secure exchange of data in an open and distributed environment such as a network. They include authentication, authorization, confidentiality, integrity, non-repudiation, availability, and auditability. There are several security-related requirements that are also of interest for end users but can partly be met without reliance on symmetric or asymmetric cryptography. Organizations attach different importance to different types of security. In healthcare, however, great importance is attached to both availability and disaster recovery as safety of patients and access to information ranges first.

Results

Several European and national projects have defined scope, motivation and objectives as well as health-political aspects for the use of machine-readable cards in healthcare. As a short-term challenge, the reliable implementation of pilots has been mentioned to demonstrate the possible use of such cards and to rationalize time-consuming administrative work in the context of patient's request for health services. Health-political aspects concern facilities for de-centralized medical documentation, a coincidence with constitutional and data protection rights as well as with ethical principles in case

the Electronic Health Record is held by patients, a significant improvement of data quality, integrity and consistency by a unique document, and finally a significant improvement of quality and efficiency of health delivery procedures and processes in general [3].

Using a smart card as a tool means implementing application functionality along with data on the card. Such card-based health information system is characterized by the chance for optimization of medical and administrative workflow, the improvement of information flow between different healthcare providers within a shared care framework, the enhancement of information security using reliable, valid and in-time as well as in-location available data, the facilitation of emergency care by directly available emergency data set as well as a support of prevention and intervention. However, some weaknesses can be discovered, like the possible lost of information due to the restriction of data caused by storage capacity limitations or some unsolved legal problems of information ownership. Data stored on cards used as tools need to be permanently updated.

Using a card as an access token does mean storing and processing all information within extended networks based on an advanced identification and authentication framework. Such network-based health information system requires the provision of services and the existence of unique identifiers. Advantages can be found in a comprehensive level of interoperability and real interactions between all parties involved into the shared care as well as in the chance for a comprehensive, complete, high-quality electronic health record system. Information stored in networks accessed using smart tokens allow for facilitating emergency care by directly accessible emergency data right in time and an enhanced level of quality, integrity and consistency by provision of appropriate services. Availability, however, aims to be the most important service in this case as tokens only provide reliable authentication of principals. Any other service needs to be provided by the infrastructure.

Discussion

Apart from such plastic cards that are only used to physically access rooms, applications, systems or information sources respectively, smart cards in healthcare can be deployed in several different ways. On the one hand, the card can bear the vital information subset of a health record. In case of a patient data cards designed and used mainly as a storage card, e.g., relevant medical data can be stored there as parts (sub-sets, extracts) of an electronic health record [3], [4]. The card is then a tool.

On the other hand, the card may solely be seen as a pointer providing references and links to information stored in shared-care networked systems. This is true, e.g., for patient identification cards. The token approach seems to be the more promising one as medical data are dynamic data, and current cards can only bear parts of the information that is needed for a comprehensive EHR structure [2]. The card is then used as a token.

Confidence in and acceptance of the healthcare systems depend on the citizens' awareness, which needs yet to be raised. Citizens have to realize healthcare is a concern of theirs at all times. The shift from acute to life-long preventive healthcare has to be enforced and speeded up. Citizens shall and will have to form alliances and associations to advocate their interests.

Conclusion

The concepts of eHealth and personal(ized) Health (pHealth) see the citizen in the center of healthcare and welfare. Patient cards are first line communication tools. They carry limited medical data and improve the accessibility to information on health services as well as to personal data. Or cards serve as authentication token. They enable better health provision [4].

Smart cards are widely used as identification tokens not only in healthcare. Many European countries are scheduling the introduction of citizen cards, insurance cards, or just electronic ID cards. The European Health Insurance Card is being introduced in countries of the European Union. Both possession and appropriate use of cards can empower citizen. Furthermore, a card needs to support the collaboration with network-based systems. For that purpose, link information has been specified.

Cards have an impact on the related security infrastructure, certification of processes, process interoperability, and certification of state and relations of principals in longer terms. The use of cards as tokens and the use of networking systems have to closely be linked to each other. This allows for making extensive use of the benefits of both advanced technologies.

Module for Easy and Interoperable Data Analysis in Electronic Medical Records

Bruno Cadonna[a], Peter Beck[a], Ivo Rakovac[a], Thomas Truskaller[a], Thomas R. Pieber[a, b]

[a] *Institute of Medical Technologies and Health Management, JOANNEUM RESEARCH Forschungsgesellschaft mbH, Austria*
[b] *Department of Internal Medicine, Diabetes and Metabolism, Medical University Graz, Austria*

Abstract

Data analysis in electronic medical records (EMRs) is crucial for patient treatment, quality management, administration and research. The widely used SQL queries quickly become complex in the medical domain resulting in difficult and time-consuming development and maintenance. The aim of this work is to develop a data analysis module using Java, XML and SQL, which eases development of analyses by utilising recurring patterns in SQL queries, minimises dependence of analysis on databases, makes analyses modifiable at runtime and visualises results as customisable charts and tables. The data analysis module developed is a first step toward easy-developing and interoperable data analysis in EMRs.

Keywords:

data analysis, medical records system, databases

Introduction

Data analysis in electronic medical records (EMR) and visualisation of its results is crucial for patient treatment, quality management, administration and research. Widely used, often complex, plain SQL queries are tightly bound to database schemas (DBSs) and database management systems (DBMSs) resulting in difficult and time-consuming development and maintenance. Current reporting tools avoid direct use of SQL, but they do not decrease complexity of queries nor do they reduce dependencies of queries on DBSs.

SQL queries in the medical domain often have recurring requirements with similar or identical patterns – e.g. patient classification regarding their habits (e.g. non-smoker, moderate smoker, chain-smoker) and average calculation of laboratory values (e.g. blood pressure) – which could be reused among queries. Greater flexibility can be obtained through parameterisation of SQL queries – e.g. selecting only female, only male or all patients (see Figure 1).

The aim of this work is to develop a data analysis module for integration in information systems, which

a) eases analysis development by providing abstractions for recurring patterns in SQL queries,
b) minimises dependence on DBSs and DBMSs,
c) makes analyses modifiable at runtime and
d) executes analyses and visualises results as customisable charts and tables.

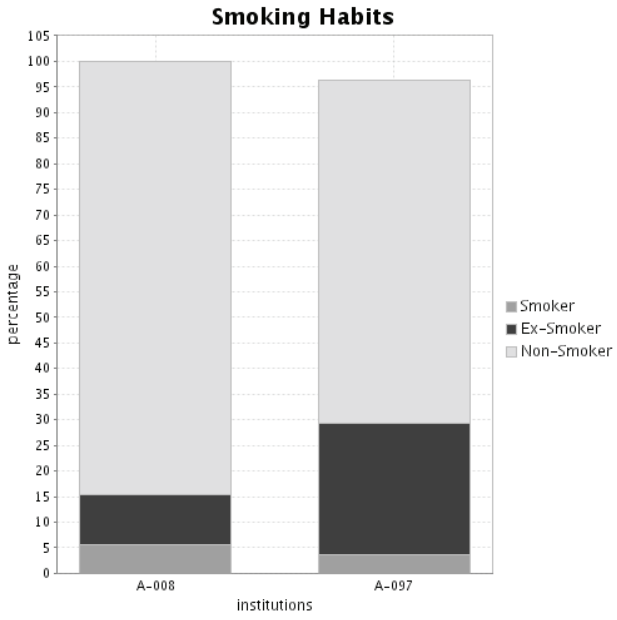

Figure 1 - Comparison of two institutions regarding the smoking habits of their female patients (100% are not reached for A-097 due to missing data). For this analysis the classification pattern was used classifying patients regarding their smoking habits. Additionally the analysis was parameterised in order to select only female patients

Methods

The module was implemented in Java using open source libraries. XML Schema was used to define valid mark-up for analysis and configuration instances. An analysis XML instance contains mark-up for

a) generalised SQL query patterns,
b) a parameter-based definition of the data to analyse referencing reusable sets of data in the configuration XML and
c) default visualisation properties.

A configuration XML instance has to be defined once per database and contains metadata about

a) DBMS,
b) DBS
c) reusable sets of data to analyse and
d) available parameters for parameterisation of the data to analyse.

It is used for runtime generation of database-specific SQL queries. A second configuration XML instance specifies which chart types are permitted for visualisation of analysis results depending on attributes of analyses. This configuration XML instance avoids meaningless combinations of chart types and analyses such as longitudinal trends of patients' blood pressures visualised as a pie chart.

Results

The data analysis module developed generates SQL queries from database-independent analysis XML instances and database-specific configuration XML instance, executes the SQL queries and visualises results with default visualisation properties (see Figure 2). Visualisation properties such as chart type, colour schemas etc. can be further modified. A web interface for query selection, execution and visualisation of results has been developed. Internationalisation was achieved by means of Java resource bundles.

Discussion and conclusion

The work presented is a first step toward faster and easier development and maintenance of interoperable analysis of data in EMRs. The analysis structure developed allows easier development, maintenance and reuse of analyses on a higher level of abstraction. Modularity of analysis structure simplifies parameter-based modifications at runtime. Visualisation of results can be easily customised. Analysis XML instances unify query and result visualisation in one place.

The module developed is currently integrated in quality management web applications for hepatitis and cardiovascular disease hosted at www.healthgate.at and in a module for generation of PDF reports.

Future work will focus on improving visualisation capabilities (sorting and filtering of obtained results), user interface integration using metadata (e.g. dynamically generated input elements for parameter values), adding dynamic analysis descriptions (i.e. descriptions which adapt to results) to analyses XML instances and further separation of database-independent components from database-specific ones.

Moreover to foster further development of the data analysis module practicability of an open source release will be explored.

JOANNEUM RESEARCH

Introduction

- **Data analysis** in electronic medical records (EMR) is crucial for **patient treatment, quality management, administration** and **research**.

- Nowadays **SQL** is **widely used** to accomplish this task

JOANNEUM RESEARCH

Introduction

Characteristics of plain SQL queries:

- **tightly bound** to **database schemas** (DBSs) and **database management systems** (DBMSs)
- in medical domain queries often have recurring requirements with **similar or identical patterns**
- **greater flexibility** can be obtained through **parameterisation** of SQL queries

JOANNEUM RESEARCH

Introduction

The **aim** of developed data analysis module:

- to ease analysis development by providing **abstractions for recurring patterns** in SQL queries,
- to **minimise dependence on DBSs and DBMSs**,
- to make analyses **modifiable at runtime** and
- to visualise results as **customisable charts and tables**.

JOANNEUM RESEARCH

Methods

Used technologies:

- The **Java** platform and **open source libraries**
- **XML Schema** to define mark-up for analysis and configuration instances
- **SQL** to query databases

Methods

Analysis XML instances contain:

- **generalised SQL query patterns**
- **parameter-based definition** of the data to analyse **referencing reusable sets** of data in the configuration XML instance
- **default visualisation properties**

Methods

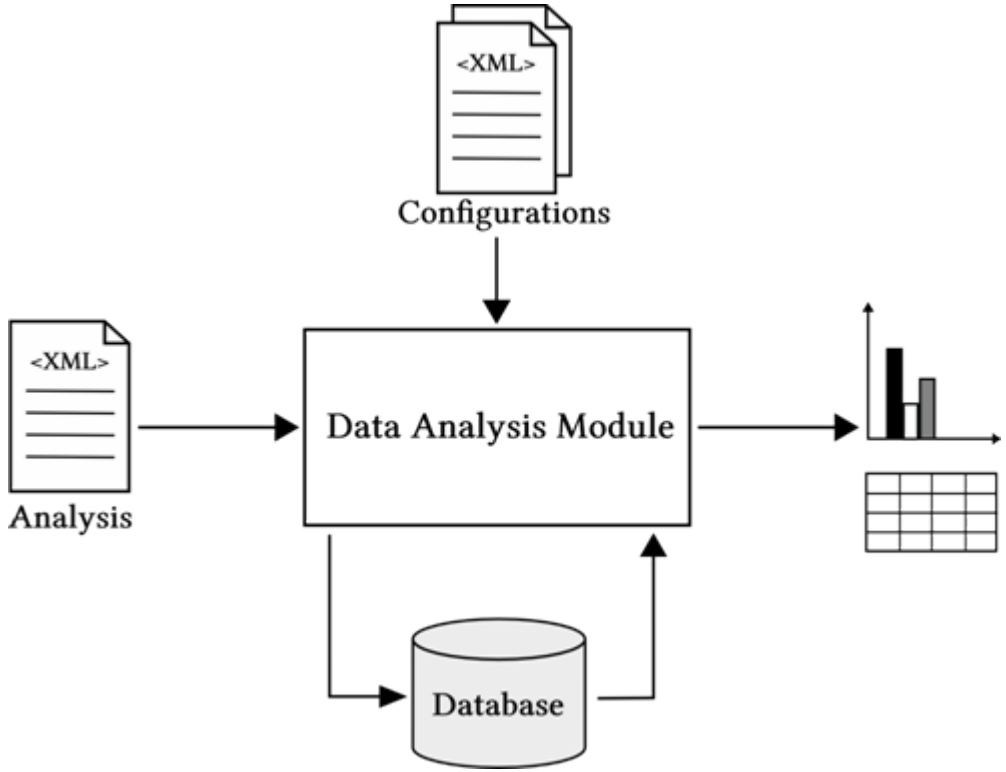
Configuration XML instances for queries contain:

- **metadata about DBMS**
- **metadata about DBS**
- **reusable sets** of data to analyse
- available **parameters for parameterisation** of the data to analyse

Configuration XML instance for visualisation contains:

- specification of which chart types are permitted with which kinds of analyses **avoiding meaningless combinations** such as longitudinal trends of patients' blood pressures visualised as a pie chart

Results

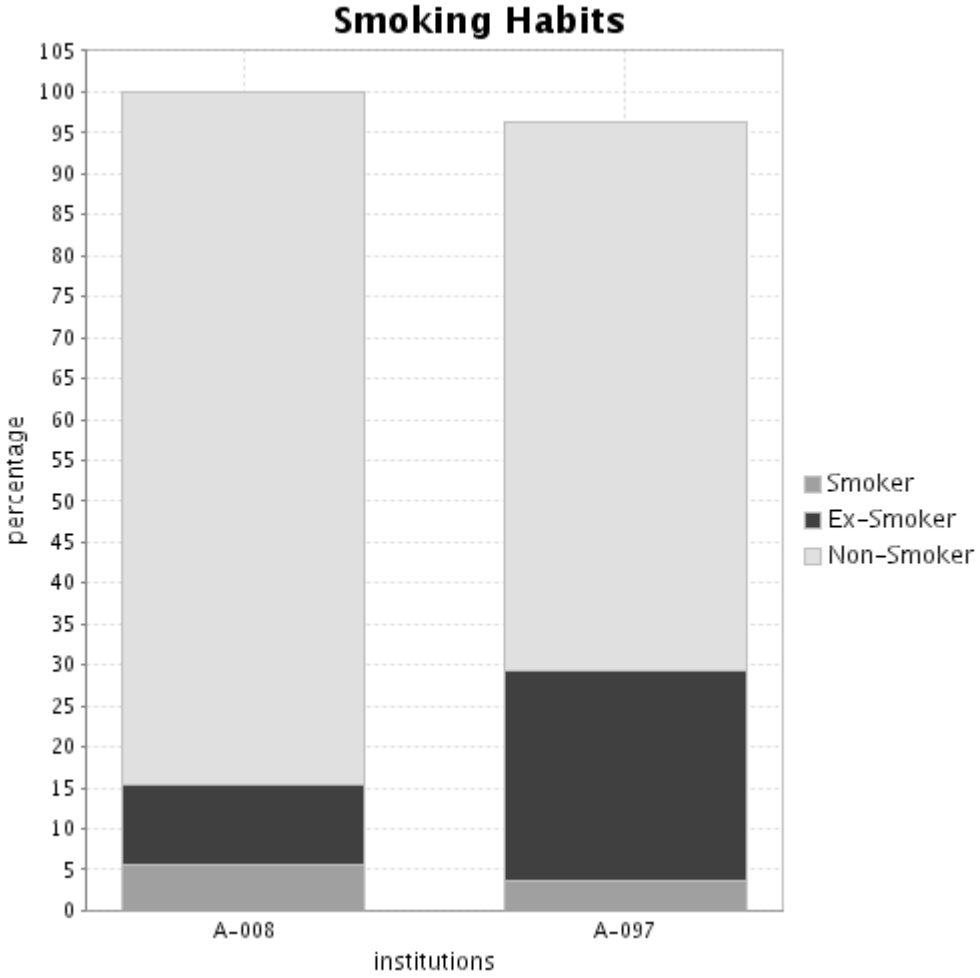


The data analysis module developed **generates** SQL queries from **database-independent analysis** XML instances and **database-specific configuration** XML instance, **executes** the SQL queries and **visualises** the results.

Configurations have to be defined **only once** per information system.

Results

Analysis results generated by the module



Comparison of two institutions regarding the smoking habits of their female patients. For this analysis the **classification pattern** was used classifying patients regarding their smoking habits. Additionally the analysis was **parameterised** in order to select only female patients.

(100% are not reached for A-097 due to missing data)

JOANNEUM RESEARCH

Conclusion

Benefits:

- easier development, maintenance and reuse of analyses **on a higher level of abstraction**
- faster and easier development and maintenance of **interoperable analysis** of data in EMRs
- Modularity of analysis structure simplifies **parameter-based modifications at runtime**
- Visualisation of results can be easily **customised**
- Analysis XML instances unify query and result visualisation **in one place**

Conclusion

Data analysis module integrated in:

- **quality management web applications** for hepatitis and cardiovascular disease hosted at **www.healthgate.at**
- module for **generation of PDF reports**

Future work:

- improving **visualisation capabilities**
- **user interface integration** using metadata
- adding **automatically adaptable analysis descriptions** to analysis XML instances
- further **separation** of database-independent components from database-specific ones
- Exploration of practicability for **open source** release

A Multiagent System's Proposal for Chronic Patients' Relationship Management

Leandro Ramos da Silva[a], Márcia Ito[a]

[a]*Information Technology Application Center, "Paula Souza" State Technology Educational Center, Brazil*

Abstract/Objective

This paper presents the proposal of a multiagent system development for the Chronic Patient Relationship Management (CPRM) model. This model is proposed with the purpose to increase the adherence from the patients to their treatment. The CPRM model is based on the Customer Relationship Managemen concepts, which intends to leave the information on all the communication channels available. The datawarehouse, datamining and Distributed Intelligence's concepts play an important role on the CPRM model, once that one of its propositions is to guarantee an effective patient's follow-up, inter-relating information that are dispersed in institutions' departments as well as amongst institutions. To support the CPRM model execution, multiagent system is proposed once it can enable the use of models and techniques to deal with the model's complexity. For this purpose, it will be given a general view of the proposed system's, which tends to apply concepts on solving complex problems and on inter-systems integrations standardization for the model's success.

Keywords:

chronic disease, telemedicine, outpatient monitoring

Methods

Critical factors to a successful implementation of the model have been studied and it has become clear the need of a deeper study of the techniques and methodology to be adopted, including the examination of engineering softwares to implement an agent's software. At last, it has also become necessary to test performance, usability and portability to verify the resultant implementation.

Results

In the medical computering context, the telemedicine systems are composed by complex subsystems with dissimilar components, managing shared data and resources, and they occasionally require integration with the legacy systems.

This essential feature of the model should be kept and according to Booch, the agents technology has powerful characteristics to the complex softwares project.

In accordance with this, an agent is abstracted to solve a problem particularly, but it is able to interact with others in order to enable the resolution of a problem that, individually, it would not have been possible. Thus, the proposed system to the model is about an Agents Platform that can support the feature of a distributed intelligence guided to agents.

The proposed architecture implements the Agents' characteristics, in a way that each agent acts independently in his own health unity. Its rationalization is based on a rules shape through a subsystem based on the Jess framework that allows that new rules are put in, keeping the system operating even when expanding.

Finally, Service Oriented Architecture (SOA) is a mighty candidate to provide practical implementation to agents' system, and once its representation model of services and components esteems for communication standards and the independence in architecture, the integration between the various health unities is possible in a simple way.

Conclusion and discussion

The proposed implementation's aim is to provide the expansion of the CPRM model into a collaborative intra-institutions model using the agent's technology and new proposals of systems' integration, like the SOA.

Once there is an implementation able to support the requirement for the autonomy of the health unities at the same time that there is integration between them and availability of information on the necessary channels, its practical utilization becomes possible.

Development of Computerized Adverse Drug Event Surveillance System in Korea: Retrospective and Prospective Patient Medical Record Reviews

Hyun Kyung Koo[a], Yoo Mi Cho[a], Soo Hee Hwang[a], Kyung Suk Choi[b], Eun Sook Lee[b], Byung Koo Lee[b], Sukhyang Lee[c], Yoon Kim[a,d]

[a] *Center for Interoperable Electronic Health Record, Korea*
[b] *Department of pharmacy, Seoul National University Bundang Hospital, Korea*
[c] *Graduate School of Clinical Pharmacy, Sookmyung Women's University, Korea*
[d] *Department of Health Policy and Management, Seoul National University College of Medicine, Korea*

Abstract and objective

A computerized adverse drug events surveillance system (CADESS) was implemented in Seoul National University Bundang Hospital (SNUBH), Korea with advanced electronic medical record systems. For the purpose of system evaluation at the beginning stage of implementation, two months were randomly selected and patient medical records screened with ADE signals were reviewed in retrospective and prospective respectively. The knowledge base of CADESS was developed by clinical experts and the ADE identifications were reviewed by 6 clinical pharmacists. The incidences of ADEs were 4% and 3.4% in retrospective and prospective respectively. Rates of preventability and severity were different; however, most differences of our results were due to the system errors and the natural characteristics of the prospective information flow.

Keywords:

Clinical Decision Support Systems, Adverse Drug Events, ADEs, Computerized Medical Record Systems

Introduction

Adverse drug events are common, costly and often preventable. Monitoring ADEs is the most important part of ADE prevention. Computerized ADE surveillance systems using signals to detect potential ADEs have been reported more cost-effective than other types of ADE monitoring system. To identify and prevent ADEs, the Computerized Adverse Drug Event Surveillance System (CADESS) was developed in the hospital information system, SNUBH.

Methods

SNUBH is an educational hospital with 909 beds in Bundang, Korea and has been operated an computerized medical record system, BESTCare, since 2003. CADESS was implemented in the pharmacy information system in early 2006. Signals detecting ADEs were adopted from the previous studies and reviewed by clinical experts in SNUBH. Patient medical records screened with ADE signals were reviewed to identify ADEs by 6 clinical pharmacists for selected months. After the training of medical record reviewers, the reliability among reviewers was measured. The medical record of inpatient during April 2005 was reviewed retrospectively; from Jul. 18, 2006 to Aug. 17, 2006, prospectively. Severity, preventability, suspicious drugs, ADE mechanism, and so on were recorded in a structured format by trained reviewers.

Results

The total numbers of hospitalized patients were 3,608 for a month of April 2005 and 3,510 from August to July in 2006. The percentage of patient generated ADE alerts was 12.7% and 13.6%; the incidence of ADE, 4% and 3.4% of inpatient in retrospective and prospective reviews respectively. The preventability was 29% vs. 10%; the severity of significant, serious and life-threatening was 75.2%, 22.8% and 2.1% vs. 80.3%, 13.3% and 1.7%.

Conclusions

The difference between retrospective and prospective reviews was mostly due to simple computational errors. 4 signals were missing in the retrospective review and it caused the differences in the total number of ADE alerts, incidence and others. Preventability still significantly differs although the availability of information sources and the data completeness were considered. Lastly, sample size was too small to compare the predictive positive values of each signal. But the comparison between retrospective and prospective reviews was a meaningful at the beginning stage of system development process.

CiEHR
Center for Interoperable EHR

Introduction

- Medication errors and health care costs
  - Common and expensive medication errors
  - Known issues on patient safety and health care costs
- Preventable medication errors & CDSS
  - Many medication errors known to be preventable
  - Many studies on medication errors and medication CDSSs in US and other countries
- However, still significant
  - In 2006 IOM reports, medication errors are reported still significant and costly
  - Few studies in Korea, very early stage of medication CDSSs
  - Need more opportunities to show how it works and it is effective to prevent with CDSS.

Methods (1/3)

- Computerized Adverse Drug Event Surveillance Program (CADESS)
  - Using 46 ADE signals including lab test, drug level, medication, & diagnosis codes
  - Screened EMR for patients with ADE signals checked
  - 6 pharmacists reviewed electronic medical records of ADE signal monitored patients to identify ADE occurrence
  - ADE identified patients data was recorded in a structured format to collect data for the statistical analysis

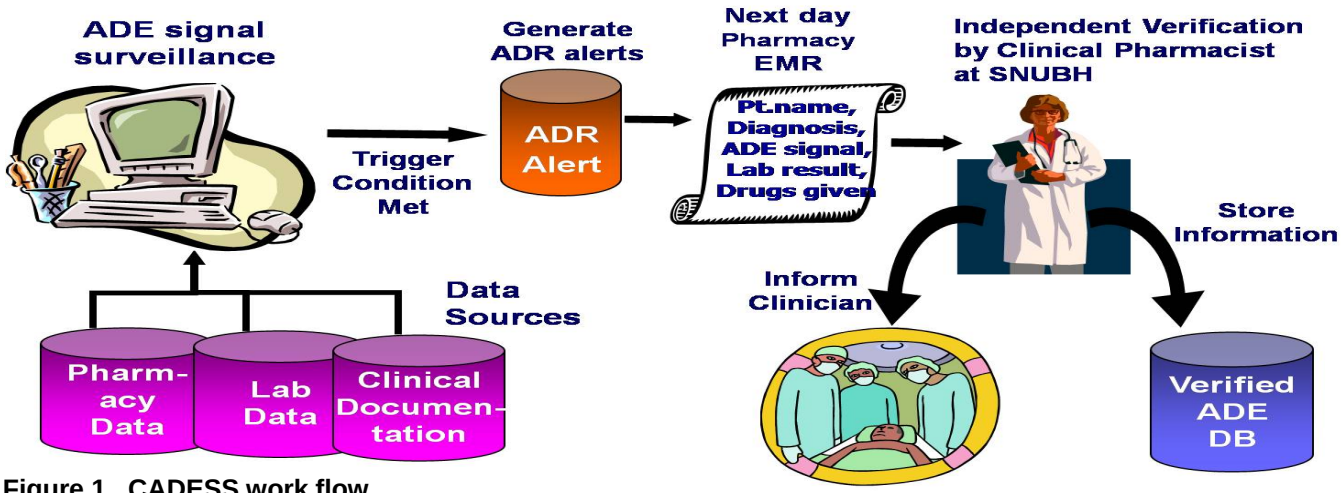

Figure 1. CADESS work flow

Methods (2/3)

- *Study settings*
  - Seoul National University Bundang Hospital, Korea
  - 990-bed, secondary, academic hospital
  - Advanced electronic medical record system and medication related CDSS in operation (order duplication checking, drug-drug interaction, contraindications, etc.)
- *Medical Record Reviews*
  - Training of reviewers & reliability test in advance of study
  - Retrospective & Prospective chart review for 1 month each
  - By 6 pharmacists under the supervision of clinical pharmacists and physicians
- *Statistical analysis*
  - SAS, SPSS ver.12.0
  - Descriptive analysis, kappa value for reliability test

Methods (3/3)

Reviewer's training
- ADE review manual & study reviews
- 6 reviewers reliability test
- Reviewed 30 randomly selected inpatients w/ ADE signals

Retrospective EMR review
- April. 2005 inpatients for a month
- EMR Reviewed by 6 pharmacists for suspected ADE
- Supervised by clinical pharmacists & physicians
- ADE identified

Prospective EMR review
- 7/18/2006 ~ 8/17/2006 inpatients for a month
- EMR Reviewed by 6 pharmacists for suspected ADE
- Supervised by clinical pharmacists & physicians
- ADE identified daily

Data Analysis
- Data collected in a structured format
- Kappa value for reliability test using SAS
- Descriptive statistics using SPSS 12.0

Figure 2. Study flow

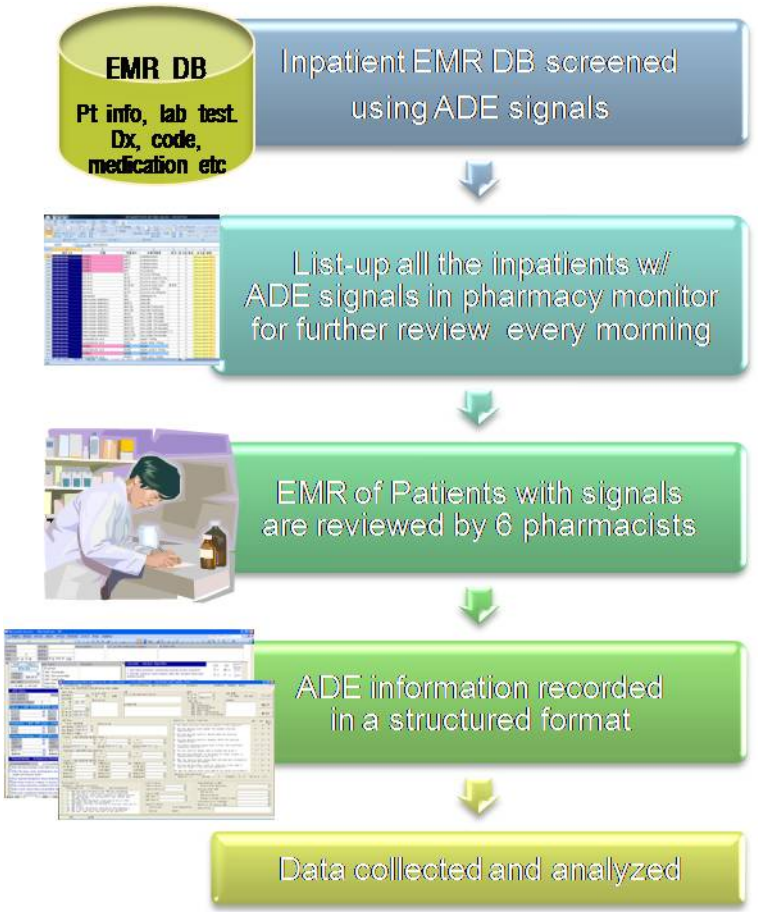

Figure 3. ADE identification process

Results (1/4)

- Reliability test among reviewers
  - Kappa value was .87 which meant almost perfect agreement among reviewers.
  - For 30 patients sample reviewed by 6 pharmacists
- Summary of study results

Methodology	Retrospective	Prospective
Study period	2005. 4/1~4/30	2006.7/18~8/18
total inpatients	3608	3510
Signal screened patients	457	478
Signal screened rate among inpatients	12.7%	13.6%
# of Signals detected	609	698
# of ADE during the study	145	120
ADE incidence among inpatients	4.0%	3.4%
PPV of ADE signal	23.8%	17.2%

Results (4/4)

Table 4. Medications with high frequency of ADEs in retrospective chart review

Medications	Frequency	Percentage
antiinfectives	80	46.5%
NSAID	17	9.9%
anticonvulsant	14	8.1%
analgesic	14	8.1%
radiocontrast	14	8.1%
gastrointestinal	12	7.0%
cardiovascular	8	4.7%

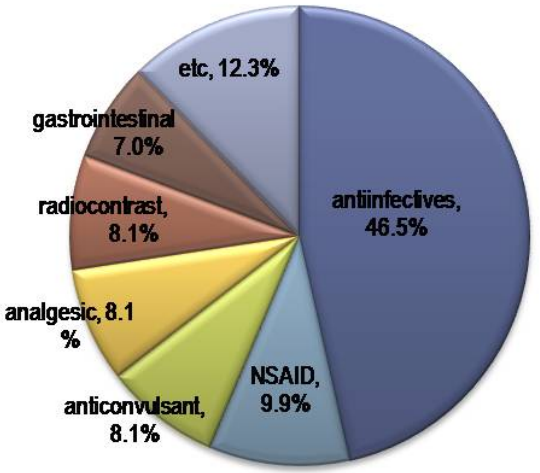

Table 5. Medications with high frequency of ADEs in prospective chart review

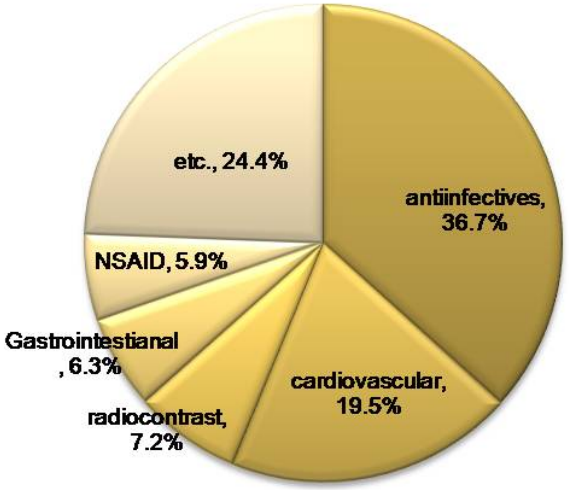
Medications	Frequency	Percentage
antiinfectives	81	36.7%
cardiovascular	43	19.5%
radiocontrast	16	7.2%
Gastrointestianal	14	6.3%
NSAID	13	5.9%
Diabetes medicatio	11	5.0%



Discussion

- Comprehensiveness of ADE signals
  - Lab and medication oriented signals
- Sample size of each signal
  - Statistically enough sample size for ADE incidence
  - However, not for each signal validation
- Technical errors
  - Missing signals in retrospective study
  - Signal errors by technical mistakes
- Medication CDSSs already in operation
  - Contraindications, drug-drug interactions, order duplication, etc in EMR system
- Methodology characteristics In nature
  - Since the care process was ongoing, ADE identification was ongoing in prospective chart review without conclusion.

Conclusions

- Failed to compare methodological differences
  - Better assumed to compare ADE reporting types
  - Not enough sample size to compare each signals
- Future direction for ADE surveillance system
  - ADE signals refined compared to previous studies
  - Model of ADE system for EMR hospitals to show what kind of EMR data collected in DB
- Further research needed
  - Evidence of clinical and economical benefits of the system
  - System usability
  - Physician attitudes to improve the practice patterns

Sustainable Health Care Information Systems by Activity Driven ISD Model

Anja Mursu[a], Marika Toivanen[a], Irmeli Luukkonen[a], Anneli Ensio[b]

[a] *Department of Computer Science, University of Kuopio, Finland*
[b] *Department of Health Policy and Management, University of Kuopio, Finland*

Abstract

The purpose of our project is to 'zip up' the distance between the different worlds of work improvement and information systems development. The initial premise for development activity comes from the needed improvements of services provided to e.g. health care customers. In addition to the suitability of the technology itself, the development activity should be participative and transparent through the organization. We have developed an applicable model for work and information systems developers to create sustainable information system. The model has been applied in several pilot cases in health care sector (in collaboration with researchers, system developers and health care practitioners). In this paper the basic idea of the model is presented and reflected to the aspects of sustainable information system.

Keywords:

work, information systems, program development

Introduction

The purpose of information system (IS) - which is a socio-technical system including technology and people - is to facilitate and help work activities. To develop effective health care services with the help of information and communication technology (ICT), we have to combine IS development with work development.

In the ZipIT-project[1] (2004-2007) we have participated as researchers on IS development projects in various health care organizations. The objective is to develop a model to be used when a health care organization needs to improve their information system. The model is based on activity theory, and participatory design. It is meant to be used for example by work developers in health care organization, data administration professionals in health care organization, and system designers and analysts in software companies. The purpose of this paper is to discuss the model in light of sustainable information system development by advocating the users' position.

1 www.uku.fi/zipit/english

Methods: Activity driven research approach and sustainability

In order to create appropriate, sustainable and usable information systems in organizations, the basic object of analysis should be activity system instead of information system [1] [2]. Activity theory cf. [3] has been elaborated and re-developed at the University of Kuopio and Savonia University of Applied Sciences for the needs of IS research in several research projects [1] [4].

The basic value of technology comes from the improvements achieved by technology and how these improvements are sustained and enjoyed over time in organization. Sustainable development means a process that meets the need of the present state without compromising the ability of future development. The criteria of sustainability must be considered during information systems development (ISD) that should empower user community, meaning user participation [5]. The aspects of sustainable IS are derived from appropriate technology, supportive activities and the real need of ICT [4].

Result: Activity driven ISD model

According to the activity driven ISD model (Figure 1) we have to analyze activity at different levels, and integrate the different levels to each other; individual level (actions), group/activity level (work processes), and organizational level (network of activities). At each level the work and information system, linked up with each other, are analyzed with different fineness of detail.

Level 1: Network of activities and information needs

This level of description provides shared understanding of the network or the chain of activities focusing on:

- Overview of activities: Networked health care service providers, stakeholders, patients, motivation.
- Overview of Information systems: Infrastructure, information entities, communication in the network.
- Sustainability factors: supportive activities (technical, system, intellectual, managerial), top management competence and commitment.

Level 2: Work activity and information system

This level zooms in to the essential activities focusing on:

- Work activities and processes**:** professionals' work, goals, inputs and outputs of processes, users, tasks, tools.
- Information systems and data flows: Means of communication and coordination**,** information needs and information tools in processes, information flows
- Sustainability factors: appropriateness to group work, operational and technical suitability of ICT, usability, affordability, flexibility.

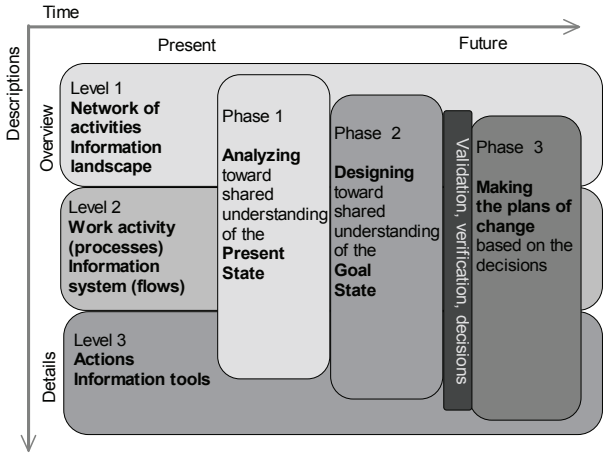

Figure 1 - Dimensions, levels and phases of the Activity Driven ISD Model

Level 3: Actions and information tools

This level of description provides shared understanding of the actions of individual actors focusing on:

- Actions: information processing tasks, interaction between user and information tools
- Information tools: data compositions, interfaces
- Sustainability factors: appropriateness to individual tasks, standards, usability.

On the other hand, the model has three main phases of development: analyzing the **present state** of an activity, defining the **goal state**, and **planning** how to reach the goal state. The phases do not follow each other like a water-fall, but the process is usually iterative. Also, depending on the case, the project can be restricted for example on the first phase if we only need to find out problems in our activity for decision making. The change actions can be in different scales. Sometimes it is necessary to take big steps, but also less dramatic gradual changes can be planned based on different time perspectives.

Discussion and conclusion

When it comes to requirements of appropriate and sustainable information system, user participation is one key element. Firstly, clinical staff, like nurses and doctors, is responsible to provide the nursing services as good as possible. As experts of their work, they are in key position to give requirements to appropriate tools, e.g. ICT.

The main responsibility of the service chain is for top management. Top management is in the position to realize the impact of new ICT in the service chain; what is the real need of ICT for better services. Top management should be able to set long distance and short distance goals, and decide the proper actions for next development phase. They should provide sufficient resources to development work, and create proper supportive activities for sustaining the use of IS.

We believe that the Activity driven ISD model can act as a tool in decision making and practical realization of IS development and work development. Top management can apply the two uppermost levels to decide the real need of ICT, the need for resources, and essential changes in work activities. With the help of the model it is possible to illustrate the real impact of ICT for services, and this way to improve ICT's suitability to work. On the other hand, clinical staff and people operating with development activity have a tool to analyze the present state and to decide the proper actions in ICT introduction. With the help of the model the management and the practical level have a common tool to see the development objectives and phases and thus achieve a common understanding of the development and make the development process more transparent.

Acknowledgments

Activity Driven ISD Model

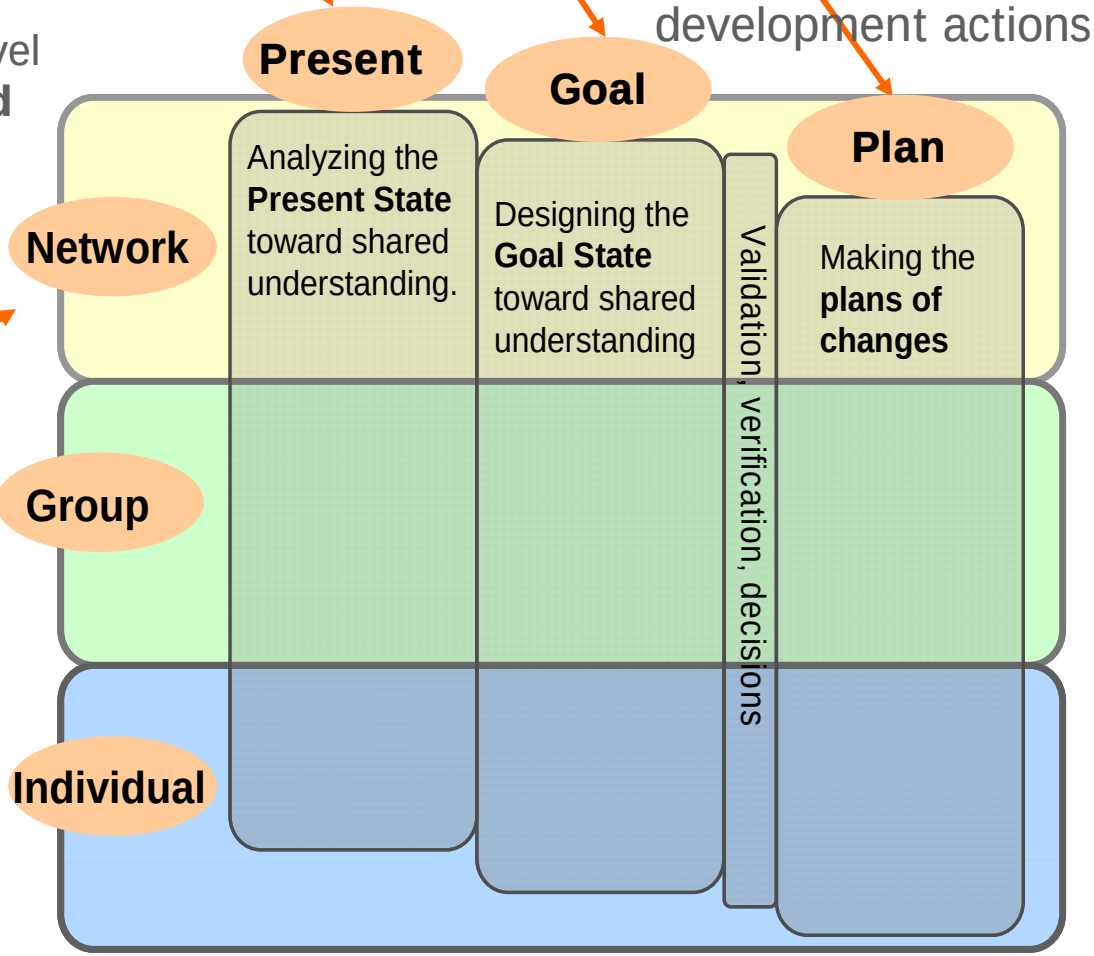
The process for activity driven requirements includes **three main phases of development**.

The idea is to **analyze activity at different levels**, and integrate the different levels to each other. At each level the work and information system, **linked up** with each other, are analyzed with different fineness of detail.

Three phases of development:

1. **Analyse** the present state
2. **Design** the goal state
3. **Make a plan** for development actions



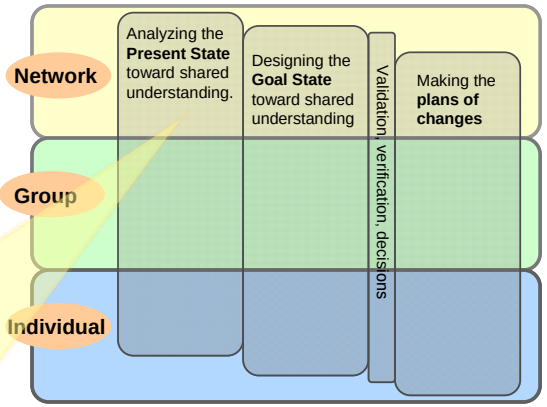
Three levels of analysis:

1. Organizational level
Network of activities & information landscape

2. Group/activity level
Work activity (process) & information system

3. Individual level
Actions and information tools

Level 1: Network of activities and information landscape



Level 1: Network of activities and information landscape. This level of description provides shared understanding of the network or the chain of activities focusing on:

Overview of activities:
Networked health care service providers, stakeholders, patients, motivation.

Overview of Information systems:
Infrastructure, information entities, communication in the network.

Sustainability factors:
Supportive activities
(technical, system, intellectual, managerial),
top management competence and commitment.

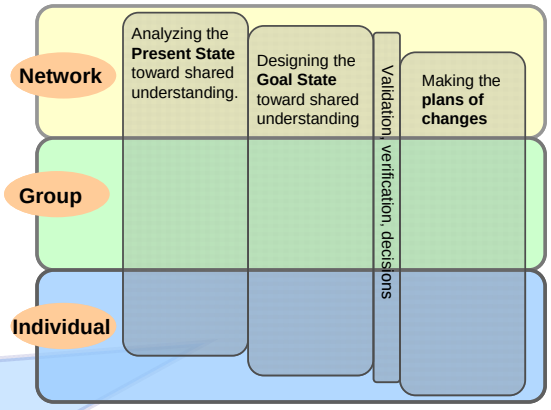
Level 3: Actions and information tools

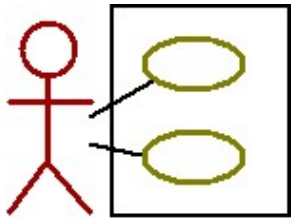


Level 3: Actions and information tools. This level of description provides shared understanding of the actions of individual actors focusing on:

Actions:
Information processing tasks, interaction between user and information tools

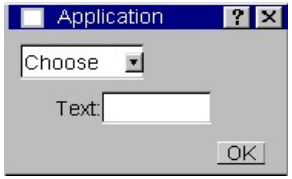
Information tools:
data compositions, interfaces

Sustainability factors:
Appropriateness to individual tasks, standards, usability.



USE CASES

Photo: ZipIT project



DRAFT OF USER INTERFACE

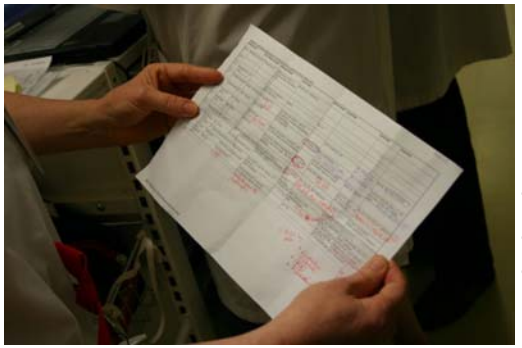


Photo: ZipIT project

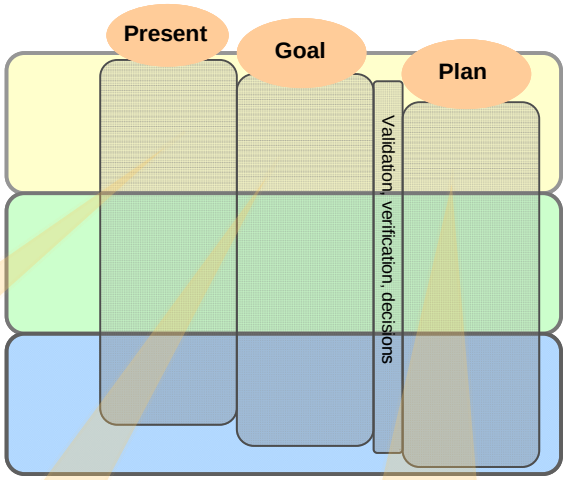
Phases

The Activity driven ISD model has three main phases of development. The phases do not follow each other like a water-fall, but usually it is necessary to **iterate**.



1.Analyzing the **present state** of an activity

For eliciting data e.g. interviews, observation, guided work-tours.
For validating data e.g. workshops and focus group sessions.

2.Desining the **goal state**
For goal state elicitation e.g. brainstorming and workshops.

What would be the perfect world look like?
How would we like the information system to serve us?

3. **Planning** how to reach the goal state.

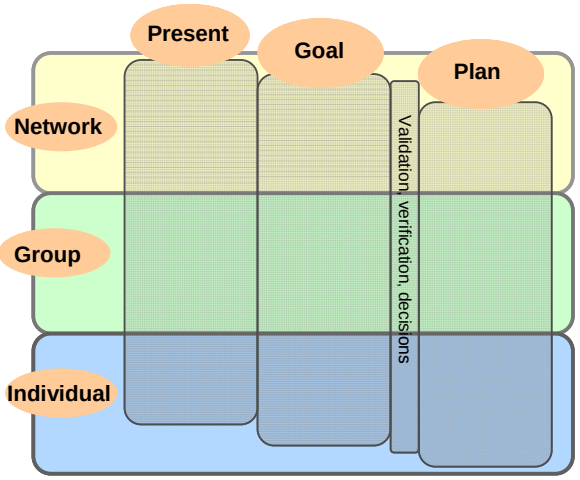
Based on the present state and the goal state the development actions need to be planned and organized.

Also, the project can be **restricted** for example on the first phase if we only need to find out problematic points in our activity for decision making.

The change actions can be in **different scales**. Sometimes it is necessary to take big steps, but also less dramatic gradual changes can be planned based on different time perspectives.

Sustainability

The basic value of technology comes from the **improvements achieved by technology** and how these improvements are **sustained** and enjoyed over time in organization. Sustainable development means a process that meets the **need of the present state** without compromising the ability of **future development**.



The criteria for sustainability are threefold:

- Firstly, the **capacity to sustain** the IS in use by the network of **supportive activities** and the possibility for **further development** must be ensured.

- Secondly, the **appropriateness of ICT** as means to use activity must be analyzed. New ICT must fit technically and be functionally correct.

- Thirdly, the demand of ICT for **improving the service** for clients must be real, and the impact of ICT for the service must be clear.

These criteria must be considered during information systems development that should empower user community, meaning **user participation**.

Participation

- advocating the users' position
=> **involving users** to the development process
- make the development process **transparent**
- **different** professionals have their own **viewpoints**
=> need to achieve **shared understanding**

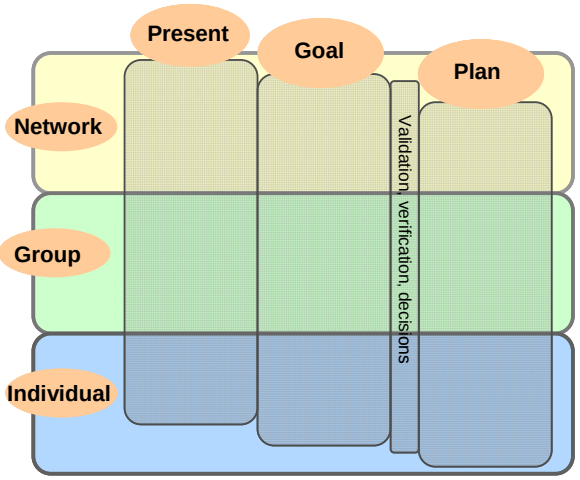


Photo: ZipIT project

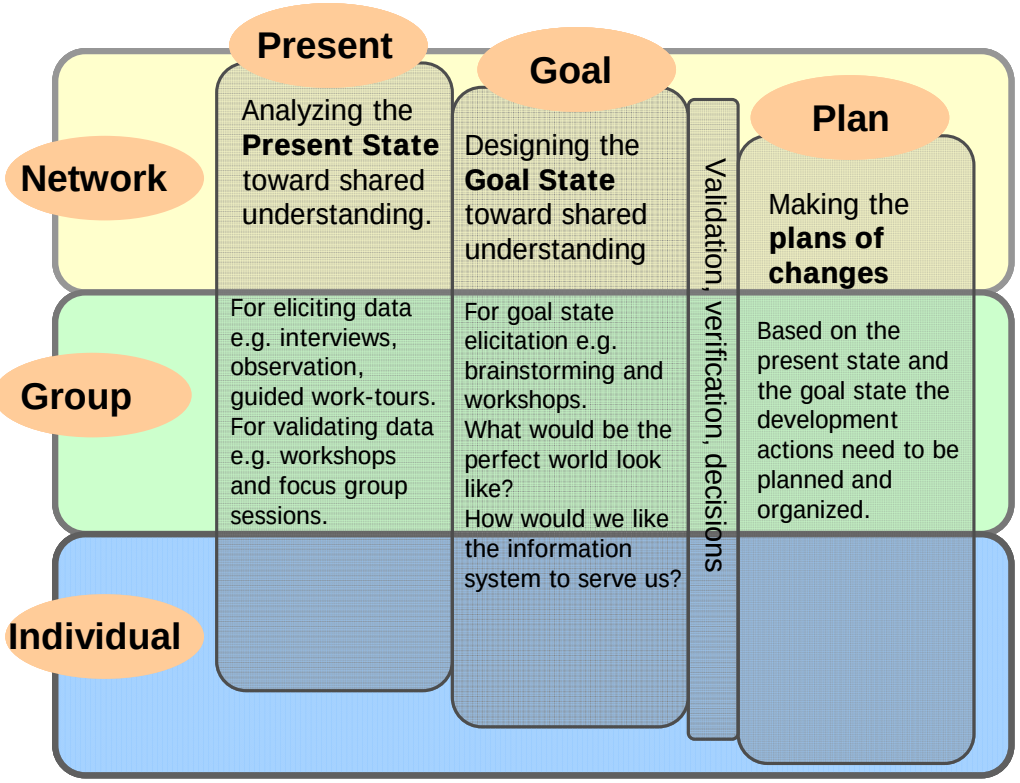
As an example we had a pilot case where the task was to analyze how a new digital radiological imaging and archiving system would impact on activities in a health care centre, before purchasing any equipment. Radiological imaging unit produces services to other health care units, and information needs of those units do have impact on how radiological imaging should be arranged in future.

In couple of multi-professional workshops
the work flows and related information and information system were discussed.

With the help of the activity analysis,
- the changes were easy to locate,
- the goal state of an activity was possible to define and
- ensure the suitability of technical solution to the workflows.

Summary & Discussion



When it comes to requirements of appropriate and sustainable information system, **user participation is one key element**.

Activity driven ISD model can act as a **tool in decision making** and practical realization of IS development and work development. It is possible to illustrate the **real impact of ICT for services**, and this way to improve ICT's **suitability** to work.

Clinical staff and people operating with development activity have a **tool to analyze the present state**, **ideate the goal state** and to **plan the proper actions in ICT introduction**.

With the help of the model the management and the practical level have a common tool to see the **development objectives and phases** and thus achieve a **shared understanding** of the development and make the development process more **transparent**.

분당서울대학교병원
SEOUL NATIONAL UNIVERSITY BUNDANG HOSPITAL

Introduction

- Electronic medical record (EMR) coupled with clinical decision support systems (CDSS) is highly effective in reducing the frequency of medication error, thereby improving the safety of the patients.

- A number of important therapeutics agents are excreted from kidney thus, renal patients are likely to necessitate the adjustment of the dosage for these agents.

- However, the implementation of such assistant function has not been reported nor evaluated in CDSS.

Objective

The purpose of this study is to develop knowledge based renal dose adjustment system which can be applied into electronic medical record at real time in Korean clinical practice

Methods

Establish drug dosing guideline

- Screening : all medications prescribed in patients with renal impairment
- 255 medications were finally selected
- The guideline reviewed by physicians
- The finalized guideline was then applied in the dosage adjustment system

Classification renal impairment

- Cockroft-Gault Equation **GFR(*mL/min*) <10, 10-50, >50**
- At the time of physician's prescription

  CLcr , dosing guideline, potential renal insufficiency
- Real-time displayed relevant dosing guideline
- Allows the physician to change or discontinue order or ignore

Methods

- Creatinine Clearance (ml/min)
  collecting 24 hour urine
  calculated by Cockroft-Gault equation
- Adjusted doses were decided by experts
- Produced dose adjustment system were applied into BESTCARE (Seoul National University Bundang Hospital Electronic Medical Record System)
- Efficiency in real practice was analysed retrospectively.

Results

The current system is operated from August of 2006.
Revised for the further reduction of the false positive alerts and the ratio for the override

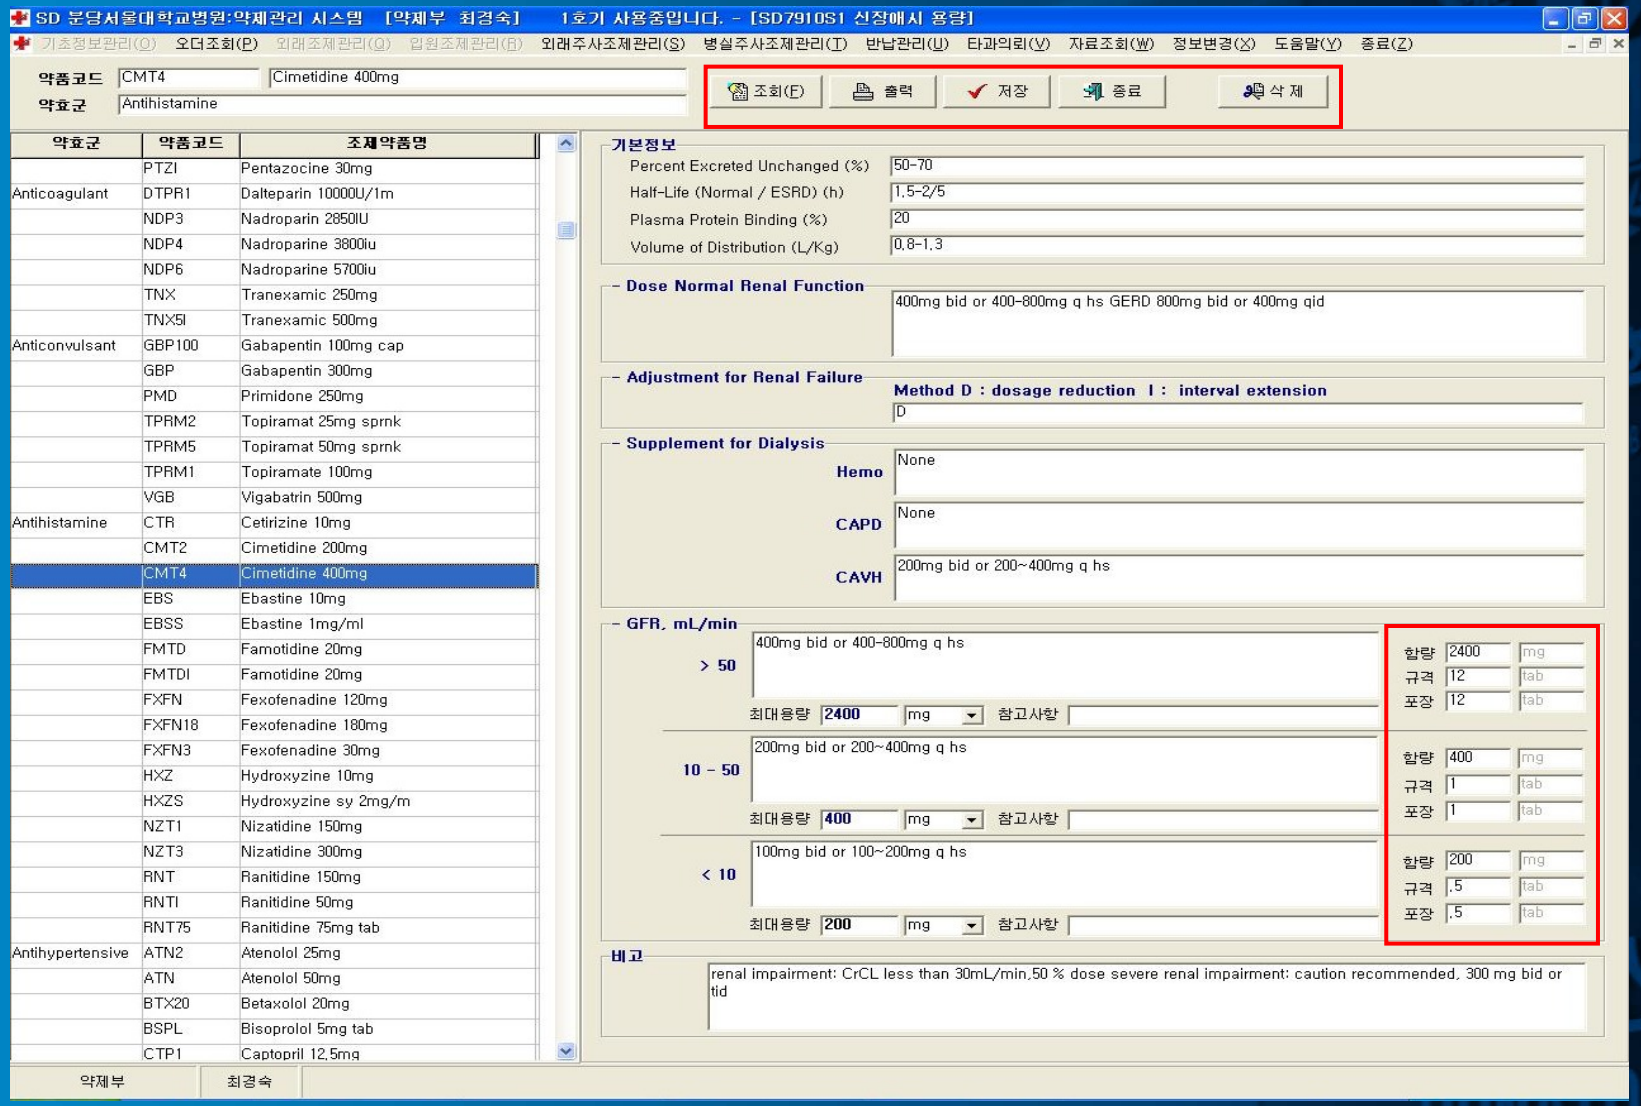
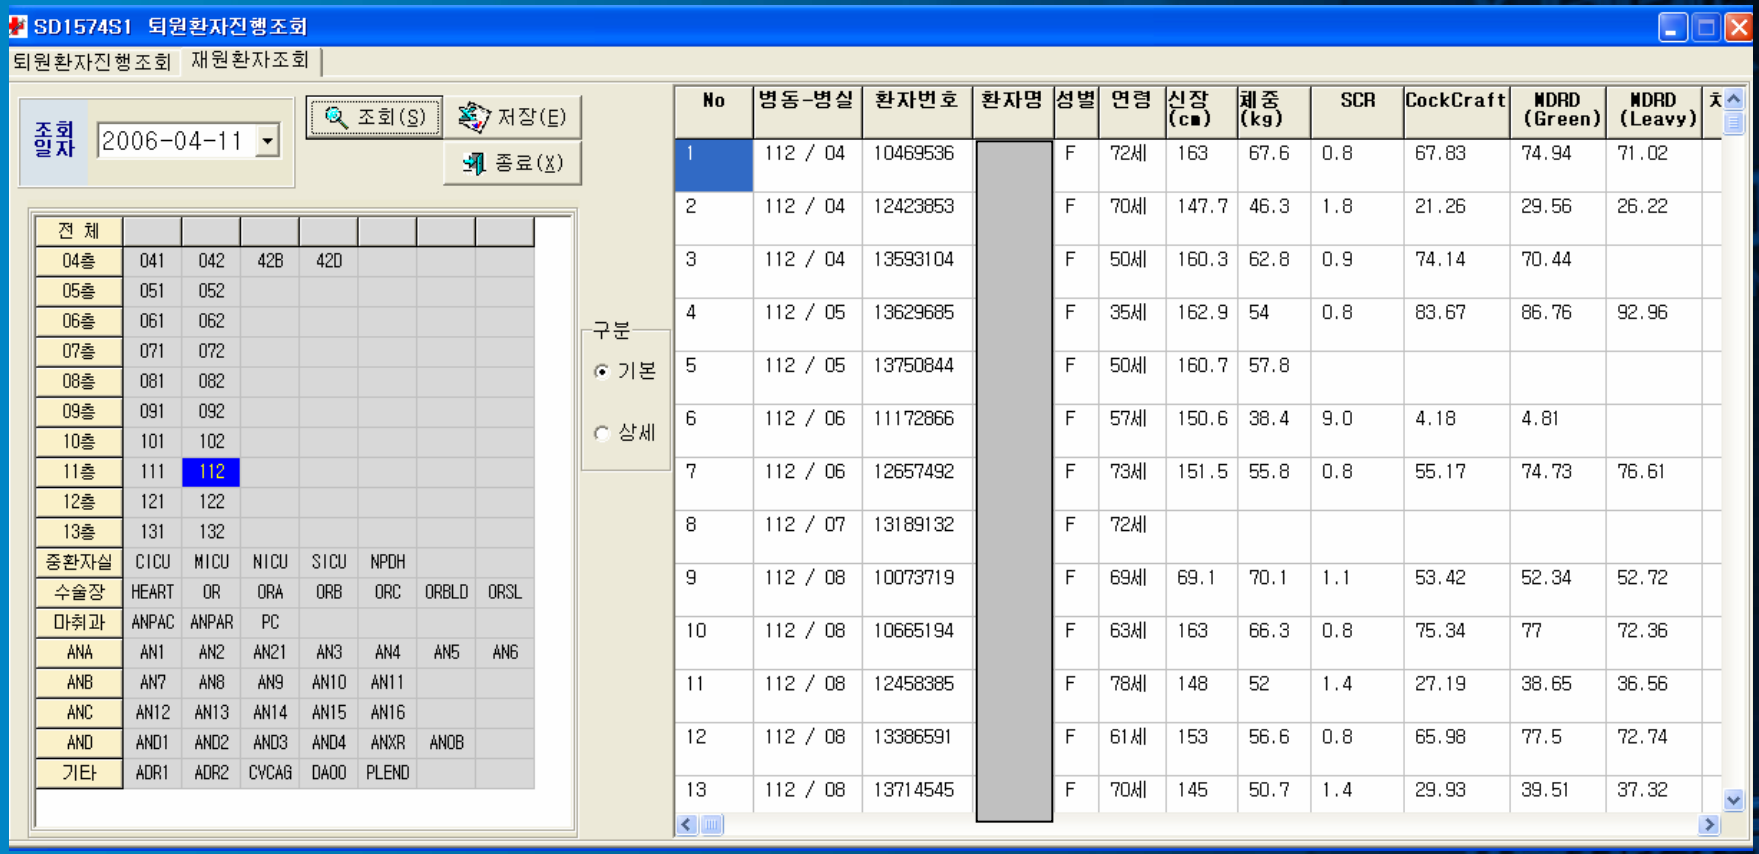
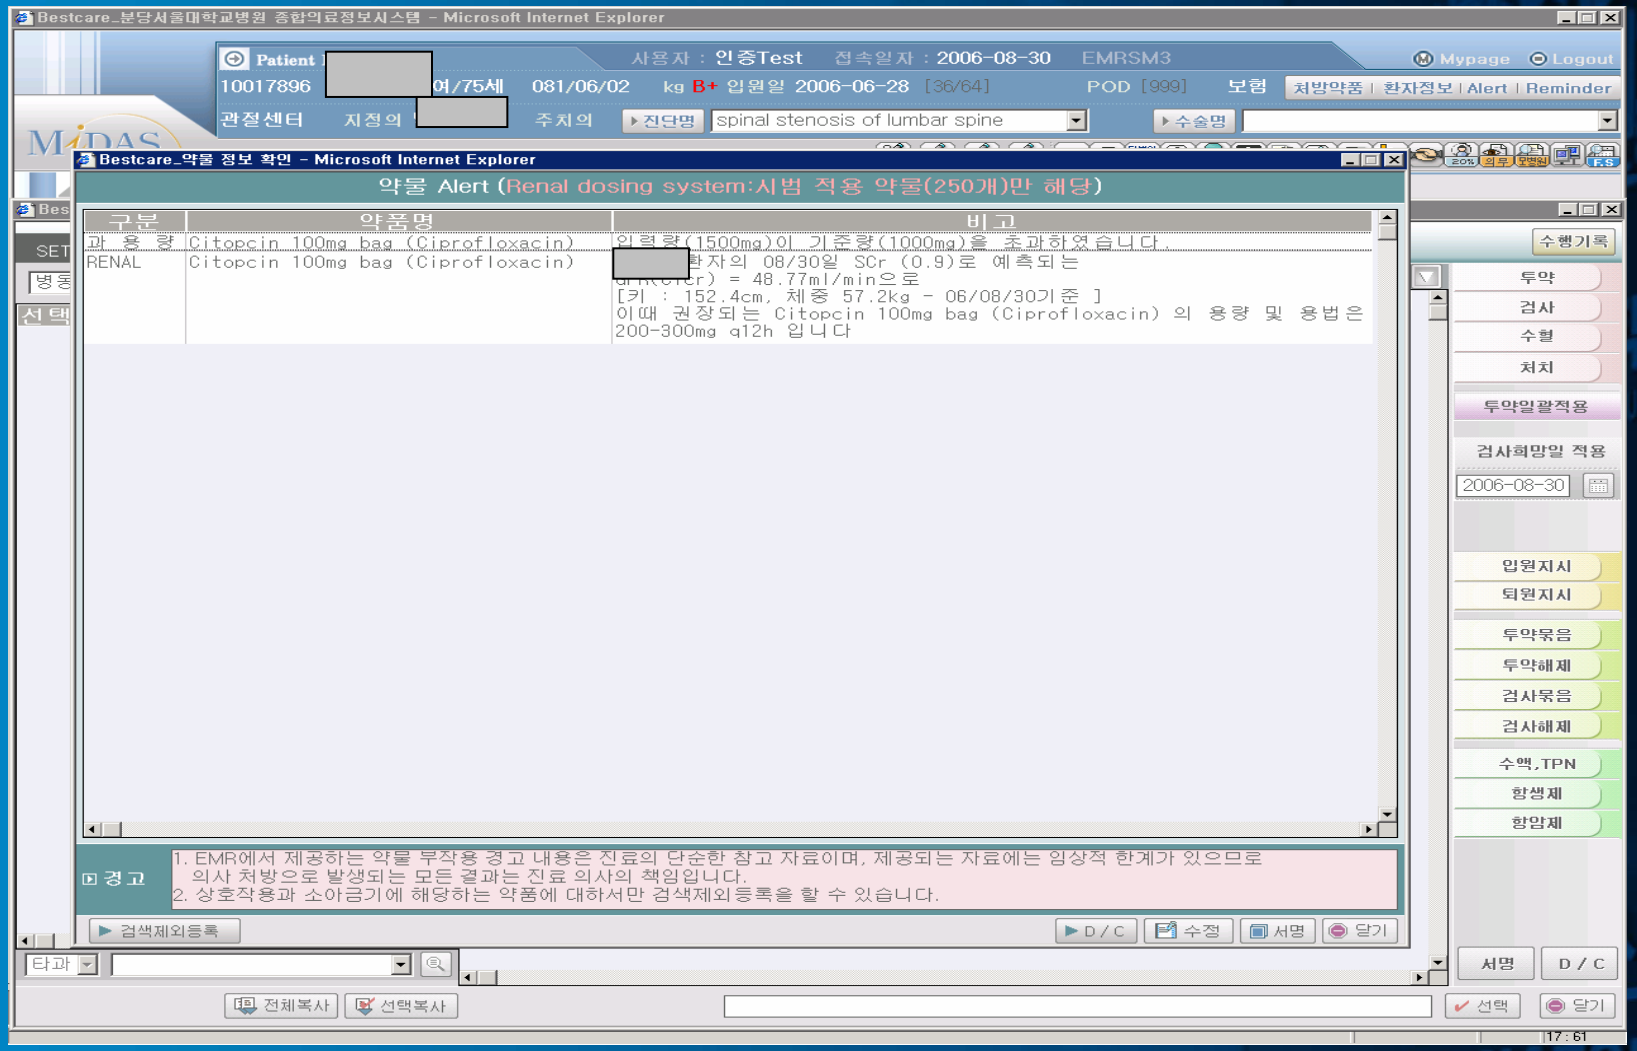
The Dosing guidelines in pharmacy master



Dose adjustment system in Ward as a unit



real-time alert window



Conclusions

- Produced dose adjustment system were successfully applied into BESTCARE (Seoul National University Bundang Hospital Electronic Medical Record System) from August, 2006.
- Real-time alert window was effectively realized to clinician's monitor at office simultaneously if inadequate doses were prescribed.
- This help physician's dose adjustment and prevent overdose in renal patients.
- The current system may be practically useful in the improvement of the safety in renal insufficient patients resulting in the realization of the effective Pharmacotherapy.

[c] Graduate School of Clinical Pharmacy, Sookmyung Womens's University, Korea
[d] Center for Interoperable Electronic Health Record, Korea

Abstract and objective

It is now widely accepted that the electronic medical record (EMR) coupled with clinical decision support systems (CDSS) is highly effective in reducing the frequency of medication error, thereby improving the safety of the patients. A number of important therapeutics agents are renally excreted from the body and, thus, a renal insufficiency of a patient is likely to necessitate the adjustment of the dosage for these agents. However, the implementation of such assistant function has not been reported nor evaluated in the literature for the case of CDSS. Therefore, the objective of the current study was to develop, implement and evaluate the renal function based dosage adjustment system in the CDSS, SNUBH

Keywords:

computerized prescription order entry,
renal dosing system, clinical decision support systems

Introduction

Seoul National University Bundang Hospital (SNUBH) represents one of the first medical institutions in Korea that has the full implementation of EMR-CDSS. The current system allows additional implementation of computerized prescription order entry (CPOE), e.g., CDSS for the identification of drug induced allergic reaction, drug-drug interaction, therapeutic duplication and assistant functions for the rationale prescription of antibiotics/anticancer agents. We were particularly interested in, if necessary, the provision of appropriate dosage and the dosing interval to the physician at the time of the completion of the order entry.

Methods

The Dosing guidelines were compiled for all medications used in our institution that are renally excreted. The guideline was then reviewed for the appropriateness by the physicians in the Departments of Nephrology and Infectious Diseases. The finalized guideline was then applied in the dosage adjustment system. Depending the availability of patients' measured creatinine clearance (Ccr) values, the system may use Cockcroft-Gault equation, if necessary for the evaluation of the renal insufficiency. Upon the completion of the order entry, the system checks for Ccr value of 50 mL/min or higher and the daily dose. Depending on the dosing guideline and the potential renal insufficiency, a warning message, along with the Ccr value and the relevant dosing guideline is real-time displayed. The system allows the physician to change or discontinue the order or ignore the alert to complete the order as it is.

Results

The current system is operational in our institution from the August of 2006. The initial evaluation has been completed and the system revised for the further reduction of the false positive alerts and the ratio for the override.

Conclusions

The current system may be practically useful in the improvement of the safety of the renal insufficient patients and the realization of the effective pharmacotherapy.

Developing a System to Provide Patient-centered Information Handouts about Laboratory Tests

Emiko Yamada[a], Yutaka Yatomi[b], Kazuhiko Ohe[a]

[a] *Department of Medical Informatics and Economics, University of Tokyo, Japan*
[b] *Department of Clinical Laboratory, University of Tokyo Hospital, Japan*

Abstract and objective

The explanations given to patients scheduled for laboratory tests tend to be inadequate because medical doctors are faced with too much work and too little time. To improve this situation, we developed a system to provide printed handouts using a hospital information system (HIS). First, we conducted a questionnaire survey to clarify the patients' needs for explanations regarding specific blood tests. Next, we developed a system that generated explanation handouts for those blood tests. The results showed that patients have high demands for sufficient blood test information and preferred printed explanations. As our system required only 1.36 sec after receiving an arrival message from the server to the start of printing, we believe that our system is practical.

Keywords:

information disclosure, hospital information systems, information services, patient handout

Introduction

While providing patients with sufficient explanations about medical practices is important, those given to patients scheduled for laboratory tests tend to be brief. The main reason in Japan is that physicians are constrained by heavy workloads that leave too little time [1, 2]. This study clarified patients' needs using a questionnaire survey and developed a system to provide patients with handouts that explained blood tests.

Methods

We surveyed outpatients on their needs for information about specific blood tests. Outpatients at the University of Tokyo Hospital were asked to complete a questionnaire consisting of 27 questions. Based on the results, we chose paper as the information medium because it has the advantages of being able to be 'read anytime, anyplace, without any tools' [3]. We selected 72 items for the handout content, which covers about 70% of the target orders, and wrote an explanation for each These explanations were verified by a physician and the staff of the clinical laboratory center. We developed a system for printing the handouts explaining laboratory tests (Figure 1) and evaluated its performance by measuring the operational time.

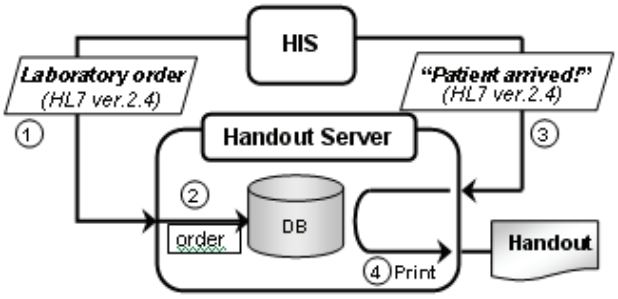

Figure 1 - An overview of our system (1) The HIS sends a laboratory order to the Handout Server. (2) The Handout Server parses the order and saves the information. (3) The HIS sends the patient's arrival message to the Handout Server and (4) the Handout Server prints a handout for the patient

Results

The results of our survey indicated that over 80% of the respondents demanded that information and handouts be provided before blood tests. They were particularly interested in the purpose and subitems of the test (Fig. 2).

The response time speed was shown in figure3. Since it was on average 1.36 sec from receipt of a patient's arrival message to the start of printing (Fig 3), our system was shown to be practical.

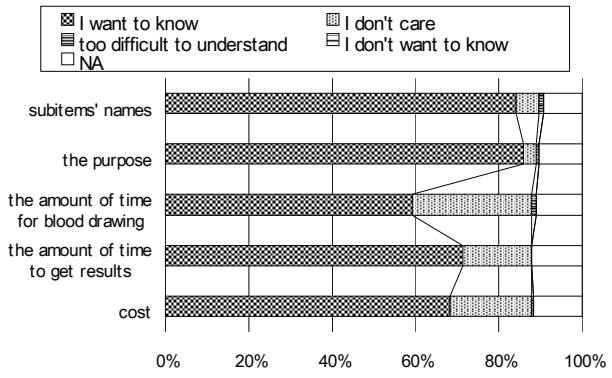

Figure 2 - "Would you like to know this information of the test?"

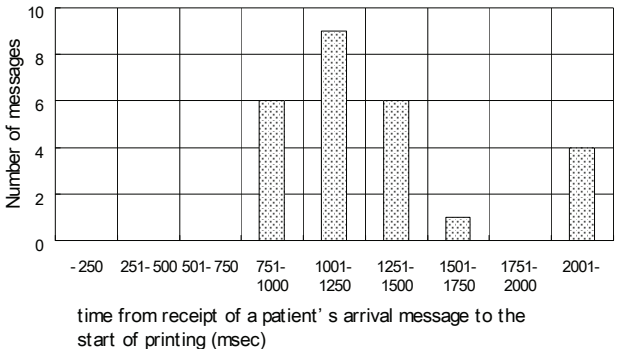

Figure 3 - The response time speed of our system

Discussion

Since the handout server is connected to the HIS over HL7, one can easily introduce it in another hospital.

Both the amount and the quality of information are limited as long as using paper as the information medium. One could direct patients who need more information to other information sources (e.g. web pages and books) and our system serves to provide minimal information.

Conclusion

So far, we have seen that many patients have needs for information about specific blood tests, and developed a system to provide them with handouts that explained blood tests. A further evaluation on the usefulness of the handouts is scheduled in 2007.

Developing a System to Provide Patient-centered Information Handouts about Laboratory Tests

Emiko Yamada[a], Yutaka Yatomi[b], Kazuhiko Ohe[a]

[a] Department of Medical Informatics and Economics, University of Tokyo, Japan

[b] Department of Clinical Laboratory, University of Tokyo Hospital, Japan

Introduction

Explanation given to patients scheduled for laboratory tests tend to be insufficient

- Physicians' workload
  - Too busy [1,2]
  - Laboratory tests is less invasive

Purpose

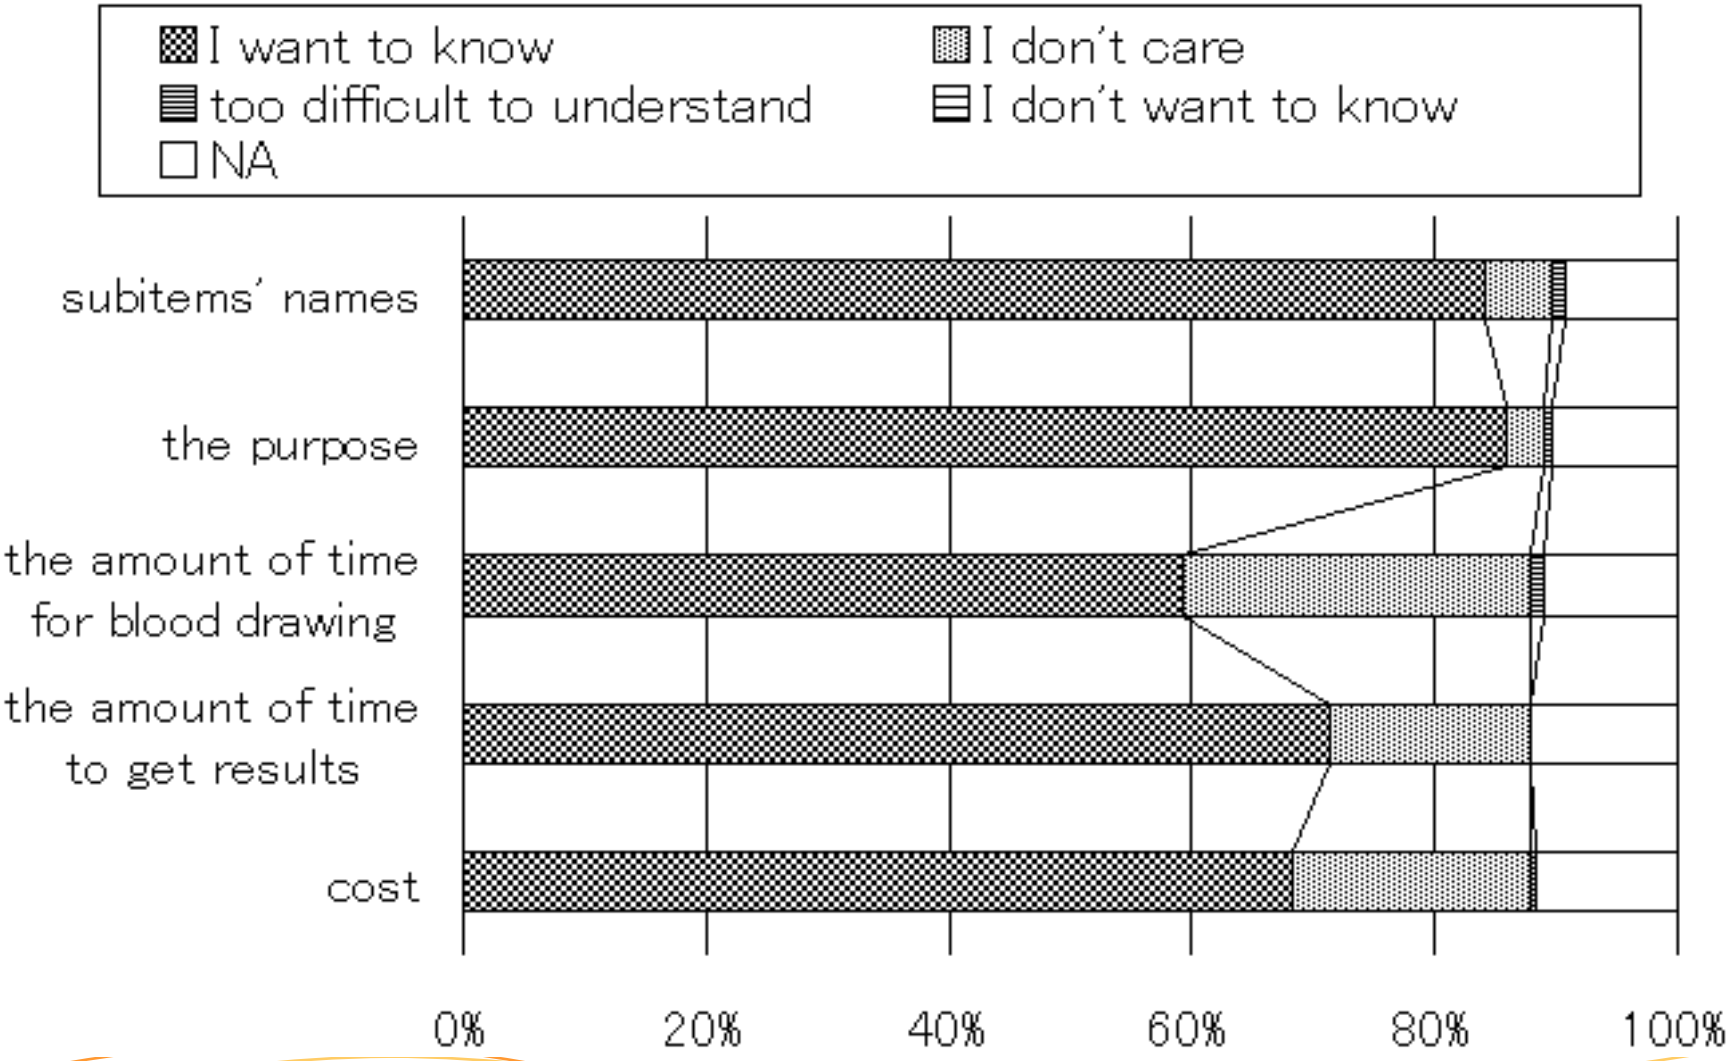
1. Clarify patient's needs for information about blood test
   - a questionnaire survey

2. Develop a system to provide handouts
   - Make use of Hospital Information System

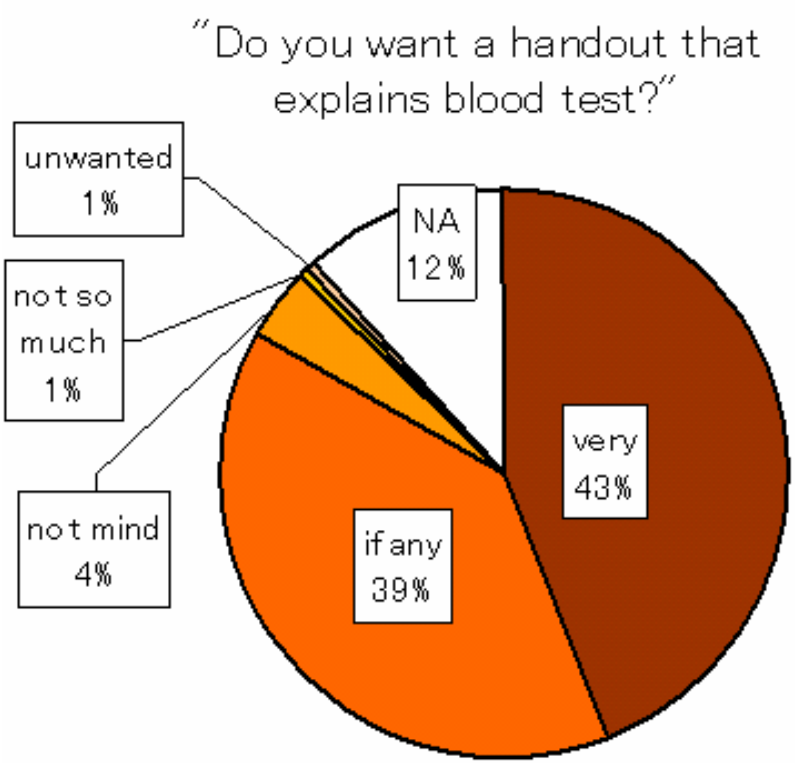
A Questionnaire survey

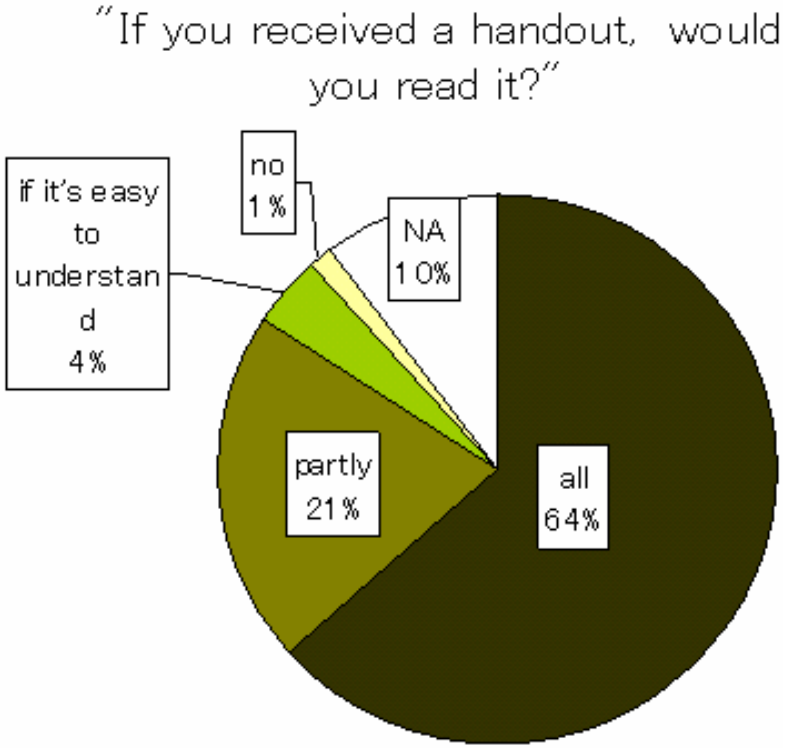
- Purpose
  - Which information of blood tests do patients need?
  - Do patients need handouts that explain blood tests?
- Method
  - Self-administering method
  - Period : 2005/7/1, 2005/7/2 (2 days)
  - Outpatients at the University of Tokyo Hospital
- 164 respondents

“Would you like to know this information?”



Do patients need handouts?

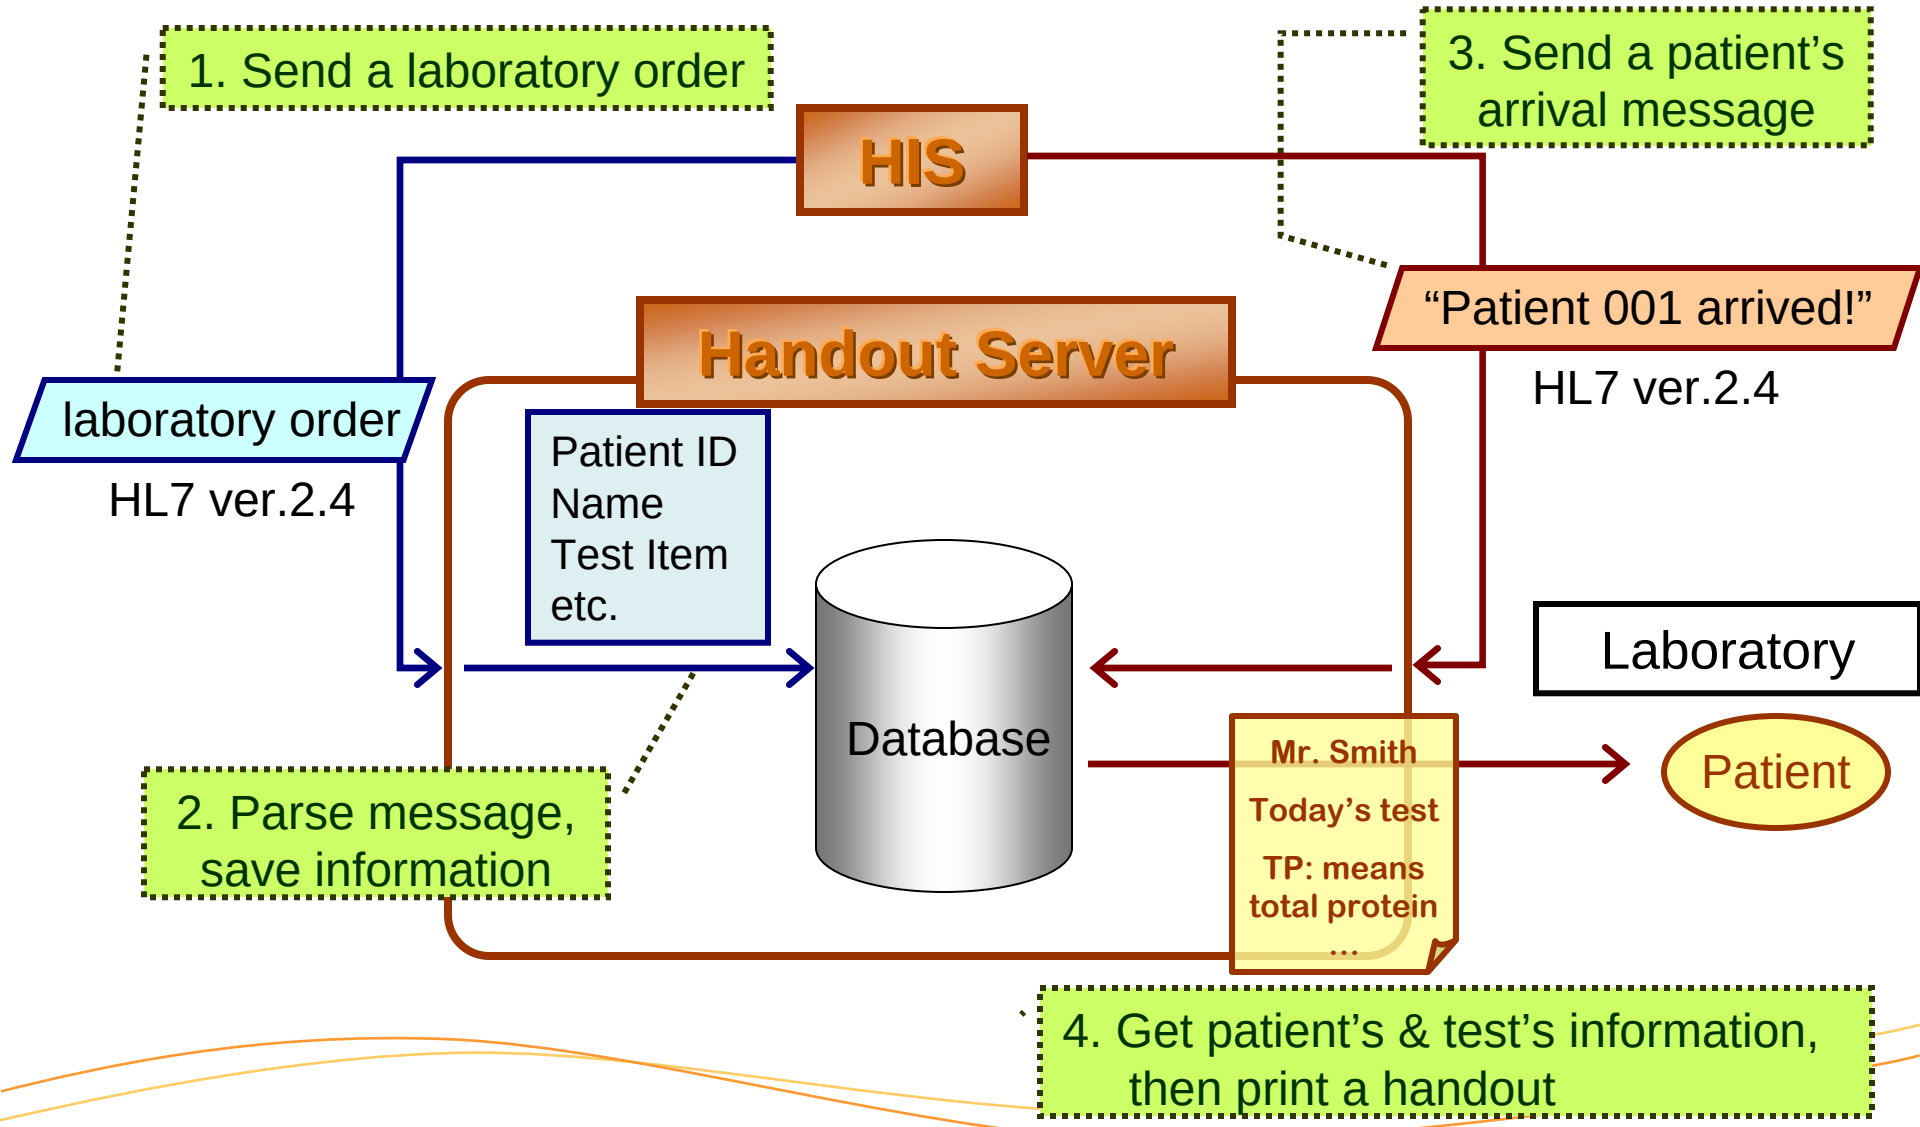




System development

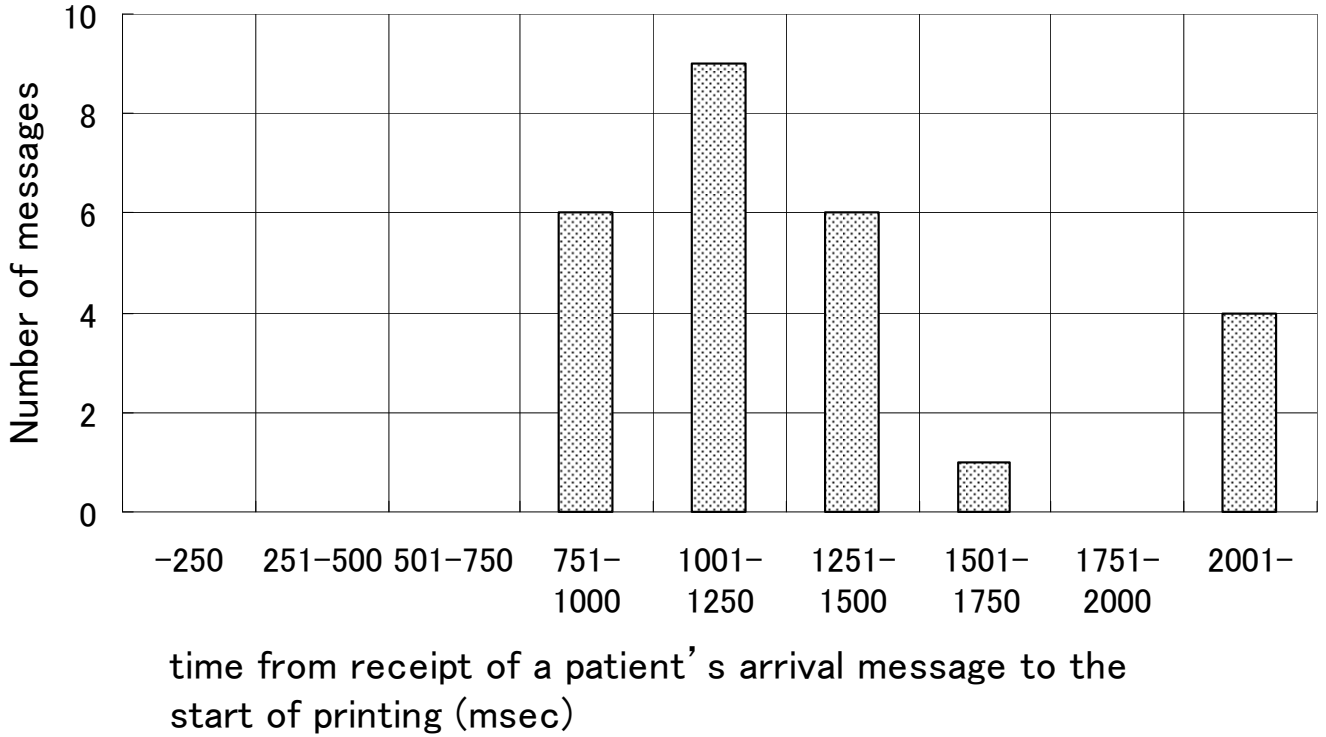
- The information medium : paper
  - Able to be ‘read anytime, anyplace, without any tools’ [3]
- The handout server
  - The HIS sends a laboratory order
  - Print a handout when a patient arrived at the laboratory
    - Connected to the HIS over HL7
- The handout
  - Patient’s name, date
  - Explanation of blood test
  - Names and the explanations of each items
    - Verified by a physician and the staff of the clinical laboratory center

System architecture



system evaluation

- The response time speed from receipt of a patient's arrival message to the start of printing (1.36 sec on average) ⇒ ***practical***



Discussion

- High connectivity
  - HL7
  - Easy to introduce the handout server in another hospital
- The information medium
  - Paper: limited quality and quantity of information
    - Provide minimal information
  - Compensate by directing patients to other information sources (e.g. Books, web pages)

Conclusion

- We have …
  - seen that many patients have needs for information about specific blood tests
  - developed a system to provide them with handouts that explained blood tests
- A further evaluation on the usefulness of the handouts
  - scheduled in 2007

Development and Evaluation of PACS, a Parallel Operation System with Improved Fault-tolerance

Masami MUKAI[a], Takumi TANIKAWA[a], Kouji UEMURA [b], Yutaka ANDO [a]

[a] *National Institute of Radiological Sciences, Chiba, Japan*
[b] *Kawasaki University of Medical Welfare,Kurashiki,Japan*

Abstract

We developed the dual PACS to enforce the robustness and the redundancy. These PACSs were made by two different vendors. We assumed that we had to continue the service without serious problems. By the different systems, users can select the suitable interface, and the systems become inevitable for the hospital information system.

Keywords:

PACS, filmless, fault-tolerance

Introduction

The Research Center of charged Particle Therapy Hospital, affiliated to the National Institute of Radiological Sciences (hereinafter called "this hospital"), began archiving digital medical images from 1995, and launched film-less operation from the summer of 2005. Image data obtained by inspection have been stored without being deleted because they are necessary for following up radiation therapies on a long-term basis. As of October, 2006, approximately ten million images obtained from approximately 120,000 cases of inspection are available, and all of them are stored on hard disks.

This time, with the expiry of the lease period of the former version of PACS, we changed PACS's configuration into a duplex one to upgrade equipment and avoid problems. This paper reports our experiences from this system's introduction together with the current operation status.

We set the following goals as the basic premise of the system upgrade. The first goal was to maintain the volume of work procedures to be performed by engineers or medical physicians at sites where images are created. Then, for the system to be used, we judged it was difficult to immediately switch over the system because terminals exclusive to viewing images coexist with researchers' individual workstations. The second goal was therefore to allow more than one systems to operate in parallel at any time.

Methods

As the systems, the first PACS was TechMatrix's "SDS-ImageServer," and the second PACS was Fuji Film Medical's "SYNAPSE."

For the former version of PACS, image data flowed as follows: 1) Images shot by inspection equipment (modalities) are sent to an intermediate server called, "AQGW (Acquisition Gateway)." 2) AQGW checks consistency between received images and patient master images, and then sends ones from which no problem was detected to a registered image server. The sent data are saved for a particular period, and then deleted automatically. 3) The image server makes it possible for users to view saved images using the viewer function as target images to be referred to. Thus, we designed a transfer procedure as follows: 1) Expand the functions of AQGW on the network for storing images so that images can be stored in more than one servers in parallel. 2) Start up a new PACS server (the first PACS) as a server exclusive to image viewing together with the former image server. Then, transfer image data using DICOM C-STORE along the course from transfer source to transfer destination. 3) Start up the second PACS server while maintaining parallel operation with the first PACS server when possible, and transfer image data using DICOM Q/R from transfer destination to transfer source. Figure 1 shows a schematic of the current system configuration.

Results

The system transfer finished without causing major problems such as long discontinuation of services or deficiency of data. At the end of August, 2006, approximately 20,000 images obtained from 60 cases of inspection were stored a day. Images stored in the first and second PACS servers become ready to view in five to fifteen minutes after a case of inspection has ended (this depends on the category of the inspection).

For users, the range of options was broadened because it became possible to use the viewer function according to uses. For the status of system use, we observed a trend that cases were classified into two types: One is viewing images obtained from more than one patients simultaneously, such as at a conference, and the other is viewing images obtained from one patient at a session of image interpretation.

Before the system transfer, a method to set up the viewer function on each workstation should have been simplified.

For the data transfer, approximately seven million target images were transferred in 32 days when the first PACS server was started up. On the other hand, it took approximately two and a half months to transfer approximately eight million images when the second PACS server was started up. This indicated that image storing can be completed from transfer source to transfer destination in a shorter time if a suitable work environment can be prepared.

For the current operation, it is necessary to check images by comparing them to each other based on the number of the user IDs assigned to images to maintain the consistency among multiple servers.

As future issues, for the first PACS, we are considering operation transfer to image-saving using a reversible compression method to effectively use disk space for image-saving. For the second PACS, we are going to allow authentication using individual user IDs to ensure correct audit trail.

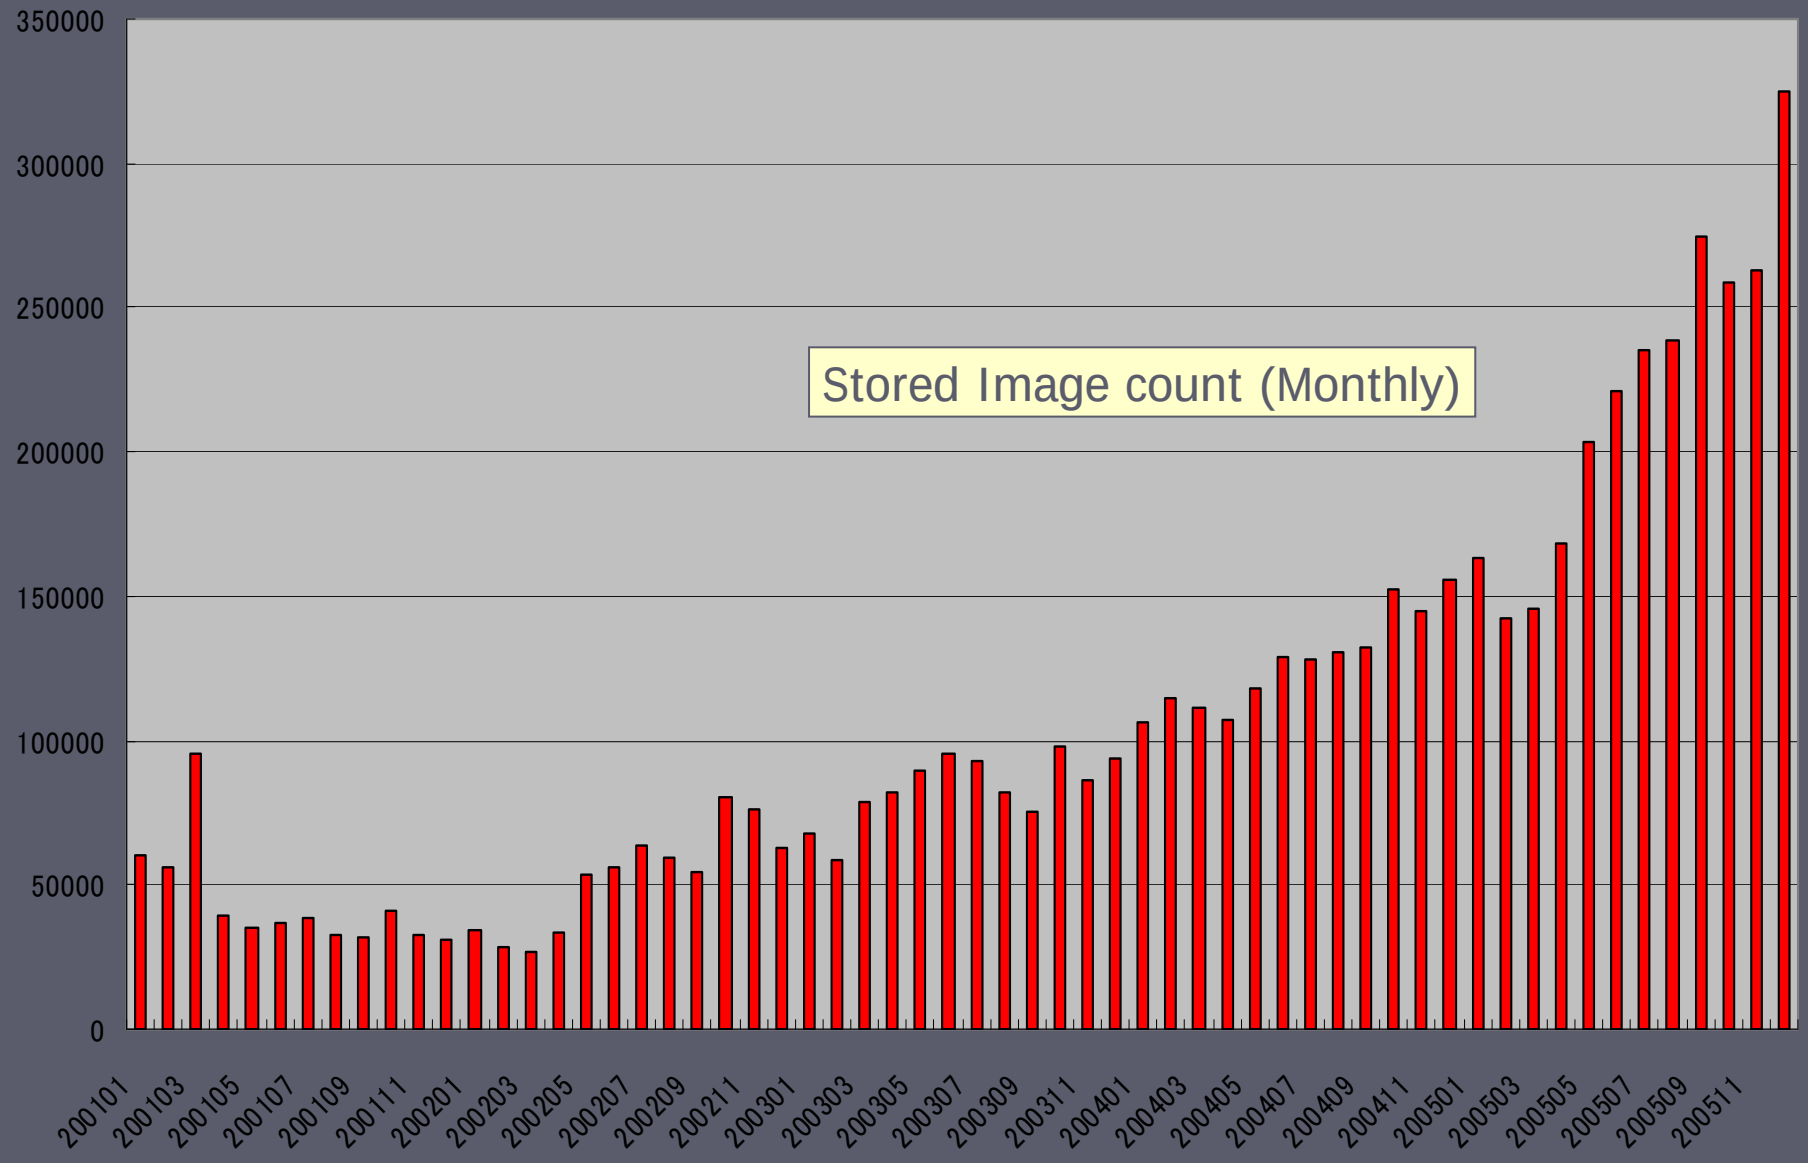
Client-Viewer
70 terminals

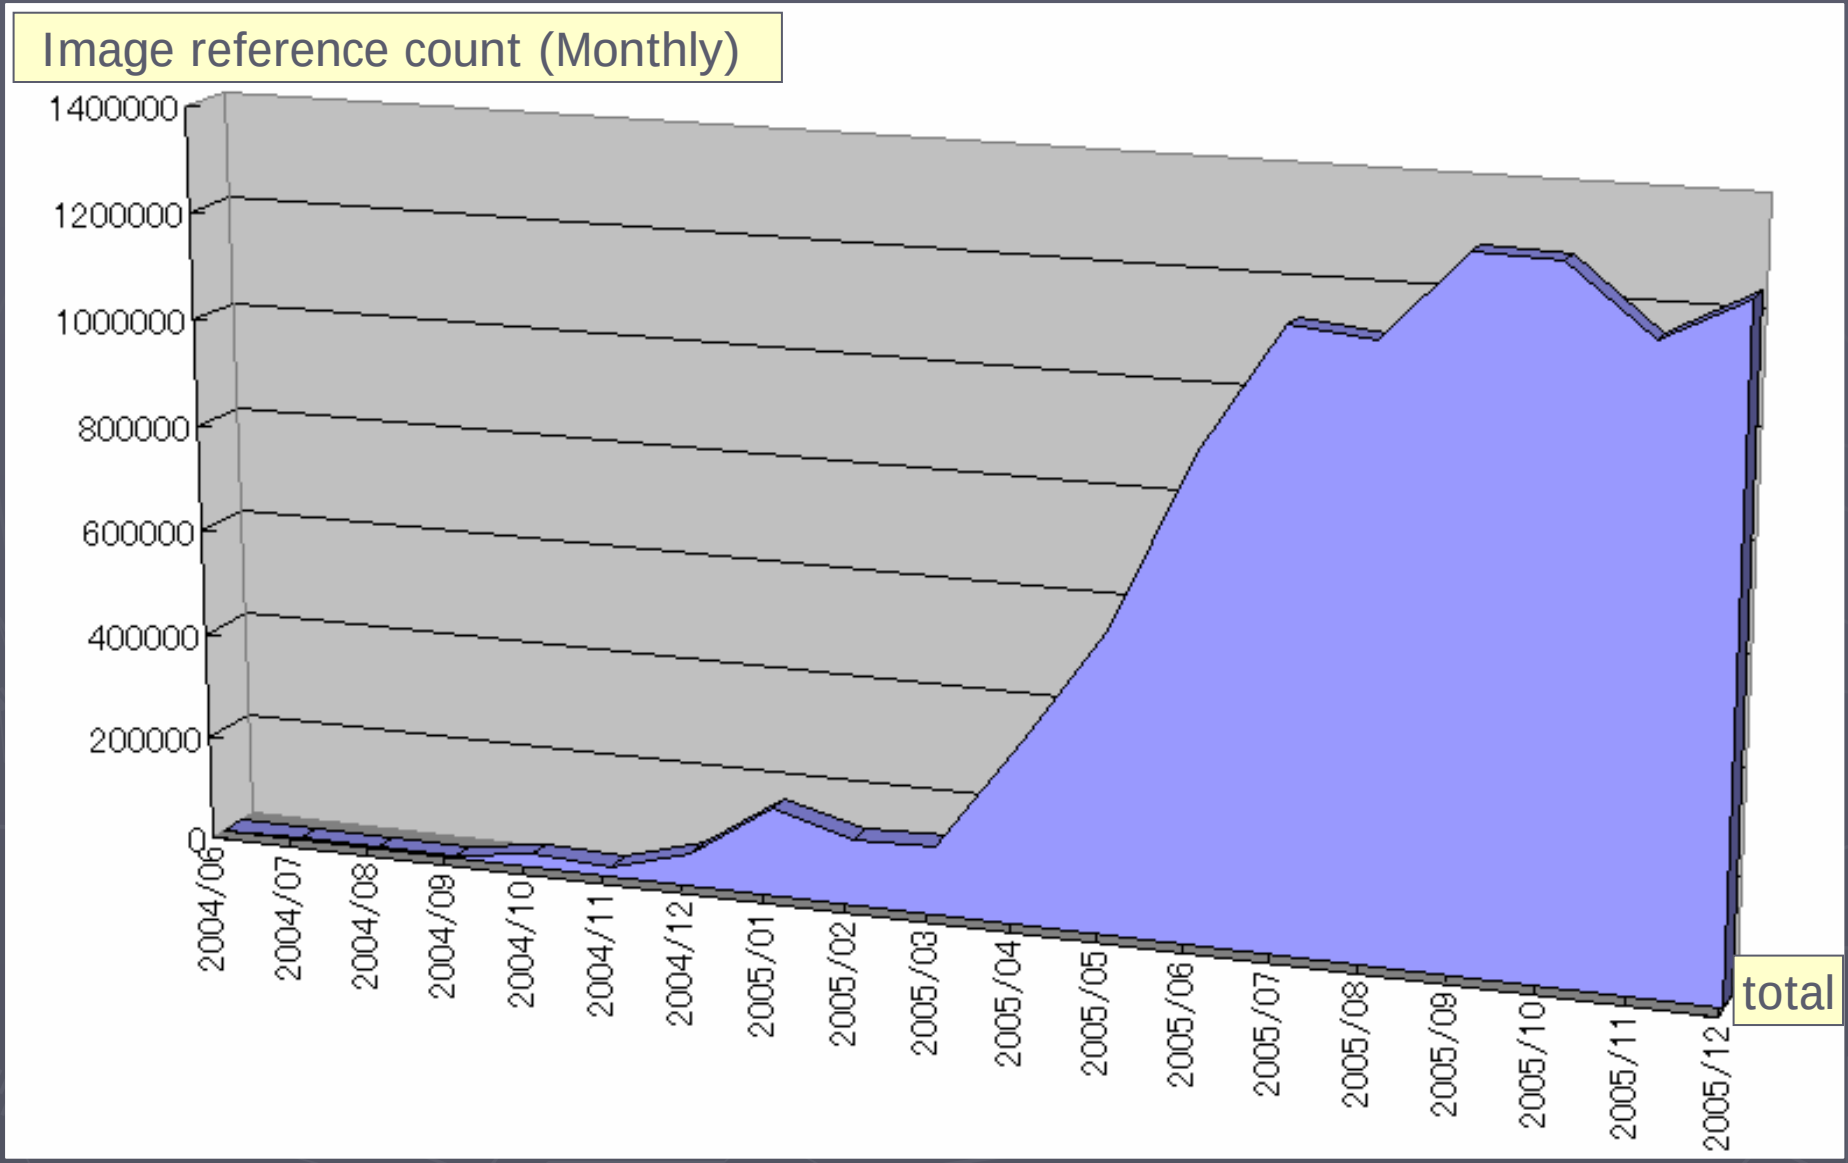
Client-EMR
100 terminals

Parallel PACS with Fault-tolerance

Number of images stored in PACS



Number of Image References



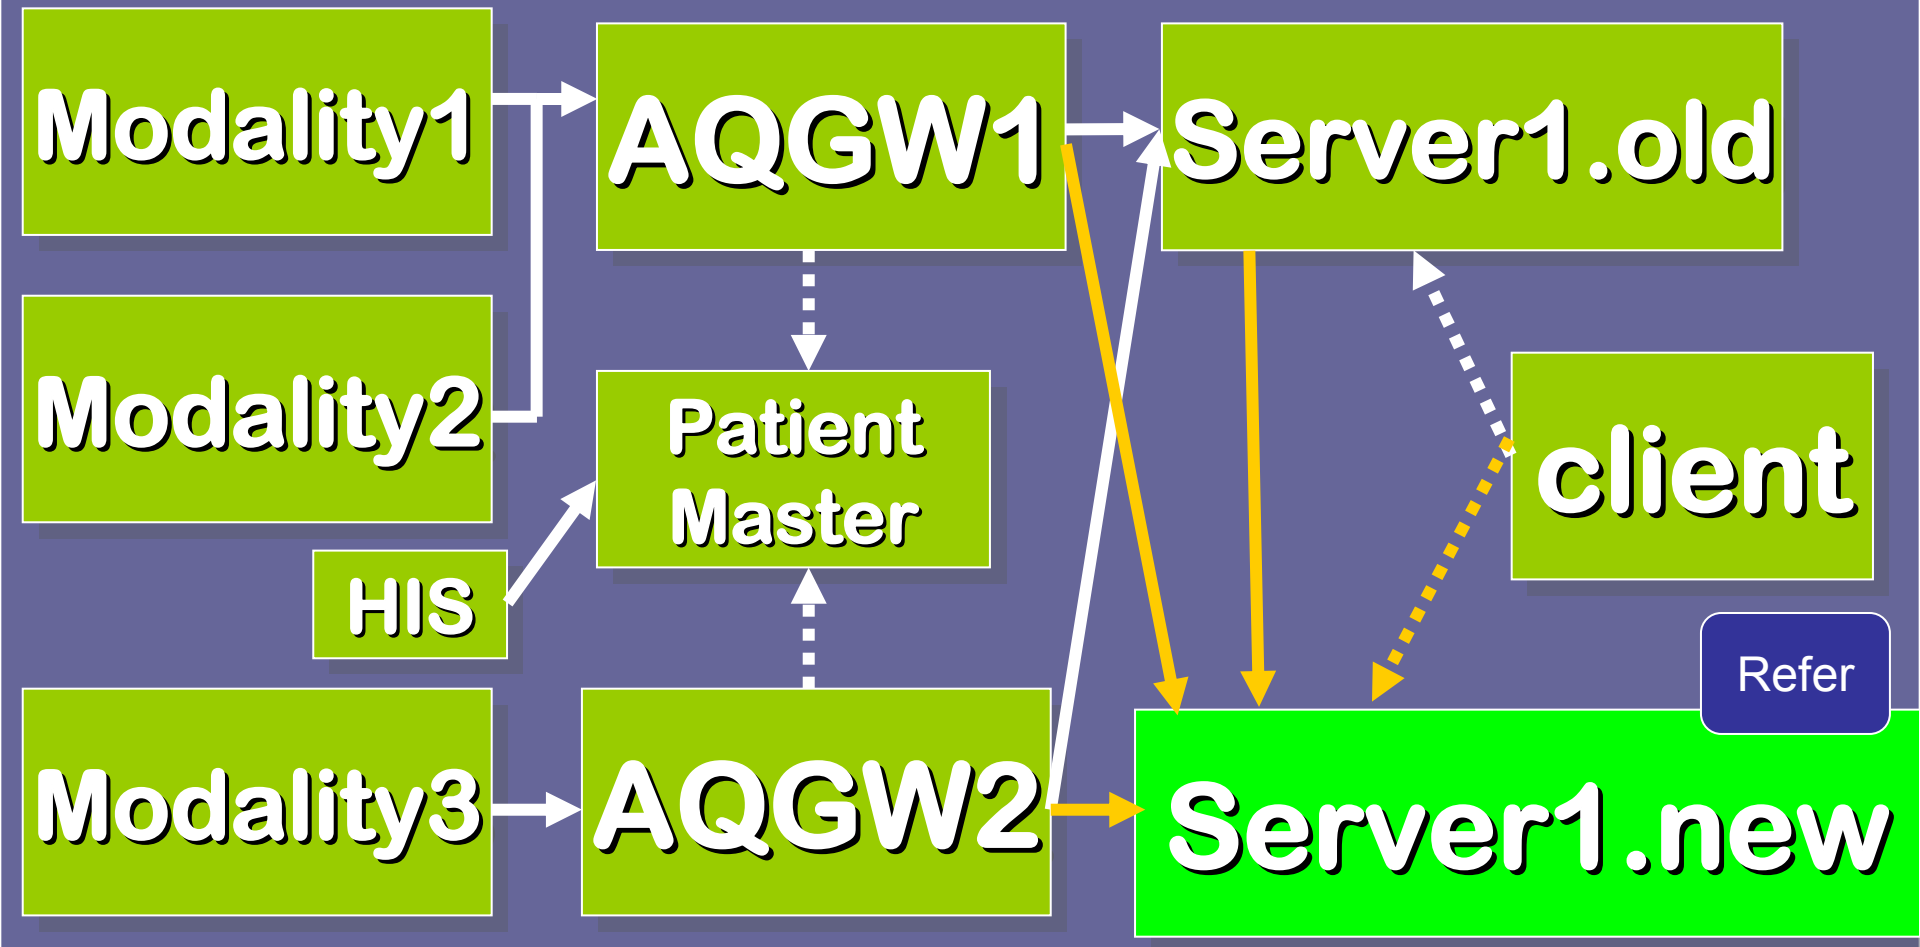
Flow of Image Archive

1) Images were sent from modalities to the AQGW (Acquisition Gateway), an intermediate server.
2) AQGW was to ensure the consistency of patient information of images with that of the master information. If the patient information were matched, images were stored to PACS servers. The images were also remained on AQGW for a week, and then automatically deleted.
3) Physicians could refer the images from the PACS server using the two kinds of viewer applications.

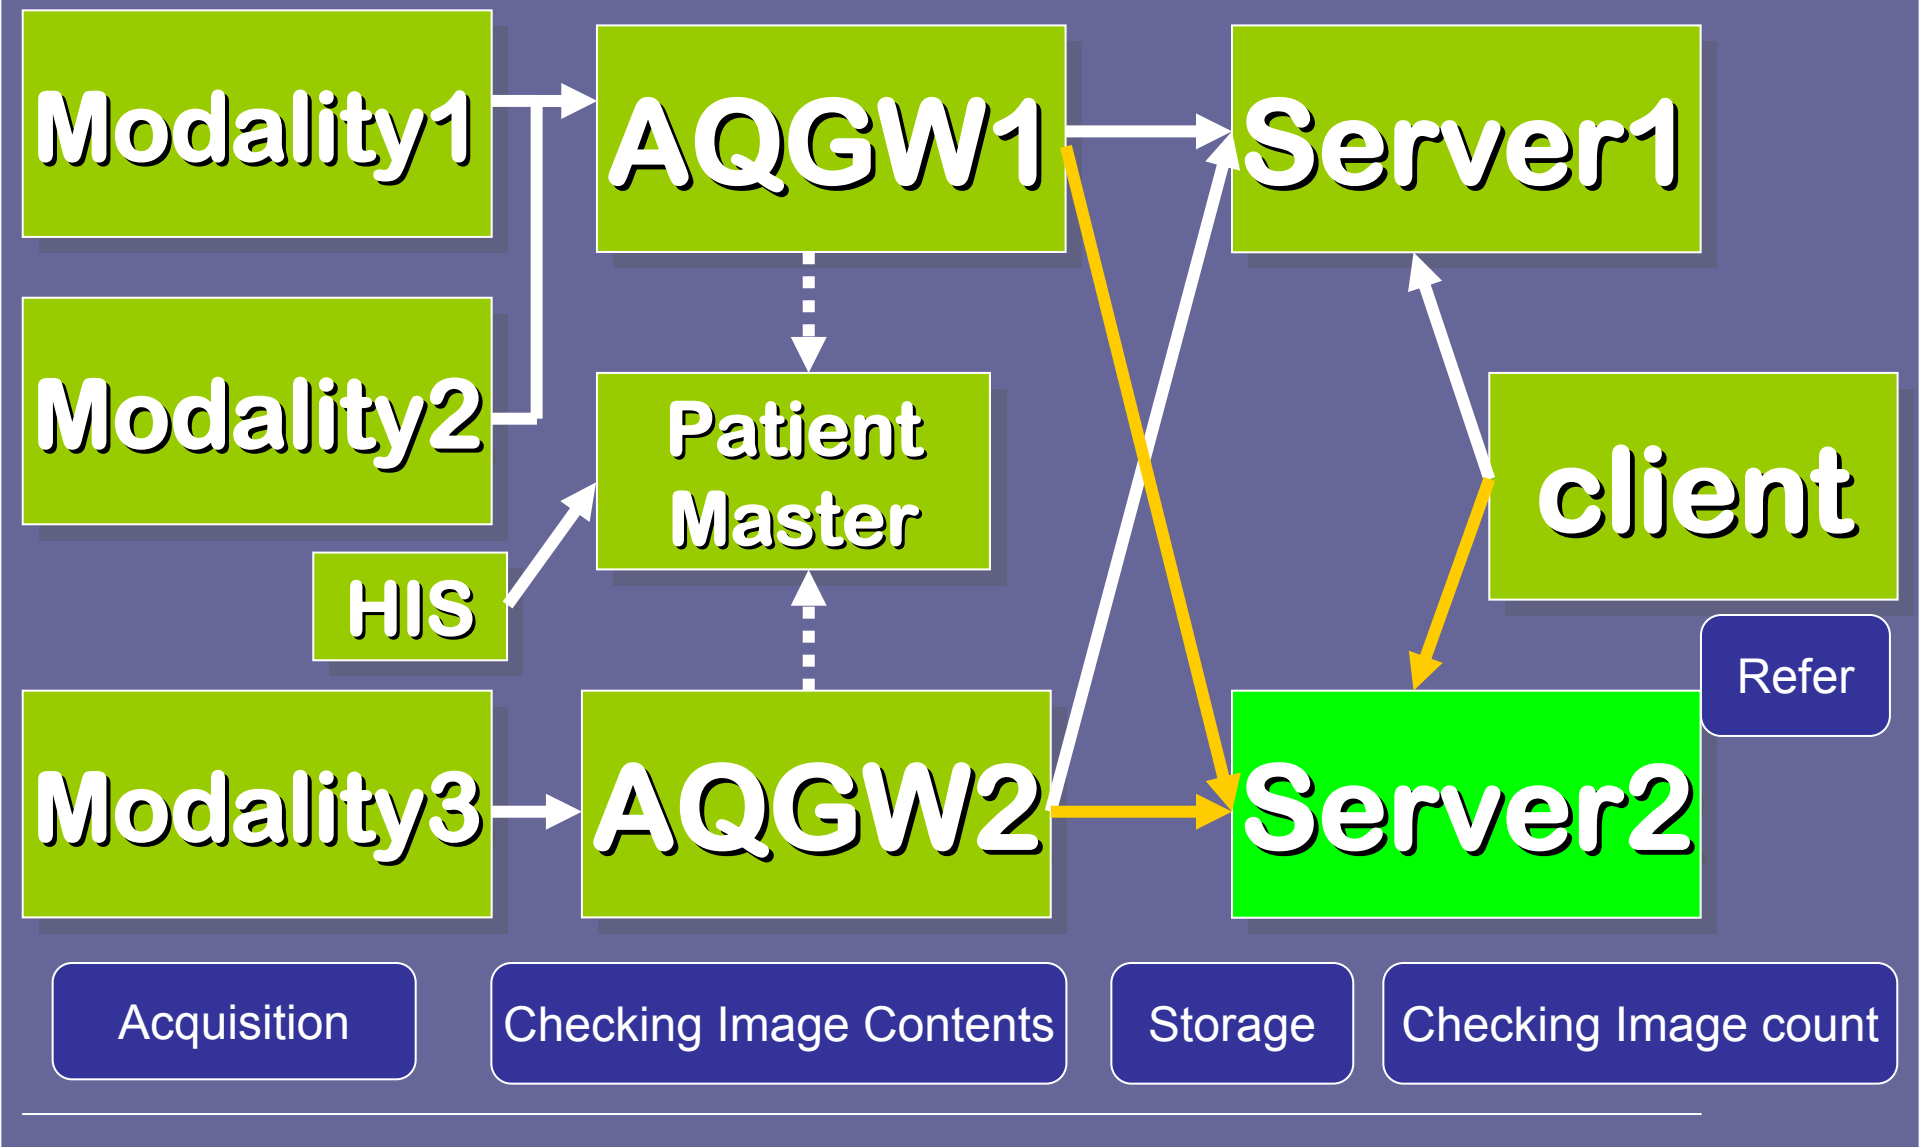
Transfer Procedure

1) When the PACS-1 server was started up, the server was used only for viewing images which was transferred from the former PACS server. DICOM C-STORE was used to transfer image data from transfer source to transfer destination.
2) When the PACS-2 server was started up, DICOM Q/R（Query and Retrieve） from transfer destination to transfer source was used for transfer image data in order to maintain a parallel operation with the PACS-1 server.
3) Then AQGW had also extended function to send multiple servers on the network in parallel.

Outline of PACS （During a shift）



Outline of PACS (Goal)



Results and Future Issues

- The system migration was finished without problems such as long discontinuation of services or data deficiency.
- Users can select the viewer applications on their demand.
- As future issues
  - PACS-1:For effective disk management, a reversible image compression may be applied to image store.
  - PACS-2: User authentication may be ensured for correct audit trail.

An Evaluation of the Usability of Accessing MEDLINE over Short Messaging System

Alvin B. Marcelo[a], Paul Fontelo[b]

a *National Telehealth Center, University of the Philippines Manila**b*** *Office of High Performance Computing and Communications, National Library of Medicine, Bethesda, MD*

Abstract

The Philippines is the texting capital of the world with over one billion messages exchanged every day. With the increasing ubiquity of cellphones in this country, it becomes a popular tool for accessing many types of information. This study aims to determine the usefulness of short messaging system (SMS) for accessing the bottom line of articles in MEDLINE. Two groups of residents at one of the largest tertiary government hospitals in the country were trained on the SMS interface for txt2MEDLINE. After four weeks of interactions, their responses were analyzed and they were given survey on the usability of the interface as well as their ability to comprehend the abridged text-speak of txt2MEDLINE. Results showed that residents did not find additional usefulness with txt2MEDLINE over SMS but cited convenience of access from any point of care as one of its benefits.

Keywords:

Short messaging system, text, Philippines

Introduction

In the Philippines, over 22 million of the total 80 million Filipinos have mobile phones. In contrast,

only 5 million Filipinos have access to the Internet. Overall, there are only 1.53 million PCs in the country.[1]

Immediate access to current information is a must in today's rapidly evolving practice of health care. Both health care personnel and their patients have gained access to a wealth of information available on the World Wide Web. In this new arena, access to a knowledge-base must be at the point-of-care. However, available online access through a computer terminal is not always present, even in tertiary hospitals. The ubiquity of SMS on mobile phones provides an alternative way of accessing health care information. More importantly, health care practitioners have begun to appreciate the value of using mobile devices in practicing evidence-based medicine. [2]

The BBC reports that the Philippines is the SMS text messaging capital of the world. More than 200 million text messages are sent daily in the Philippines. The use of text messaging is major social phenomenon, widespread and pervasive. It is woven into the day-to-day activities of the people. Mobile phones are used in every aspect of life-media, religion, education, commerce and health care. English is an official language of the Philippines. More than a third of Filipino own mobile phones. Doctors and health care providers actively use SMS in daily clinical practice. Doctors regularly exchange information with patients via SMS. Residents use text messaging and multimedia messaging to refer patients to their attending physicians. Because of this, the local study participants--attending physicians, post-graduate trainees and other health care providers are already experts in the technology, no training is required. This will facilitate the implementation of the project. It is the ideal laboratory to evaluate this application.

Methods

An SMS gateway to MEDLINE was established in the Philippines, and two groups of residents (otorhinolarygology and family medicine) were trained to use the SMS interface of txt2MEDLINE [3]. In order to eliminate the effect of individual differences in comprehending text-speak (abridged words), they all underwent baseline assessment where they were asked to back-translate sample messages from the txt2MEDLINE system into conventional English. For the clinical aspect of the evalaution, they were also asked to fill out a survey that determined the usefulness of the service to their daily needs.

The Txt2MEDLINE architecture used by the National Library of Medicine in a previous study was modified to adapt the system to local needs and services. [3]. A TER-GX101 TriBand (900/1800/1900 MHz) GSM modem (Round Solutions Ltd) connected to a Linux computer (Ubuntu Server ver. 6.10) comprises the Txt2MEDLINE server. A Subscriber Identity Module from SMART Philippines mobile phone network, and SMStools interfaces between the GSM modem and MySQL database. The SMStools [4] (SMS Server Tools for GSM modems) was used instead of UltraSMS. This modification was done because of the flexibility of SMStools. Segmentation of long messages is handled by SMStools easily instead of passing the burden to the scripting language. PHP was

used as the scripting language that processes data coming in and out of the server.

Results

The clinical evaluation was done in two phases. Each phase lasted approximately two weeks.

Mean number of queries, evaluations and comments sent per day for the first phase was 40.5 messages per day. The queries done and the corresponding evaluations were grouped according to five main categories: Diagnostics,

Etiology, Prognosis, Treatment, and Prevention. The categories were adapted from a previous study by Florance [5] where the author did a structural analysis of clinical questions by physicians. This categorization is important to determine how the participants are using the Txt2MEDLINE system and to better explain the results of the study.

Conclusion

The txt2medline system succeeded in bringing immediate access to MEDLINE resources in a convenient and portable package. However several innovations in technology had intervened that made the SMS interface as costly or less cost-effective as online cellular communications protocols such as general packet radio services (GPRS) or 3G. An SMS-based information access facility given this environment may not be the most appropriate solution.

Information requirements in terms of usefulness and reliability of information were not satisfied. Given the larger volume of data that can be sent through GPRS or 3G, it appears an SMS based interface to MEDLINE such as txt2MEDLINE will be difficult to promote. This is especially true when participants had to make several

attempts in sending and reformulating queries before receiving the appropriate citation. Furthermore, the information available to the SMS system is very limited even with the longer messages used. A mobile phone browser-compatible website of PUBMED may be able to give more information at a lower overall cost.

There are more things to consider in developing a mobile information retrieval solution. We have to take into account the culture of research and information source biases found among our health professionals.

Studies suggest that doctors tend to rely on other sources of information for their practice other than Medline [6]. We may try to develop more appropriate information systems for physicians, but if the culture for using these are not present, we will inevitably fail.

Txt2MEDLINE is a novel idea for bringing EBM information closer to health care professionals. However, given the complexity of information needs of these health care professionals and the governing costs of communications in a specific area, it may not appear to be the best solution in the current configuration of this study.

An Evaluation of the Usability of Accessing MEDLINE over Short Messaging System

Alvin B. Marcelo [a], Paul Fontelo [b]

[a] National Telehealth Center, University of the Philippines Manila
[b] Office of High Performance Computing and Communications, National Library of Medicine, Bethesda,MD

Abstract

- Short messaging system is one of the most popular messaging protocols especially in developing countries
- MEDLINE is a resource that provides health workers access to peer reviewed articles that can help in the care of patients

Introduction

- The Philippines is the texting capital of the world
- One billion SMS messgaes pass through its three cellular networks
- Cellphones and SMS is a convenient, portable protocol for accessing information
- Can MEDLINE be delivered effectively to cellphones over SMS?

Methods

- Fontelo et al created a special portal to MEDLINE which delivers The Bottom Line (TBL) in text-speak
- Examples of text-speak
  - preprtv --> pre-operative
  - muscl --> muscle
  - intensv --> intensive
- A pilot (first phase) was done which was followed by the formal second phase of the study.

Results

Categories of Queries	Evaluation Scores				
	1	2	3	4	5
Diagnosis	10	2	1	1	1
Etiology	7	0	1	0	0
Prognosis	1	1	0	1	0
Treatment	139	19	17	21	13
Prevention	0	0	0	0	0

Table 3-1: Summary of evaluation scores according to category during the second phase

- Most of the queries were for treatment options.

Results

Comments:	Hits:
More relevant journals	19
Delays in delivery	15
Responses not matched/unrelated to query	13
No available literature	13
Limit results within previous query	6
Abbreviations cannot be understood/too ambiguous	5
Others	4
Total	75

Table 3-2: Summary of comments during the second phase

- Qualitative results of the study.

Conclusions

- SMS most convenient communications protocol.
- SMS limited in display area and limits viewability of result set.
- Participants can understand text-speak.
- Lower costs for online access to MEDLINE (GPRS/3G) makes the limited interface of SMS of txt2MEDLINE a less practical solution to information seeking.

The Rhône-Alpes Health Platform

Fadila Farsi, Hervé Spacagna

Réseau ONCORA (community cancer network), Lyon, France

Abstract

As a consequence of recently passed governmental policies, medical information systems must now comply to new standards aiming at improving communication between as yet very different platforms. On a large scale, differences between IS are observed within medical subspecialties as well as medical IS structures.

Taking into account all specific features of the health information systems in current use in Rhône-Alpes, we present here the way we achieve the Rhône-Alpes health platform currently in use by numerous physicians and caregivers and the choice we took to make the electronic patient record flexible and efficient.

This solution is based on a bottom up model to insure an evolvement of practitioners. The method we used to aim this goal was based on this bottom up model for each component of the project: analyzing the level of computerization, find a solution for every hospital, develop our own patient identification liking local patient numbering systems, no centralization of data but creating a link to these information stored in each hospital repository.

The platform is currently considered as the consolidated shared health record and has received approval from French supervision authorities. Eleven healthcare facilities and 15 community health networks are now connected, sharing more than 80 000 records with 1.2 million medical items indexed.

Keywords:

medical informatics, medical record linkage,
medical record systems, health networks

Introduction

Rhône-Alpes is the second largest administrative region in France. As large as Denmark in size and with 6 million inhabitants, Rhône-Alpes has 300 healthcare facilities, one regional comprehensive cancer center, three academic medical centers, more than 20 000 physicians and over ten thousand caregivers. The concept of a universal electronic patient record (DPPR) was initiated in 2000 by health professionals from the ONCORA community cancer network (ONCOlogy Rhône-Alpes). Cancer care implies indeed a multidisciplinary and multicenter organization.

Health networks currently represent the most friendly and innovative concept in terms of coordination of patient care between health practitioners. The concept of a health platform at the state level dates back more than ten years where many differences between IS were observed within medical subspecialties (e.g. cardiology, nephrology, emergency care, ambulatory medicine, etc.) as well as medical IS structures (e.g. departmental IS, distributed IS, etc.).

Methods: Reference knowledge and former experience

Several major issues are at stake: the type of Regional Health Record system depends on the level of computerization in the health sector, the suitability of existing information systems for elaborating the new regional system. To answer those questions, we used a bottom-up model allowing to involve key health actors in the implementation of the record. All ideas started from observations in the field by practitioners themselves. Involvement of end users was a key aspect of our project.

Oncora was originally confronted with the incredible heterogeneity of existing IS, the management and consultation of local patient records depended entirely on the type of institution. We decided to conduct a preliminary appraisal of the computerization level of hospitals and existing information systems. Our major goal was to identify organizational differences between facilities, which would help elaborate connections adapted to each type of structure. We built a scale of 6 different levels of computerization and asked the 300 facilities in Rhône-Alpes to position themselves on this scale. The span of the survey and proportion of responses (more than 86%) ensured the credibility of the results and their relevance for determining our current development strategy. Consequently, we decided to work on two different connections taking into account the specificity of each hospital.

We also draw inferences from a former experience of centralized specialized cancer record that was stopped a few years ago because it was found unsuitable for use in the healthcare environment. We decided to go the opposite way to avoid repeating the same problems. The regional IS described in this paper is a fully distributed, multi-disease model.

Results: Architecture of the Rhône-Alpes platform (SIS-RA)

The first part of the project consisted of making hospital document repositories connectable. Connection was achieved through connectors developed in partnership with software editors in each hospital (for 48% of them). For scattered members (52%) of the health community network, SIS-RA provided a communication tool that also ensured connections with the regional IS. Finally, all health facilities in Rhône-Alpes became able to share their data, whatever their computerization level.

An essential requirement for SIS-RA is patient identification, which allows to organize data. French law does not permit to use national patient identifiers, so every legacy IS has developed its own local patient numbering system. The challenge was to match all the local records available for a given patient.

Then the DPPR federates all regional health repositories and serves as a unique web-based portal to health information in Rhône-Alpes. The system handles the authentication of users, authorizations for record queries and displaying of structured or unstructured data. On each record query, the system generates a new query to the hospital repository known to store the information needed. In this decentralized system, hospitals are responsible for updating the information they produce. The DPPR is just a pointer system and authorization manager.

The Rhône-Alpes Health Information System (SIS-RA) was possible because Rhône-Alpes doctors have been involved in the project and have understood what benefit they would derive from it (patient medical information available in a very short time). The system is also exclusively based on medical documents, which facilitates its use by medical teams. The universal interface which is proposed allows very simple retrieval of medical information. At least, this project was possible because there has been a total consensus between the three university medical centers, Léon Bérard cancer center and the 53 hospitals from the ONCORA community network regarding the direction of the project.

Conclusion

The DPPR is currently considered as a consolidated shared health record and has received approval from French supervision authorities. Eleven healthcare facilities and 15 community health networks are now connected to SIS-RA, sharing more than 80 000 records with 1.2 million medical items indexed.

The third generation development plan for the organization of health foresees that, in 2010, all healthcare facilities of the region should be connected to the DPPR.

Many other French of foreign healthcare organizations are interested in the functionalities of the system, all the more so as many other projects should shortly be incorporated: development of information flows in emergency care, introduction of medical items by independent physicians.

Information Portal – An Important Tool for Health Registries

Chavan Shaila, Forero Marcela, George Carol

For the Australian and New Zealand Intensive Care Society Database Management Committee

Abstract

Information portals are largely perceived as web sites which display information to the general public. Although this is true to a certain extent, portals are much more interactive and provide a gateway to a data repository. Access to information on these portals is channeled through an intricate network layer of assigned permissions. In healthcare, such information access is not often heard of - mainly because of the need to ensure an appropriate security system is in place to protect health information at a patient and hospital level. Overcoming the abovementioned shortcomings, ANZICS is successfully running a secure portal with over 200 users and 130 different channels for individual contributing units and governance groupings.

Keywords:

Health Registry ANZICS Portal audit research intensive care

Introduction

Easy and quick access to data in registries is often a complicated procedure for health researchers. Use of an information portal could prove to be an answer to this time consuming and complicated process. The Australian and New Zealand Intensive Care Society (ANZICS) commenced implementation of its information portal for contributing hospital adult intensive care units (ICUs) in 2005. In this paper we will discuss the methods used by ANZICS to achieve the results as well as the benefits and difficulties in setting up a secure portal for a health registry holding a large amount of confidential data and requiring multiple levels of access dependent on user status.

Information portals are largely perceived as web sites which display information to the general public. Portals are capable however, of much more interaction and provide a gateway to a data repository. Access to information on these portals is channeled through an intricate network layer of assigned permissions.

Method/Process

The ANZICS Databases Web portal was established for contributing units to have direct access to their data. This access is provided by using a unique combination of username and password. Following are the steps in creating the security layers for controlled access to the information:

- Subset the database into datasets for each contributing units
- Save the subsets to a location on public domain
- The security layer is put on these subsets to create channels for each set of data
- User management should be put in place with username and password allocation
- Usernames are assigned to a respective group for specific information access

Issues of concern

Several problems were identified in the process of setting up and managing the ANZICS portal :

- Creation and maintenance of programs to subset the data based on user and group profiles
- Monitoring and optimization of server performance to provide appropriate speed in the delivery of web based information
- Sharing of password and other confidential information by users
- Information security in a closed network computer laboratory setup

Results

Overcoming the abovementioned shortcomings, ANZICS is successfully running a secure portal with over 200 users and 130 different channels for different contributing units.

The wide geographical spread of ANZICS contributing units which are connected using the portal is shown in figure 1.

Web based Information Portals

Important tools for health registries

- Shaila Chavan
- Carol George
- Marcela Forero

For the Australian and New Zealand Intensive Care Society Database Management Committee

ANZICS Health Registries

- ANZICS Registries
  - Adult Patient Database
    - 730,000 individual patient records from over 140 individual intensive care units (ICUs) across Australia and New Zealand
  - Paediatric Registry
    - Individual patient records from 8 dedicated paediatric units and admissions from 8 adult/ paediatric ICUs – 7203 admissions in 2005 [1]
  - Research Centre for Critical Care Resources
    - 15 years of physical and human resource usage information on Australian and New Zealand ICUs
- Purpose
  - Intensive care quality assurance, epidemiological research and information provision to government for future health planning and resource management

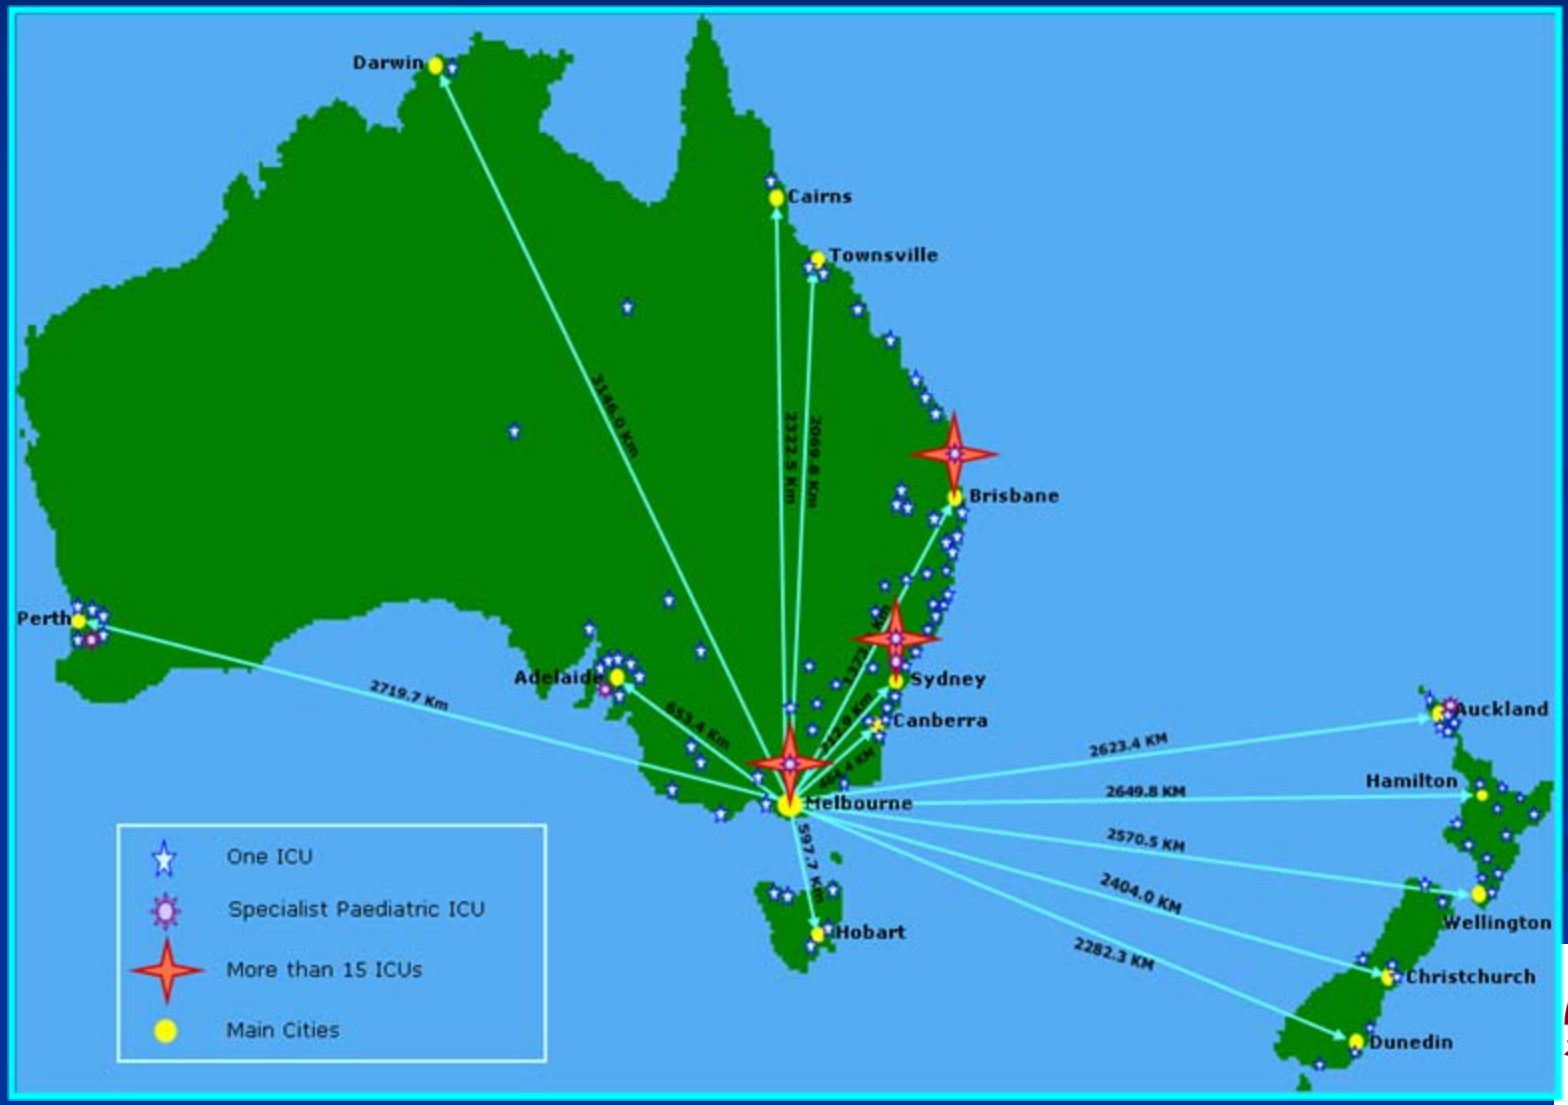
Data warehousing

- The data is held at ANZICS house on a secure server and is appended with new records after every submission round (quarterly submissions) from Adult Intensive Care Units
- This data is then used to create comparative reports for individual units
- Data is appended annually from ICUs surveyed by the ANZICS Research Centre For Critical Care
- In 07 / 08 data admission data collected by paediatric units will also be added and made available through the information portal

Why need for portal?

- Geographically vast area for coverage
- Time zone differences 4 – 6 hrs
- Increasing demand of medical data for research purpose
- Improved timely delivery of reports to contributors
- Increase utilisation of data by contributors and other stakeholders
- Improve data quality and stakeholder participation

ANZICS contributors : Geographical spread



Method

- Implementation of SAS BI Enterprise Server software
  - Acquisition of hardware in consultation with SAS vendor
  - Loading of the multi tier software [2]
    - Server tier including: Metadata server, Workspace server, Stored process server, OLAP server
    - Mid tier including: WebDAV server and the SAS Web Infrastructure Kit
    - Presentation Client Tier
  - Modification of existing the SAS (AF)application to allow delivery of electronic reports to publication channels within the portal software

Method

- Security
  - Planning and implementation of user and group hierarchy
  - Thin Client reporting tools - Web report Studio, Information portal
    - Security applied at the Information map level through the use of stored processes to subset data according to group and individual user permissions
    - Folder permissions defined within SAS Management console to limit navigation of users to appropriate reports
  - Full Windows clients – Enterprise Guide, Add in Tools for Microsoft
    - Security must be defined at the data source level
    - Implementation of security by creating a separate workspace server for these clients to occur in the near future to allow distribution and use by external users

Method

- Report development
  - Development of web reports in Web report studio – security provided through stored processes allowing one data source with one defined information map and one WRS report to deliver individual reports to multiple sites
  - Design of portal pages and publishing of web site (http://sas.anzics.com.au)
- Training
  - Internal employee training in SAS Management Console, Information Map, Enterprise Guide, Add in Tools for Microsoft
  - Establishment of online education (http://education.anzics.com.au) and training for end users through use of the web and face to face workshops

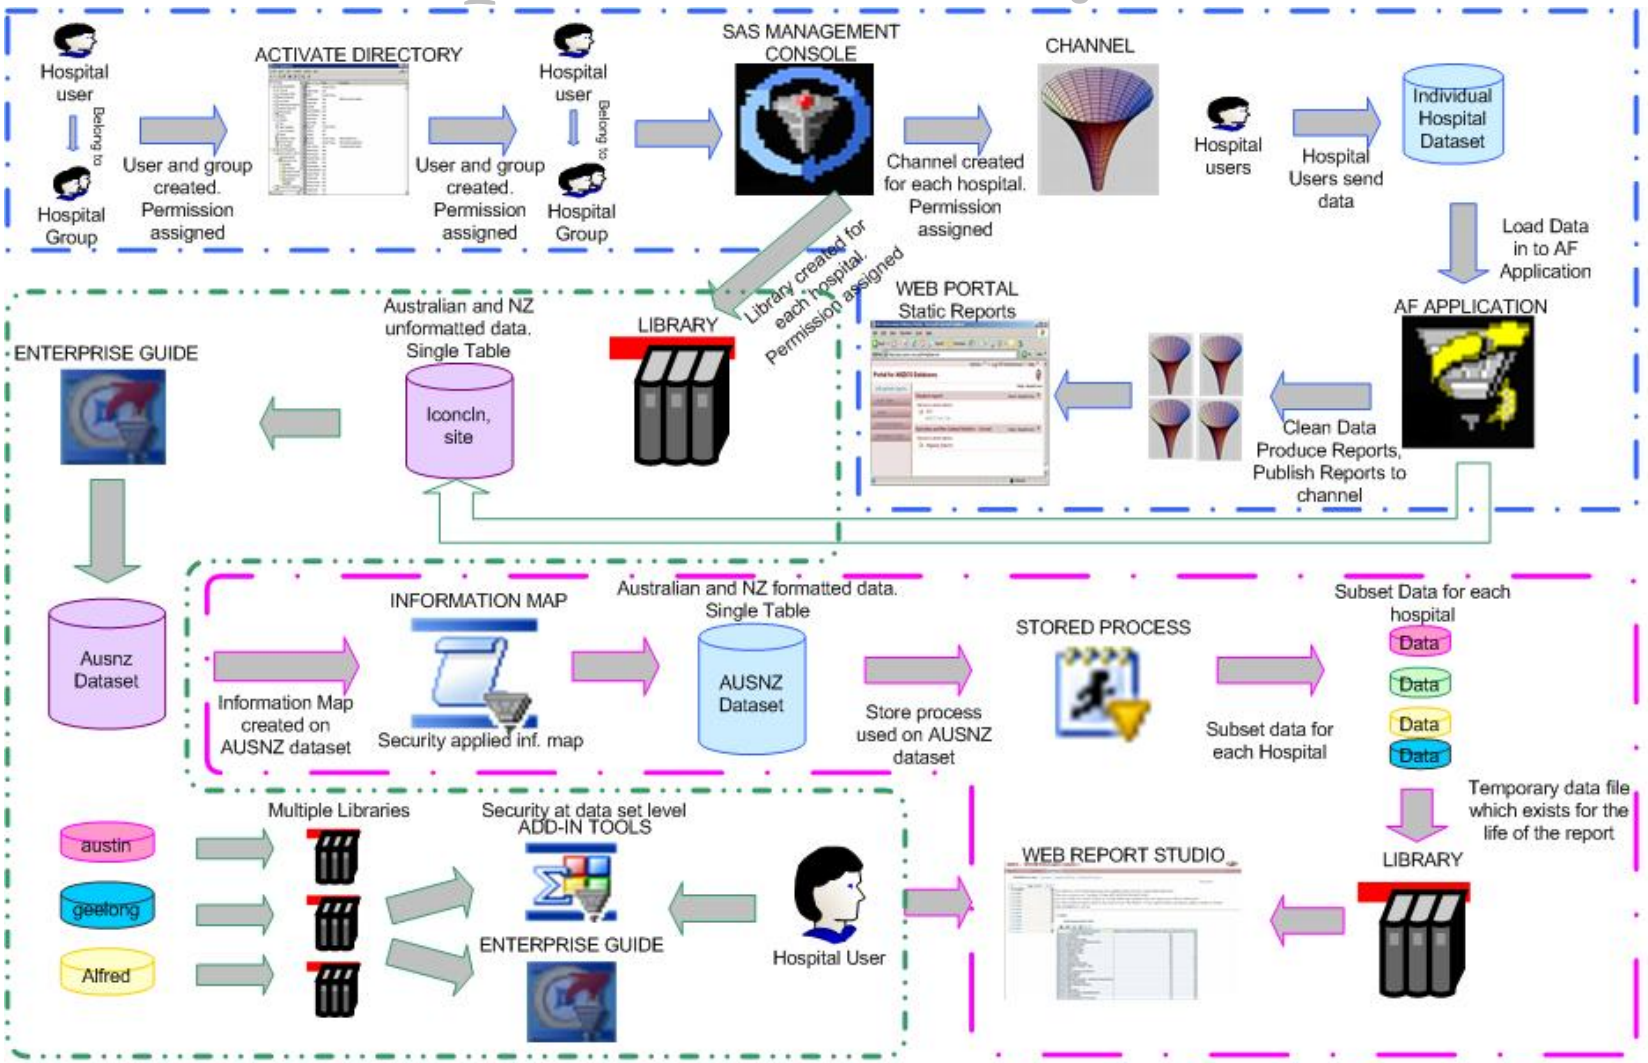
Implemented system



Lessons learnt

- The SAS BI enterprise software should be regarded as a developmental tool and requires a high level of resource to implement, develop and maintain as an information portal and analytical application for multiple users
- Implementing SAS BI on a single server architecture resulted in the web portal performance not meeting response time expectation.
- Future architectures under consideration include:
  - Separation of the mid tier onto a second server
  - Upgrading the current two CPU server processor to multiple quad core Intel processors
- Security – unresolved issue
  - User and group security failed to work during training sessions utilising the Information portal and Web report studio at two hospital based computer laboratories – The problem is not replicated outside this environment

Patient-Safety Improving Medication Information System for Care Workers in Taiwan

Tun-Yang Lawrence Sung[a], Chung-Lei Huang[b], Woei-Chyn Chu[b], Hung-Wen Chiu[a]

[a] *Graduate Institute of Biomedical Informatics, Taipei Medical University, Taipei, Taiwan R.O.C.*
[b] *Institute of Biomedical Engineering, National Yang-Ming University, Taipei,Taiwan R.O.C.*

Abstract

In Taiwan, 23% of medical errors come from medication error, however, pharmacists are barely possible to prevent or correct these errors at present. To reduce them, we constructed a computerized drug deliver cart with a drug information system plus drug image and a Web-based intravenous drug incompatibility system to assist first-line care workers practicing medication monitoring such as adverse drug reactions (ADR), educating patients correct medication usage, and reducing medication errors which are preventable. Both of these two systems are passive systems, and we think that maybe we could increase the frequency of using these systems by fixing them become more active, increases the rate of systems usage, and raise the pharmaco-vigilance of care worker in Taiwan.

Keywords:

drug information system, drug image, intravenous drug incompatibility system, care workers, adverse drug reactions, medication monitoring, pharmaco-vigilance

Introduction

Medication error is one important kind of medical errors. In America, at least 4,000 patients died due to medication errors every year, furthermore, 42% of medication errors were caused from anthropogenic source. Same as America, a study made in Japan shows that 16% of care workers had ever administrated drug to wrong patients, as a result, many computerized assistive system are provided, but few of medication administrating.

In Taiwan, especially for hospitalized patients, administrating and monitoring of medication are often executed by nurses. Care workers use paper-based drug administration records and IV solution administration records to insure if medications fit to physician's order sheets or not, which is a complicated but an important job. And the truth is, the currency of medication errors for inpatients is approaching 2%, which is very serious. To reduce this kind of error, we designed a computerized drug deliver cart combined with drug information system which could help checking these looks of drug, and let it be much easier for nurses to identify if adverse drug events occurred.

Another important issue for care workers in Taiwan is language problem, lots of medical and drug information were written in English, whereas information written in traditional Chinese form will be much easier for nurses to comprehend, therefore, to build a traditional Chinese-based drug information system seems to be a requisite.

Last but not the least, intravenous drug incompatibility is an important drug information for care workers in medication administrating, especially when dispensing intravenous mixture, therefore , we constructed an intravenous drug incompatibility system which would provide nurses an easy way to check when mixing different intravenous medicines, it could also reduce the working load of pharmacists.

Materials and methods

In our study, we designed three assisting systems to reach our goal to reduce medication errors caused by care workers, figure 1 shows these three structures of our system.

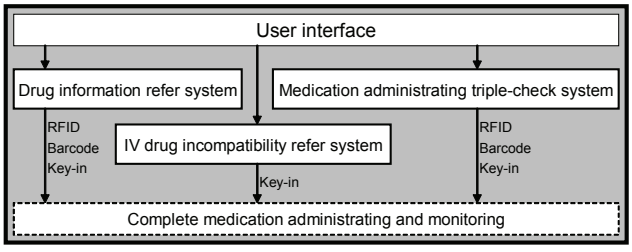

Figure 1 - Flowchart of computerized drug deliver cart

The first part is a drug deliver assisting system with RFID and bar-code devices which could help care workers practicing such as three-read five-right checks. The second part is to construct a drug information system with drug image for care workers. To build an easy-to-use drug information system for care workers in Taiwan, drug information have to be written in Chinese form, drug images is also added, moreover, we use bar-code and RFID query interface. Automatic update process is a necessity for our system, once a hospital changed their brand of a medicine, our system could respond immediately. Language translating is never an easy job, especially when it's in medical specialty, to find the way out, we cooperated with MIMS poc, MIMS poc have a complete drug information database

written in mandarin, it could also provide us accessible up-to-date drug information, and images of Taiwan's currently used medicines.

The last part is to construct an intravenous drug incompatibility system, in this system, we use key-in from touch panel instead of RFID or bar-code devices as input, care workers will choose two to three medicines' generic name by their fingers to check if intravenous incompatibility occurred, then the system will show four kinds of results to present if there is any problem adding them together.

Results

Figure 2 shows the prototype of our computerized drug deliver cart we'd constructed and the information display result of our drug information system with drug image. Ten kinds of drug related issues are chosen to provide care workers adequate drug information, they include brand name, generic name, usage, package, contraindication, precaution, side effects, drug interactions and drug image.

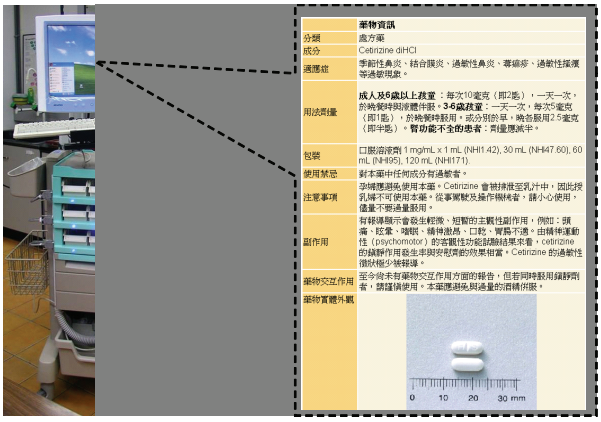

Figure 2 - The prototype of our computerized drug deliver cart and a Chinese translated drug information chart with drug image

Another function of our drug information system is MIMS poc SDK, combined with EMR information, four kinds of Alerts are provided, drug alert could find if any drug prescribed conflict with another, health alert also finds if any disease is contraindicated with those drug prescribed, allergy alert finds drug allergic problems, duplicate alert warns users when any medication is duplicate ordered. Figure 3 shows the drug decision support module.

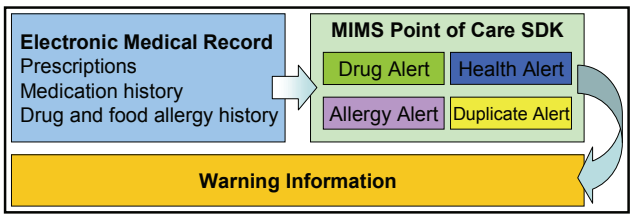

Figure 3 - The drug decision support module, based on patients' information in EMRs, this module could find preventable medication errors

The Web-based intravenous drug incompatibility system could also assist care workers dispensing intravenous mixture, they could simply find the answer by choosing drug's name through touch screen to check if incompatibility occurred. Since draw-down lists are not suitable when using on touch screen, we designed another kind of drug list to make it easier to choose form. Four kinds of answers would be displayed as the result, they are compatible, incompatible, variable results and no result. Nurses could then check the details of the result displayed which is written in traditional Chinese form. This system could also reduce the work burden of clinical pharmacists in Taiwan. Figure 4 shows the drug list we designed and the result of this system.

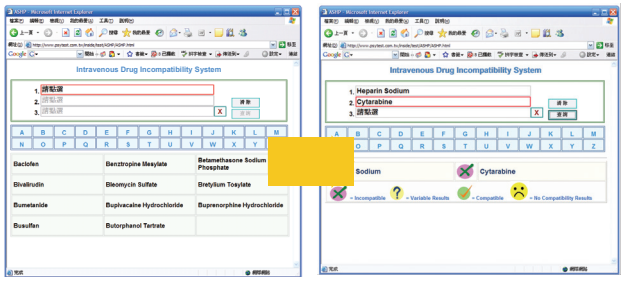

Figure 4 - The drug list of intravenous drug incompatibility system designed for touch panel (left side), larger items could make it much easier to choose by fingers, on the right side is the result displayed of the system, four different icons represent different results

Discussion

The main purpose of our study is to promote patient safety by reducing medication errors caused from care workers, however, nurses in Taiwan seems too busy that the rate of using of our system were lower than our expectation. A key question is that shall we make our system acts from passive to active? Will this

action raise the rate of using, help reducing medication errors or actually nurses would be even bothered? In the other sub-project, they used active way instead of passive one's, somehow nurses think it's too clumsy. To find the threshold that would both reduce medication errors and

with good usability would be an interesting part that we might study in the future.

Another issue is some of workers in the field of medical informatics seem lack of clinical experiences, in this situation the program designed might have low usability, to avoid trapping in the plight, maybe we have to spend more time communicating and observing. The most efficient way is to stay in a unit where we're going to cooperate for a period of time. After increasing the real experience, the design should be far more functional.

Conclusion

Care workers in Taiwan are medication administrators who play important roles in adverse drug reaction (ADR) reports. The adequate and easy-to-get drug information provided to nurses could raise their pharmaco-vigilance. Further more, it improves patient safety. Intravenous drug incompatibility system would also provide nurses an easy way to check when dispensing intravenous drug mixture, and reduce avoidable errors. Both of our programs exists as passive systems, we wonder that if they change to be more active, would the using rate raises or falls. It seems that we need to know clearly from their work and with our own experience, the design of assisting systems would be more acceptable.

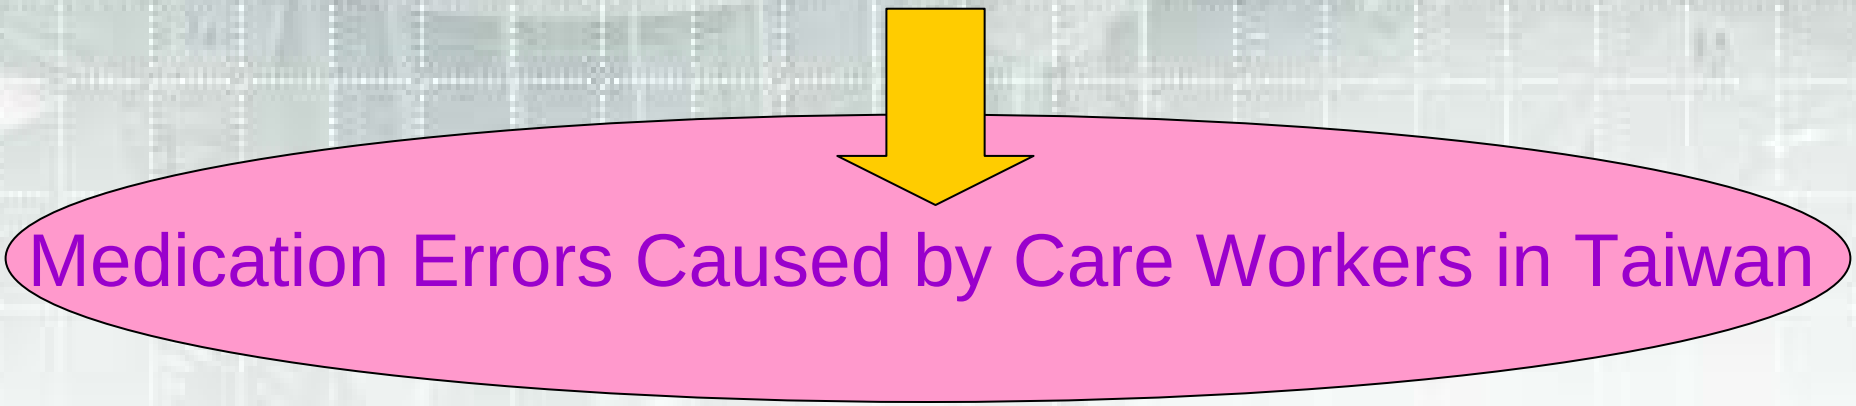
Patient-Safety Improving Medication Information System for Care Workers in Taiwan

Tun-Yang Lawrence Sung [a], Chung-Lei Huang [b], Woei-Chyn Chu [b], Hung-Wen Chiu [a]

[a] *Graduate Institute of Biomedical Informatics, Taipei Medical University, Taipei, Taiwan R.O.C.*
[b] *Institute of Biomedical Engineering, National Yang-Ming University, Taipei,Taiwan R.O.C.*

Introduction

- Medication errors
  - Most important kind of medical errors [1]
  - Killed 4’000 patients per year [2]
  - 42% of medication errors → anthropogenic source (USA) [3]
  - 16% nurses had given wrong drug to wrong patients (Japan)
- CPOE → Medication errors caused by physicians and pharmacists



Introduction (cont.)

- To reduce medication errors caused by care workers in Taiwan:

1. A computerized Drug Deliver Cart
   - ✓ With Bar Code & RFID devices
2. Drug Information System including Drug Image
   - ✓ Help nurses checking such as adverse drug events, educating patients right usage, etc.
3. Intravenous Drug Incompatibility System
   - ✓ To check if it's proper to mix different intravenous medicines

Language Problem

- Nurses in Taiwan:

English Information:
Have difficulty to read and comprehend

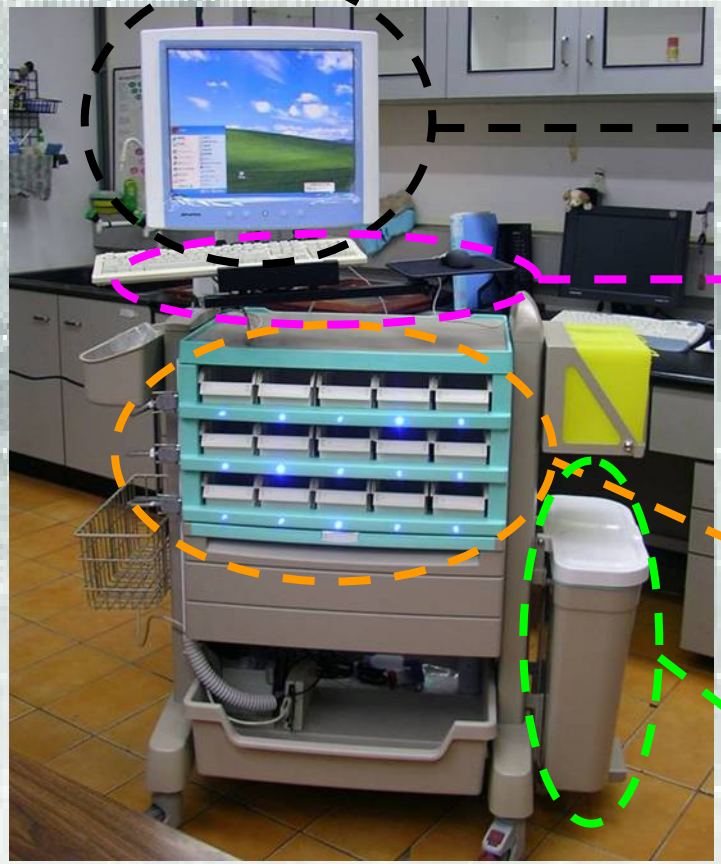
Chinese Information:
Easier and more friendly to use

Use Graph instead of script
Ex. Drug image

Language Translation:
Cooperate with MIMS poc
(Up-to-date Drug Information)

CMP
United Business Media

Result - Drug Deliver Cart with RFID and Barcode Devices



Touch Screen:
Instead of keyboard to increase usability

RFID & Bar Code devices:
Help nurses identifying patients and medications

Drug Drawers:
With patients' medication dispensed by pharmacists

Trash Can

Results – Drug Information System

Brand name &generic name:
Basic Drug information

Indications:
To show if the drug fits to the patient's diagnose

Usage:
To show if there is any special using way of this medicine.

Package:
To show the package and form of the drug.

Contraindication:
To show some diseases or other special conditions that are contraindicated to the drug

Precaution:
To show that some patients with these special conditions should be closely monitored or consider withdraw this drug

Side effects:
To show some side effects that patient would complained, nurses would note them and inform pharmacists and doctors

Drug interactions:
To show which drugs are forbidden to use with this medicine.

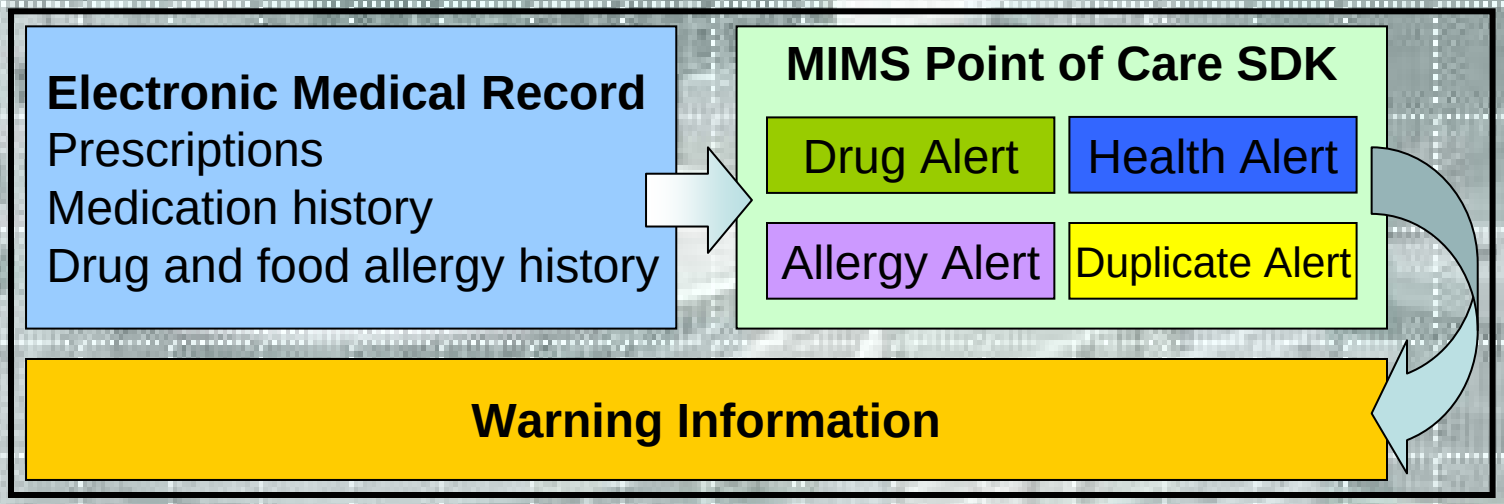
成分	Cetirizine diHCl
適應症	季節性鼻炎、結合膜炎、過敏性鼻炎、蕁麻疹、過敏性搔癢等過敏現象。
用法劑量	**成人及6歲以上孩童**：每次10毫克（即2匙），一天一次，於晚餐時與液體伴服。**3-6歲孩童**：一天一次，每次5毫克（即1匙），於晚餐時服用。或分別於早，晚各服用2.5毫克（即半匙）。**腎功能不全的患者**：劑量應減半。
包裝	口服溶液劑 1 mg/mL x 1 mL (NHI1.42), 30 mL (NHI47.60), 60 mL (NHI95), 120 mL (NHI171).
使用禁忌	對本藥中任何成分有過敏者。
注意事項	孕婦應避免使用本藥。Cetirizine 會被排泄至乳汁中，因此授乳婦不可使用本藥。從事駕駛及操作機械者，請小心使用，儘量不要過量服用。
副作用	有報導顯示會發生輕微、短暫的主觀性副作用，例如：頭痛、眩暈、嗜眠、精神激昂、口乾、胃腸不適。由精神運動性（psychomotor）的客觀性功能試驗結果來看，cetirizine 的鎮靜作用發生率與安慰劑的效果相當。Cetirizine 的過敏性徵狀極少被報導。
藥物交互作用	至今尚未有藥物交互作用方面的報告，但若同時服用鎮靜劑者，請謹慎使用。本藥應避免與過量的酒精併服。
藥物實體外觀	

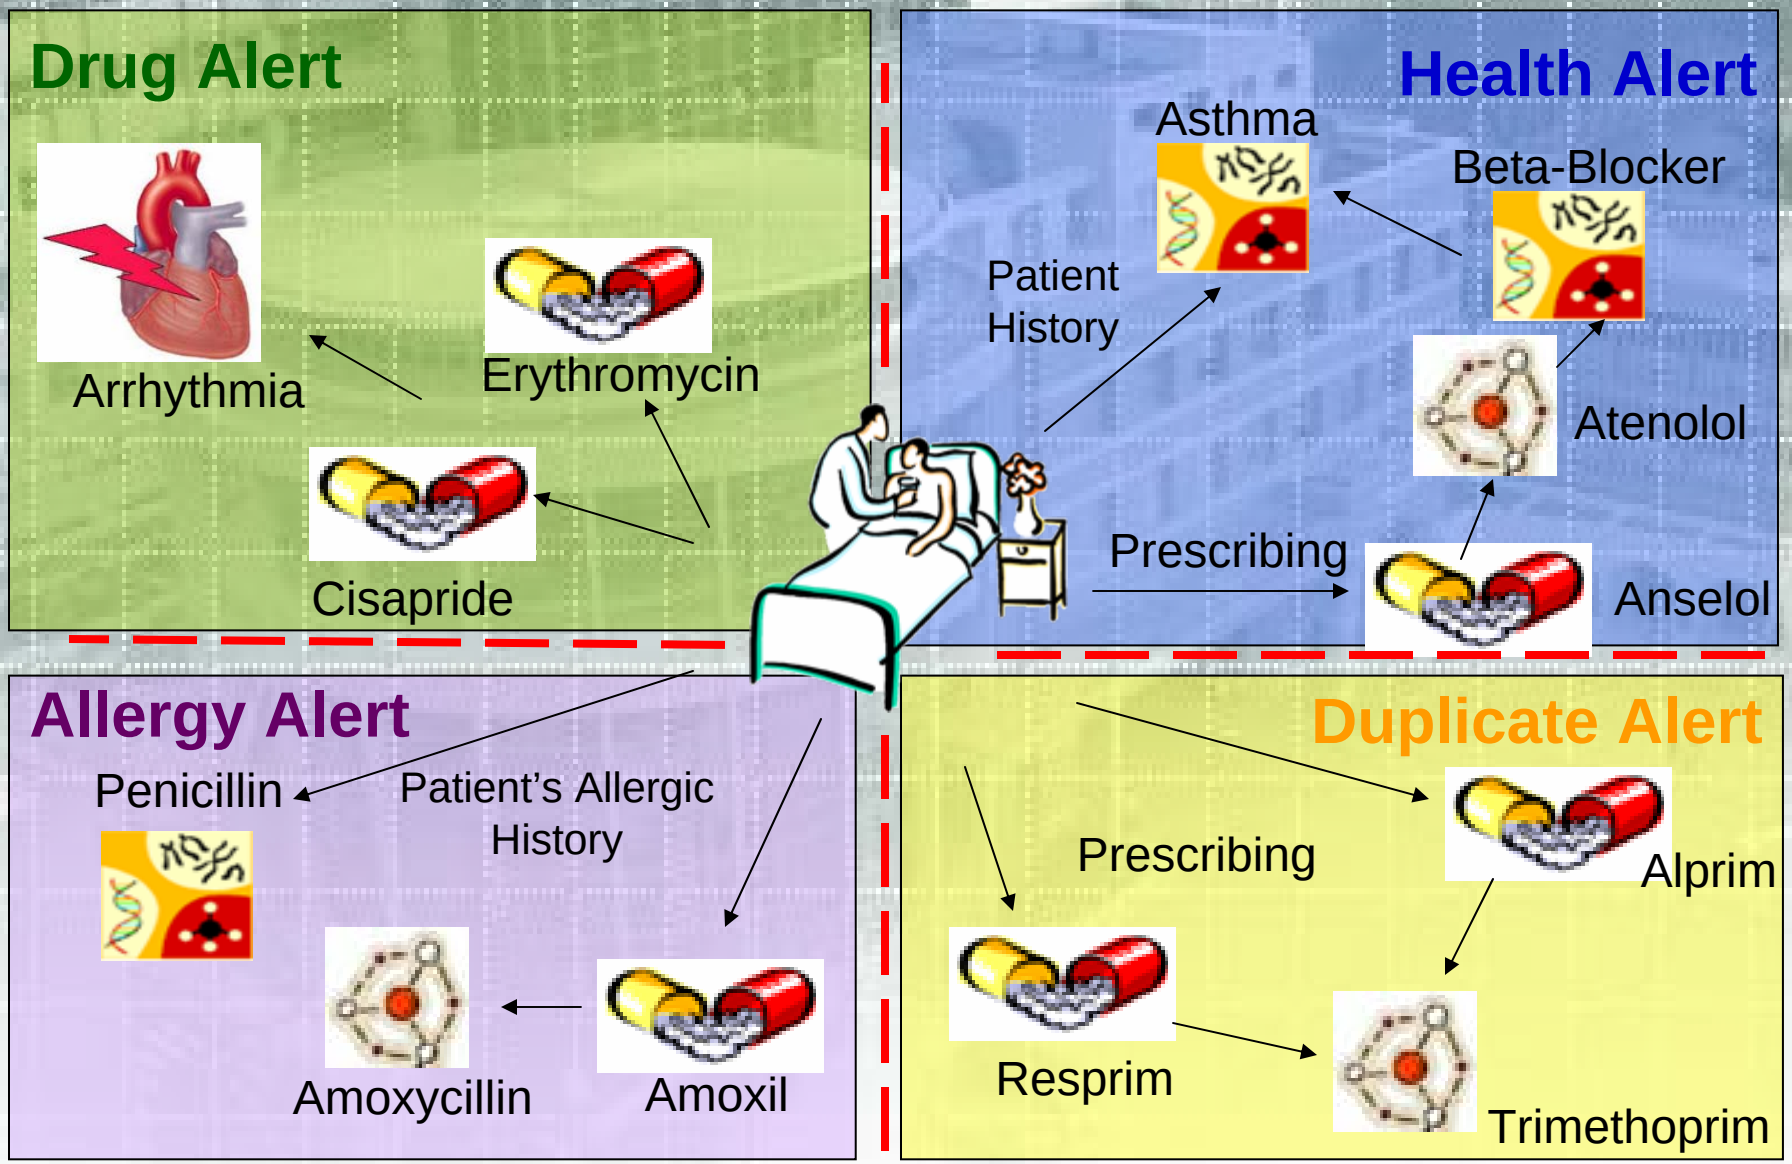
Drug Image:
Help recognizing the appearance of medicines

Drug Decision Support Module

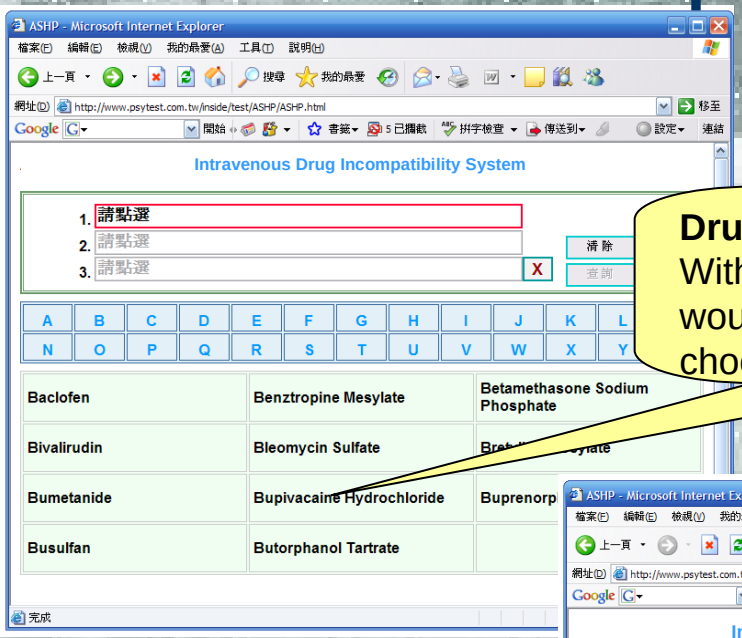


- ✓Drug Alert:
  - ✓ To find if any drug prescribed conflict with another
- ✓Health Alert:
  - ✓ To find if any disease is contraindicated with those drug prescribed
- ✓Allergy Alert:
  - ✓ To find drug allergic problems
- ✓Duplicate Alert:
  - ✓ Warn users when any medication is duplicate ordered

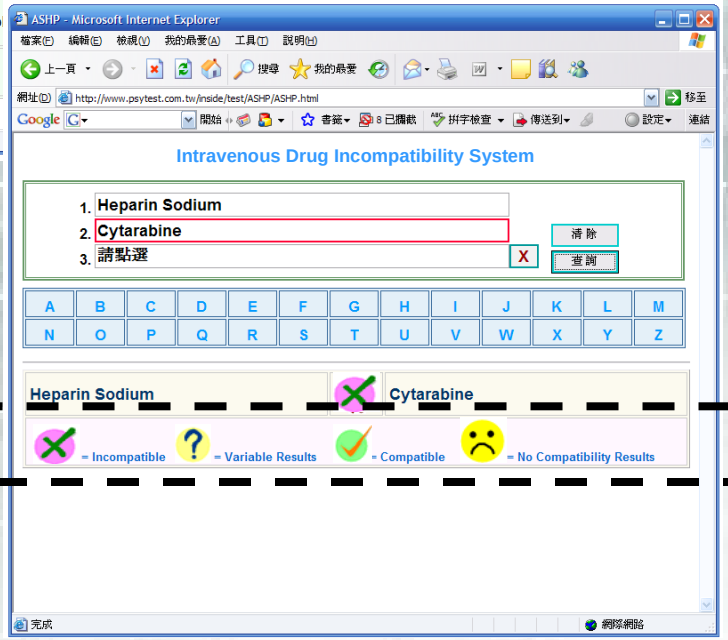
Drug Decision Support Module



Results - Intravenous Drug Incompatibility System



Drug list designed for touch panel: Without draw-down drug lists, it would be much easier for nurses to choose drug from touch panel.



Incompatible: Two drugs could not added together

Compatible: Two drugs could added together

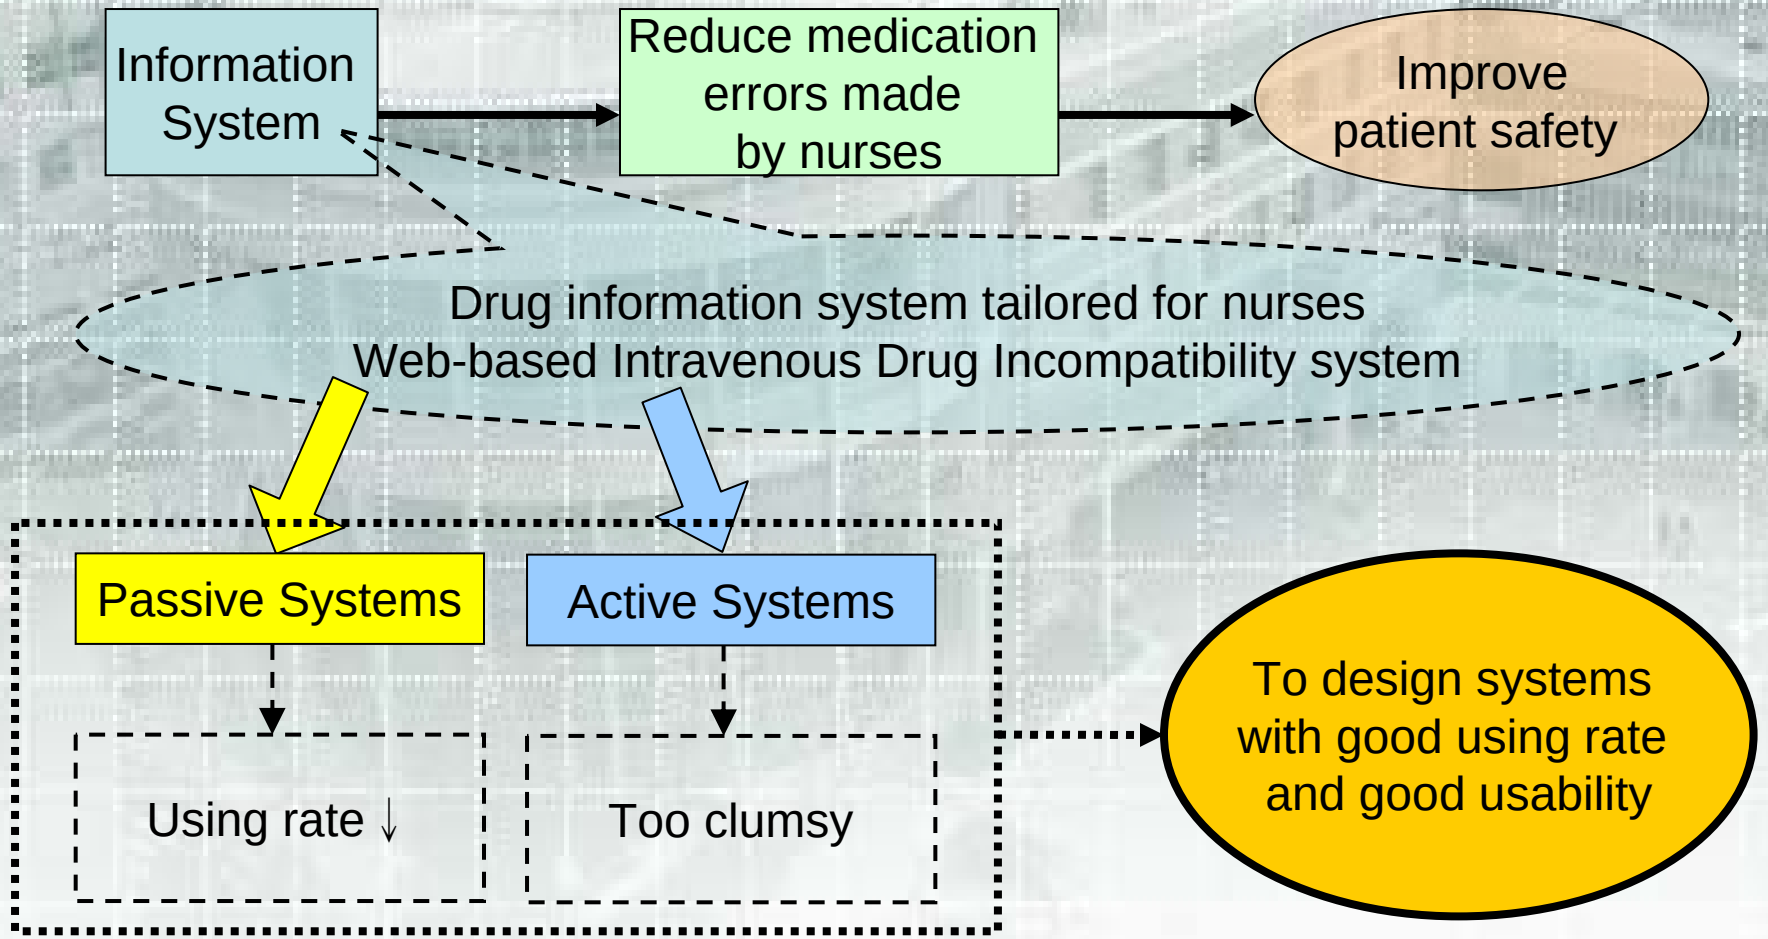
Variable results: Consult pharmacists to insure.

No results: No data available

Four kinds of results would show

Discussion

- The main purpose:



Conclusion

- Care workers in Taiwan
  - Medication administrators who play important roles in adverse drug reaction (ADR) reports where physicians and pharmacists would hardly to.
- Two of our systems:
  - The adequate and easy-to-get drug information system
    - ↑ Pharmaco-vigilance [11]
    - ↑ Patient safety
  - Intravenous drug incompatibility system
    - An easy way to check when dispensing intravenous drug mixture, and reduce avoidable errors
- Both of our systems exist as passive systems
  - Change to be more active, would the using rate raises or falls?
  - To know clearly from their work, and with our own experiences, then the design of assisting systems would be more acceptable.

Computer-assisted Cancer Chemotherapy Planning and Alerting System

Yoshimasa Kawazoe[1], Toru Endo[2], Yutaka Mitsuishi[2], Kengo Miyo[3], Kazuhiko Ohe[1]

[1] Department of Medical Informatics and Economics, the University of Tokyo, Japan
[2] FUJITSU LIMITED, Japan
[3] Department of Planning, Information and Management, the University of Tokyo Hospital, Japan

Abstract and objective

Chemotherapy misadministration can be serious devastating to patients. One reason for iatrogenic injury during chemotherapy is the information management is complicated. The use of computerized chemotherapy management system has been proposed to improve patient safety and quality of care. To develop a computer-assisted chemotherapy planning system, we set two requirements. i) Creating the chemotherapy planning model emphasized on the physician's decision-making process. ii) Building up expressions to reason about particular knowledge associated with each decision-making process. Based on the requirements, we have developed the model of chemotherapy planning. In this paper, we present development of web-based prototype system of chemotherapy planning and alerting system. Through the inspection by implementing prototype system, it seems to be useful from the viewpoint of preventing physician from overlooking the information about patient.

Keywords:

chemotherapy, decision support system, alerting system

Methods

We have developed the model[1] of chemotherapy planning, emphasized on the decision making process of the physician. This model consists of entity model of chemotherapy, process model of chemotherapy planning, and expression language to reason about particular status of the patient. Based on this model, we structured chemotherapy regimen into computer readable form. Figure 1 shows a part of structured regimen.

Results

We constructed a knowledge base that includes several kinds of structured-regimen, and developed web-based prototype system. Overview of the system architecture is shown in Figure 2. There are two functions in this system. 1) Providing decision support for the physician to create administration schedule. In each decision point such as pretreatment evaluation and dosage modification, system evaluates decision criteria based on the patient data, and shows the result to the physician. 2) Providing notification support all day long. When dosage should be modified depending on the additional patient data, system sends a recommendation message to physician. Through the inspection by implementing prototype system, it seems to be useful from the viewpoint of preventing physician from overlooking the information about patient.

```
<regimen name="CHOP" code="001" cycle_frequency="5">
  <cycle duration="21">
    <pretreatment_evaluation>
      <lhs> phenomenon(NCICTC_Leukocytes_Grade).greaterThan(3) </lhs>
      <rhs> Recommend beginning at the cycle to be postponed </rhs>
    </pretreatment_evaluation>
    <drug name="vincristine" standard_dosage="1.4" max_dosage="2.0" dosage_unit="mg">
      <date_allocation> 1 </date_allocation>
      <administration_method route="iv">
        <division unit="min">60</division>
      </administration_method>
      <dosage_modification time_context="14" unit="day">
        <lhs> phenomenon (NCICTC_Leukocytes_Grade).greaterThan(2) </lhs>
        <rhs> Recommend reduce to 80% dose </rhs>
      </dosage_modification>
```

Figure 1- Example of a structured chemotherapy regimen. Element of "pretreatment evaluation" is a decision criteria of start of the therapy cycle. Element of "dosage modification" is a decision criteria of modification of a drug dosage

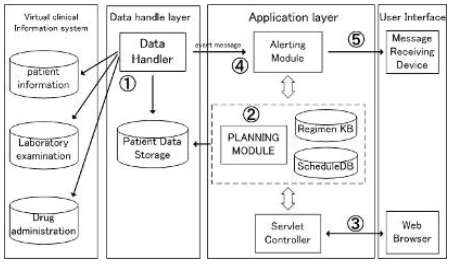

Figure 2 - Overview of the system architecture. 1) Different kind of patient data are collected and unified into the data storage. 2) Planning module provides an administration schedule while evaluating decision criteria based on the patient data. 3) Physician can operate planning module to create an administration schedule. 4) Alerting module is evoked by data handler and evaluates drug dosage using planning module. 5) If dosage should be modified, alerting module sends recommendation massage to the physician

Interaction between Clinical Departments and Express Laboratory in the Context of Information System of Multifield Hospital

Victor V. Tarasov[a], Sergey F. Lutoshkin[b], Andrey A. Nazarov[a], Tatiana E. Tsimbalova[b], Oleg V. Dzubina[a]

[a] *General Research Computer Center, Moscow, Russia*
[b] *Central Clinical Hospital, Moscow, Russia*

Abstract

Interaction between clinical departments and express laboratory of big multifield hospital is provided by integration of CIS and LIS. It comprises test order entering in clinical departments and their transfer to laboratory system, immediate acknowledgment of clinical departments of the status of running orders, sending of generated result reports to clinical departments, planning bio-substance collection. The systems integration resulted in saving the order running time, reducing redundant orders, improvement of informational provision of physicians and planning the work of laboratory.

Keywords:

laboratory information systems, clinical information systems, systems integration, medical order entry systems

Methods

Laboratory tests are among the most requested and informative diagnostic studies. The overall output of Central Clinical Hospital laboratories is 2 mln. tests of more then 400 parameters per year. About 25% of all tests are urgent. These studies are carried out by the express laboratory. Usually running of such a test takes not more then an hour. Mostly they are requested by intensive care departments (reanimation, post-surgery, cardio-reanimation etc). Capillary blood sampling is done by the laboratory personnel, other kinds of sampling and their dispatch is done by the personnel of clinical departments.

Until interaction between clinical departments and laboratory was automated there were certain problems of different kinds: order forms for express laboratory had been filled in manually, personnel of clinical departments and the laboratory had to dispatch and receive requests, and often redoubling of requests sent to express laboratory and other labs by different physicians had taken place.

Cooperation of clinical departments and the laboratory is provided by integration of Clinical information system (CIS) and Laboratory information system (LIS). CIS combines about 200 workplaces in clinical departments, and is designed for entering orders and receiving test results, and entering medicaments orders. LIS combines 40 workplaces and provides automatic fulfillment of all working cycles of the laboratory.

After integration of CIS and LIS entering of test orders is performed by physicians via their computers in clinical departments. During this procedure a doctor can look through the already planned patient orders, and ready test results. It will be of great help in making a reasonable decision to select this or that test, and to avoid redundancy. Immediately after entering into CIS the new order is transferred into LIS of express laboratory; and the laboratory personnel is informed by a special sound signal. A person in charge receives the orders, print them, and if necessary fulfill the bio-substance sample collection according to the state of urgency of the order. The system provides grouping of orders in dependence of their urgency, and develops a schedule of collecting bio-substance samples. Accuracy and validity of the running test is improved by the possibility for laboratory personnel to review previous tests results, clinical diagnosis, and other parameters of the patient. Test result is transferred to clinical departments electronically (preliminary result) right after the running is completed, and as a paper result report signed by a doctor of laboratory (final result). System also comprises electronic digital signing of the test result. Physician is informed by a special message on the screen of his computer when the result report is in CIS, and can review test results in the form of result report page, histogram or in dynamics.

Delphi and SQL Server were used for system implementation. Exchange of orders and test results is implemented in XML-format files.

Results and conclusions

As a result of CIS and LIS integration the automatic interaction of clinical departments and express laboratory in the process of order and test result transfer was provided. It helped to reduce the total time of fulfilling orders by 20% and eliminate redundant orders. Informational provision of physicians was improved. Man-hours for paper work, transfer or reception of orders and for bio-substance collection were substantially reduced.

[c] *Saitama Medical Centre, Saitama Medical University, Japan*
[d] *Graduate School of Medicine, Course of Health Science, Osaka University, Japan*
[e] *Cancer Institute Hospital of Japanese Foundation for cancer Research, Japan*

Abstract

The IHE-Japan RO(IHE-J RO) working group is started in February 2006 by JRS, JASTRO, JSRT, JIRA, four university, and eleven vendors, and the necessity of a Japanese extension to digging up and Japan of standard work flow models in Japan is examined. The consideration of special steps in approval is necessary for QA, and systematization for safety is important.

Keywords:

IHE, radiation oncology, DICOM, HL-7

Introduction

The Integrating the Healthcare Enterprise (IHE) is started by Radiological Society of North America (RSNA) and the Healthcare Information and Management Systems Society (HIMSS) in 1999, and it is wide to Europe and Asia. The object field has extended to not only the radiology but also the heart decease and the endoscope, etc.

It is necessary to approach the radiation therapy, too. In the radiation therapy field and IHE Radiation Oncology(IHE RO) started operations from 2005 in North America. And they are making the guideline of the information exchanges of standard work flows that used HL7 and DICOM-RT. Actor and the transaction in the irradiation of the treatment planning and radiotherapy treatment delivery, and the standards are proposed. Also in Japan The IHE-J RO working group is started in February, 2006. We reports the activity of IHE-J RO.

Activities of IHE-J RO

It is enumerated that facilities where a full-time radiation oncologist doesn't exist are not few in Japan. The radiation oncologist or other department physician makes treatment plans, and the oncologist or radiation technologist designs the irradiation beam. And radiation technologist executes the treatment. The process is divided by two occupations (the oncologist and the technologist). The Physicists are very few in Japan, the oncologist or the technologist design the beams, and make dose calculation. There are actually a lot of facilities to which the technologist design the beams. This situation especially influence the approval procedure. When the oncologist design the plan and beams by self, The possibility of making a mistake increases. Recently the mistakes were reported in the calculation with RTP, and the overdose and the underdose accident happened frequently in Japan. It is recommended for safety to compare the MU units of RTP and that of the hand calculation or other dose calculators. This recommendation should be taken in the integration profiles.

Conclusion

The workflow: Common workflow to most of facilities in Japan has been extracted by the scene of the examination, the irradiation, and the treatment plan. The mechanism that progress is managed a lot and the cooperation of the hospital information system and the electric medical record become it. Not a one-sided flow but the repetition and the divergence : the flow of the radiation therapy.

Peculiarity of Japan: It is enumerated that physicists are very few, and facilities where a only part-time radiation oncologist works are not few. This has the influence in the approval procedure. The consideration of special steps is necessary for QA, and systematization for safety is important.

Application of an RFID tag to medical equipment management support - Construction of an operation manual system for medical equipment

Atsuko Matsuda[a,c], Akiko Shindo[b], Terutaka Marukami[a], Shoko Tani[a], Masaki Miyamoto[c], Hiroyuki Horio[a], Hiroshi Inada[a]

[a] *Graduate School of Applied Informatics, University of Hyogo, Japan*
[b] *Hyogo Prefectural Amagasaki Hospital,Japan*
[c] *Department of Medical Informatics, Hyogo College of Medicine, Japan*

Abstract and Objective

Operation confirmation of medical equipments is indispensable for safe and accurate operation in medical care. In Japan, the standardization of information for medical equipments is in progress and some information such as operation manual one is offered. We already developed a medical equipment management system with an RFID. In the present study, a manual information referring system for operation was developed as one of the system by converting the manual information offered in SGML into an XML file and a PDF file. The manual information is able to be obtained on the bedside by using a PDA with an RFID reader. It was expected that the newly developed system contributes to safety operation of medical equipments.

Keywords:

medical equipment management system, manual information referring system for operation, XML file, PDF file, PDA

Introduction

It is important to manage medical equipments to prevent medical accidents because frequent accidents originated from inadequate management of equipments have occurred recently. Therefore, we intended to develop a safety management support system for medical equipments and started study on construction of the system by which the maintenance and inspection management and alibi management of the equipments can be supported by using an RFID tag. In this study, a manual information referring system for operation of medical equipments was constructed by using an RFID tag and a PDA with an RFID tag reader as operation confirmation is indispensable for safe and accurate use of equipments.

Methods

In Japan, the standardization of information for medical equipments is in progress and a manual information for operation of equipments can be offered by SGML. We converted the information to a PDF file via an XML file and the PDA terminal was used for convenience. In designing a form in the PDF file, opinions of nurses and clinical engineers were adopted, considering that they are major users of equipments. We made the file by calling the form from the browser software on a PC. The XML files for the manual information with the illustration were made by entering the additional information to the form.

Results and Discussion

The safety of medical equipments could be executed by making it possible to grasp detailed information on operation and control by the medical equipment management system constructed by us. In this study, attached document information besides essential information was included in the created PDF file for the operation manual. We could make the input work for the manual efficient by taking the information included an RFID such as ID information to access a medical equipment database, lending and inspection records etc. into the manual. The PDA terminal with small screen size became possible easy to obtain the necessary information by adopting the PDF file with the tab for the tap operation. In addition, it was considered that the efficiency of the reorganization work of the manual has been improved by preserving former information that made the manual as an XML file. The constructed system enabled medical personnel to refer to the operation information, the history of use, repair and check of medical equipments on the bedside by adopting the PDA.

Conclusion

In this study, a manual referring system for operation as one of the safety management system for medical equipment was successfully developed by applying an RFID and the system was thought to be useful from the result of a trial. In the next place, we have a plan to build the system on a full scale and confirm the utility of the system by installing it in a hospital.

Application of an RFID tag to medical equipment management support

- Construction of an operation manual system for medical equipment -

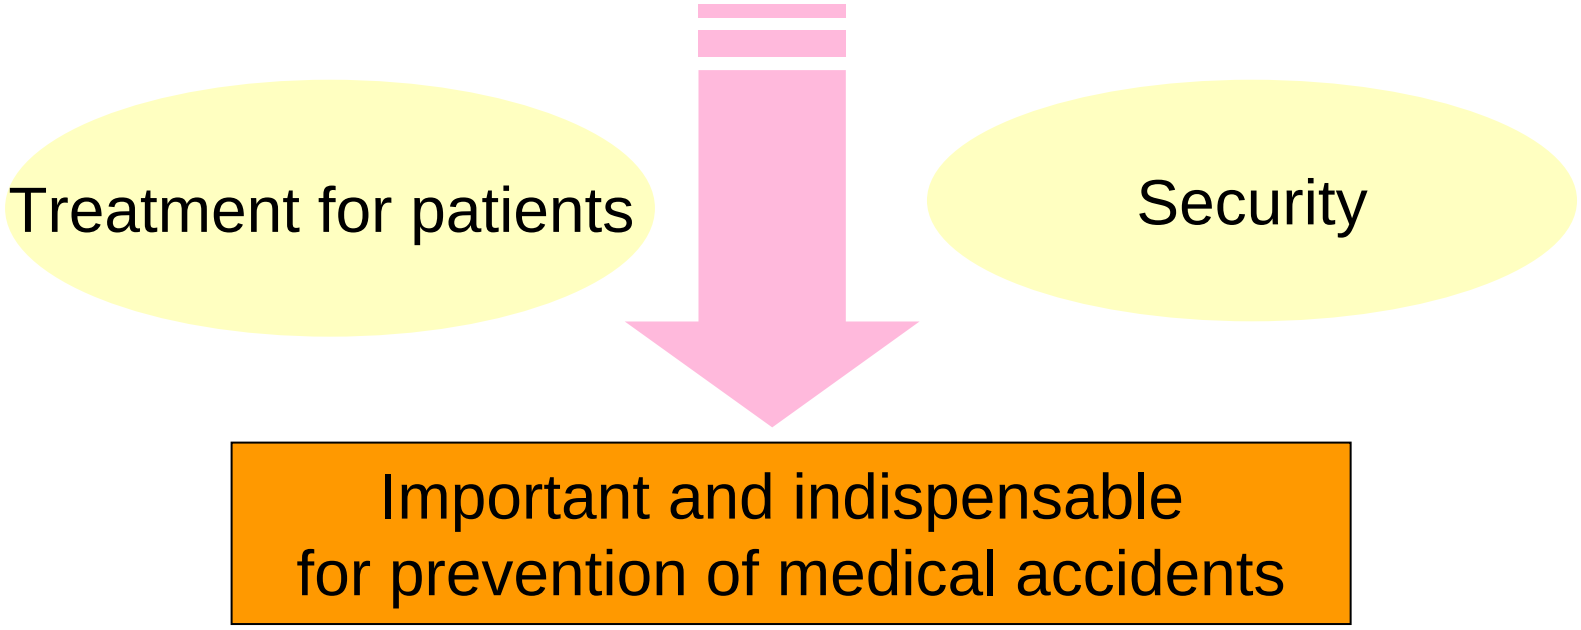
Introduction

Medical equipment is essential for present medical services.

Safety management of medical equipments in a perfect state



Targets of the development system

1. Centralized management of information of medical equipments
2. Recording use / maintenance histories of medical equipments → **Improvement of accidents Prevention accidents**
3. Making a database for medical equipments
4. Managing sterilization / disinfection of medical equipments by patient information → **Quick and efficient works**
5. Lending / return works of machinery in a lump → **Improvement of safety in use**
6. **Reading of information such as manual one**
7. Traceability → **Alibi management**
8. Planning assets management → **Rationalization of hospital management**

Hardware 1

- **RFID tag reader/writer**
  - (a) Table type
    (made by OMRON - V720-HS03)
  - (b) PDA type
    (made by OLYMPUS - pt1016 ticzizjp-c)

(a)

(b)

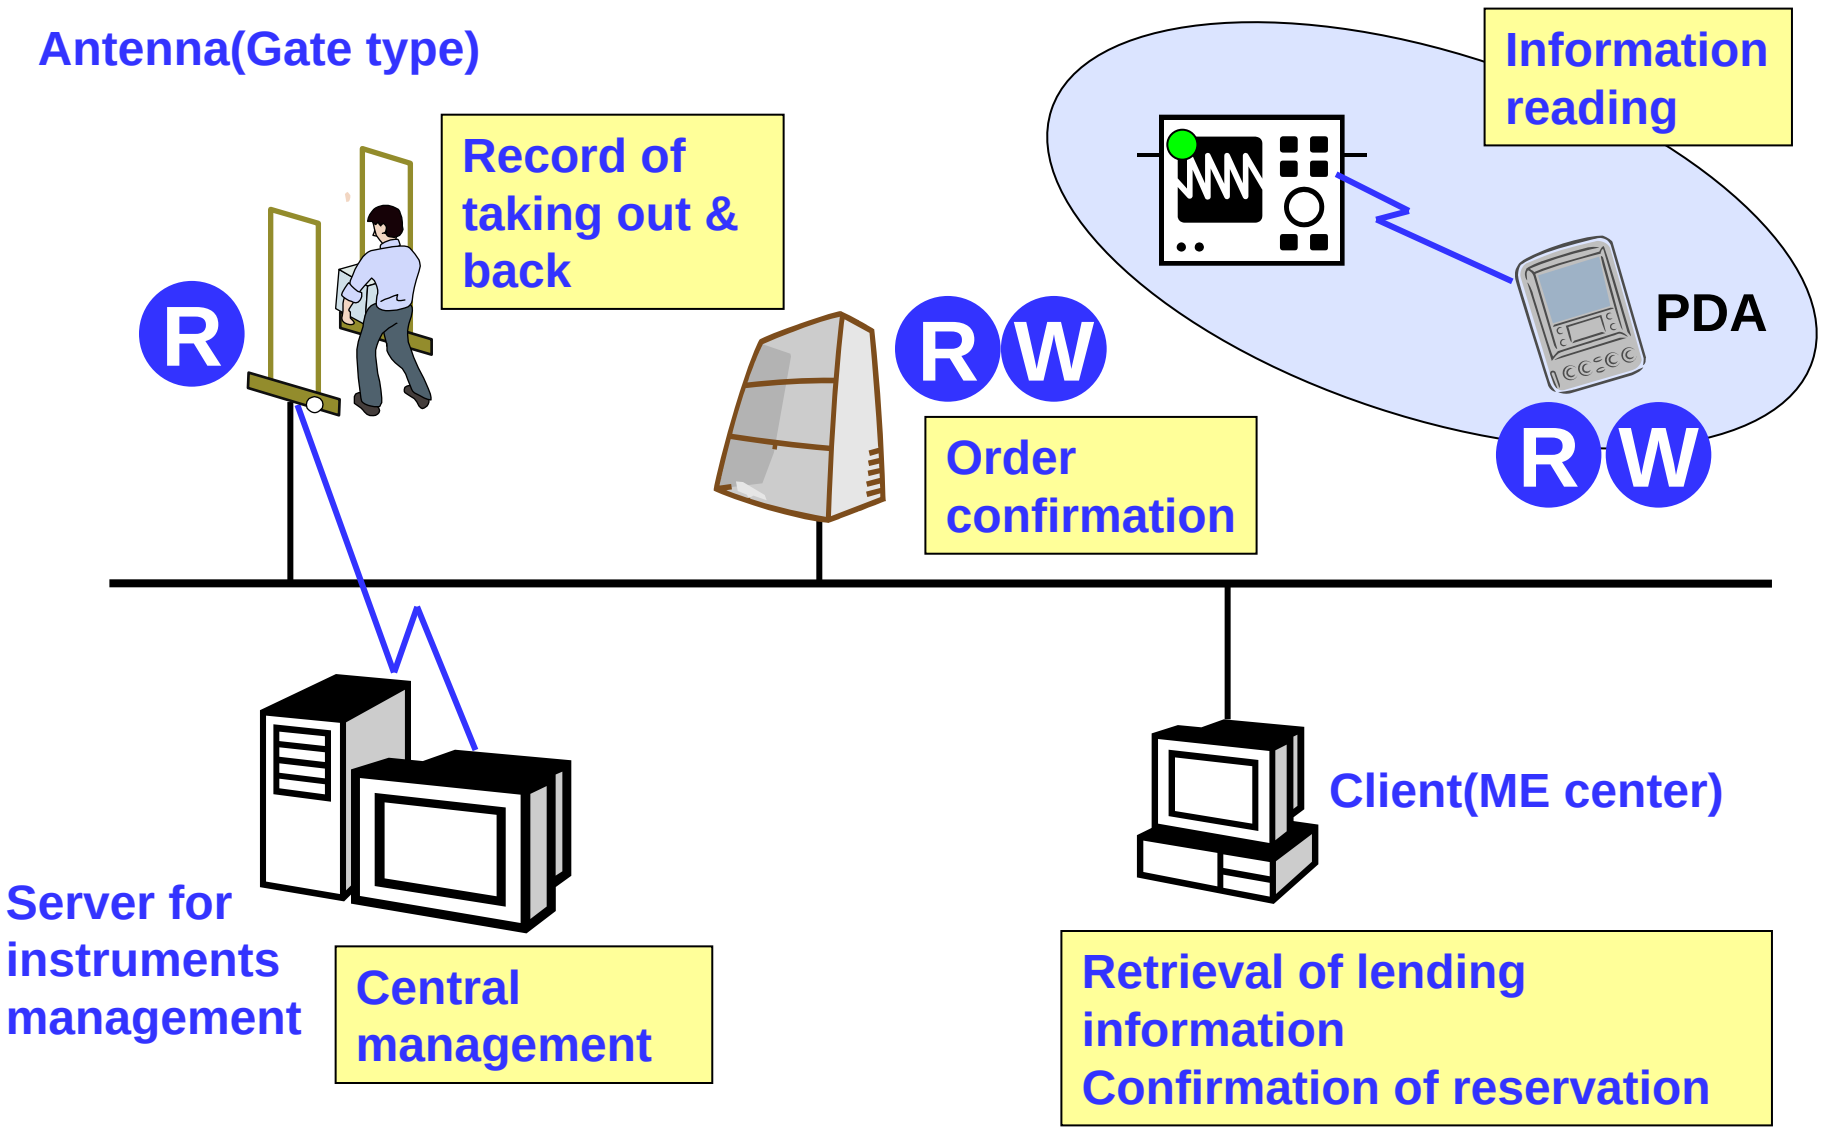
- **RFID tag**

  - Use for medical equipment ･･･13.56MHz / Label type for metal
  - Nameplate for medical personnel ･･･13.56MHz / Card type

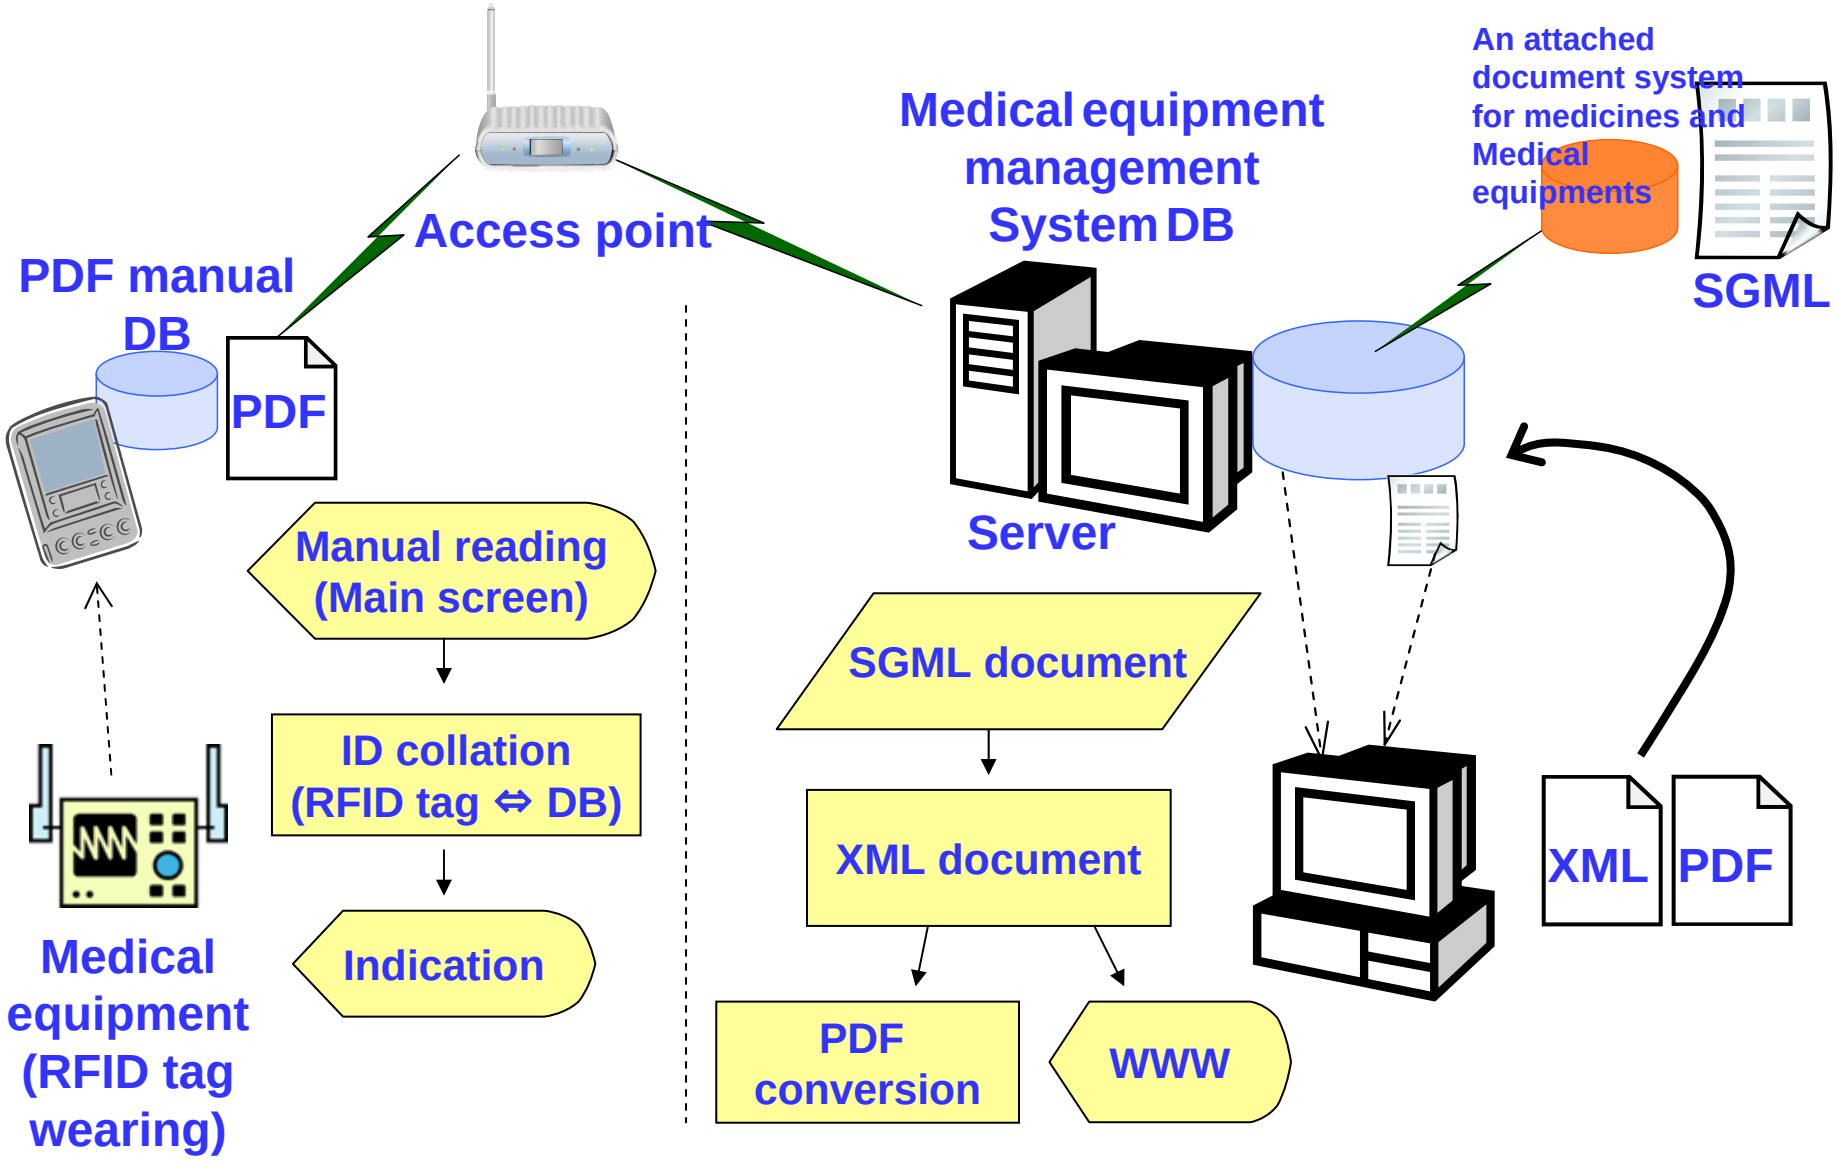
Software and Others

- An operation manual system for medical equipments

- **Form design**
  - Adoption of nurses' opinions
  - Choice of the information for the manual by clinical engineers
- **PDF file**
  - Use of Adobe Reader for Pocked PC2.0
  - The file made with the tag (A bookmark function)



System composition (ME Center)



Manual information referring system for operation

Results

Investigation of the function of the basic system - PDA terminal operation -

- Operationability / Function …Good

  A check function of equipments at the opening work promotes careful operation.

- Operation manual …Referable at the bedside

  The screen is small, but necessary information can be read

Improvement of safety by the developed system

- Reference of an operation manual at the bedside with a PDA terminal
- Check operation at the opening / closing work with a PDA
- Information for sterilization / disinfection of equipments from the infectious disease information of the patient

Advantage of an operation manual system for medical equipments

- **Improvement of Efficiency of the manual making work**
  - Using the information of machinery DB and the attached document information
  - Facilitating reedition work by adoption of XML
- **Improvement of the screen operation**
  - Realizing the quick and efficient screen operation by the PDF file with the tag
- **Reading manual information in the area available for a wireless LAN**
- **Acquirement of every information at the bedside**

Conclusion

In this study, a safety management system for medical equipment including a manual referring system for operation was successfully developed by applying an RFID and the system was thought to be useful from the result of a trial.

In the next place, we have a plan to build the system on a full scale and confirm the utility of the system by installing it in a hospital.

Implementing and Evaluating a Laboratory Information System to Optimize the Treatment of Tuberculosis Patients in Peru

Joaquin A. Blaya[a,b], Sonya S. Shin[b,c], Martin JA Yagui[d], Luis Asencios[d], Javier Vargas[d], Carmen Suares[e], Gloria Yale[f], Hamish SF Fraser[b,c]

[a] *Harvard-MIT Division of Health Sciences & Technology, USA,* [b]*Partners In Health, USA,* [c]*Division of Social Medicine & Health Inequalities, Brigham & Women's Hospital, USA,* [d]*Instituto Nacional de Salud, Perú,* [e]*Dirección de Salud IV Lima Este, Perú,* [f]*Dirección de Salud V Lima Ciudad, Perú*

Abstract and objective

Multi-drug resistant tuberculosis patients in resource-poor settings experience large delays in starting appropriate treatment and may not be monitored appropriately. A web-based laboratory information system "e-Chasqui" has been deployed in three laboratories and 12 health centers in Peru to reduce communication delays and missing or error-prone laboratory. Since November 2005, 30696 culture and 7237 drug sensitivity test results have been entered with 99% viewed online by health personnel. High user satisfaction and heavy use led to e-Chasqui being expanded to more institutions. In total, e-Chasqui will serve institutions providing medical care for over 3.1 million people. A study is being performed to measure its impact and generalizability.

Keywords:

Clinical Laboratory Information System, Computerized, Evaluation Studies, Developing Countries

Introduction

Treatment for MDR-TB in Peru is often delayed by over three months after initial presentation.(1) These potentially dangerous delays occur because of long test processing time, cumbersome communication procedures, and loss of specimens and test results. Similar problems are prevalent in other settings including South Africa.(2). An electronic information system can improve the handling of these data between institutions. Decreasing treatment delays and ensuring an appropriate drug regimen should improve outcomes and reduce transmission.

Methods

Partners In Health has developed a web-based medical record system (PIH-EMR)(3) to support the treatment of TB, with data on 15523 patients. We created a web-based laboratory information system, "e-Chasqui" to connect laboratories to health centers to reduce delays and facilitate communication and analysis. e-Chasqui includes tools to improve data quality, notify health centers of new results, alert physicians and create laboratory reports. Here we report on the system's implementation, use, and preliminary results from its evaluation.

Results

e-Chasqui has been implemented in the national reference laboratory, two of five regional laboratories in Lima and twelve health centers. Since its implementation in November, 2005, 28600 smear, 30696 culture and 7237 drug sensitivity test results have been entered. In 2006, 99.5% of all DST results and 98.8% of all culture results for the 12 pilot HCs were viewed online. Due to user satisfaction and heavy use, public officials have asked to expand the system to 3 other laboratories and over 10 other health centers. In total, e-Chasqui will serve a network of institutions providing medical care for over 3.1 million people.

Conclusions

This experience demonstrates the possible benefits of a web-based laboratory information system in a low resource setting. A retrospective and prospective randomized study is being performed to measure its impact on delays, errors, and quality of care, including time to prescribe an effective drug regimen. Using this experience we are developing a module to manage lab data for MDR-TB treatment in Lesotho and Rwanda, based on a new EMR architecture, OpenMRS (www.openmrs.org).

Problem Statement (1)

- Peruvian National Tuberculosis Program
  - One of the largest MDR-TB programs in the world
- Laboratory data are essential for treatment
  - Drug Sensitivity Test (DST):
    - Determines appropriate drug regimen
  - Monthly bacteriology tests (smear & culture)
    - Clinical measure to monitor treatment response
- Timely and accurate data are essential through the 2 years of MDR-TB treatment

Problem Statement (2)

- Metropolitan Lima
  - 3 times land area of NYC
  - Population of 8.2 million
- Challenges
  - Among highest TB rates in the world
  - Poor Transportation
    - 3 hours to cross city
  - Lack of Public Health Funding
    - Require external support

Clinical TB System
PIH-EMR

- Secure web-based Electronic Medical Record (EMR)
- Open source software, open data standards
- Usable over low-speed dialup connections
- Bilingual: English/Spanish
- 13,000+ patients, 5,700+ received MDR-TB treatment
- Also used in Philippines (Tropical Disease Foundation)

- Developing Version 2 (OpenMRS) for wider use
  - Supports HIV and TB

Fraser et al. Proc AMIA Symp 2002

PIH-EMR

Handheld Data Collection

E-Chasqui System

Smears
Cultures
DSTs

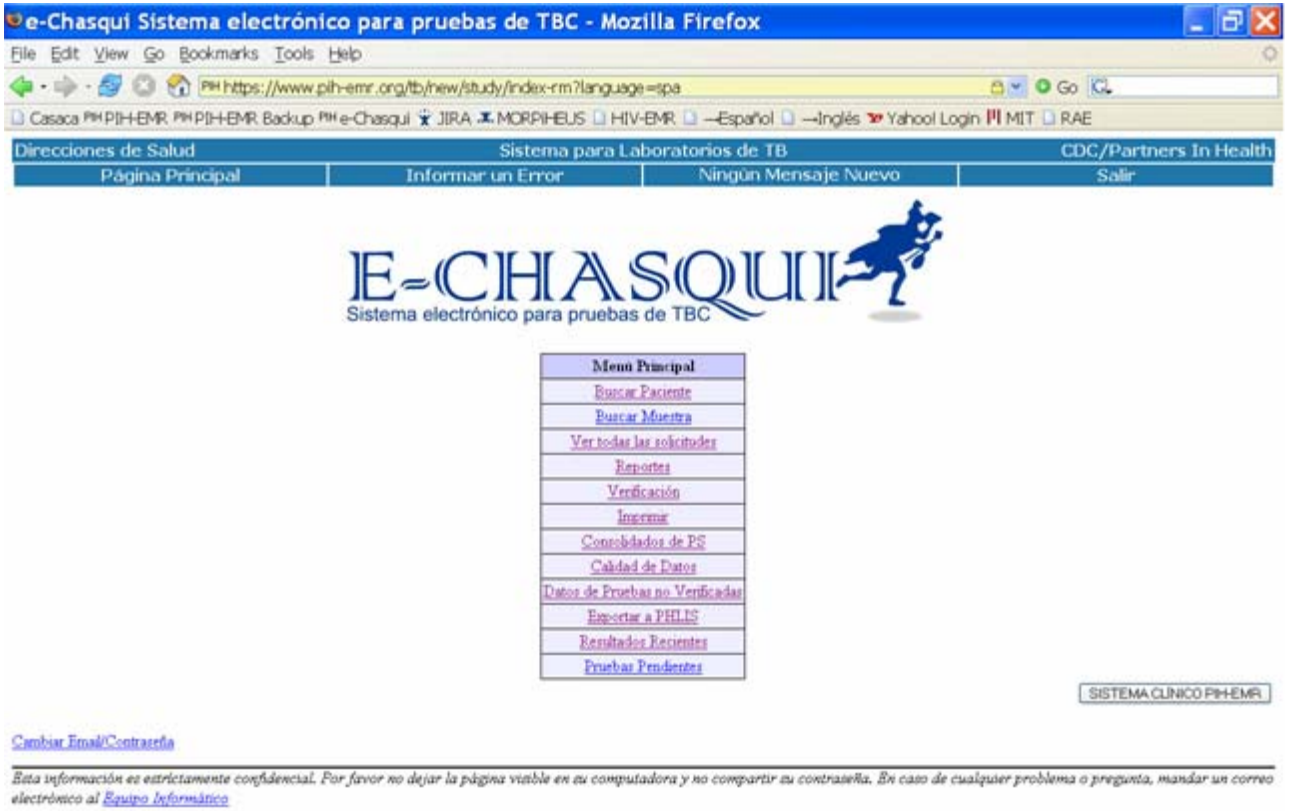
Hematology

Registration form
History/exam
Previous Rx
Previous Dx
Contacts

Follow up
Chest X-ray

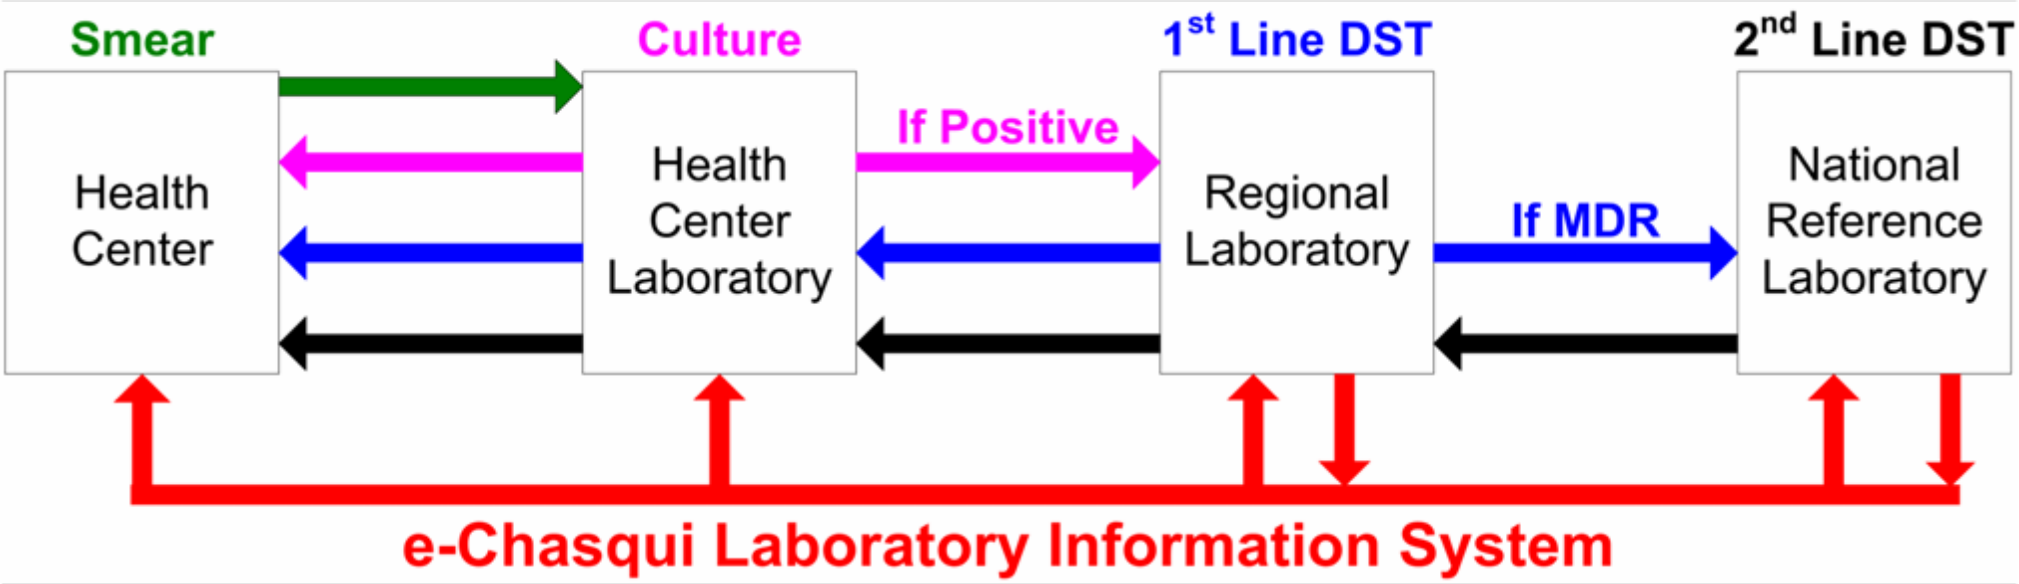
Drug regimens
Pharmacy



- Laboratory information system, e-Chasqui, extends the functionality of the PIH-EMR
- Web-based system to connect all TB treatment institutions

Lab Results Communication

Paper & e-Chasqui System Workflows



– 10% of results took > 60 days to arrive at clinic

– 16% of patients waited > 100 days to start treatment

Yagui et al. Int J Lung Dis 2006

Advantages of e-Chasqui

1. Automatically connects laboratories to health centers
   - Email notifications to health center personnel
   - Constant access to all information
2. Tools to improve data quality
3. Reporting functions for laboratory personnel
4. Alert clinicians & coordinators of high-risk patients
   - Patients with MDR-TB not on appropriate treatment

Implementation of e-Chasqui

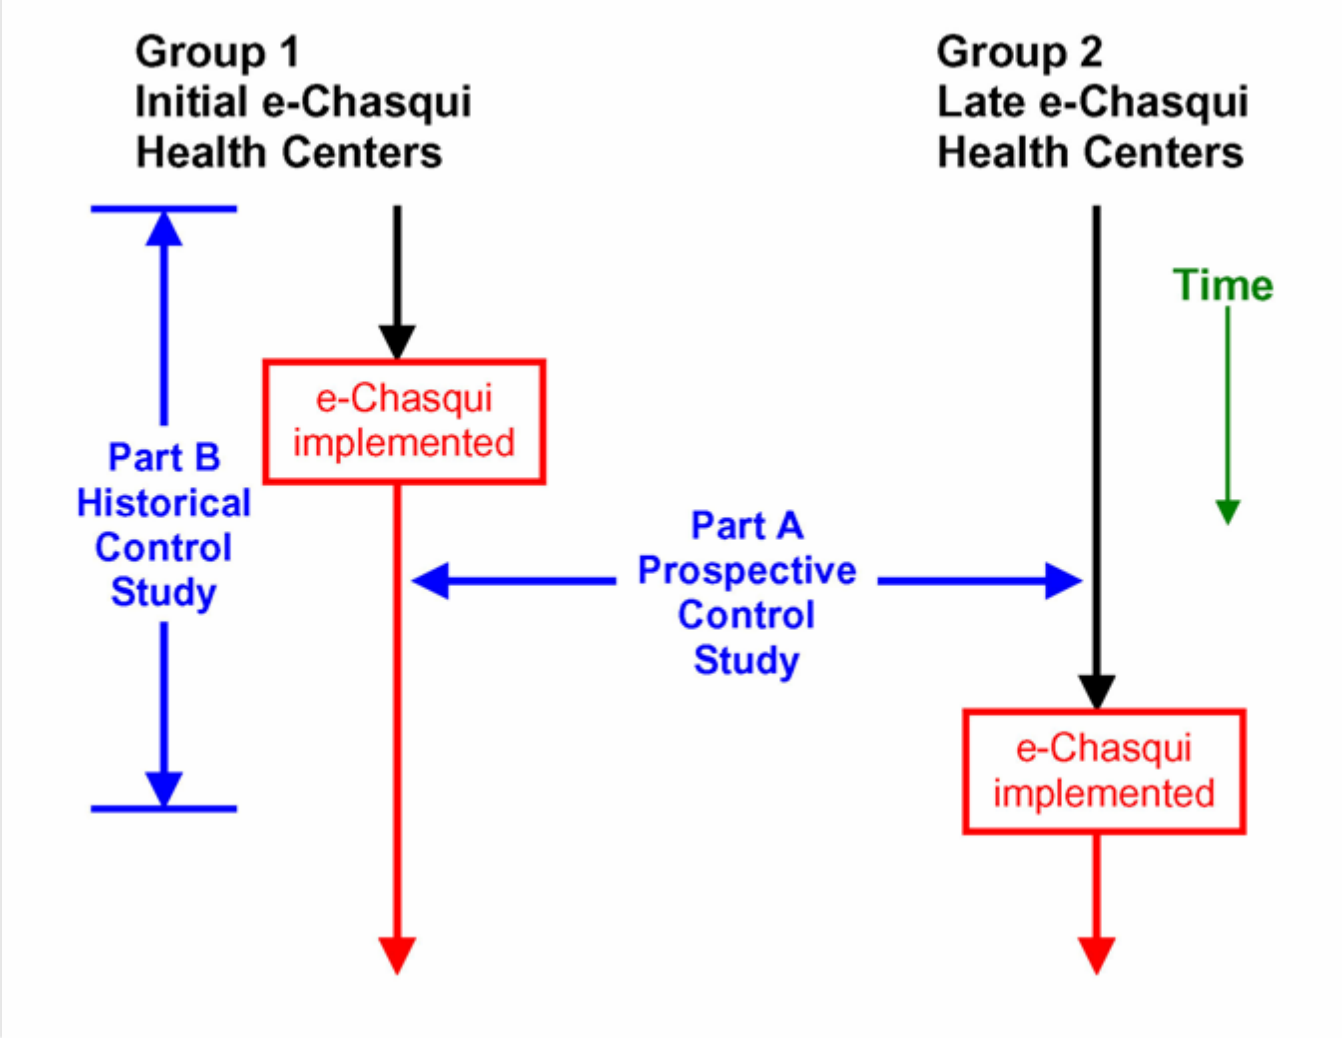
- Data Entry
  - National Reference Laboratory (INS)
  - 2 of 5 Regional Laboratories
    - Smears (28,000+), Cultures (30,000+)
    - 1st Line (7,000+) and 2nd Line (350+) DSTs

- Data Viewing
  - 20 health centers in 2 health districts
  - ~100 users including clinicians, nurses and lab staff
  - Connect centers providing care for 3.2 million people

Evaluation of e-Chasqui

- Prospective **(A)** & historical **(B)** controlled study

- Controls
  - **A.** Later access establishments
  - **B.** Self Controls



Evaluation of e-Chasqui

- Outcomes of Interest:
  1. Average communication delays
  2. Frequency of "Lost Results"
  3. Quantity of laboratory errors
  4. Approximate cost of the intervention
  5. Users' perception of e-Chasqui and nation-wide EMR
  6. Reduction of duplicate DSTs performed

Abstract

Automatic word alignment in parallel texts can be used to generate lexicons, but the lexicons' quality is depending on the quality and type of the input resources. In this study the English and Swedish versions of the medical terminology systems ICD-10, ICF, NCSP, KSH97-P and MeSH are automatically word aligned and the influence the different systems have on the quality is evaluated. The most generally useful resources were generated from ICD-10 and the size of the partitions used to generate the resources only partly affects the quality.

Keywords:

classification, linguistics, medical informatics computing, terminology, medical terminology systems, word alignment

Introduction

One solution to cut costs for manual translations of medical terminology systems are to reuse already translated systems. In word alignment the task is to find correspondences on the word or phrase level between a source text and its translation, and the result can be reused in new translations. In an earlier study we word aligned a union of ICD-10, ICF, MeSH, NCSP and KSH97-P [1]. In this study we explore the influence the different terminology systems have on the recall and precision by varying how the systems are utilized in word alignment.

Materials and methods

Alignment tools

The ITools suite is used in this study for the word alignment [2]. First the user creates word alignment training data in an interactive environment. Then automatic alignment is done in a primarily linguistically oriented manner where different types of resources are combined in a voting procedure to select the best possible alignments. The static resources used are dictionaries and pattern resources for common and unwanted parts-of-speech correspondences and standard punctuation. The dynamic resources used are generated during the training stage. The statistic resources used are dictionaries produced using statistical analysis on the parallel texts.

Used terminologies and terminology partitions

The rubrics of the medical terminology systems ICD-10, ICF, MeSH, NCSP and KSH97-P that exist in parallel in both English and Swedish have been extracted for use in the study. A manual exploration divided the terminology systems into partitions with similar content and ordered the partitions from partition 1 with the highest assumed quality to partition 8 with the lowest. The exploration found the partitions 1: MeSH one word in English or Swedish rubric (13,514 rubrics), 2: MeSH more than one word in English and Swedish rubric (5,568 rubrics), 3: ICF (1,496 rubrics), 4: KSH97-P (968 rubrics), 5: ICD-10 except chapter 2 level 4 (10,791 rubrics), 6: NCSP except chapter N (4,137 rubrics), 7: ICD-10 chapter 2 level 4 (713 rubrics), 8: NCSP chapter N (1,388 rubrics). Partition 1 was used as a static dictionary for the alignment of partition 2–8.

Preparation and manual word alignment

Statistical resources were generated from each of the partitions 2–8. Then from each of the partitions 2–8, 5 % were randomly sampled to a training set and 5 % to a test set. These sets were interactively aligned by one of the authors following a style guide. The training sets were used to build training resources and the test sets as gold standards for evaluating the automatic word alignment's recall, precision and F-score.

Automatic word alignment

The test sets were automatically word aligned and the partitions used for building the statistic and dynamic resources and to automatically word align were altered according to Table 1. The main assumption to examine in batch 1 was similarities and differences inside each partition, in batch 2 the similarities and differences between a partition and the union of all partitions, in batch 3 if the performance of the automatic word alignment improves monotonously when resources from more and more partitions are used or if some partitions worsen the performance and in batch 4 the similarities and differences between the union of all partitions and a partition.

Results

The results of the word alignment are presented below.

Table 1 - Word alignment configurations and results

Batch	Run	Resource partition	Align partition	Recall	Precision	F-score
1	1	2	2	0.72	0.70	0.71
	2	3	3	0.80	0.80	0.80
	3	4	4	0.71	0.68	0.69
	4	5	5	0.80	0.78	0.79
	5	6	6	0.83	0.78	0.80
	6	7	7	0.63	0.58	0.60
	7	8	8	0.84	0.85	0.84
2	1	2	2–8	0.65	0.65	0.65
	2	3	2–8	0.62	0.63	0.62
	3	4	2–8	0.64	0.64	0.64
	4	5	2–8	0.75	0.73	0.74
	5	6	2–8	0.67	0.67	0.67
	6	7	2–8	0.64	0.65	0.64
	7	8	2–8	0.64	0.65	0.64
3	1	2	2–8	0.65	0.65	0.65
	2	2–3	2–8	0.67	0.66	0.66
	3	2–4	2–8	0.69	0.67	0.68
	4	2–5	2–8	0.77	0.74	0.75
	5	2–6	2–8	0.80	0.76	0.78
	6	2–7	2–8	0.80	0.77	0.78
	7	2–8	2–8	0.81	0.77	0.79
4	1	2–8	2	0.73	0.71	0.72
	2	2–8	3	0.81	0.81	0.81
	3	2–8	4	0.81	0.76	0.78
	4	2–8	5	0.81	0.78	0.79
	5	2–8	6	0.84	0.79	0.81
	6	2–8	7	0.74	0.65	0.69
	7	2–8	8	0.85	0.85	0.85

Discussion

In batch 2, all partitions except partition 5 have quite a similar recall and precision despite their varying sizes. This indicates that the sizes of the partitions used to generate the resources only partly influence the alignment results.

In batch 3, the recall and precision increase or remain unchanged for each added partition. This implies that none of the added resources decreases the word alignment quality.

Batch 4 has better results than the other batches, but compared to batch 1 the improvements of using resources generated from all partitions are in general small.

Partition 2 gives not as good results as most of the other partitions in batch 1 and 4, which indicates that there might be content-related aspects that make the alignment difficult.

The best resources are generated from partition 5, and this partition seems to cover the medical domain, represented as the union of all partitions, best of the single partitions. This is probably because it contains the highest number of rubrics of the partitions. This result is interesting because the partition contains ICD-10 and most of the other included terminology systems cover other sub-domains of medicine than diseases. Resources from partition 5 show in general better result than partition 4. Both partitions have similar content and structure, but partition 5 is eleven times larger than partition 4. The large difference in size and the moderate difference in results show that only adding larger resource partitions can be an expensive way to improve the results.

Partition 7 is difficult to align according to the results of batch 1 and 4. This can probably be explained by structural and semantic differences between the Swedish and English versions.

Conclusions

A larger resource partition generates resources that only to some extent have higher quality, so only adding larger resource partitions can be an expensive way to improve the results. ICD-10 seems to cover the medical domain best of the included terminology systems and generated the best general resources. Systematic differences in structure between rubrics and their translations make the rubrics harder to align.

b Department of Computer and Information Science, Linköping University, Sweden

Introduction

Translations of medical terminology systems are necessary if the systems are used in countries with different languages.

Manual translations are expensive, but one solution to cut costs are to reuse already translated medical terminology systems for translation of new systems. The systems already existing in two languages are word aligned to generate lexical resources for reuse in new translations. The translation of new systems can then be semi-automatic instead of manual.

Terms in medical terminology systems have a more repetitive structure than natural language texts and the quality of the generated resources are therefore expected to be higher for medical terminology systems.

In an earlier study we used word alignment to generate a medical English-Swedish dictionary from a union of medical terminology systems[1]. In this study we explore the influence the different terminology systems and resource types have on the results.

Objective

The method used for the automatic word alignment of the terminology systems uses resources generated from the terminology systems.

In this study the aligned partitions and the partitions used to generate the resources of the terminology systems are varied. The variations give the possibility of evaluating similarities and differences within and between the terminology systems.

The similarities are mainly based on whether the contents in the rubrics consist of unique words or not, if the structures of the rubrics are repetitive and if the structure in the translated rubrics remains unchanged compared to the original rubric.

Background - Word alignment

Word alignment is the task of finding correspondences on the word or phrase level between a source text and its translation. Languages are not structured in identical ways across language borders and translations contain additions as well as omitted information. It is therefore no straightforward mapping techniques between two languages.

The standard approaches to word alignment in parallel corpora are statistical approaches and linguistic approaches. The statistical approach use probabilistic translation models. The linguistic approach often use rules for segmentation into lexical units, bilingual dictionaries and rules on word order and positions, as well as rules on corresponding part-of-speech labels.

The primary usefulness of word alignment is that it will recover and present candidate word and term pairs from a potentially previously unknown domain through a text corpus.

Methods - Alignment tools

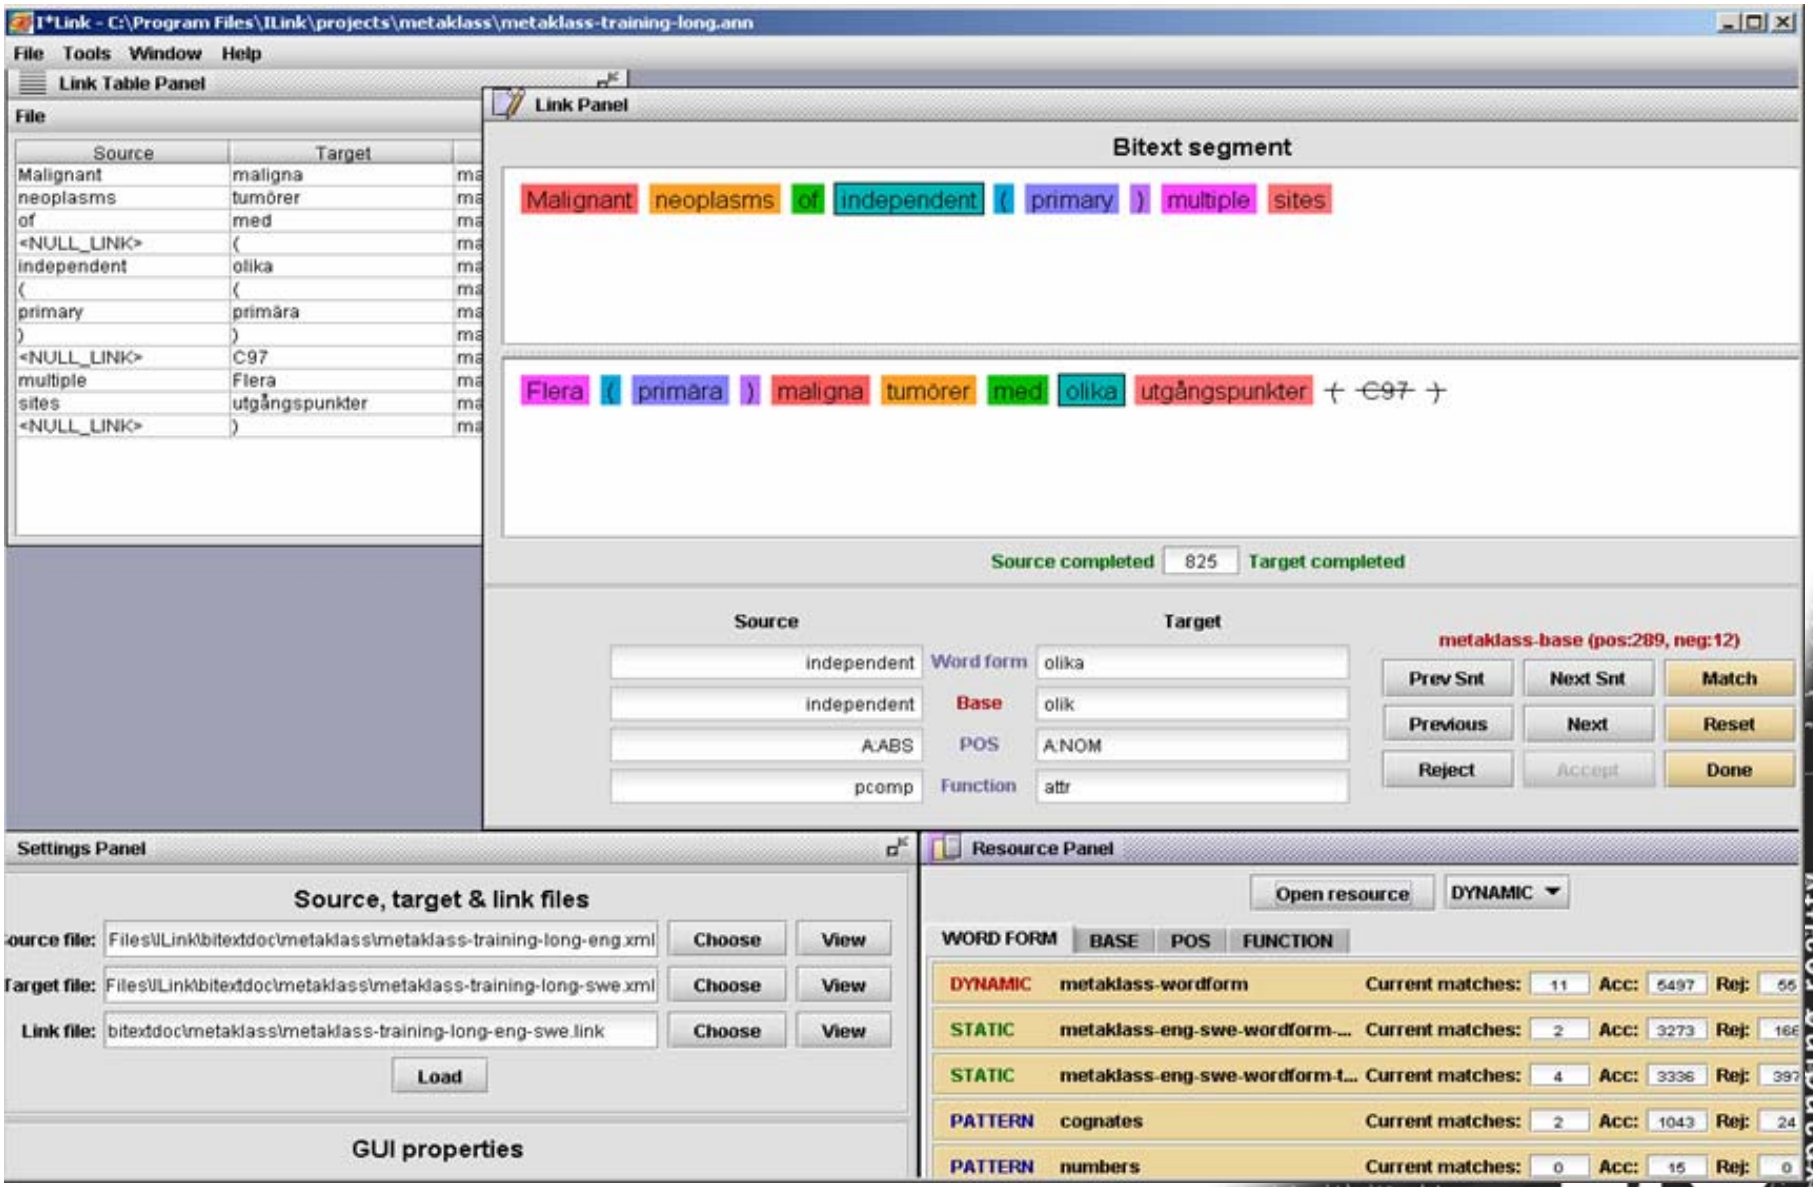
The ITools suite is used for the word alignment [2-4]. First morpho-syntactic tagging and statistical processing are performed. Then the user creates word alignment training data in an interactive environment. After that automatic alignment is done in a primarily linguistically oriented manner where different types of resources are combined in a voting procedure to select the best possible alignments.

The static resources used are dictionaries with a total of 22,500 general English-Swedish entries and pattern resources for common and unwanted parts-of-speech correspondences and standard punctuation.

The dynamic resources used are generated during the training stage. These resources are supposed to reflect the specific characteristics of the used material. The dynamic resources are built on four levels simultaneously, namely word form, lemma form, parts-of-speech and syntactic function levels.

The “statistic resources” used are probabilistic dictionaries produced using statistical analysis on the parallel texts with the GIZA++ tool kit.

Methods - Interactive word alignment tool



Evaluating bilingual medical terminologies with word alignment methods, Mikael Nyström et al.

Methods - Preparations

The preferred English and officially translated Swedish rubrics were extracted from the used medical terminology systems. An exploration was then carried out to find partitions of the systems with assumed similar quality for the word alignment.

Considering the exploration the systems were divided into 8 partitions and ordered from partition 1 with the highest assumed quality to partition 8 with the lowest. Partition 1 was selected to be included in the static resources as a dictionary.

Statistical resources for the automatic word alignment were generated from each of the partitions 2–8.

From each of the partitions 2–8, 5 % were randomly sampled to a training set and 5 % to a test set. These sets were interactively aligned following a word alignment style guide. The training sets were used to build training resources and the test sets as gold standards for calculating the automatic word alignment's recall, precision and F-score.

Materials - Terminology partitions

Parti-tion	Content	Rubrics	English rubric average number (standard deviation) of words	Swedish rubric average number (standard deviation) of words
1	MeSH, one word in English or Swedish rubric	13,514	1.5 (0.7)	1.0 (0.1)
2	MeSH, more than one word in English and Swedish rubric	5,568	2.6 (0.8)	2.3 (0.7)
3	ICF, whole	1,496	4.7 (2.5)	4.2 (2.8)
4	KSH97-P, whole	968	4.0 (2.5)	3.5 (2.4)
5	ICD-10, except chapter 2 level 4	10,791	5.2 (3.0)	5.2 (3.4)
6	NCSP, except chapter N	4,137	5.8 (2.7)	5.0 (2.5)
7	ICD-10, chapter 2 level 4	713	3.6 (2.2)	6.3 (2.7)
8	NCSP, chapter N	1,388	9.4 (2.6)	7.7 (2.3)

Methods - Automatic word alignment

The test sets were automatically word aligned in 4 batches and the partitions used for building the resources and to automatically word align were altered. The same partitions were used to generate the statistic and dynamic resources. The main assumptions to examine in the batches are

1. The performance of the automatic word alignment when a partition is aligned with resources generated from the same partition. The performance reflects the similarities and differences inside each partition.

2. The performance of the automatic word alignment when generalizing resources from one partition to other partitions. The performance reflects the similarities and differences between a partition and the union of all partitions, which can be seen as an approximation of the medical language in healthcare records.

3. If the performance of the automatic word alignment improves monotonously when resources from more and more partitions are used or if some partitions worsen the performance.

4. The performance of the automatic word alignment for the different partitions when resources from all partitions are used. The performance reflects the similarities and differences between the union of all partitions and a partition.

Results

Batch	Run	Reso-urce parti-tion	Align parti-tion	Recall	Preci-sion	F-score
1	1	2	2	0.72	0.70	0.71
	2	3	3	0.80	0.80	0.80
	3	4	4	0.71	0.68	0.69
	4	5	5	0.80	0.78	0.79
	5	6	6	0.83	0.78	0.80
	6	7	7	0.63	0.58	0.60
	7	8	8	0.84	0.85	0.84
2	1	2	2–8	0.65	0.65	0.65
	2	3	2–8	0.62	0.63	0.62
	3	4	2–8	0.64	0.64	0.64
	4	5	2–8	0.75	0.73	0.74
	5	6	2–8	0.67	0.67	0.67
	6	7	2–8	0.64	0.65	0.64
	7	8	2–8	0.64	0.65	0.64

Batch	Run	Reso-urce parti-tion	Align parti-tion	Recall	Preci-sion	F-score
3	1	2	2–8	0.65	0.65	0.65
	2	2–3	2–8	0.67	0.66	0.66
	3	2–4	2–8	0.69	0.67	0.68
	4	2–5	2–8	0.77	0.74	0.75
	5	2–6	2–8	0.80	0.76	0.78
	6	2–7	2–8	0.80	0.77	0.78
	7	2–8	2–8	0.81	0.77	0.79
4	1	2–8	2	0.73	0.71	0.72
	2	2–8	3	0.81	0.81	0.81
	3	2–8	4	0.81	0.76	0.78
	4	2–8	5	0.81	0.78	0.79
	5	2–8	6	0.84	0.79	0.81
	6	2–8	7	0.74	0.65	0.69
	7	2–8	8	0.85	0.85	0.85

Discussion and Conclusion

Larger resource partitions generate resources that only to some extent have higher quality, so only adding larger resource partitions can be an expensive way to improve the results.

Partition 5, which contains the major parts of ICD-10, seems to cover the medical domain best of the included terminology systems. It can also be used to generate the best general resources of the included partitions. The large size of partition 5 is probably the main reason.

Systematic differences in structure between rubrics and their translations make the rubrics harder to align. The automatic word alignment can be improved by filtering out these rubrics.

Of the investigated partitions, two of them are harder to align than the others, namely partition 2 and 7.

Online Transmission of Clinical Data for Disease Management and Registers

Peter Beck[a], Ivo Rakovac[a], Bruno Cadonna[a], Armin Harrasser[a], Thomas Truskaller[a], Thomas R Pieber[a,b]

Abstract

There is growing demand for collection of structured clinical data for administrative and medical purposes such as quality management, registers and health care system planning. Especially integrated care concepts for chronic diseases put higher requirements on the availability of longitudinal common data. The aim of this work was to provide a flexible system to collect clinical data from routine care, available area-wide across institutional borders in Austria and Germany. It was our goal to implement plausibility checks and manual data revision while keeping the technical entry-barrier as low as possible. Data could be collected from various sources: a) paper forms made available electronically using an OCR scanner, b) online data entry through a web browser, c) data extracted from EPRs. A text-based comma separated file format was defined for data import from scanner and EPRs and made public. Until February 2007 more than 275.000 data-sets have been collected. Online data import was widely accepted: Between 2002 and 2006, 78 % of data were imported online by 34 different centres for 206 participating centres. EPR data import gained importance recently due to a physician incentive by a certification programme, which lead to an escalating increase of transmitted data sets.

Keywords:

data collection, quality assurance, health care, information systems

Introduction

Administrative and medical purposes such as quality management, registers and health care system planning create a growing demand for collection of structured clinical data in primary and ambulatory care, especially in the management of chronic diseases. Effective quality improvement strategies have been identified and published [1,2]. Many of these strategies such as audit and feedback [3] rely on clinical data collected by physicians. We report experiences with data acquisition implemented in our online web application Healthgate BARS over 5 years.

The aim of this work is to provide a flexible system to collect clinical data from routine care for quality management and patient registry in diabetes care, available area-wide across institutional borders. Plausibility checks and manual data revision had to be provided to make structured data available at a required minimum quality level to sub-

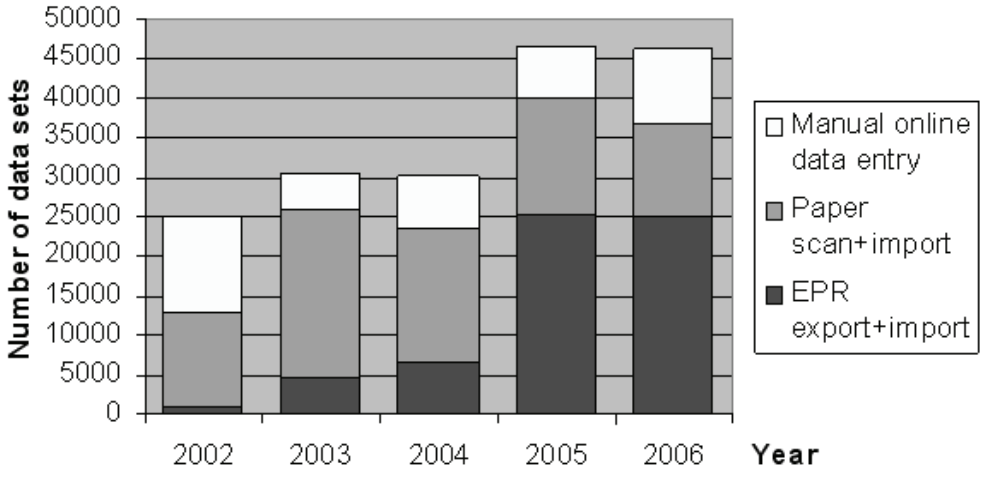

Figure 1- Data entry per year by input method

sequent data analysis. As the system was introduced in 2002 in Austria and Germany, common infrastructure such as electronic health record systems or health information networks were not available. In both countries, electronic patient records (EPR) in GP (general practitioner) practices often were available in very basic form only or not present at all. It was therefore our intention to fulfil the above requirements while keeping the technical entry-barrier as low as possible.

Material and methods

Data could be collected from various sources: a) data from paper forms made available electronically using an OCR (optical character recognition) scanner, b) online data entry through a web browser, c) data extracted from EPRs. A text-based comma separated file format was defined for data import from scanner and EPRs and made public. Data import was carried out through a Java 2 Enterprise web application and split into two sequential steps: Upload and revision. Files were uploaded and imported asynchronously using Message Driven Beans. All records passing plausibility checks were immediately stored in the database and remaining records marked for revision. Users were notified by email about import status. All data-sets not yet imported could be revised online and saved to the database. Data extracted from EPRs typically required only minor or no revisions. For this study, changes in data entry behaviour and data sources were analyzed over time.

Results

Until February 2007 more than 275.000 data-sets have been collected. Since 2002, 78 % of data have been imported online by 34 different centres for 206 participating centres in Germany and Austria (Figure 1). The web-based approach made the system easy to reach, use and administer. Data collected on paper was scanned and imported in two centres and could be revised locally in physicians' offices. The system was used in Austria and Germany by the voluntary quality management initiative “Forum for Quality Systems in Diabetes care”, as well as in routine care in Diabetes education projects in four Austrian provinces (Styria, Salzburg, Carinthia, Vienna). Since 2005 a certification programme introduced by the German Diabetes Association is supported by Healthgate, which increased demand for EPR interface development and lead to a dramatic increase of data imported from EPRs in Germany. Particularly specialized centres (9 hospitals, 22 diabetes clinics and 1 GP) managed to adopt EPR data extraction. These 32 centres contributed more than 40 % of overall data.

Discussion and conclusion

Our experiences show, that data acquisition tools for quality management are required and accepted by physicians. Automatic extraction of data entered in EPRs is the most practical solution to establish regular and high volume data transmission. However, this alternative has the highest entry barrier, because it requires development and modification of existing software systems in physician’s offices, achievable only by regulations or incentives for physicians.

In Germany, the HL7 based Sciphox (Standardized Communication of Information Systems in Physician Offices and Hospitals using XML) standard [4] is currently used in a follow-up project, to make data collected in the nation-wide Disease Management Program available for open benchmarking. In Austria, health information network and health smartcard, which have been rolled out about a year ago, provide a promising infrastructure for secure and high-performance data transmission and seamless system integration. In both countries, especially on the GP level, standards for data transmission only exist for administrative purposes and separation of healthcare sectors is prevalent. Introduction of a national Electronic Health Record (EHR) is discussed [5], which could reduce many of the existing barriers. However, presumably several years will pass until the fragmented market for EPR software on GP level will be penetrated by these initiatives. Meanwhile, as a step by step approach towards common EHR standards for connectivity and semantic interoperability, in both countries there is a strong need for harmonization and standardisation of data transmission as well as for algorithms to extract structured data from EPRs. Harmonization and Standardization on a national level as well as incentives and support for clinics and physicians are more important than technical innovation to achieve positive short and medium term results.

Introduction

- **Growing demand for collection of structured clinical data in primary and ambulatory care**
  - ➔ Administrative and medical purposes such as
    Quality management,
    Registers and
    Health care system planning
  - ➔ Especially in the management of chronic diseases
- **Effective quality improvement strategies have been identified and published [1,2].**
- **Many of these strategies such as audit and feedback [3] rely on clinical data collected by physicians.**
- **We report experiences with data acquisition implemented in our online web application Healthgate BARS over 5 years.**

Project Aims

- **Provide a flexible system to collect clinical data from routine care for quality management and patient registry in diabetes care**
  - ➔ Area-wide availability across institutional borders
  - ➔ Provide plausibility checks and manual data revision to make structured data available at a required minimum quality level to subsequent data analysis
- **Keeping technical entry-barrier as low as possible**
  - ➔ The system was introduced in 2002 in Austria and Germany.
  - ➔ Common infrastructure such as electronic health record systems or health information networks were not available.
  - ➔ In both countries, electronic patient records (EPR) in GP (general practitioner) practices often were available in very basic form only or not present at all.

Data collection

- **Available data sources**

  a) data from paper forms made available electronically using an OCR (optical character recognition) scanner

  b) online data entry through a web browser

  c) data extracted from EPRs.

- **A text-based comma separated file format was defined for data import from scanner and EPRs and made public.**

JOANNEUM RESEARCH

Data Import

- **Carried out through a Java 2 Enterprise web application**
- **Two sequential steps: Upload and revision.**
  - ➔ Upload
    - *Files imported asynchronously using Message Driven Beans*
    - *All records passing plausibility checks immediately stored in the database*
    - *Remaining records marked for revision*
    - *Users were notified by email about import status*
  - ➔ Revision
    - *Revision of data-sets not yet imported via online interface*
    - *Valid data sets saved to the database*
    - *Data extracted from EPRs typically required only minor or no revisions*

Use of the system

- **In Austria and Germany used by the voluntary quality management initiative "Forum for Quality Systems in Diabetes care"**
- **In routine care in Diabetes education projects in four Austrian provinces**
  - ➔ Styria, Salzburg, Carinthia, Vienna
- **Difference:**
  - ➔ Germany: Mainly specialised diabetes clinics and hospitals
  - ➔ Austria: All health care system levels, also many GPs
- **Data collected on paper was scanned and imported in two regional offices and could be revised locally by the physicians.**

JOANNEUM RESEARCH

Objective of this Study

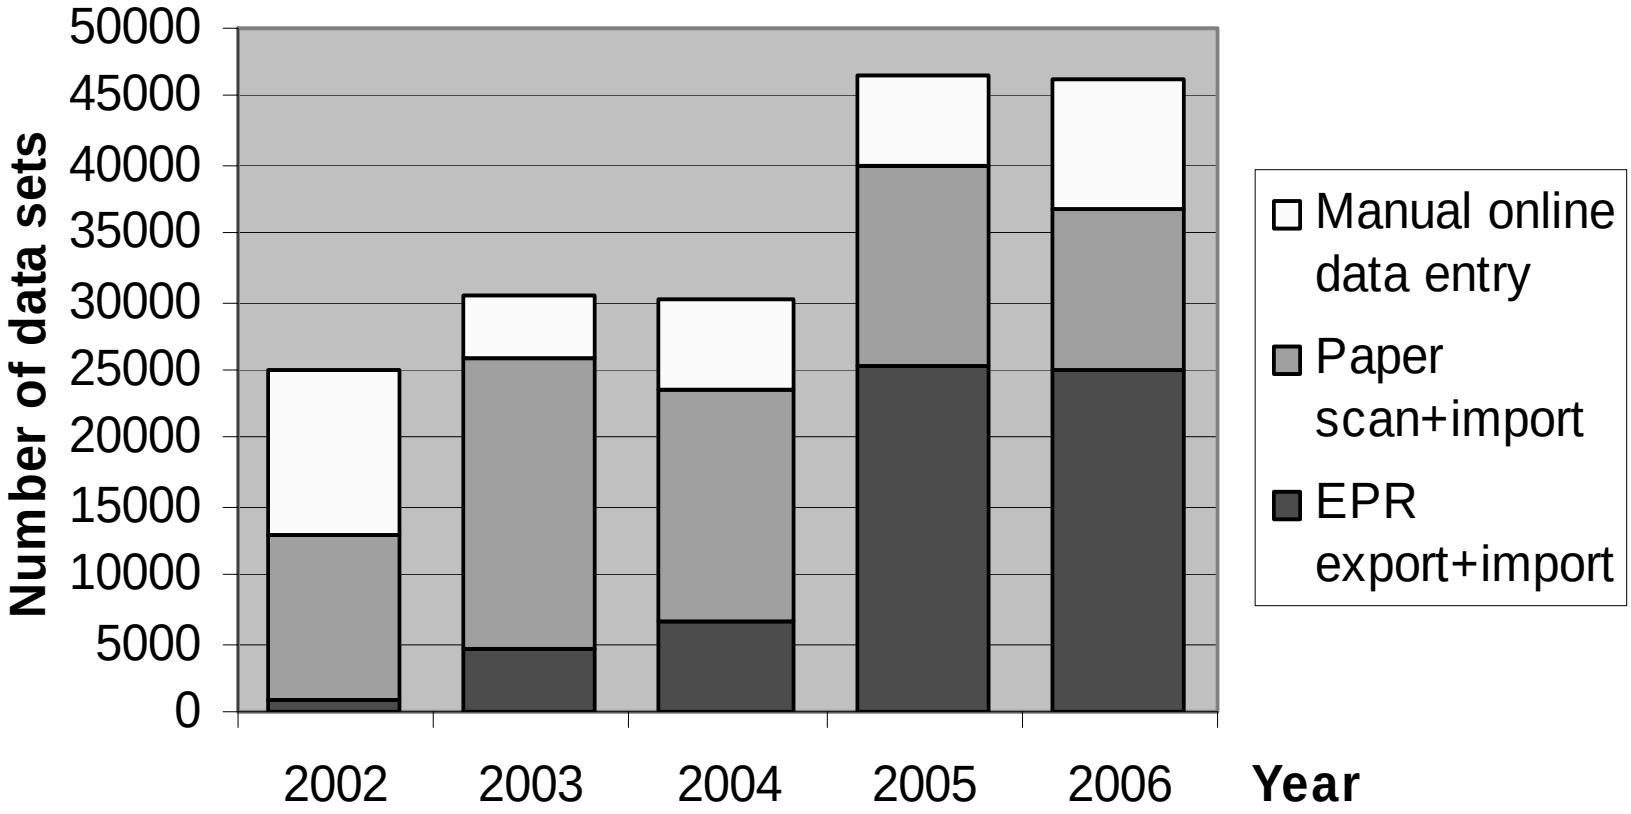
- Which data input methods are accepted and used in practice by physicians?
- Are there differences in smaller / bigger centres?
- Did data entry behaviour and data sources used change over time?

Results

- **More than 275.000 data-sets collected in Germany and Austria (February 2007).**
- **Since 2002, 78 % of data imported online**
- **Imports were performed by 34 different centres for 206 participating centres.**

- **32 specialized centres (9 hospitals, 22 diabetes clinics and 1 GP) managed to adopt EPR data extraction.**
- **These centres contributed more than 40 % of overall data.**
- **A certification programme introduced by the German Diabetes Association in 2005 is supported by Healthgate**
  - ➔ This increased the demand for EPR interface development
  - ➔ and lead to a dramatic increase of data imported from EPRs in Germany

Results
Data entry per year by input method



Discussion

- **Data acquisition tools for quality management are required and accepted by physicians**
- **Automatic extraction of data entered in EPRs**
  - ➔ is the most practical solution to establish regular and high volume data transmission
  - ➔ has the highest entry barrier, because it requires development and modification of existing software systems in physician's offices.
  - ➔ Incentives for physicians or regulations are required
- **The web-based approach made the system easy to reach, use and administer**
- **Germany**
  - ➔ HL7 based Sciphox(*) standard [4] currently used in a follow-up project for data collected in the nation-wide Disease Management Program
- **Austria**
  - ➔ Promising infrastructure provided by health information network and health smartcard

(*) Standardized Communication of Information Systems in Physician Offices and Hospitals using XML

Discussion
Need for standardisation

- ➔ Especially on the GP level, standards for data transmission only exist for administrative purposes and separation of healthcare sectors is prevalent
- ➔ Introduction of a national Electronic Health Record (EHR) is discussed [5], which could reduce many of the existing barriers
  - *Presumably, several years will pass until the fragmented market for EPR software on GP level will be penetrated by this initiative*
- ➔ Strong need for harmonization and standardisation
  - *As a step by step approach towards common EHR standards for connectivity and semantic interoperability*

Developing a Health Information Integrated Web Service With a Concept of "Mash up"

Po-Yen Li, Hui-Jou Chang, Dau-Jeng Huang, Polun Chang

Institute of Biomedical Informatics (formerly Health Informatics and Decision Making), National Yang-Ming University, Taiwan

Abstract

By using the concept of Mash up of the Web 2.0, we integrated search engines ,and show the results by tabs in the same page, our purpose lies in leading users to find out the desirous information ,and to provide some searching guidelinefor people who without professional health knowledge, and finally we reach the goal to perform the satisfying information web-pages with tabs.

Keywords:

Web 2.0, Mash up, health information, ASP.NET 2.0

Introduction

With the knowledge exploring time arriving, the demand of health information getting more and more, in order to satisfy this demand, we use the concept of Web 2.0 to design a system, the concept of Web 2.0 is very popular in recently years, especially in providing interaction between websites and users, open resources and sharing wisdom with each other, in brief, it offers better experience for user to use .One of the concepts is Mash up, through many web procedures combine outside resource in a easy way, The brand-new integrated service helps users to omit some unnecessary steps and reach the goals more effectively while they're browsing, for example: flickr(the largest photo-sharing website in the world)is "Mash up" by ThinkFree(the document-editing website), users can obtain the photos from flickr and put them into their own document by some simple steps, and Google Map is quoted to some websites as geographical information, Thus, we choose the program language of ASP.NET 2.0 and Google AdWordsyahoo and Google search engineWikipedia...etc integrated into one service for health information, therefore we use the concept of Mash up to design such service for the general people.

Methodology

We offer the "keyword suggestion" button (this part is top in Figure1.) for users by using the AdWords keyword tool in Google, which can count and show the other related keywords used by other users when they looking for information, and therefore guiding a searching direction for users , especially for those people without general sense of health.

There are always too much disorderly information to read at the same time , we use google search api to integrate better health web information which were elected by DOH in Taiwan.

Users can select which database they want to look for information and present the information be found in the first tag, and then the second tag present the other information which is not presented in first tag. The third tag present videos related with keywords from Youtube. This system uses component of an adjustable transparency of technical design of Ajax, this component can turn on the webpage that the user want to browse through among them, and can adjust the component position and size by oneself in mother's page. Advantage : 1. Preventing users from opening too many webpages at the same time and lead to inconvenient browsing. 2.By using Ajax technology, this design automatically recording the users' browsing time and report to the server in the situation of interference the users'reading . 3.When the user want to compare with the browsing time of all webpages, the system would present these webpages with different transparency. 4. When the mouse move over the keyword of searched abstract, the system would present related keyword information with a frame. This information provide a reference of definition for users, and the source of these data are from http://hospital.kingnet.com.tw/

Figure 1 - By using the user-friendly interface, it is convenient for users friendly to search and view the health information

Discussion

Nowadays the search of health information in the internet network in Taiwan ,the users may probably be confronted by two questions: 1.Beacause of lacking common health information people don’t know how to quiz and obtain the desirable information 2.There is too much information searched out through the internet search engine and telling apart which is the correct and helpful information is difficult for general people.

By using the concept of Mash up of the Web2.0, and the ASP.NET 2.0 technology, we design a well performed web-based system with good user interface to reach the main goal that can help users to screen and integrate the desirable information into this page, the same as all network services of utilizing Mash up, the copyright of WebPages is a topic to be discussed, too. But what we can make sure is, the more the websites be quoted as source references, the more valuable they would be, This tool with providing searching and integrating function of these websites will have the existing value because of saving user's time of searching satisfying information.

Primary Health Care Information System for the Epidemiologic Study of Farmers

Dimitris Zikos, Marianna Diomidous, John Mantas

Health Informatics, Faculty of Nursing, National and Kapodistrian University of Athens

Abstract

The agricultural work is associated with a series of adverse health effects. Health informatics could potentially contribute to the organization and development of the health data, therefore the need for an organized electronic file regarding farmers' health is crucial. The current project aims to develop an Information System which shall gather and store information not only about farmers' health, but also about the level of exposure to hazardous substances, the extend of use of Personal Protective Equipment (PPE) by farmers and the type of agricultural work. The above structure is expected to allow the use of the collected data in epidemiologic studies on farmers' health in order to associate exposure with the development of various diseases. A questionnaire was used as a methodological tool in order to set the appropriate fields that would finally be included to the Information System. The evaluation is being performed by assessing the effectiveness of the application as an epidemiologic tool as well as the various characteristics of the Information System itself.

Keywords:

agricultural workers, diseases, information systems, epidemiologic studies,
computerized medical records system

Introduction

Epidemiology of farmers' health

The agricultural work is associated with a series of adverse health effects, which are mainly caused by exposure to pesticides, allergenic agents, bad posture and weight lifting. According to the literature, the exposure to pesticides can cause several types of cancer, whereas allergenic inorganic and organic dusts are associated with the development of asthma, rhinitis and chronic bronchitis. As far as the ergonomic factors are concerned, inappropriate body posture, vibrations and heavy weight lifting may cause osteoarthritis and other musculoskeletal adverse effects. Accidents also consist an important hazard for the safety of farmers.

The use of Electronic Health Record in Primary Health Care

Most Primary Health Care Units in Greece do not use any kind of Electronic Health Record for the organization of the patient data at all. The health centers of the countryside routinely collect data into hand-written health records, but the data is not easily utilizable for the efficient surveillance of the patient health. In many countryside regions, the majority of people who visit the Primary Health Care facilities are occupied as farmers and stock breeders. Due to their occupation, they are are exposed to various hazardous agents, thus the need for an organized Patient Health Record is crucial. An effectively organized health record could be efficiently used for the improvement of the surveillance of farmers' health.

The use of an Electronic Health Record as a tool for epidemiological studies

A carefully designed Health Information System which includes various fields related with occupational health of farmers could be used as a tool for epidemiological studies. The use of information systems for this purpose is a practice that is being studied recently. The 2004 Utrecht study combined the traditional epidemiological studies with the strength of the Electronic Health Record that is being kept in Primary Health Care Facilities. Another study was carried out in 2004 by Majeed, which concludes that the data files stored in electronic form are potentially available for process and analysis. Manson et al. studied the applicability of data extraction from an Electronic Health Record and concluded that the collection of data is feasible.

The utilization of a reformed Information System for Primary Health Care Units to improve organization of health data of farmers is expected to assist Primary Health Care workers in their everyday practice. In addition, such a reformed Information System could be based not only on health data fields, but also on data of exposure to harmful factors, data regarding the extend of use of Personal Protective Equipment (PPE) and data on the type of production. Thus it can be used as a tool for the research of farmers' health and the fulfillment of epidemiological studies.

Materials and methods

The aim of the current project is to develop an Information System which can effectively be used in Primary Health Care facilities. The Information System shall be used as a tool for the surveillance and epidemiological study of farmers' health.

In order to build the fields of the Information System, a literature research was carried out regarding farmers' health, habits and factors related with the various hazardous exposures. Specifically, studies regarding farmers' health problems were studied and the results were summarized by type of risk and type of production. Also, literature research was carried out regarding the appropriate Personal Protective Equipment that should be used for each agricultural work.

Based on the above data, a questionnaire was built which was used as a tool to test the applicability and feasibility of the selected fields, before the actual development of the Information System. The questionnaire includes sections that resemble the actual structure of the Information System.

Once the specification and selection of the fields to be included in the Information System was completed, a careful design of the database schema was performed and the data fields were organized in normalized tables, connected with the appropriate relationships. The Information System is going to be installed in Primary Health Care Units and the extracted data shall be used by healthcare institutes and organizations for the surveillance of farmers' health as well as for the efficient utilization in epidemiological studies. The evaluation of the Information System is being performed in two levels.

The Questionnaire

After the completion of the literature research regarding farmers' health, habits and exposure factors, a questionnaire based on the results was created. The questionnaire is an important tool towards the development of the Information System, due to the fact that the fields selected are the ones that would be included in the e-health application.

The questionnaire has 4 sections. The first section includes questions about the demographic characteristics of farmers and their occupational history. The second section includes questions regarding the health record of farmers and their families. The third section refers to the type of production and the hours/days of work for each type of agricultural production type. Finally, the last section is about the exposure to hazardous substances, accidents related to the agricultural work, and questions about the use of various Personal Protective Equipment. The selected questions were based on a literature research aiming to recapitulate the main findings of studies on the appropriate PPE the farmers should use. The main sources of information are relevant organizations and Universities conducting research on farmers' health.

The Application

The Information System is being developed with Microsoft SQL Server 2005 in conjunction with Microsoft .net platform. The tables of the database include fields that were applied in the questionnaire. The application is being installed in Primary Health Care facilities and the data collected shall be used by any relative healthcare institute/ organization interested in conducting epidemiological research on farmers' health.

The Information System itself includes statistical calculations based on the data collected and further analysis can be performed once the extraction of the e-health record is done. The careful selection of the fields included in the information System and the way the data is being stored into the database, allows for easy extraction and direct use of the data in statistical packages such as SPSS.

Correlation of data

The data collected in the Electronic Health Record can be used in various correlation studies regarding farmers' health. The selection of the fields that were included in the Information System as well as the way the data is being stored makes it possible to directly extract data for statistical analysis and use it in order to carry out epidemiological studies.

Correlation of personal characteristics of farmers with the development of specific diseases, correlation of personal characteristics of farmers with the extend of use of Personal Protective Equipment, correlation of the level of use of PPE with the development of certain symptoms and diseases, correlation of type of production/hours-days of work per sector with the development of diseases/ symptoms and correlation of exposure to pesticides, noise from tractors and other hazards with the development of diseases/symptoms.

Evaluation

The evaluation of the Information System will be performed once the development of the application is complete. The evaluation is going to be carried out in two levels. The first level includes the evaluation of its use as an epidemiologic tool. A correlation study will be carried out on a well known health issue in order to assess the efficiency of the Information System as a tool for epidemiologic research. The second level of evaluation includes the assessment of the application in terms of content quality, usability, responsiveness and appearance.

Discussion

The use of the Electronic Health Record will contribute in the everyday work of healthcare professionals in terms of time, accuracy and operational costs. The use of the International Classification of Diseases (ICD) in all fields referring to diseases and symptoms will help towards the accuracy and fidelity of the health data. Every piece of health information will only be recorded once in the Electronic Health Record, without the existence of any kind of data redundancy. The Health Record of farmers is

expected to be easily distributed across granted interested parties. Finally, the backup system developed for the security needs of the Information system is expected to ascertain the security of the health data.

Primary Health Care Information System for the Epidemiologic Study of Farmers

Dimitris Zikos, Marianna Diomidous, John Mantas

Health Informatics, Faculty of Nursing, National and Kapodistrian University of Athens

INTRODUCTION

- Greece is a country with significant agricultural production
- 11% of the population are occupied as farmers.
- The agricultural work is associated with a series of adverse health effects, which are related with a series of characteristics of the specific sector.

Risk factors

- Physical (ie. exposure to sun)
- Chemical (ie. pesticides)
- Biological (ie. viruses)
- Ergonomical (ie. musculoskeletal problems)

MAIN OBJECTIVES

Development of an Information System

- For the epidemiological study of farmers health
- For the surveillance of heath and other health and safety parameters concerning farmers health
- For the improvement of farmers health

FIELDS OF THE INFORMATION SYSTEM

- Demographic data
- Health data
- Data concerning type of production and duration of farming work
- Exposure to risk factors
- Data on the use of Personal Protective Equipment
- Knowledge of farmers on health and safety issues

CORRELATIONS

- Correlation of personal characteristics of farmers with the development of specific diseases.
- Correlation of personal characteristics of farmers with the extend of use of Personal Protective Equipment.
- Correlation of the level of use of PPE with the development of certain symptoms and diseases.
- Correlation of type of production/hours-days of work per sector with the development of diseases/symptoms.
- Correlation of exposure to pesticides, noise from tractors and other hazards with the development of diseases/symptoms.

SELECTION OF FIELDS

- Research on farmers habits.
- Research on farmers health problems.
- Research on the Personal Protective Equipment that should be used.
- Research for the appropriate scales for each selected field
- Development of Questionnaire for the simulation of the Information System to check possible problems concerning the selected fields and feedback

THE QUESTIONNAIRE

The questionnaire is an important tool towards the development of the Information System, due to the fact that the fields selected are the ones that would be included in the e-health application.

- SECTION A: Demographic information, years of work, education
- SECTION B: Health record, current diseases, family health record, gynecologic record, accidents, smoking and alcohol consumption, inoculations.
- SECTION C: Type of production, hours /days of work by type of production, land use.
- SECTION D:Exposure to hazardous agents (noise, pesticides), description of occupational accidents, use of Personal Protective Equipment, Self-assessment of knowledge about hazards related to the agricultural work.

DEVELOPMENT OF THE INFORMATION SYSTEM

- MS Access ,SQL Server and .NET platform are being used
- Direct connection of Information System with Statistical Packages
- The Information System itself includes statistical calculations based on the data collected and further analysis can be performed once the extraction of the e-health record is done.
- The application is being installed in Primary Health Care facilities and the data collected shall be used by any relative healthcare institute interested in conducting epidemiological research on farmers' health.

EVALUATION

Assessment of the application in terms of

- Content quality
- Usability
- Responsiveness
- Appearance

- The evaluation of these parameters will be performed by healthcare professionals and healthcare students.

- A questionnaire will be used for this step.

EPIDEMIOLOGICAL STUDY

PURPOSE

- To detect the habits/level of knowledge in Health and Safety issues of farmers in Greece
- To detect correlation between exposure to hazards and development of diseases/symptoms

DISCUSSION

- The use of the Electronic Health Record will contribute in the everyday work of healthcare professionals in terms of time, accuracy and operational costs.
- The use of the International Classification of Diseases (ICD) in all fields referring to diseases and symptoms will help towards the accuracy and fidelity of the health data.
- The Health Record of farmers is expected to be easily distributed across granted interested parties.
- The backup system developed for the security needs of the Information system is expected to ascertain the security of the health data.

Projects Integrating Information Systems are Going Regional – A Systematic Review

Ricardo Cruz-Correia[a,b], Pedro Vieira-Marques[b,c], Ana Ferreira[b,c], Filipa Almeida[a,b], Jeremy Wyatt[d], Altamiro Costa-Pereira[a,b]

[a]Department of Biostatistics and Medical Informatics, Faculty of Medicine, Univ. of Porto, Portugal
[b]Centre for Research in Health Technologies and Information Systems – CINTESIS, Faculty of Medicine, Univ. of Porto, Portugal
[c]Informatics Department, Faculty of Medicine, Univ. of Porto, Portugal
[d]Health Informatics Centre, Univ. of Dundee, Dundee, Scotland, UK

Abstract and objective

Integrating Information Systems (IS) is essential to support shared care. Many different integration approaches have been implementation through the years. This paper summarises studies examining approaches to integrate patient data from different IS. The literature was systematically reviewed in the last decade (1995-2005) to identify articles that mention patient records, computers and data integration or sharing. Of 3124 articles, 84 were included describing 58 distinct projects. Most of the recent projects were regional. More recently significantly more IS are integrating referral letters and extending to primary care. We conclude that patient information is becoming more accessible as there are more integrated IS which are more likely to involve primary care and a wider range of patient level data.

Keywords:

computerized medical records systems,
systems integration

Introduction

A patient record is a set of documents containing clinical and administrative information regarding one particular patient, supporting communication and decision making in daily practice, and having different users and purposes. Today more data on patients is recorded than ever before [1]. In hospitals, information technologies tend to combine different modules or subsystems, resulting in a best-of-breed approach. Integration of healthcare Information Systems (IS) is essential to support shared care in hospitals, to provide proper care to mobile individuals and to make regional healthcare systems more efficient. However, to integrate clinical IS in a way that will improve communication and data use for healthcare delivery, research and management, many different issues must be addressed [2-4].

Consistently combining data from heterogeneous sources takes a great deal of effort because the individual feeder systems usually differ in several aspects, such as functionality, presentation, terminology, data representation and semantics [5]. Over the years different solutions to these problems have been proposed and some applied. Many of these solutions coexist in today's healthcare settings and are influenced by technology innovation and changes in healthcare delivery.

This review appraises studies examining the different approaches to integrating patient data from heterogeneous IS. Special attention is given to the type of integration engine and the type of integrated data. Articles published in the English literature with abstracts available were reviewed between 1995 and 2005. We aimed to specifically review the integration of patient data, and how systems are evolving in practice to meet patient, professional and organisational needs.

Methods

Only studies describing or evaluating IS implementation for integrating patient data from heterogeneous IS were selected.

The review team was composed of three Computer Scientists, namely Ana Margarida, Pedro Marques, and Ricardo Correia, one medical doctor Filipa Almeida advised by health informaticians experienced in systematic reviewing, Jeremy Wyatt and Altamiro Costa Pereira.

Studies were identified in the bibliographic databases from September to October 2005. Since there is no specific standardised MeSH term, we developed a search string that includes the concepts of patient record, computers and data integration or sharing. Only articles with an abstract in English were considered. Given the significant evolution in ICT in the last decade, only studies published after 1994 (the last ten years) were included.

Three distinct bibliographic databases were searched: Medline (via Pubmed - www.ncbi.nlm.nih.gov/entrez), IEEE (IEEE Xplore - ieeexplore.ieee.org) and ISI (ISI Web of Knowledge - isiknowledge.com). The query search string used in each database was ((medical or clinical or patient) and record*) and (comput* or digital or electronic*) and (integrat* or link* or sharing or share or shared).

This search method found 2443 articles in Pubmed, 961 in ISI and 414 in IEEE Xplore, a total of 3818 articles. After eliminating duplicate articles 3124 were selected.

All four reviewers from the review team were involved in study selection. Six combinations of reviewer pairs were defined, due to the large number of articles found. The first selection was based on the study title. Each pair of reviewers read 512 titles.

A total of 923 of 3124 articles were selected in this first selection on title alone.

The second phase of the study selection was based on abstracts. Again, six combinations of reviewer pairs were defined. Each pair of reviewers read 154 abstracts.

To maximize specificity, only selection by both reviewers was considered adequate. In cases of disagreement (n=215) a third reviewer was called to decide. A total of 159 out of 923 articles were selected.

The variables examined in this paper are related to these stages and intend to describe the context where the integration takes place (country, date, area covered, institutions involved, type of final users).

To analyse time trends, we divided the total period up into three shorter periods because of the small overall number of projects identified. The first period includes projects with their last publication 1994-1999, the second period last publication 2000-2002 and the last period 2003-2005.

The statistical analysis was performed with SPSS® version 14. P values were calculated using linear-by-linear association chi-square test with significance level of 0.05.

Results

Countries with the most published projects were the USA (15), Germany (8), Greece (6), Denmark (5) and China (4). 60% of the IS covered only a region, while 28% covered a hospital, 9% a department and 4% a whole country. There was a downward trend in publications related to projects that cover a hospital from 57% until 1999, 35% in 2000-02 and 17% in 2003-05 (p=0.022). The number of projects covering a region has increased over the years, and currently represents 73% (p=0,005).

Most of the integrated information comes from hospital IS (68%), with departmental (40%) and primary care (34%) IS representing the next two most frequent institution types. Four projects (9%) integrated information from health portals; all were published in the most recent period, 2003-05.

As expected, all information systems provided access to health professionals. Two recent projects were the first to claim giving data access to patients.

Currently there are more projects carrying out regional integration, especially between hospitals and primary care. Referral letters are mentioned in 8 of the 31 projects described in articles published 2003-05. It is also clear that patients are also becoming active participants because they appear for the first time as a user group in more recent projects.

Conclusion

Our results show an increasing number of publications describing projects which integrate data from multiple IS. This is in agreement with our initial assumption about the interest in improving the communication of health related data to support person-centred healthcare. As the number of heterogeneous health IS grows, their integration becomes a priority. Moreover, we may be witnessing an increasing interest in regional integration between heterogeneous healthcare information systems across different institutions, to help communication between the different stake holders (primary and secondary care doctors, nurses and patients). This is also supported by the increasing communication of referral letters.

Currently people have more mobility, longer lives and health care is more shared than ever before. It is clear that Information Systems are evolving to meet people's needs by implementing regional networks, allowing patient access and integration of ever more items of patient data.

One key omission from the literature reviewed is that most of the project publications failed to mention any type of error detection. We feel that is mandatory to verify the quality of integrated data, so that instead of propagating data errors, alerts regarding data quality can be triggered and correction processes can take place [6].

Note: Due to the lack of space it was not included in this article the references of the studies considered in this review. A full description can be asked to the first author. A full paper of this review is expected to be published in the near future.

Integration of Specialist and Ancillary Services System into HIS: Development and Implementation of a Generic Report System

Gustavo Sosa, Hernán Navas, Alfredo Cancio, Fernando Plazzotta, Paula Otero, Daniel Luna, Enrique Soriano, Fernán González Bernaldo de Quirós

Department of Medical Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract

A common characteristic of medical specialties within hospitals is the generation of reports of complementary studies carried out. Considering the importance of the primary capture of data, the easiest alternative is the generation of specific reports for each study or a single system for all of these reports in a free text fashion. The great disadvantage is the impossibility of terminological control, analysis, or systematic use of this information. Using a Clinical Data Repository makes possible to use data-driven systems that satisfy present and future necessities. By these means the Hospital Italiano of Buenos Aires toke a development initiative and the Generic Report System was created. It was successfully implemented in the following Areas: Endoscopy, Fonoaudiology, Imaging Diagnosis, Pathology, Cardiology and Telemedicine.

Keywords:

point of care systems, forms and records control, user-computer interface

Introduction

The complementary studies ordered by primary care or specialist physicians are carried out, in some cases, by providers or other professionals of the healthcare team. In other cases they are performed by complex equipment, with or without human intervention. Independently of the way in which they make these complementary tests, these ancillary services or medical specialties are so called Effectors Services. This services shape the obtained results of the test that generates the reports; and each effector has its own way to do this, according to the particular needs of each specialty. Further more, one effector can make several tests, each requiring different reports. Thus, we can find long narrative texts without structure, tables with measurements, graphics, waves, images, etc.; and all the possible combinations. In contrast, in a hospital information system (HIS) setting, involving every patient's healthcare aspect, the primary capture of data in the instances it's created is a key issue.

Systematic incorporation of reports with such dissimilar characteristics raises a considerable challenge. A possible alternative is to generate computerized reports, each one dedicated to the particularities of each specialty. It arises then what medical literature denominates SPIS (Specialties Information systems), which includes the LIS (Laboratory Information Systems), RIS (Radiology Information Systems), CIS (Cardiology Information Systems), etc. Another possible option is a more simple approach, which involves a single reports system that allow the creation of different reports in free text, having as a disadvantage, the impossibility of terminological control[1], analysis, or systematic use of this information. In addition to the limitations of each alternative, any modification, adaptation to new necessities, or incorporation of new technologies, in both, requires modifications on the software that supports them.

Due to this reality, we arrived to the conclusion that the true solution was to create an integrated and unique system, adaptable to each effectors service's needs.

Materials and methods

Scenario

The Italian Hospital of Buenos Aires (HIBA) is a tertiary care, teaching and research hospital with a 150 year old history. Since 1998 a full scale HIS has been gradually implemented, including ambulatory Electronic Health Record (EHR)[2]., inpatient discharge summary, administrative systems, scheduling systems, inpatient tracking systems, pharmacy systems and complementary studies report and visualization. Several health informatics standards had been implemented, including HL7, CDA Version 2, ICD-9CM, DRG, ICD10, and ICPC.

Considering our scope and thinking about a generic system of reports, we developed unique software capable of been used by the different specialties of the Hospital, adaptable to the very different requirements for different information types, not requiring new developments each time new needs appear, regarding different structured forms of representing data, able to use controlled vocabularies and standard codifications, integrated with the administrative processes as with the EHR, offering a user friendly and versatile interface, able to generate an electronic but printable report, and having the capacity of to gaining functionality

Therefore come into sight the conception of a completely data-driven system. This system was called RptGen, as abbreviation for Generic System of Reports. Its fundamental concept is indeed to be generic; a way of being able to cover the most varied reporting needs.

Operational model

Creation of the report

The RptGen system allows defining groups for input forms and visualization of information generated and presented to the user in real time; and storage and data recovery of these groups; tabular representation for queries, the way in which these are stored or modified; the flow through these forms as well as their accessibility according to different roles for security purposes, as the generation of printable reports, export of queries, use of Web Services, etc; the use of different APIs (Application Programming Interface) to interface with hardware devices or integrate with other applications; the presentation format, as well as the actions and answers to events that are required while being with the client.

Like this, diverse types of fields can be included, from simple data type: text, numerical, dates, etc. (for which validation ranks can be defined); to complex data type: multiple lists (for which its domain of origin can be defined). They can also contain images, with DICOM format; or electronic documents. The amount and combination of these fields are defined according to the needs and they can be grouped in labels, helping its presentation and functionality.

Operation

It can work like an independent application, offering all the functionality that is defined, or offering presentation services or some specific functionality to other applications, that can invoke it by Web. In our case, it is fully integrated with the EHR in every scope, which allows physicians to access the complete information in real time.

Data flow

When an application performs an administrative act, an event within it sends an HL7 message with the patient's identification data and the detail of the ordered test. An interface disaggregates the message and enters the request to the Rptgen for its later processing. At the moment in which the request begins to be processed, the RptGen sends a message HL7 indicating the state has changed (from "Solicited" to "In process") to the administrative application as to the EHR. When the request is completed, a message is sent indicating the change of state to Fulfilled. Another message is also sent to the EHR with the results and/or the report (CDA).

Architecture and technological model

The RptGen was developed in a Web architecture [3], Java (IAS- Oracle) and Oracle database. MQSeries (IBM) as messaging engine, HL7 V2.X standard for transactions and CDA for the clinical document exchange[4].

Implementation

With the objective of initiating a process that would include most of the Effectors, in July of 2004 the first implementation of RptGen began for Gastroenterology. With this implementation the system was tested and adjusted, and we began to confirm the versatility of its data-driven concept, that enormously simplified modifications and updates.

Few months later, before the end of 2004, it was implemented in the Audiology area. A great challenge aroused that had not specifically been planned when designing the system: the upload of the test had to display a previsualization of audiometric graphics as data was loaded. The printed report had to contain graphics with the curves and symbols (in colors) of the study, preserving the corresponding standards. It was then confirmed that the approach and the architecture of the system were the correct ones, since no modification or internal aggregate to the system were required to satisfy these requirements.

It was also implemented giving workflow support to the test processing in Cardiology, Pathology and Radiology.

Conclusion

Designing and developing this system allowed us to create an application able to adapt to the needs of the Effectors and each professional, according to the way in which they prefer to upload data. It is possible to choose a completely structured interface, as it is the case of audiometry; an intermediate model with structuration of diagnosis and tests, like in G.I. Endoscopy, or free text, as in radiology reports.

This, as many other applications, can be supported with no need for internal modifications to the system, thanks to the great potentiality of its data-driven design. Within a more ambitious project, it will be integrated with the PACS that will be implemented during 2007.

Finally, as the implementations advance we are identifying improvements that can be incorporated to offer new characteristics as to simplify present solutions. RptGen is in a continuous process of improvement.

How Should Interfaces Specify Application Behaviors?

behavior, conformance, DICOM, HL7, IHE, imaging, interface, interoperability, messaging, PACS, semantic

Introduction

A distinguishing feature of healthcare informatics in the 21st century has been the recognition that a patient-centric multi-enterprise health record is not only desirable but essential to the provision of safe, appropriate care.

Systems exchange information both to document healthcare activities in comprehensive records, and to share information necessary for current patient care, either locally or remotely. A local inpatient care system may accumulate test information from a remote laboratory system for the purpose of integrating it with local information in a flowsheet that is part of the patient health record. Based on the information received, a clinician using the same local system may immediately request further testing from the remote laboratory system, or may use the flowsheet information to inform a medication decision that will result in the placement of one or more orders to a local or remote pharmacy system.

However, it is not enough for patient care systems to agree on what they *know*: they must also agree on what they *do*. Interface specifications must address the expectations and responsibilities of both senders and receivers. Such requirements necessitate a quantum leap from legacy interface specifications through the middle 1990s, which typically confined themselves to the behavior of their own applications in providing data to other systems with which they might happen to be interfaced. Present-day interoperability architectures, both within and across enterprises, need to be able to constrain application behavior as well as interface contents.

Methods and results

Standards and the interoperable clinical record

The development of the concept of the interoperable health record is in part a logical extension of the application of such interface standards as LIS05-A (formerly ASTM E1238) [1] for transmission of clinical observations, Health Level Seven (HL7) [2] for dissemination of patient administrative and clinical information across single-enterprise systems, and DICOM [3] for the transmission of imaging information. It also owes its existence to the efforts of researchers such as Hammond [4] in distinguishing the *flow* of information from the information *stores* (both intra-enterprise and inter-enterprise).

However, there are a number of specific legal, ethical, policy, and operational requirements that have been developed by healthcare systems and that are not fully addressed by existing standards. These requirements apply both to manual operations and to information systems in the institution. Therefore, they must be supported by commercial systems that are interfaced to the institution's internal systems. For example:

- Privacy issues
- Patient safety issues (including patient identification issues, synchronization of systems, correction of errors, acknowledgement of messages from other systems)
- Health information management rules
- Data custody requirements and the role of "system(s) of record"

Early commercial interfaces

A typical method of interfacing clinical systems from the 1970s into the 1990s was for a system to advertise that it would make certain information available, such as testing results or billing transactions, to other systems that might happen to be interested in the data. The sending system (generator) could include the interface as part of its general data production requirements. This approach was successfully adopted both by vendors of systems using proprietary interfaces, as well as by some early commercial adopters of the ASTM E1238 standard.

HL7-based and DICOM-based interfaces

Early HL7 messaging definitions – those developed for Versions 2.0 through 2.4 of the HL7 Standard between 1987 and the late 1990s – standardized the elements communicated in interfaces, while continuing to apply minimal constraints to application behavior. Such minimal constraint has been axiomatic even into the 21st century.

HL7 added a conformance mechanism in Version 2.5 [5] that provides a template for interface specification. This template includes a dynamic definition that incorporates an interaction model as well as acknowledgment responsi-

bilities. While the template does not explicitly provide for the specification of application behaviors, these could conceivably be enumerated as an extension of the dynamic definition. This approach has been followed by the U.S. Veterans Health Administration's VistA Imaging Team to specify interfaces from its in-house-developed, open-source VistA software to commercial Picture Archiving and Communication Systems (PACS).

DICOM Conformance Statements (DCS) [6] are required documents (by the DICOM standard) that are designed to unambiguously define a product's specific DICOM features. VA uses the DCS as a primary communications tool in understanding a vendor's product. The DCS is used to compare system integration possibilities and, most importantly from the point of view of the current discussion, to perform validation conformance testing before use in the VA.

Each DCS includes a sequence of real-world activities to define interactions between its vendor and others. For example, the Storage Commitment transaction, as defined by the DICOM standard, allows a local system to request that a remote system commit to the safekeeping of one or more images, thus releasing the responsibility for storage from the local system. Each vendor states in its DCS how this functionality is implemented on its product.

IHE-based interfaces

The Integrating the Healthcare Enterprise (IHE) Initiative and the IHE Technical Frameworks, besides providing contexts for the constraint of messages using standards such as HL7 and DICOM, can assist in determining system behavior.

An IHE radiology transaction definition typically incorporates one or more DICOM or HL7 messages and defines the trigger events, message semantics and expected actions. The "expected actions" section generally includes the behavior that is expected of the receiver of the message. [7]

Specifying and testing behaviors of applications in VistA Imaging interfaces

The next step toward interoperability using IHE-based profiles is to incorporate context-specific requirements into interface specifications. "Context" in this case may refer to a single department or to a nationwide medical enterprise such as VA.

VA has requirements that apply to all of their systems, whether internally developed or commercially procured. These include specific requirements for patient identification, privacy, records custody, and patient safety. Commercial system interface specifications published by VistA Imaging incorporate these requirements as extensions to the behavioral conditions imposed by standards and by IHE.

Testing and lessons learned

Having developed interface profiles based on user input, organizational policies, and regulatory requirements, VA published its interface specifications and a testing summary on a public web page [8]. PACS vendors access this page to find what is required of their systems in communicating with the VistA Radiology and VistA Imaging PACS modules. As vendors develop new products, they contact the VistA Imaging Team to schedule testing of their interfaces.

Our experience over 18 months of testing has been that commercial products are not always prepared to meet the behavioral requirements as stated in our specifications. Evaluation of interface test results, feedback from vendors, and internal reviews have resulted in clarifications to the interface specification, such as the enumeration of table values for error acknowledgment codes.

Discussion and conclusion

It is not only desirable and possible, but also essential, to specify application behaviors as part of interoperability requirements. Such requirements, although presented here in the context of the VistA Imaging software, are not specific to the VA. All interoperating medical institutions will share many of the same needs. Some institutions may have more well-defined application requirements, perhaps due to more experience with clinical information systems. Thus, every vendor will need to meet the needs of a variety of healthcare systems. These needs can be met by enumerating behavioral constraints in addition to what is provided for in the HL7 and DICOM Standards and the IHE Technical Frameworks.

How Should Interfaces Specify Application Behaviors?

Michael L. Henderson
Ruth E. Dayhoff MD
Andrew E. Casertano
Dezso Csipo

U.S. Department of Veterans Affairs
Office of Information
Silver Spring, Maryland USA

Introduction

- Standard of care for 21st century health record
  - Patient-centric
  - Multi-enterprise
  - Both longitudinal and real-time orientations
  - Patient safety considerations
- Interface specification requirements
  - Static (what is known)
  - Dynamic (what is to be done)

Introduction

- Progress from last-generation interface specifications
  - Must work across enterprises
  - Must constrain interface contents
  - Must constrain application behavior
  - Quality of integration must be designed in, not retrofitted

Standards and the interoperable clinical record

- EHR models derived in part from early interface standards
  - LIS05-A (aka ASTM 1238)
  - HL7
  - DICOM
  - Vocabulary standards (SNOMED, etc.)
- Business requirements not generally addressed

Standards and the interoperable clinical record

- Privacy and trust issues
- Patient safety issues
  - Patient identification
  - Synchronization of systems
  - Correction of errors
  - Acknowledgment of messages received from other systems
- Health information management rules
- Custody requirements and the role of “system(s) of record”

Early commercial interfaces were minimally constraining

Characteristic	Description
Elements	Usually well-understood, sometimes proprietary
Transaction(s)	Few reporting-type ("generator") transactions
Controlled vocabularies	Frequently proprietary, some standard (*e.g.*, CPT4 for billing codes)
Acceptable identifier domains	Implementation-specific
Acknowledgment responsibilities	Often undefined for either sender or receiver
Receiver behavioral responsibilities	Storage: often minimally defined Application behavior: often undefined

IHE-based interfaces provide for greater and more explicit constraint...

Characteristic	Description
Elements	Always standardized
Transaction(s)	Both reporting-type ("generator") and order-type ("placer/filler" transactions
Controlled vocabularies	Can be proprietary or standard depending on element
Acceptable identifier domains	Depends on the standard being used
Acknowledgment responsibilities	Can be rigorously constrained
Receiver behavioral responsibilities	Can be rigorously constrained

... but behavioral requirements are needed too

- Example: Data storage requirement

ADT Message Received – ICN Not Found

When PACS receives an ADT registration message for a patient for which it does not find an Integration Control Number in its system, PACS will create a new patient record. It will extract the Basic Patient Data Set and the Basic Visit Data Set from the HL7 message, and will store this information in its system.

Requirements issuance process at USDVA

- Need orders and ADT interface between integrated in-house system
- Compiled and reviewed a set of fully constrained requirements, including behavioral specifications, based on:
  - normative HL7 conformance template
  - IHE Radiology Scheduled Workflow (SWF) profile
- Published requirements on web
- Developed and reviewed test suite
- Mutually agreed-on results

Testing and lessons learned

- Scheduled validation testing between any requesting PACS vendor and ex-firewall USDVA validation system
- Commercial products don't always meet requirements
  - Common issues: Error reporting, patient sensitivity
- Revisions and clarifications to interface requirements document

Conclusions

- Interface requirements must include behavioral constraints for standard of care
- Standards and IHE are essential bases
- Cross-enterprise behavioral requirements are in our sights
  - *e.g.,* to facilitate XDS-based implementations of wide-area repositories and registries

Computerized System of Regulation and Evaluation of Emergency Attending Mobile Unit Service – SAMU in the State of Santa Catarina Brazil

Grace T. M. Dal Sasso[a], Fernanda Paese[b]

[a] *Nursing Department, Health Science Center, Federal University of Santa Catarina, Brasil*
[b] *Nursing Student, Nursing Department, Federal University of Santa Catarina, Brasil*

Abstract

This study, which is characterized by a technological production and a methodological research presents the report of the development and the evaluation of a Computerized System of Regulation and Evaluation of the quality of SAMU in SC. The system was structured in 03 modules consisting of regulation, Web evaluation and mobile unit evaluation. The analyzed data revealed that the system has ergonomic criteria, usability and adequate content to work in emergency situations and it is multiplatform due to using open source language. Further, by including in its reports the SAMU quality evaluation indicators stablished by the Health Department , the system contributes to the continuous and systematic control of service quality.

Keywords:

information systems, emergency, regulation, evaluation

Introduction

The QualiSus program, result of a research applied by the Health State Secretaries National Council - Conselho Nacional de Secretários de Estado da Saúde (CONASS) and the Health Department, revealed that the lines in hospital emergency room, the long period of waiting to examinations and surgeries, as well as the inability of health units to receive patients, were frequent complaints among SUS usurers. The study data, concluded in the end of 2003, revealed that more than 90% of the Brazilian population is somehow Health System usurer [1], [2], [3], [4].

Facing this situation the Health Department elaborated the QualiSUS, which aims establishing a group of changes to offer more comfort to the usurer, encourage care according to the risk level, provide effective attention by the health professionals and decrease the period of permanence in hospitals. [1], [2], [3], [4].

As integrating part of QualiSUS it is noticeable the Emergency Attending Mobile Unit Service (SAMU/192). The service enables the organization and rationalization in the public sector. In the SAMU/192 regulation center, the doctor answering to an emergency call has autonomy to sort by triage and decide about the allocation of the patient according to information about emergency room availability in hospitals. With SAMU/192 there will be organization to the access to emergency rooms.

Historically , we know that the level of response to the critical life situation of victims of accidents, traumas and violence has been not enough, causing and perpetuating spontaneous patient demands in urgency situation and real or presumptuous emergency, in direction to hospital emergency rooms causing them not being able to offer a more qualified assistance[5].

SAMU was implemented in Sc in 2005 including seven (7) urgency regulation centrals, with 18 UTI Mobile Units and 56 Basic Life Support Units of SAMU.

In this way, the systematization of na integral attention network to the assistance of urgencies, organizing the flow of patients of basic needs until high complexity and giving a quality assistance is one of the priorities of the Health Department and State.

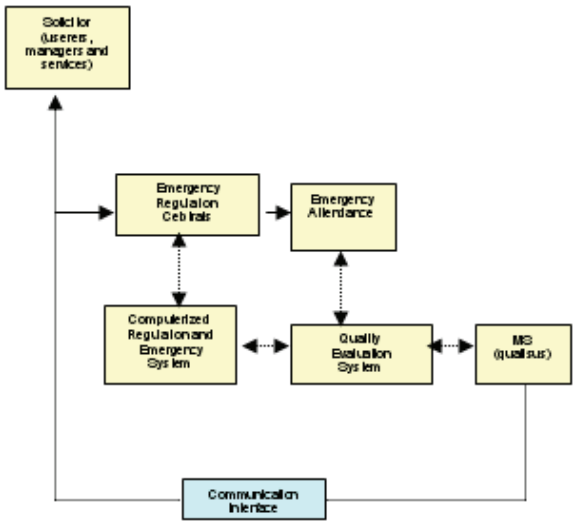
Following, in order to SAMU work properly , it is fundamental, through regulation centrals, the continuous and systemic accompaniment of urgency/emergency situations. This is possible by means of the development of a computerized systems of regulation and urgency assistance, with an ordinary language which can evaluate the suitability of this service in terms of controlling the indexes of demand and quality established by the Health Department. [1], [3],[4], [6].

Facing this ponorama, this study aimed developing and implementing a computerized system of urgency regulation of SAMU in the state of Santa Catarina as well as establishing the data which should integrate the information system of urgency regulation to evaluate the quality of SAMU in the State of Santa Catarina, form the indexes established by the Health Department.

Methodology

Technological Production and methodological research [7] which involved the participation through intentional or criteria choice of 06 people specified as follows: 01 regulator doctor, 01 nurse from intensive care unit, 03 systems analysts, 01 IT state manager and 01 Nursing student. The study followed ethical principles determined by the 196/96

Decree which determines the Regulating Rules and Norms of Research involving Human Beings and received the approval of the Research Ethics Committee of UFSC according to Protocol number 212/2005. The developing of SAMU system was based in the following flow structure:



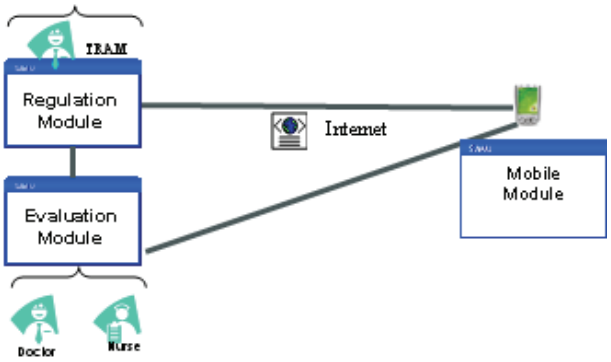
Picture 1 - Flow diagram

To the data collection the computerized regulation and evaluation of urgencies was used taking into account the following indexes: the number of attendance in emergency mobile units; the percentage of regulated emergency attendance, according to residential area; the percentage of emergency attendances regulated according to period of time; the percentage of attendances regulated according to demand; SAMU demand index according to neighborhood; time of response of emergency teams; time in local occurrence; time of total response; emergency mortality tax and main doctor diagnose. These items can be observed when implementing the system in the state of SC. However, they can already be obtained from the reports previously programmed. Still, a specific systems evaluation tool was used regarding the content criteria, usability and ergonomics [8]. The data were analyzed through descriptive statistics and qualitative description.

Results

In the development of the SAMU regulation and evaluation system the following phases were followed [8]:

1) Requirement Collection: problems of the emergency service and limitations to the development like time, place and economic. The system consists of 3 modules: regulation, Web evaluation and mobile unit according the following structure:

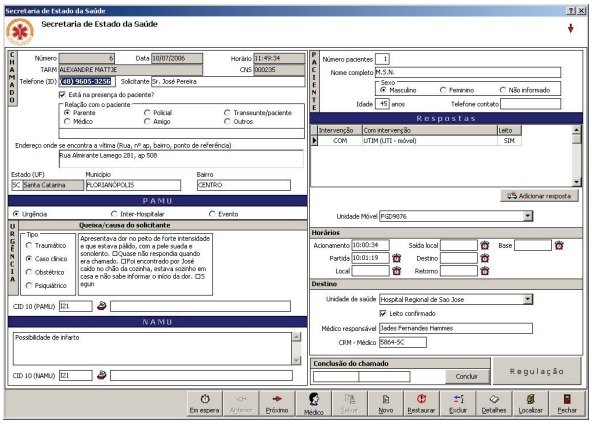


Picture 2 - SAMU Modules Structure

2) Analyses: choosing of the informatics tools to be used in and the design of the system. It was chosen that the Medical Regulation Module would be developed in Object Pascal language (Delphi environment) and JAVA to the File of Attendance of Web and Mobile patient, with database MY-SQL-SERVER. Delphi was chosen to the Medical Regulation Module due to the experience in the development of this language, made available by SES-SC and due to the facility of communication of other equipments. In the Web Evaluation Module JAVA was used, because it is an open code language, the framework available by SES-SC and its security. The database used was chosen because it is the pattern used at SES-SC in both Delphi and JAVA. It was also decided that the mobile system would be developed with Java technology (J2ME) because of, among other characteristics, its portability among different types of existing mobile devices in the market.

3) Project: definition, modeling of data and implementation in the computerized platform. The database of Regulation and Patient Evaluation via Web Modules was designed using IDEF1X patterns (definition of entity, relationship and characteristics) and, as a design tool of data, the ER-WIN was used. The Patient Mobile Evaluation system was conceived and implemented using the Objective Oriented Programming approach, in a way each distinctive group of evaluation was treated independently; however, keeping integration among all the groups in the general evaluation context. In this way, the system enables a progressive interaction and not necessarily sequential among the information universe which consists all the evaluation.

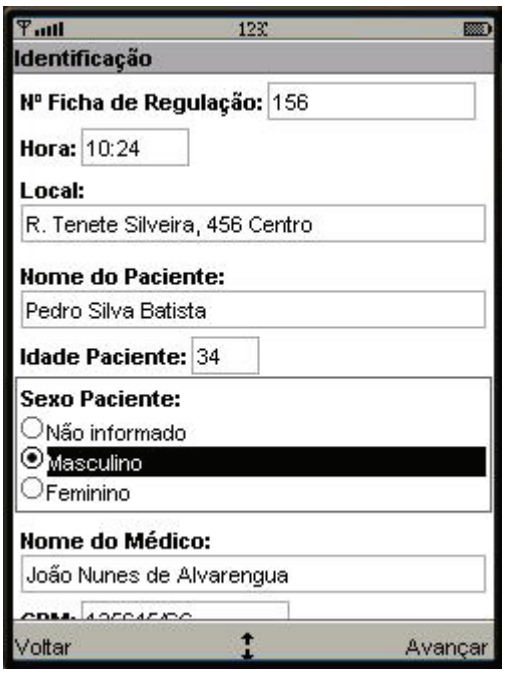
4) Implementation: development of the system in the reality of emergencies and test: pilot test of the system implementing and analysis of ergonometric and usability functions. In this phase, the system was structured in the computerized platform established this way:



Picture 3 - Example of Medical Regulation Module Screen

Picture 4 - Example of WebEvaluation of Patient Module Screen

The form of Medical Evaluation consists by items which identify the patient's situation in many areas. This evaluation comprehends in: Place Identification, Patient, Doctors Team. Initial State, Vital signals control and basic examinations, Breathing Evaluation, Cardiovascular, Neurological, Abdominal, Gynecological, Trauma, Burn, Hypotheses Diagnostics, Actual State and Doctor's Prescription. It also includes Glasgow scale, burn scale and progressive evaluation of trauma. The forms to emergency evaluation were also developed and organized according to CIPE – Classificação Internacional da Prática de Enfermagem - Nursing Practice International Classification - version 1.0



Picture 5 - Example of Mobile Evaluation Module Screen

The minimum necessary to the Mobile System work basically consists in a mobile device (PDA), which presents some type of implementation of the Java Virtual Machine (JVM) and has GPRS access through the qualified telephony operator. The readings carried through the patient's evaluation can be, when needed, typed and in other cases, selected by the usurer. The system presents synchronized menus to send and receive data and to browse among the evaluation modules. All access to the system is obligatory notarized through a login and password previously registered in the Web system.

From the structuring of the system, progressive evaluations were applied with the developing team discussing and reformulating the data in the system according to the needs and problems found. After that, a pilot test was organized simulating two real emergency attendance situations: one meningea syndrome and a hypovolemic chock due to displayed breaking.

04 appraisers from the informatics and health areas participated in this test, they evaluated the items: ergonometric and usability. The item ergonomics evaluated the criteria of organization, interface, content and technical. To each item scores were established from 1 to 5, being (5) excellent, (4) very good, (3) good, (2) regular, (1) bad. The data are presented in a statistics descriptive way. In the usability criterium 24 items were evaluated determined by scores from 1 to 5, being (5) totally agree, (4), agree, (3) disagree, (2), totally disagree and (1) not applicable according to qualitative analyses.

Table 1 - Ergonomics Evaluation

Score		Regulation Module						Evaluation Module						Móbile Module					
Critery		f1	f2	f3	MÉD	M.G.	D.M.	f1	f2	f3	MÉD	M.G.	D.M.	f1	f2	f3	MÉD	M.G.	D.M.
Organization	A	4	4	4	4,0	4,5	0,50	4	4	4	4,0	4,4	0,42	4	4	4	4,0	4,3	0,25
	B	5	5	5	5,0			5	5	5	5,0			5	4	4	4,3		
	C	4	4	4	4,0	4,3	0,17	4	4	4	4,0	4,7	0,33	4	4	4	4,0	4,2	
	D	5	5	5	5,0			5	5	4	4,7			5	5	4	4,7		
Interface	A	5	4	4	4,3			5	4	5	4,7			5	5	4	4,7		0,50
	B	5	4	4	4,3			5	5	5	5,0			5	5	4	4,7		
	C	4	4	4	4,0	5,0	0,0	4	4	4	4,0	4,8	0,2	4	3	3	3,3	4,3	
	D	5	4	5	4,7			5	5	5	5,0			5	4	3	4,0		
Content	A	5	5	5	5,0			5	5	4	4,7			5	4	4	4,3		0,0
	B	5	5	5	5,0			5	5	5	5,0			5	4	4	4,3		
Tecnic	A	4	5	4	4,3	3,8	0,29	3	4	4	3,7	4,0	0,33	3	4	3	3,3	3,3	0,17
	B	3	4	4	3,7			4	5	5	4,7			4	4	3	3,7		
	C	4	3	4	3,7			3	4	4	3,7			3	3	3	3,0		
	D	4	3	3	3,3			3	4	5	4,0			2	4	4	3,3		
					MG	4,4	0,4				MG	4,5	0,3				MG	4,0	0,3

Legend: Excelent (EX) 5; Very good (MB) 4: Good (B) 3; Regular (2); Bad (1). General Average (MG), Average shunting line (DM)

It was observed in the ergonomics evaluation according to table above in the evaluators perspective that the system is Very Good with an average variation of 4,0 to 4,4. The items content and interface received the best evaluations inside the ergonomics criterion with an average variation from 4,3 to 5,0. The technical item inside ergonomics criterion received a minor score, with average score variation from 3,3 to 4,0, specially because the system is under construction and the connection and communication among the modules (especially from mobile to fixed) are not finished. The average deviation among variables of ergonomics evaluation was around 0,4 to the Regulation Module and 0,3 to the Evaluation Module of patient form fixed and mobile.

Evaluation of usability

The main items approached by the evaluators to the usability criterion evaluation with scores (5) and (4) corresponding to totally agree and respectively agree were: the system easily runs on fixed and mobile platforms with no interferences, the system screens are clear, easy to read and interpret, the usurer is able to access the system easily, the menus are viable and easy to use, the system is modular and shows the structuring in the programming, the system has a limit of growing appropriate to the use demands, the memory requirements do not hinder the program running on the platforms, the system has automatic saving, the connection and communication among the Regulation and Fixed and Mobile Evaluation modules are appropriate, the system enables the recovery of data in the various modules, the hardware requirements are compatible to the reality, the system holds attendance network, the system has data locking.

Amongst items which received evaluation do not agree, with score (3), and that were marked only in the evaluation Regulation Module, are distinguished: does not run in different platforms; does not accept inexistent data and the system allows recovery of data in the various modules.

Positive aspects of the system are also distinguished: the agility, the neatness, the system is complete, it is easy to use it, friendly and it accomplishes the objectives. Another positive aspect is that it enables the emission of reports which contribute to the control and accompaniment of the quality of the attendance in SAMU from the indexes established by the Health Department. As negative aspects we have: the absence of the item help top the usurer in the menu of the Regulation and Web Evaluation Module, little functionality of tables of vital signals, scale of coma of Glasgow and progressive evaluation of trauma in the Mobile Evaluation module, as well as the lack of a complete database of streets and avenues of the State.

Discussion and conclusions

Although the system is not completely developed, it was perceived through the data collected during the pilot test that it has appropriate ergonomic criterion, content and usability to the emergency situations enabling the feeding of the system directly from the place of the accident. It is a pioneer and innovator system in Brazil due to including a complete structure of Regulation, Web and Mobile Evaluation of emergency embracing the doctor and nurse attendance.

The study also enables emphasizing that the information is a key element in the decision making and an essential requisite in the support and efficient management of health care, once it enables a systematic way of evaluating and comparing. It is recognized, though, as it is scored in OMS/OPAS[9],[10][11], that the access to information is an essential ingredient of the health services and planning, of supervising and health programs control, because it is a vital tool to evaluate the clinical interventions and management of health promoting activities.

In this way, the development of a computerized system of emergency regulation and attendance quality evaluation, from the establishment of definite indexes of quality which serve as ordinary and homogeneous measurement pattern, which constitutes in a permanent strategy of improvement of quality, at the same time it serves as a tool to the generation of new study fields.

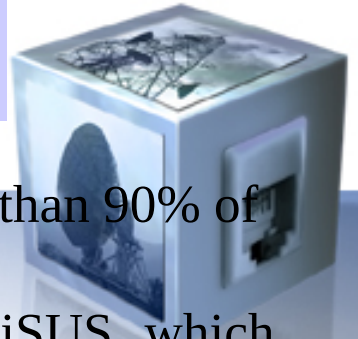
GIATE: GROUP OF NURSING RESEARCH IN INFORMATION AND INFORMATICS

Computerized System of Regulation and Evaluation of Emergency Attending Mobile Unit Service – SAMU in the State of Santa Catarina Brazil

Grace T. M. Dal Sasso, RN, ND - Professor of Nursing Department, Health Science Center, Federal University of Santa Catarina, Brazil

Fernanda Paese, Nursing Student, Nursing Department, Federal University of Santa Catarina, Brasil

Introduction



- The study data, concluded in the end of 2003, revealed that more than 90% of the Brazilian population is somehow Health System usurer.
- Facing this situation the Health Department elaborated the QualiSUS, which aims establishing a group of changes to offer more comfort to the usurer, encourage care according to the risk level, provide effective attention by the health professionals and decrease the period of permanence in hospitals .
- As integrating part of QualiSUS it is noticeable the Emergency Attending Mobile Unit Service (SAMU/192). The service enables the organization and rationalization in the public sector.
- Following, in order to SAMU work properly , it is fundamental, through regulation centrals, the continuous and systemic accompaniment of urgency/emergency situations.
- **Objective: Facing this ponorama, this study aimed developing and implementing a computerized system of urgency regulation of SAMU in the state of Santa Catarina as well as establishing the data which should integrate the information system of urgency regulation to evaluate the quality of SAMU in the State of Santa Catarina, form the indexes established by the Health Department.**

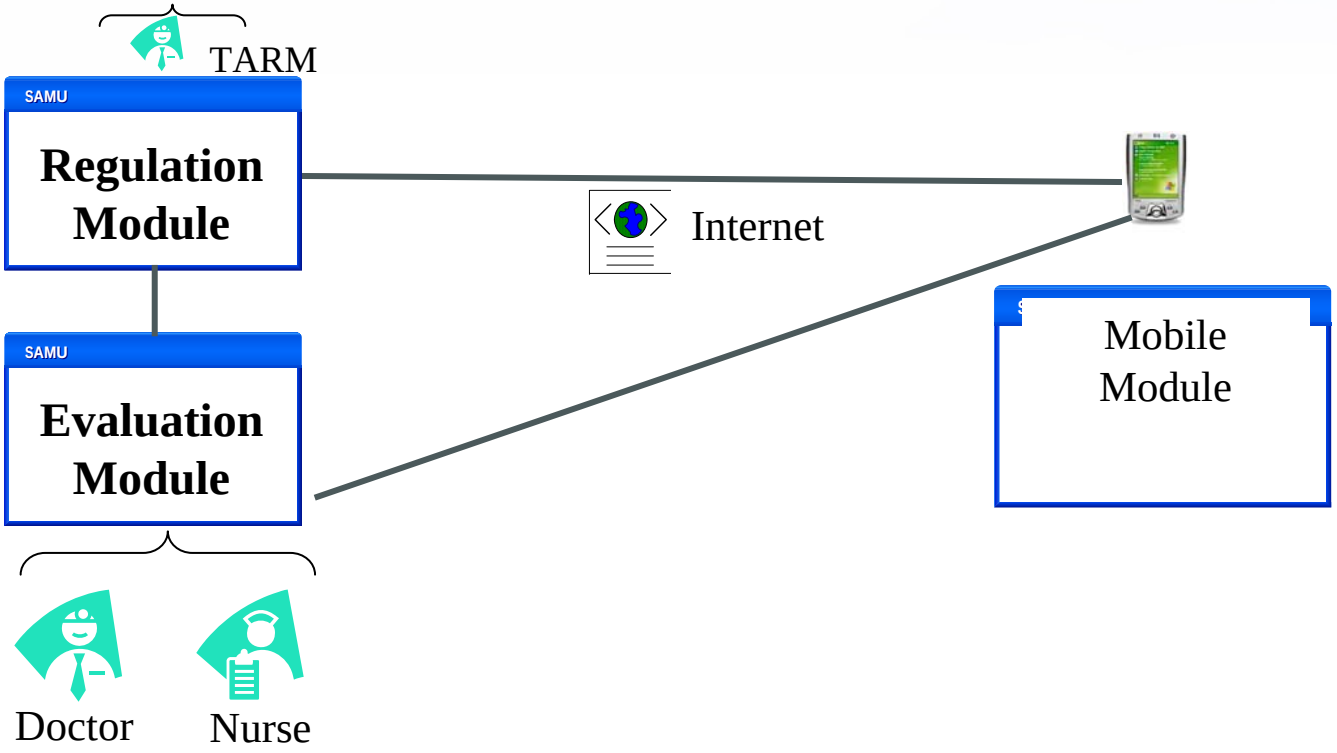
Methodology

- Technological Production and methodological research.
- Involved the participation through intentional or criteria choice of **06 people** specified as follows: 01 regulator doctor, 01 nurse from intensive care unit, 03 systems analysts, 01 IT state manager and 01 Nursing student.
- The study followed ethical principles determined by the 196/96 Decree which determines the Regulating Rules and Norms of Research involving Human Beings and received the approval of the Research Ethics Committee of UFSC according to Protocol number 212/2005.
- A specific systems evaluation tool was used regarding the content criteria, usability and ergonomics.
- The data were analyzed through descriptive statistics and qualitative description.

Results

- In the development of the SAMU regulation and evaluation system the following phases were followed:

  1) **Requirement Collection:** problems of the emergency service and limitations to the development like time, place and economic. The system consists of 3 modules: regulation, Web evaluation and mobile unit according the following structure:



Results

2) Analyses: choosing of the informatics tools to be used in and the design of the system.

- It was chosen that the Medical Regulation Module would be developed in Object Pascal language (Delphi environment) and JAVA to the File of Attendance of Web and Mobile patient, with database MY-SQL-SERVER.

- Delphi was chosen to the Medical Regulation Module due to the experience in the development of this language, made available by SES-SC and due to the facility of communication of other equipments. In the Web Evaluation Module JAVA was used, because it is an open code language, the framework available by SES-SC and its security. The database used was chosen because it is the pattern used at SES-SC in both Delphi and JAVA.

- It was also decided that the mobile system would be developed with Java technology (J2ME) because of, among other characteristics, its portability among different types of existing mobile devices in the market. :

Results

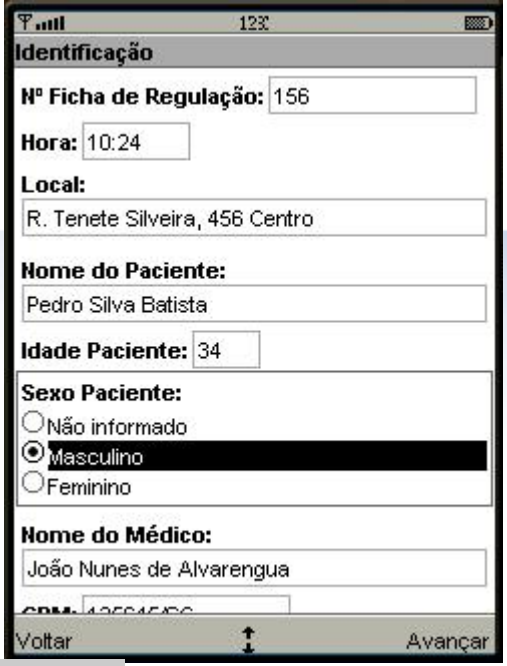
3) Project: definition, modeling of data and implementation in the computerized platform. The database of Regulation and Patient Evaluation via Web Modules was designed using IDEF1X patterns (definition of entity, relationship and characteristics) and, as a design tool of data, the ER-WIN was used.

- The Patient Mobile Evaluation system was conceived and implemented using the Objective Oriented Programming approach, in a way each distinctive group of evaluation was treated independently; however, keeping integration among all the groups in the general evaluation context. In this way, the system enables a progressive interaction and not necessarily sequential among the information universe which consists all the evaluation.

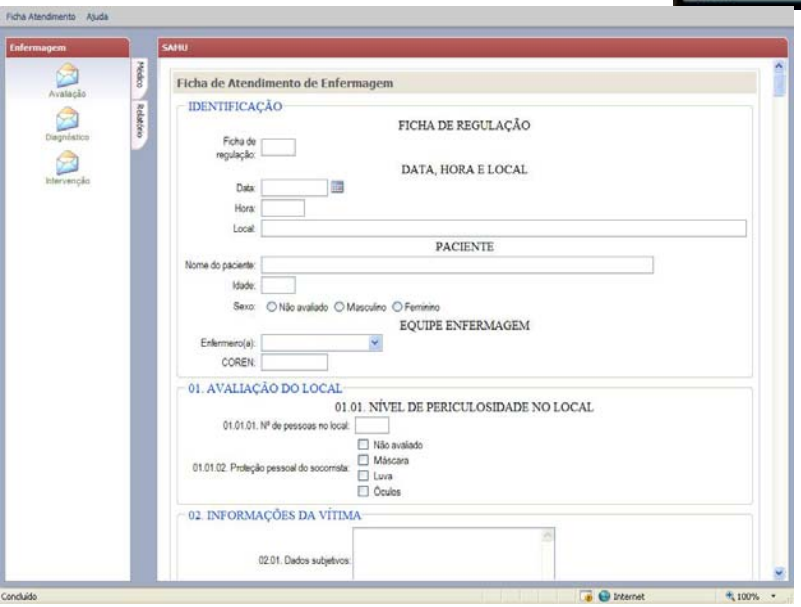
4) **Implementation**: development of the system in the reality of emergencies and test: pilot test of the system implementing and analysis of ergonometric and usability functions.

In this phase, the system was structured in the computerized platform established this way:

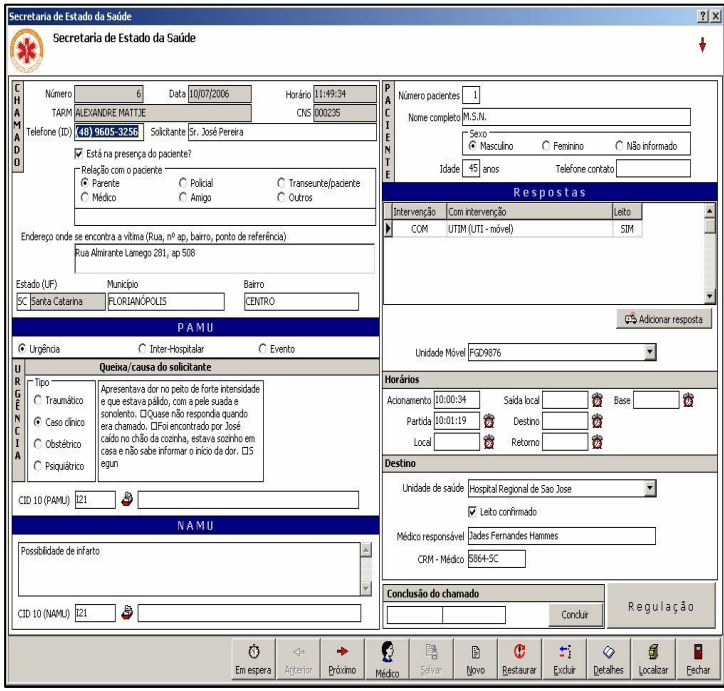
Exemples



Example of Mobile Evaluation Module Screen



Example of WebEvaluation of Patient Module Screen



Example of Medical Regulation Module Screen

Results

- The form of Medical Evaluation consists by items which identify the patient's situation in many areas. The forms to emergency evaluation were also developed and organized according to ICNP version 1.0.
- The minimum necessary to the Mobile System work basically consists in a mobile device (PDA), which presents some type of implementation of the Java Virtual Machine (JVM) and has GPRS access through the qualified telephony operator. All access to the system is obligatory notarized through a login and password previously registered in the Web system.
- From the structuring of the system, progressive evaluations were applied with the developing team discussing and reformulating the data in the system according to the needs and problems found. After that, a pilot test was organized simulating two real emergency attendance situations: one meningea syndrome and a hypovolemic chock due to displayed breaking.
- 04 appraisers from the informatics and health areas participated in this test, they evaluated the items: ergonometric and usability. The item ergonomics evaluated the criteria of organization, interface, content and technical. To each item scores were established from 1 to 5, being (5) excellent, (4) very good, (3) good, (2) regular, (1) bad.
- The data are presented in a statistics descriptive way. In the usability criterium 24 items were evaluated determined by scores from 1 to 5, being (5) totally agree, (4), agree, (3) disagree, (2), totally disagree and (1) not applicable according to qualitative analyses.

Results – Ergonomics Evaluation

- It was observed in the ergonomics evaluation that the evaluators perspective the system is Very Good with an average variation of 4,0 to 4,4. The items content and interface received the best evaluations inside the ergonomics criterion with an average variation from 4,3 to 5,0.
- The technical item inside ergonomics criterion received a minor score, with average score variation from 3,3 to 4,0, specially because the system is under construction and the connection and communication among the modules (especially from mobile to fixed) are not finished.
- The average deviation among variables of ergonomics evaluation was around 0,4 to the Regulation Module and 0,3 to the Evaluation Module of patient form fixed and mobile. The main items approached by the evaluators to the usability criterion evaluation with scores (5) and (4) corresponding to totally agree and respectively agree were:
  - the system easily runs on fixed and mobile platforms with no interferences, the system screens are clear, easy to read and interpret, the usurer is able to access the system easily, the menus are viable and easy to use, the system is modular and shows the structuring in the programming, the system has a limit of growing appropriate to the use demands, the memory requirements do not hinder the program running on the platforms, the system has automatic saving, the connection and communication among the Regulation and Fixed and Mobile Evaluation modules are appropriate, the system enables the recovery of data in the various modules, the hardware requirements are compatible to the reality, the system holds attendance network, the system has data locking.

Results – Usability Evaluation

- Amongst items which received evaluation do not agree, with score **(3),** and that were marked only in the evaluation Regulation Module, are distinguished: does not run in different platforms; does not accept inexistent data and the system allows recovery of data in the various modules.

- Positive aspects of the system are also distinguished: the agility, the neatness, the system is complete, it is easy to use it, friendly and it accomplishes the objectives. Another positive aspect is that it enables the emission of reports which contribute to the control and accompaniment of the quality of the attendance in SAMU from the indexes established by the Health Department. As negative aspects we have: the absence of the item help top the usurer in the menu of the Regulation and Web Evaluation Module, little functionality of tables of vital signals, scale of coma of Glasgow and progressive evaluation of trauma in the Mobile Evaluation module, as well as the lack of a complete database of streets and avenues of the State.

Discussions and Conclusions

Web Portal for Health Disclosure: A Promising Future

Nasriah Zakaria

Universiti Sains Malaysia, Penang MALAYSIA

Abstract

This poster presents the idea of developing web portal for health disclosure in the future. Some preliminary data on disclosure behaviors by patients give some promising hope for the use of Information and Communication Technologies (ICT) specifically for health disclosure in the coming future. A concept of web portal is also introduced in this poster.

Keywords:

Web Portal, disclosure, privacy, health information

Web Portal for health disclosure

A qualitative research [1] was conducted by the author to understand the disclosure and privacy behaviors displayed by medical patients when facing illness. One portion of the qualitative interview asked about the use of ICT for purposed of disclosure.

The data indicated that a large number of the respondents used ICT to inform their relatives, to contact someone who has similar medical history, to start a friendship with another patient, to get information on alternative treatments and to update their health status (see Table 1). The telephone was the most common technology used while electronic mail and the Internet were used by the respondents. However, there is no doubt that the medium of communication may change to other ICTs in the future. Recent market research reports have shown that the usage of Internet, text messaging and instant messaging are increasing all over the world [2]

One suggestion is to create a web-based portal for access to health information. The purpose of a portal is to provide a one-stop center for patients, where the medical team, with patient consent, can provide health information to patient's network . A portal may be useful when patients are admitted to hospital and going through treatments. One research idea would be to develop a portal prototype and recruit a patient sample to get feedback on the usefulness of a portal system. Specific aspect of disclosure like the content of information, depth of information, the timing of information and the recipient of health information will be a question when designing a portal for this purpose. With careful planning in research design and by combining mixed methodology research (think aloud and experiment), I believe that there is a great potential for a health web portal whose design takes into consideration both disclosure and privacy aspects.

Respondent	Type of ICT	Purpose
Patient	*Email* *Phone*	*Update mom*
Patient	*Internet* *Email*	*To communicate with support group* *To disseminate information*
Patient	*Email* *Phone*	*Contacted medically literate member DC* *Informed all family members about diagnosis*
Patient	*Phone*	*Update best friend about health* *Update employers about treatment status*
Patient	*Phone*	*Update relatives out of state*
Patient	*Phone*	*Check status of family member*
Patient	*Phone*	*Update sisters about health*
Patient	*Phone*	*Update spiritual community about treatment status*
Patient's family	*Phone*	*Call church members to get update*
Patient's family	*Phone*	*Inform siblings who live out of state*
Patient's family	*Internet*	*Check out alternative treatment*
Patient's family	*Email*	*Used email to update friends when sister in law already in critical stage.*
Patient's family	*Phone*	*Called mom's friends to tell about dying stage*
Patient's family	*Phone*	*Update spiritual community* *Called patients to see their status*
Patient's family	*Phone*	*Call mom's friend to update mom status*
Patient's family	*Email*	*Communicated with brother in Europe about mom's health status*

9 medical workers	*Phone*	*Consult patients* *Receive calls from family members to ask about medical decision* *Receive calls from patients' family members to access patient information*

Table 1 - List of respondents who use ICT for health disclosure

Construction of Simple Mobile PACS system Using Wireless Internet

Kyung-Hoon Hwang, Hyung Ji Lee*, Duck-Joo Choi, and Wonsick Choe**

Departments of Nuclear Medicine and Internal Medicine, Gachon Medical Center, Incheon, Korea; CAD Impact, Inc. *, Seoul Korea**

Background

Wireless mobile internet has advanced and been widely applied to a variety of social systems. We constructed a simple mobile PACS system, using this wireless mobile internet to improve the medical imaging service.

Method

The mobile PACS system consisted of intranet wired main PACS system, mobile PACS server (connected to main PACS system) and mobile notebook. KT Netspot system was used for wireless internet system. Medical images were compressed and downloaded to the mobile PACS server and displayed on the reader's mobile notebook via KT Netspot. Approach to the mobile PACS was limited to the readers with ID and password.

Results

The mobile PACS system was effectively operated and the quality of the transferred images was acceptable after file compression. However, the mobile PACS was available only in areas of wireless internet zone.

Conclusion

The simple mobile PACS system was constructed using wireless internet system and may improve the quality and speed of medical service. Further studies using more high speed wireless system and more compact mobile notebook are needed.

Automatic Appraisal System

Min-Ling Lai, BS, Polun Chang, PhD

Institute of Health Information and Decision Making, National Yang-Ming University, Taipei, Taiwan/ROC

Abstract

In Taiwan, we have systematically evaluated health web sites due to our national Health Web Award since 2002. Through appraisal of the field masters, recognized websites will be awarded by Label of Excellent. It's also the way to provide identified credit for general public. This study intends to further digger the possibility of automating the process mentioned above.

Keywords*：*text mining

Introduction

People in Taiwan are getting used to read health and medical related information on line, but they may not be capable to judge the accountability of gotten information. To lift up the quality involved in health information for people, and to encourage providers to enhance qualitative content, the government initiated annual contest for Health Information Website. Through appraisal of the field masters, recognized websites will be awarded by Label of Excellent. It's also the way to provide credit to be identified by general public. This study intends to further digger the possibility to automate the process mentioned above.

Methods

First, to collect web pages, which are to provide trained and tested function, and to utilize cutting words system, provided by Academia Sinica (http://ckipsvr.iis.sinica.edu.tw/), to cutting words on the web pages in order to calculate the weighting of feature.

Second, term selection and Extraction.

Third, design a categorizing tool by SVM, support vector machines, and by means of result, produced by first step, to classify whether health information web pages are related.

Fourth, creating a crawler to catch those web pages, which cover 'tw' in the last two words of their web addresses, automatically.

Fifth, using the categorizing tool to subgroup those web pages, filtered by the crawler, in order to get health information websites.

Sixth, initiating a phase pool system to give points to those health information websites according to scoring standard of annual contest, such as whether footnotes, creator and posting time included, are provided in the article.

Finally, comparison of grading difference between manual and the system.

Program is coded by VB 6.0, database by SQL2000.

Results

Steps one to three are almost accomplished, and steps four to six are incomplete.

Fig.1 the cutting words system to calculate the weighting of feature.

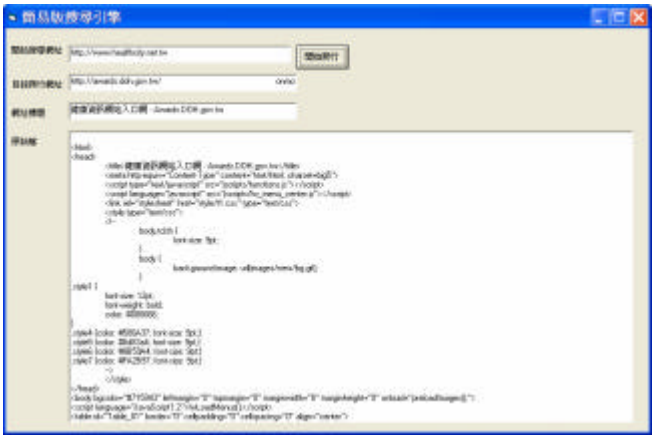

Fig.2 the crawler to catch web pages.

Discussion

Once the result of the system is accountable, it may be established broadly in public health institutions. Keep on searching and apprizing health information websites on the internet, and to be reference for people to select high profile websites. If evaluation being poor, public health institutions may review the content of web pages voluntarily and find out inappropriateness to fix it.

Sustainability of computerised Health Information System Implementation in Developing Countries: a Meta Analysis of Evidence

Rohan Jayasuriya [a]

[a] *School of Health Sciences, University of Wollongong, Australia*

Abstract

A Systematic review of studies of computerized HIS in developing countries was carried out. A realist review method was chosen to refine the questions, develop pa framework and synthesize the findings.Complexity and context of internal and external environment are key to sustainability of computerized HIS in DC. HIS system that are aligned to the technical environment of the context(country) and those that can be localized (through adaptation) will be sustainable, as long as their product has currency to the users.

Keywords: Sustainability, health information system, developing countries\, frameworks

Introduction

Information technology (IT) failure has been documented in the literature in Industrialized Countries (IC) for some time. It has been estimated that one to three fifth of IT projects do not attain major goals or have undesirable outcomes (termed partial failure) and one fifths to a quarter where it was never implemented or immediately abandoned (termed total failure), leaving only a few with success[1]. (Heeks, 2002). In the health sector few major disasters attract attention, many are not publicly discussed due to their political nature.

Such disasters also take place in developing countries (DC), in some cases in some of the poorest countries in the world. The impact can be large in economic terms. The failed hospital information system in South Africa cost the province, a total of 20.2 million pounds, accounting for about 3.8 % of the total health and welfare budget[2] . It also brings into stark contrast the opportunity cost, when these countries, cannot afford, proven , highly effective public health intervention such as immunizations. These countries, need to even resist such investments till there is clear evidence of its effectiveness, or at least build in good evaluations into the contract[2].

The identification of an IT failure, is not very clear, as it is a subjective judgment. One of the key dimensions is the timing, as today's success can be tomorrow's failure and vice versa[1]. Of particular interest, therefore is the category called " sus tainability failure" where the implemented HIS results in a successful handover, which is then abandoned later, by the organization. In most ICs, the resources and know how exists to resurrect or modify the problems and such failures do not result in publicity. However in the case of DCs, design and actuality gaps are wider and immediate " cover up" does not occur, leading to a "strech" , with provides the opportunity for a better understanding of the characteristics and factors that take place[1].

The motivation for the paper is the emergence of commercial interests in computerized HIS in DC. Most of the poorer countries, depend on development partners to provide such investments, which is eventually supplied on a commercial basis[3]. In addition, relative to the mid and late 1990's there is more literature in the public domain, of this phenomenon.

The paper is organized as follows. First the conceptual and theoretical understanding of sustainable HIS will be discussed in relation to other similar concepts. A review of theory from the will be used to develop a framework for conducting a meta analysis. A method based on systematic review will use a purposive sample of case studies, both from the published and "grey" literature. The studies will be analyzed to understand the temporal effects and seek a better understanding of sustainability of HIS in DC.

Theoretical concepts of sustainability and HIS sustainability.

Early work in development aid literature identified sustainability to relate to the capacity of recipients' (countries and institutions) need to be self reliant as a consequence of donor aid [4]. The sustainable solutions have been identified as investments that continue to provide a return. The term return is defined in a broader sense , to include social, educational ,[and health] returns[5].

In the field of HIS, many of the definitions for the term , sustainability come from public health[6] and has been used in HIS [3] .

" Sustainability implies user organizations ability to identify and manage risks that threaten long term viability of HIS following the withdrawal of external support "[3]

An important feature of these definitions is the recognition that HIS (and the institutions that install HIS) face risks of change. If one could separate the technology from the organization, the former is more prone to change than the latter. In most cases public institutions that install HIS, produce benefits by the nature of their product, that is health care services. Therefore it can be argued that HIS sustainability also needs to consider the viability and long term benefit of the technology towards health care.

A closely related concept to sustainability in the development literature is " capacity building" . The following statement illustrates the connection lucidly

" we would go further to state that it [capacity building] should enable programme execution independent of change of personalities, technologies, social structures and resource crises…it implies developing sustainable and robust systems" [7]

In the literature, the concept of capacity building seems to be used interchangeably with institution building, institution strengthening and development management. Institutional capacity, has been identified as a vital ingredient in providing effective service[7].

Methods

Realist reviews are relatively a new strategy for synthesizing research findings that are qualitative. Instead of seeking representation and generalizability, sought in positivist research, realist reviews seek to unpack the mechanisms of "how" complex programs work or why they fail in particular contexts and settings[8]. It answers the question of " what works for whom in what circumstances and what respects" [8]. Therefore this method is appropriate to address the aims set out in the introduction. As it is a relatively new method, the methods for data gathering and analyses are described , relative to the steps of the method (table 1).

Table 1. Methods of realist review

Realist review methodology steps	Description of Methods followed
Step 1. Clarifying Scope a)identify the review question (nature /context) b) refine purpose of review c) articulate key theory	Scope of the review was limited to HIS in DC. The nature of the study is a systematic qualitative meta analysis, using a realist review method. Initial purpose was identified as a comparison: how does computerized HIS work (or fail) in different settings? This was refined after initial synthesis(see below) A literature search on " sustainability" was conducted. Three theories were identified that have relevance to the purpose.
Step 2. Search for Evidence a) exploratory search to get a feel. b) progressive focusing to identify key theory and refine inclusion criteria c) purposive sampling and "snowball" sampling	Literature on HIS in DC over the last two decades was known by author. Progressive focusing occurred by reading key articles, and the concept of " sustainability failure" used as inclusion criteria. Based on framework for review (Figure 1) purposive sampling was used to search to populate it . Grey literature was included.
Step 3. Appraise primary studies and extract data a) use judgment: relevance and rigour b) develop data extraction forms and notation devices. c) Extract different data from different studies to populate framework.	Judgments made to access and use studies were based on peer reviewed publications. Grey literature was included when the author had firsthand assurance of authenticity. Data extraction from documents were used to develop case studies and comparative tables (see results)
Step 4: Synthesize evidence and draw conclusions. a) allow purpose to drive synthesis. b) use contradictory evidence. c) present conclusions	Initial synthesis from key articles, was used to refine the purpose to " How does long term sustainability of computerized HIS in DC unfold? What are the key characteristics that affect failure and success?" Contradictions were sought in the studies. Conclusions are presented as a set of principles that guide, not rules that govern the phenomenon.

Results

As a realist review is an iterative process, the results will be presented in the sequence of evidence gathering, synthesis, further extraction of evidence from studies and synthesis.

<u>Evidence on theory</u>

The literature review identified three theories of relevance to the purpose of the review.

1. IS sustainability as a design-actuality gap[1].
2. Systemic capacity building framework[7]; and
3. Framework for strategy in sustainable development of institutions[4].

The key ideas, concepts from these theories were extracted to build the framework for the study and search for evidence (step 2b).

Building a theoretical framework

Complexity is the key issue, and it is inversely related to sustainability[4]. It can be decomposed to internal and external dimensions, based on concepts for strategic planning, that identify complexity of internal processes and environmental hostility[4]. Pettigrew and Ferlie[9] has argued that useful research on change should involve the constant interplay between ideas about the context of change, the process of change and the content of change. Analysis of the context of the system, can be differentiated to an 'inner' context and an 'outer' context. The former refers to the ongoing strategy, structure, culture, management and political process of the organisation itself (eg. the Department of Health and/or Ministry of Health) and the latter includes the national economic, political and social context which is the wider public sector and the political milieu of health systems (eg. the National and/or Provincial Governments) in these countries.

Heeks[1] reviewed IS failure in DC and identified a number of dimensions by which one could understand the reasons. He proposed , using the Leavitt framework, that a design – actuality gap exists with tools, process, people and structure, is implementing IS in DC. Using the example of project implementation in India, Potter & Brough [7] proposed that within a systemic capacity building framework there exists four key components , a) tools; b) skills; c) staff and facilities; and d) structure, systems and roles. They state that it is easier (and requires less time) to build capacity in the first two, than the latter two components. A framework for evaluating sustainability of HIS in DC needs to include the concept of time. Our initial definitions of sustainability emphasized the viability over time.

Based on the above theories, a framework for sustainability analysis of HIS in DC was developed (Table 2). Studies were searched to populate the framework (step 3c).

Framework for evidence review.

Table 2: framework and studies

	Content and Process	Context (environment)
Internal Complexity hi	Northern Province HIS [2]	Northern Province HIS
low	New Hope HIS[12]	Samoa HIS
External complexity hi	FHSIS[11]	FHSIS
low	Tanzania HISP[3]	India[15]

Exemplar of a case study for longitudinal analysis

In 1989, the Department of Health in the Philippines embarked on to provide a single comprehensive system of information for all health preventive programs. The FHSIS design called for provision of one or more computers at each Provincial health office (PHO, a total of 67) and City Health Office (CHO). The viability of the FHSIS depended very heavily upon the computer processing scheme developed for the system[10] .

It was agreed that data processing using computers was necessary to enable, reduction of staff time in aggregating data, reduce time lag of reports from the field to the centre, and to have a database for further analysis[10]. A decision was taken that the lowest level of computerisation was to be at the Province and that an Information Distribution center would be established at Central level with a database that could be accessed by all relevant units in the DOH [10]. By 1993, there were numerous projects(both national and donor funded) and a number of stakeholders addressing issues of information systems. At this point, three different sections had different responsibilities for HIS, there was resultant ambiguity even among the DOH hierarchy as to the responsibilities for HIS in the DOH. Many had elements that were components of the original FHSIS or overlapped with the system[11].

A major re-organisation in Health services occurred in October 1991 with decentralisation of power, authority, responsibility and resources of certain agencies to the local government units, provinces, cities , municipalities and barangays. This resulted in the Provincial Offices, which were the key nodes for the computerized FHSIS, being under a different authority, the provincial governor. Their allegiance, with the DOH was severed.

Implementation of FHSIS had been planned to be completed by 1990, but by the end of 1993 though the computers were in place in all the provinces, many of the users in the DOH were disillusioned with the system [11]. Over the time that had been taken for the system to be implemented the needs of information of these units had changed. Since it was perceived that the system did not provide the information they required in a reliable and timely manner program managers in the DOH began to once again develop their own vertical systems of reporting to suit their requirements.

Through the period 1994-2002, a number of donor projects assisted, in strengthening the HIS in the country. The long time frame also resulted in availability of more sophisticated database environments for the DOH and the ability to develop technical skills at the central level. While the technical capacity now exists, there was no impetus for the provinces to improve the system. In 2005, the FHSIS still functioned as the official system , but with reports that were submitted as hard copies from province to DOH, with delays of transmission and with little utilization by users at local level.

Exemplar of comparative analysis of two case studies

These two case studies were selected, to look at similarities and contrasts within the framework. In both cases, the designs of the HIS was based on experience in IC. As the environment within a hospital, was expected (by the designers) to be very similar in terms of functions and processes in DC.

Table 3. Comparative analysis of Hospital Information Systems

	CIS system in Samoa	Hospital System in Northern Province South Africa
Purpose and context	A computerized Hospital information system, designed to improve clinical care and hospital management. Two main hospitals in country.	Computerization of Hospital Information in all 42 hospital in one province. To improve patient management and revenue collection
Project duration and period	1999-2001 (project still ongoing)	1998 - 2003
Design and development	Contractors for the donor driven project design on a specifications of an IC hospital	IBM contract terminated and subsequent contract given to another contractor
Internal environment (System implementation issues)	A number of promised sub – systems not delivered. No capacity in house. Trained staff leaves country. Synchronization and back up not functional. Reports not generated. Some basic core functions enabled (eg PMI). Long period of system not in use	Most application programs not completed . however, some benefits seem by staff of the system. Others resist due to lack of training. System malfunctioning, due to poor infrastructure (power supply etc). Periods of shut down creates additional work for staff. Some increase in revenue collection, but overall management of
	as no local technical support contract. Not used in hospital management	hospitals not improved. Not used in hospital management
External environment (Project management and institutionalization)	DOH not in a position to carry out technical negotiations with contractors. Change of senior staff responsible. Insufficient resources to have maintenance contracts.	Different expectation of managers, contractors and users. Change of "champions and key staff at the province. Insufficient technical know how to institutionalize systems.
Long term developments	Donor support provided from 2003- onwards to resurrect system. Decision to replace with more suitable software.	Reluctance to give up project leads to second contract which is also a failure.

A number of other case studies were also chosen for the review. Reference these are made in the discussion .

Discussion

The purpose of the review was to understand how implementation of Computerized HIS in DC , can be successful. This aim was then revised in the process of the realist method used to how does long term sustainability of computerized HIS in DC unfold? What are the key characteristics that affect failure and success?

Theory inform us that factors such as complexity (both internal and external) , content, process and context influence long term sustainability. We looked at the evidence from actual case studies to further understand the phenomenon .

HIS in DC, and specifically computerized HIS (where the technology is key tool) is vulnerable to both internal complexity and external changes in the environment. Internal complexity was analyzed using two complex Hospital Information systems, that were designed with IC environments (of both users and infra structure in mind) in Samoa and Northern Province in South Africa (see table 3). This was contrasted to the New Hope HIS in a small rural hospital in South Africa [12]. In the latter case, success of implementation was linked the ability to local adapt the system. The technology used (ie software) was a universally available database, without the need for high level design skills. In addition, this project was backed up by a consortium that had long term experience in introducing the same tools in similar poor DC environments. The key points (principles) that were revealed were:

- Technology to be introduced to green field sites need to be comparable to the environment (in the country). Ambitious plans to "leap frog" development is not sustainable till the environment comes to

that level of development (as in case of FHSIS in 2005).

- Previous experience in introducing technology (HIS) and the ability to be flexible allows sustainability of HIS in DC [13].

Complexity is also created in HIS by the variety of health programs that have different motives and "rationalities" [14]. two longitudinal case studies , illustrate the issues. The FHSIS faced the pressure from different program managers , when it failed to provide the information they required. In the case of HISP in India, over the longer term the developers were able to negotiate their " niche" within other systems [15].

Key factors that influence such long term viability of projects especially in the area of primary health care and disease prevention HIS are:

The constant change of "sponsors" and "champions" for the system, due to the high turn over of senior staff in DC situations. This was well illustrated in the Andhra Pradesh case [15].

Most HIS systems designed to produce management information, to a higher level , have an inherent deficiency, in terms of sustainability as they do not have immediate or explicit health returns. This is compounded by the fact that, in most DC situations management decisions are not based on information. There is need for a long term investment in training and changing the processes in such situations for HIS to be used.
In summary, both complexity and context of internal and external environment are key to sustainability of computerized HIS in DC. HIS system that are aligned to the technical environment of the context(country) and those that can be localized (through adaptation) will be sustainable, as long as their product has currency to the users.

A Study of Clinicians' Information Systems Usage in Patient-Centered Situations – Preliminary Results

Inger Dybdahl Sørby, Øystein Nytrø

Dept. of Computer and Information Science, NTNU (Norwegian University of Science and Technology), Trondheim, Norway

Abstract

This paper presents preliminary results from an observational study performed at a Norwegian university hospital. The purpose of the study was to identify and capture clinicians' information and communication behaviour and also to further develop a method for performing structured observation of clinicians' patient-centered work. One fifth-year medical student spent 20 days in two different hospital wards, following 7 physicians from one to seven days each. The observer recorded data from several ward situations such as pre-rounds meetings, ward rounds, and discharge situations. The data was recorded by means of an observation form consisting of a mixture of codes and free-text fields.

Keywords:

observational study, structured observations,
mobile health information systems,
requirements engineering

Introduction

This paper presents an extensive observational study performed during a three-month period in two hospital wards. The aim of the study was to identify and capture information and communication behaviour among healthcare workers in hospital wards, based on the further development of a framework for performing focused and structured observations. The framework has been developed iteratively during several previous observational studies[1]. The underlying purpose for the study and for the framework development has been to be able to elicit and produce comprehensive requirements for the user interface of mobile clinical information systems.

Methods

The study was carried out at a large Norwegian university hospital during the period July – September 2005. The observations were conducted by one fifth-year medical student. The student performed non-participatory observations of physicians in two hospital wards (Division of Gastroenterology and Department of Cardiology). During the study, the medical student followed one physician at a time, observing the physicians' daily patient-centered work. The participants included one chief physician with many years of experience in the ward, medium experienced senior residents, assistant residents, and one young intern. Both male and female physicians were among the participants.

The data was recorded by means of an observation form and processed in Microsoft Excel. The observer recorded data regarding the physicians' use of various information sources for retrieving and storing patient-related information in several common ward situations (e.g. pre-round meetings, ward rounds, and discharge). One *situation* is here defined as a time-limited process or sequence of actions/tasks (for an individual patient) in which the cast (actors filling roles) does not change, and which has an identifiable start, preconditions, end, and result. The recorded information consisted of sequences of acts with associated activity, trigger, location, main actor and role, co-actor(s) and role(s), patient ID, situation start and end time, information source, information type, purpose, and result. No sensitive or personal identifying data was recorded. Most of the recorded information was coded on-site by means of pre-defined values, while for instance 'Purpose' and 'Result' consisted of short free-text notes.

After four days of observation at Division of Gastroenterology, the recorded data was evaluated. This resulted in an expansion of the observation form of four new free-text columns; 'Illness history', 'Reason for admission', 'Previous knowledge', and 'Patient category'. The purpose of the extension was to enable more qualitative analysis of the data.

Results

During the study, 11 days of observation were conducted at Division of Gastroenterology and 9 days at Department of Cardiology. One chief physician, 5 residents, and 1 intern were followed. The co-actors of the situations consisted of other physicians, nurses, patients, and relatives. The recorded activities concerned approximately 70 different patients. One hundred and thirty-five situations consisting of a total of 525 acts were recorded at Div. of Gastroenterology, while 190 situations/1032 acts were recorded at Dept. of Cardiology. The numbers of each observed situation type are summarized in Table 1.

More than 200 of the 325 observed situations were recorded during pre-rounds meetings and ward rounds, which are the most predefined and regular, daily activities concerning all patients in the two wards. In the preliminary analysis of the data we have focused on the communication and information behaviour during these situations for *Resident1* (R1), *Resident9* (R9), and *ChiefPhysician9* (CP9). We have manually categorized the observed events into 12 different predefined communicative acts (i.e. navigate into common understanding, assess, answer inquiry, inform, evaluate, request information, prescribe, order, refer, delegate responsibility, remind, sign) and created communicative acts profiles for the physicians [2]. The profiles have been plotted as radar graphs, in order to visualize how the different information sources (categorized as paper-based, electronic, or human) have been used when performing the various communicative acts during the pre-rounds meetings and the ward rounds. Among the interesting results of our analysis were: Experienced clinicians cooperate without explicit communication, in contrast to interns who are much more explicit. Younger clinicians tend to use information systems more systematically and broadly. See elsewhere [2] for a more detailed analysis.

Discussion

Table 1 – Summary of observed situations. The table shows the number of observed situation types per main actor; Residents 'R1' and 'R2' and intern 'I1' from Div. of Gastroenterology (Gastro) and residents'R7', 'R9', and 'R14', and chief physician 'CP9' from Dept. of Cardiology

Situation type	*Gastro*			*Cardiology*				*Sum*
	R1	*R2*	*I1*	*R7*	*R9*	*R14*	*CP9*	
Morning meeting	5	-	6	-	-	-	-	11
Pre-pre-rounds	-	-	-	5	-	-	-	5
Pre-rounds meeting	37	6	20	7	22	11	24	127
Ward-rounds	15	7	-	7	21	11	24	85
Examinations	-	-	-	-	8	2	6	16
Office work	16	7	-	-	8	9	13	53
Discharge prep.	1	4	-	-	-	2	4	11
Disch. Meeting	-	-	-	-	-	-	4	4
Heart meeting	-	-	-	-	1	-	1	2
Other meetings	5	1	5	-	-	-	-	11
Total	79	25	31	19	60	35	76	325

The communicative acts profiles created so far have been for individual physicians, but it is also interesting to create role profiles (i.e. interns, senior residents etc.) in order to study differences between communicative behaviour of various groups of healthcare workers. Another approach is to profile specific activities (e.g. drug related events), as a means for eliciting and analyzing requirements for new information systems.

The recorded data are based on the observations and subjective interpretation by one medical student. In future studies, the method should be improved by using two or more observers in order to ensure consistency.

The study was mainly performed during summer time, and thus the ward staff was reduced and the remaining physicians had more responsibilities than they normally do (e.g. chief physicians performing ward rounds). However, the intention of the study was not to capture 'normality', but rather to verify a method for observation and recording of clinicians' information and communication behaviour, regardless of working conditions.

The physicians in the hospital wards work on a rotation scheme, and the observer followed various physicians on call, from one (*R2* and *R7*) to seven days (*R1*) each. So far, mainly the data of the 3 most observed physicians have been analyzed, but the remaining data can be used in qualitative analysis and to illustrate variations in the observed situations. Only physicians were followed in this study, but future studies should also include other actors/roles (e.g. nurses).

Conclusion

The observational study presented in this paper was mainly performed in order to validate and improve a method for conducting structured observation of clinicians. The results of the study confirm our previous findings:

- Structured observation by means of pre-defined forms enables efficient recording of clinicians' information and communication practice in hospital wards
- Using apprentices (medical students) as observers is beneficial due to their domain knowledge and natural, non-intrusive presence in the hospital wards
- The data recorded via observation differs from e.g. survey data, and the detailed context information of the various situations is valuable when eliciting and analyzing requirements for new mobile clinical information systems

A Study of Clinicians' Information Systems Usage in Patient-Centered Situations – Preliminary Results

Inger Dybdahl Sørby and Øystein Nytrø
Department of Computer and Information Science
& NSEP (Norwegian EHR Research Centre)
NTNU (Norwegian University of Science and Technology)
Trondheim, Norway

NTNU
Innovation and Creativity

Aims and motivation

- Aim of the study:
  - to identify and capture information and communication behaviour among healthcare workers in hospital wards
  - validation and further development of a previously iteratively developed framework for focused and structured observations of clinicians during patient-centred work

- Underlying motivation:
  - for the study and for the framework development has been to be able to elicit and produce comprehensive requirements for the user interface of mobile clinical information systems

Methods

- Non-participatory, structured observations of physicians' patient-centered work (e.g. pre-rounds, ward rounds, discharge etc.) in 2 different hospital wards
- Observer: Medical student (fifth year)
- Observation period: July – September 2005
- Field data recorded by means of a previously developed form based on pre-defined codes and free-text fields [1]
- Recorded data consist of sequences of information and communi-cation acts of one main actor, and focus on *information sources* and *information categories* (e.g. diagnosis and procedure, medication, findings and examination results, biographical data, assessment etc.)
- Additional information include situation trigger, patient ID, start and end time, and various context information like location, co-actors and roles, and patient category

Ref: Sørby & Nytrø, 2007a

Information Sources

Patient-specific:

- Patient record (paper)
- Patient chart (paper)
- Patient list (paper)
- Personal notes (paper)
- EPR (electronic patient record)
- PAS (patient administrative system)
- X-rays/CT/MRI reports/pictures
- Patient
- Nurses
- Physicians

Other information sources:

- Physicians' Desk Reference (PDR); paper-based and electronic
- ICD-10 codes overview; paper-based, electronic and personal lists

Observation form and example data

Figure 1 – Excerpt from observational data (Dept. of Cardiology). The example shows data from one pre-rounds situation, one examination, one supplementary work situation, and one ward rounds situation. The main actor in all the situations is resident 'R9', and his role is 'patient responsible' (PR). The co-actors are one nurse ('Nur9'), who's role is the team leader ('GR'), and two different chief physicians ('CP12' and 'CP13'). Patients 'P41', 'P55', 'P57', and 'P67' are in focus and the locations vary from Office 4 via Lab2 and Lab3 to Patient room 10. The resident uses four different information sources/systems; the patient list (PATLIST) for retrieval of the name of the patient, the nurse (NUR) for retrieving changes since patient admission (information code 'NEW'), the electronic patient record (EPR) for getting an overview of the patient (information code 'ALL'), and the patient chart (PC) for information about the patient's medications. Information is given to the nurse (about examination), and the medication form in the patient chart is signed. During the ward round situation, the physician informs the patient (PAT) about ceasing a drug and the result of an examination, and the patient tells the physician about any changes since the previous day.

Results (Dept. of Cardiology)

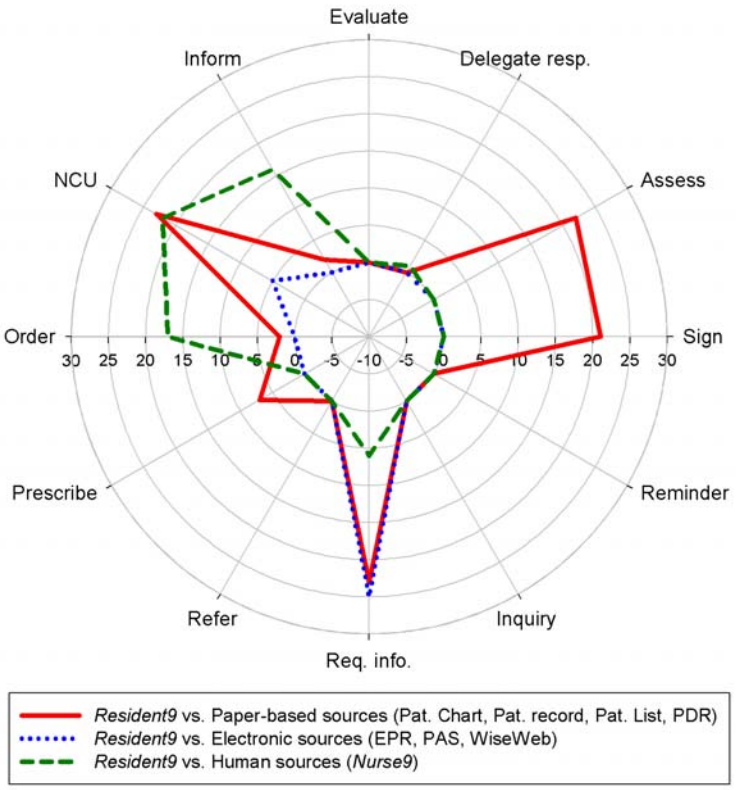
Total	19	60	35	76	190	99	-	-	-

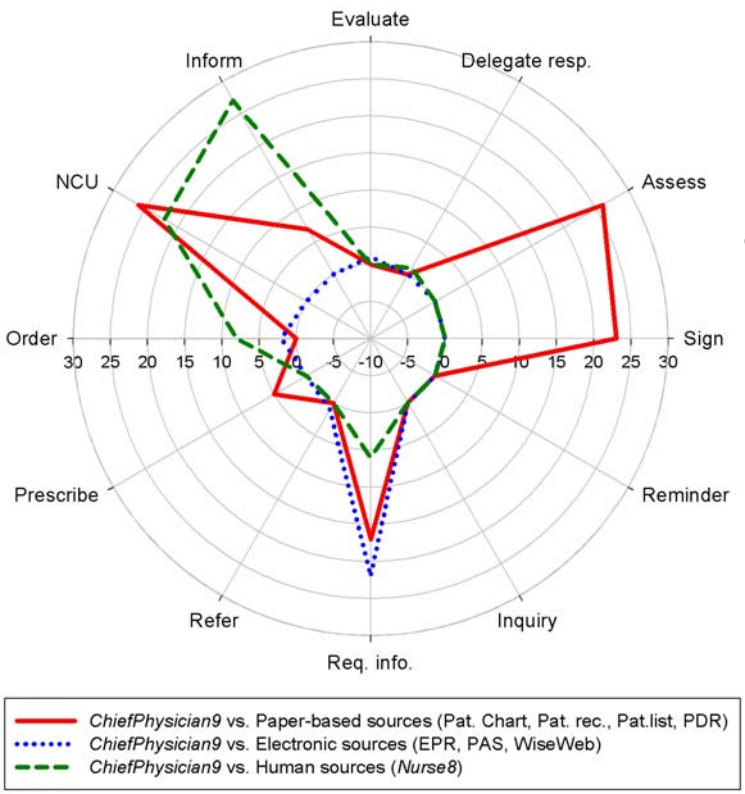
Table 1 – Summary of observations from Dept. of Cardiology. The first part summarizes the number of different observed situation types per main actor (residents"R7", "R9", and "R14", and chief physician "CP9"). The next column shows the number of situations related to drugs (prescription, administering or assessment) and the associated information sources used for gathering or recording drug information. The two last columns denote minimum and maximum number of events or communicative acts in the various situation types.

Analysis of communicative behaviour: Profiling roles and activities

- The observed events have been categorized into 12 different predefined communicative acts (i.e. navigate into common understanding, assess, answer inquiry, inform, evaluate, request information, prescribe, order, refer, delegate responsibility, remind, sign) [2]
- Resulting profiles are plotted as radar graphs that show distribution of communicative acts for several actors during various situations.
- The angular axes of the plots show the 12 communicative acts that have been identified in the observational data
- Radial axes indicate the number of each act found in the various selected observational data sets.

Example profiles, pre-rounds situations



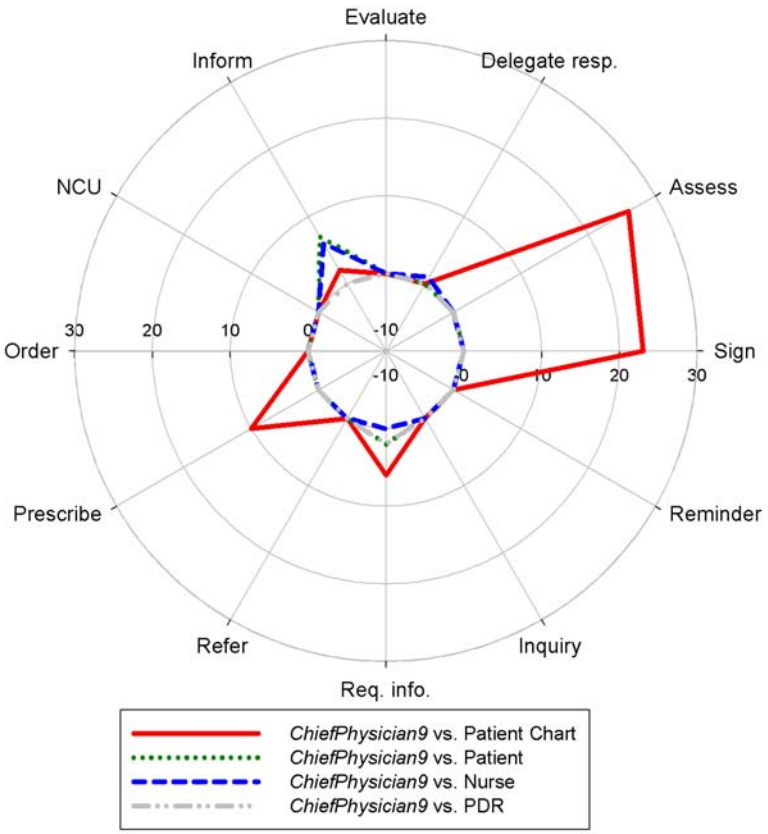


Communicative acts profile, *Resident9 (Dept. of Cardiology). 22 pre-rounds situations, #comm. acts: 214*

Communicative acts profile, *ChiefPhysician9 (Dept. of Cardiology). 24 pre-rounds situations, #comm. acts: 220*

Ref: Sørby & Nytrø, 2007b

Example profile, drug related events



Communicative acts profile, *ChiefPhysician9 (Dept. of Cardiology). Pre-rounds and ward rounds situations, drug-related events. #comm. acts: 108*

Communicative acts profiles

- give a good visual presentation of the information and communication behaviour of individual clinicians, roles, or larger groups of healthcare workers during various clinical activities
- can serve as a basis for generating use cases and scenarios
- can serve as input for systems requirements specifications (e.g. regarding medication activities)

- So far: Merely counting number of different communicative acts
- Next step: Statistical analysis and profiling of other roles and actors (e.g. nurses)

Ref: Sørby & Nytrø, 2007b

Conclusions

The results of this study confirm our previous findings:

- Structured observation by means of pre-defined forms enables efficient recording of field data during observation of clinicians' information and communication practice

- Apprentices (medical students) as observers is beneficial due to their domain knowledge and natural, non-intrusive presence in the hospital wards

- The data recorded via observational studies differs from e.g. survey data, and the combination of coded values and detailed context information of the various situations is valuable when eliciting and specifying requirements for new clinical information systems

Further Work

- Method Validation and Triangulation:
  - To improve the validation of the method, future observational studies will include an initial phase where field data recorded by two or more concurrent observers will be compared and analyzed in order to ensure consistency.
  - Data/results from an observational study carried out during summer 2007 will be compared to survey data and data from laboratory experiments

- Focus on Actors and Patient Trajectories
  - Future studies will focus on following *actors* with different roles (chief physicians, residents, interns, nurses etc.)
  - We also plan to follow *patients* from admission to discharge to enable analysis of patient trajectories.

Acknowledgments

We would like to thank the staff at Division of Gastroenterology and Department of Cardiology at Trondheim University Hospital for their cooperation during the observational studies and medical student Siri Haug Strømmen for performing the observations.

This research was partly financed by the NTNU Strategic Research Area Medical Technology and the NTNU Innovation Fund for Business and Industry.

Ubiquitous Healthcare Service in South Korea

Misook Sohn

Electronics and Telecommunications Research Institute, Daejeon, Korea

Abstract

The study presented here describes evaluation result designed to deliver the ubiquitous healthcare service in Korea. Based on the well -developed IT infrastructure, Korea has trying to find business opportunities in health-care sectors and has initiated several pilot healthcare services for last few years. The characteristics of those services are providing personal healthcare services at home to the help of portable monitoring devices and communication network.

Introduction

Delivery of healthcare service by means of ubiquitous computing has arousing a great interest in Korea in order to reduce healthcare cost pressure and promote health maintenance of aging population. The ubiquitous healthcare (in short u-Health) enables anytime and anywhere healthcare service access. In pursuit of those goals, the efforts have tried in terms of u-Health pilot study to bridge the boundaries IT and medical industries despite the business attitudes and cultures of these two industries were different. IT industry has achieved success through rapid technological advance while medical industries have more value on ensuring rapport between care recipients and providers with face-to-face interaction.

To understand these emerging integrations better and which services groups of customers with needs really want, Korea conducted several u-Health pilot studies.

The u-Health service

The u-Health ecosystem includes a broad spectrum of capabilities; monitoring devices (vital sign, weight, glucose, ECG, physical activity, etc), communications (Zigbee, Bluetooth, Ethernet, Cellular network, etc), data aggregations (PDA, cell phone, PC, etc), and services (disease management service, diet or fitness service, personal health record service, etc).

The service delivery has done by acquisition of specific health-related data (glucose, ECG, blood pressure) with the use of portable monitoring devices, forwarding data to the hospital through wire or wireless communication using PDA, cell phone or Internet, and providing feedbacks such as data presentation via Internet and consulting with medical staffs by phone and Internet.

The participated organizations for these pilot services include three government departments (Ministry of Health and Welfare, Ministry of Information and Communication, Ministry of Commerce, Industry and Energy), hospitals (Seoul, Busan, Hanyang, Gachon, Severance University Hospital, etc) and local health centers, telecommunication operators (KT, SKT) and several equipment and solution providers.

Result

From the early 2000, there have initiated several kinds of u-Health studies but in this result only aggregates major 3 pilot studies which are relatively large in scale from 2005 and aim at disease managements for elderly. Average service period is 3 months and total subjects are 284 for glucose, ECG, blood pressure, and body mass monitoring. The evaluation result, care recipients expressed that they satisfied with quick and regular checkup of their health status, felt secure at all times, and said good to see their health records anytime but they went through a little difficulties to handle devices and doubted the confidentiality of data with the use of portable monitoring devices (service satisfaction point is around 70-80%, device satisfaction point is around 50-60%).

Conclusion

Government-driven u-Health pilot service seems like to succeed to gain interests of public as well as over several industries. But there are many reasons that make u-Health service difficult. Among them the following three need urgent addressing: (1) legal and standard issues (2) developing of profitable business models for both IT and medical industries, and (3) ensuring of accuracy and reliability of monitoring data. As a result of these pilot studies, the service providers found that the some of their services were of little value to customers and now they are preparing next pilot studies to meet customers' requirements.

Abstract

Acute Respiratory Infections (ARIs) are the number one reason for antibiotic prescribing in the United States, and much antibiotic prescribing for ARIs is inappropriate. We designed an electronic health record-integrated, documentation-based clinical decision support system for the care of patients with ARIs, the ARI Smart Form. To evaluate the ARI Smart Form and assess the feasibility of performing a larger trial, we conducted a pilot study with 10 clinicians who used the ARI Smart Form with 26 unique patients. Clinicians prescribed antibiotics to 6 of 6 patients with antibiotic-appropriate diagnoses and to 3 of 20 (15%) patients with antibiotic-inappropriate diagnoses (compared to 26% during the previous winter season). The average duration of use of the ARI Smart Form was 7.5 (SD±4.5) minutes. Nine of 10 survey respondents (90%) would recommend the ARI SF to colleagues unchanged or with minor modification. Eight of 10 respondents (80%) reported that the ARI Smart Form was either time-neutral or timesaving. The ARI Smart Form requires further evaluation but has the potential to improve workflow and reduce inappropriate antibiotic prescribing.

Keywords:

Decision Support Systems, clinical,
Respiratory Tract Infections, anti-bacterial agents

Introduction

Acute Respiratory Infections (ARIs) – including nonspecific upper respiratory infections, otitis media, sinusitis, pharyngitis, acute bronchitis, pneumonia, and influenza – are the most common symptomatic reason for seeking ambulatory care in the United States, accounting for approximately 7% of visits.[1] ARIs are also the number one reason for antibiotic prescribing in the United States, accounting for about 50% of antibiotic prescriptions to adults.[2] Much antibiotic prescribing for ARIs is inappropriate due to prescribing antibiotics for viral conditions or prescribing unnecessarily broad-spectrum antibiotics.[3] Inappropriate antibiotic prescribing increases medical costs, increases the prevalence of antibiotic-resistant bacteria, and exposes patients to adverse drug events.

Health information technology, including electronic health records (EHRs) with clinical decision support, has shown the potential for improving the quality of medical care, mainly through the use of prescribing alerts and preventive care reminders.[4] Improving care for acute problems, like ARIs, may be particularly challenging because of the brevity of ARI visits.[5] In addition, partially because ARI visits are so brief, research into ARIs is frequently hampered by inadequate and non-standard documentation.

We designed an electronic health record (EHR)-integrated, documentation-based clinical decision support system for the care of patients with ARIs, the ARI Smart Form (**Figure**). The ARI Smart Form has 3 objectives: 1) assist clinicians in reducing inappropriate antibiotic prescribing; 2) improve workflow for clinicians; and 3) improve and standardize documentation. We have previously reported results of usability testing of the ARI Smart Form.[6] To further evaluate the ARI Smart Form and assess the feasibility of performing a larger randomized controlled trial, we performed pilot testing in actual clinical practice.

Methods

Setting and EHR

Partners HealthCare System is an integrated regional health delivery network in eastern Massachusetts. Partners HealthCare includes 20 primary care clinics affiliated with Brigham and Women's Hospital or Massachusetts General Hospital. The main EHR used in Partners HealthCare ambulatory clinics is the Longitudinal Medical Record, or LMR. The LMR is an internally developed, full-featured EHR including typed and dictated notes from primary care and subspecialty clinics; problem lists; medication lists; coded allergies; and laboratory test and radiographic results.

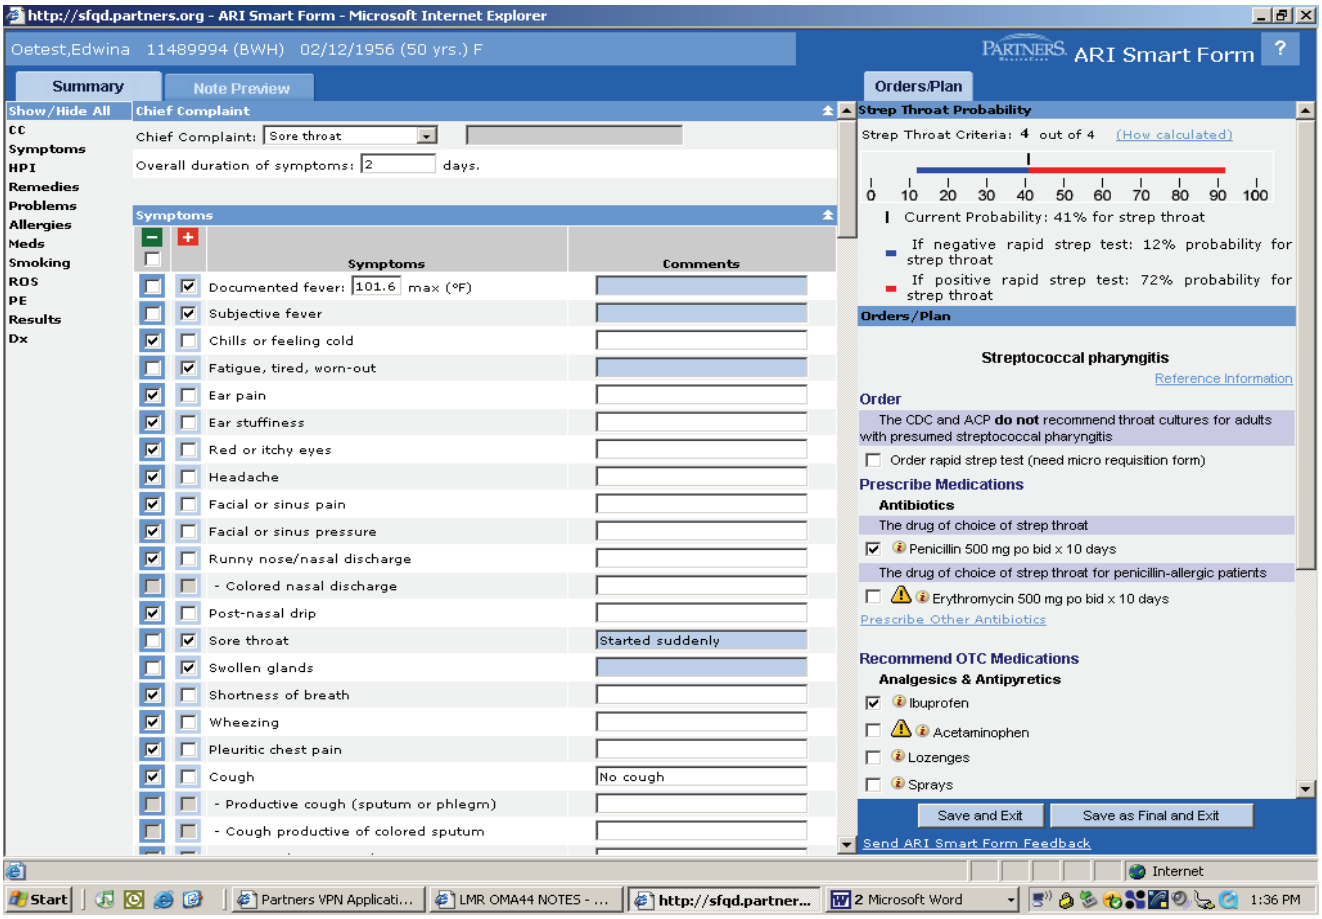

Figure – Screen Shot of the ARI Smart Form

The ARI Smart Form

The ARI Smart Form is launched from the Notes page of the EHR and is designed to be used while interviewing and evaluating patients. The ARI Smart Form integrates display of information, decision support, ordering and documentation and includes 6 components: entry of clinical information; patient data display; diagnosis selection; presentation of treatment options with integrated decision support; printing of patient handouts; and access to supporting medical literature. The ARI Smart Form imports patients' problem lists, allergies, medications, and vital signs into the visit note; speeds workflow using drop-down lists, radio buttons, and check boxes (especially "all normal" checkboxes); and provides "one-click" ordering of medicines, patient handouts, and excuse-from-work letters. The ARI Smart Form automatically generates a narrative visit note from all entered information, including orders and actions.

The ARI Smart Form provides decision support in several ways. First and foremost, clinicians' selection of a particular ARI diagnosis results in the generation of a diagnosis-appropriate order set. Antibiotic prescribing and antibiotic choices are based on the recommendations of the Centers for Disease Control and Prevention (CDC) and American College of Physicians (ACP).[7] At a basic level, the ARI Smart Form decision support strives to make the antibiotic treatment match the diagnosis (e.g., not prescribing antibiotics for patients with acute bronchitis; prescribing penicillin for patients with streptococcal pharyngitis). Second, the ARI Smart Form provides diagnostic decision support by calculating the probability of streptococcal pharyngitis based on signs and symptoms and how rapid streptococcal testing would change the probability of streptococcal pharyngitis (**Figure**).[8] Third, the ARI Smart Form has medication prescribing alerts to potential medication interactions or patient allergies to aid clinician decision-making. Fourth, the ARI Smart Form supports clinicians by providing easy access to diagnosis-appropriate patient handouts. The handouts contain information about the diagnosis and why or why not antibiotics may be indicated.

The ARI Smart Form should standardize documentation for several reasons. To obtain the workflow benefits of using the ARI Smart Form (i.e., facilitated orders and patient instructions), clinicians need to indicate a specific

diagnosis as opposed to using non-standard or vague diagnoses like "URI." In addition, clinicians use the ARI Smart Form to enter standard data elements that are stored and can be used in subsequent analyses.

Pilot clinicians

We recruited pilot clinicians by emailing 10 clinic directors and asking them to identify 2 volunteers each. Potential pilot clinicians were then contacted via email and invited to participate in using the pilot version of the ARI Smart Form. Those clinicians who accepted were instructed on how to use the ARI Smart Form through a series of emails detailing the layout, functionality, and technical issues associated with the ARI Smart Form. We encouraged clinicians to practice with the ARI Smart Form by using it with "test patients" (fictitious patients contained in the LMR) and then to start using it for all their ARI visits. On-line support for usability and technical issues was provided for the duration of the pilot via a link in the ARI Smart Form. The pilot period ran from August 29, 2005 to September 31, 2005. The Partners Human Research Committee approved the study.

Outcomes

Outcomes of interest for this pilot study included the proportion of all ARI visits for which the ARI Smart Form was used, the proportion of ARI visits at which antibiotics were prescribed, rates of antibiotic prescribing across different diagnoses, and the duration of ARI Smart Form use.

Post-pilot survey

At the end of the pilot period, we asked pilot clinicians to complete a survey by e-mail. The 5-minute survey asked questions about clinicians' satisfaction with the ARI Smart Form, focusing on areas needing improvement. In particular, the survey asked clinicians if they would recommend the ARI Smart Form to colleagues and if they felt using the ARI Smart Form saved time as compared to traditional visit note generation tools in LMR.

Data capture, extraction and analysis

We captured data about diagnosis and antibiotic prescribing from the ARI Smart Form itself. We also captured information about the prescription of non-antibiotic medications, recommendation of over-the-counter medications, and the printing of patient handouts and excuse-from-work notes. In addition, we recorded time stamps associated with starting and ending the ARI Smart Form session, which allowed us to calculate the duration of use of the ARI Smart Form. The duration of use is only a proxy for the visit duration as clinicians could choose to use the ARI Smart Form throughout a visit or use the ARI Smart Form at the end of a visit.

After the pilot was complete, we assessed our ability to compare antibiotic prescribing between visits at which the ARI Smart Form was used to visits at which the ARI Smart Form was not used. We extracted 2 groups for comparison. The first comparison group was all contemporaneous ARI visits at which the pilot clinicians did not use the ARI Smart Form. The second comparison group was all ARI visits from the previous winter season (from October 1, 2004 to May 31, 2005) made to the pilot clinicians.

We identified comparison visits using administrative data coded as International Classification of Diseases, Ninth Edition, Clinical Modification (ICD-9-CM). We identified visits with diagnoses of non-specific upper respiratory infections (ICD-9-CM 460, 464, and 465), otitis media (ICD-9-CM 381 and 382), sinusitis (ICD-9-CM 461 and 473), pharyngitis (ICD-9-CM 034.0, 462, and 463), acute bronchitis (ICD-9-CM 466 and 490), and pneumonia (ICD-9-CM 481-486). There were no diagnoses of influenza made by participating clinicians during the pilot period. We considered otitis media, sinusitis, streptococcal pharyngitis, and pneumonia to be antibiotic-appropriate diagnoses. We considered non-specific upper respiratory tract infections, non-streptococcal pharyngitis, acute bronchitis, viral syndrome, and other diagnoses to be non-antibiotic-appropriate diagnoses.

We report results as simple proportions and means with standard deviations (SD). We did not perform statistical testing because of the small sample size of this pilot study.

Results

Clinician participation and characteristics

We identified and invited 17 clinicians to use the ARI Smart Form. Sixteen of 17 used the ARI Smart Form on either test or real patients. A total of 58 notes were generated via the ARI Smart Form for test and real patients for an average of 3.6 notes per clinician (a single ARI Smart Form is used for each patient). During the pilot period, 10 clinicians used the ARI Smart Form 26 times with real patients, including 15 of 57 actual patient visits (26%) with an ICD-9-CM code of an ARI and an additional 11 visits that did not have an ARI ICD-9-CM.

This group of 10 Partners-affiliated physicians represented 9 different practices in the Partners network. Although nurse practitioners were among those invited to participate in the pilot, all 10 participants who used the ARI Smart Form with real patients were physicians. These clinicians included 5 women, had a mean age of 42 (SD±6.7) years old, and, on average, graduated from medical school 15 years previously. The pilot clinicians averaged 41 clinic visits per week. In terms of the practice site, 4 pilot clinicians worked in hospital-based clinics, 4 worked in community-based clinics, and 2 worked in community health centers. Nine of the pilot clinicians had primary care practices and 1 saw only urgent care patients.

Patient characteristics

The mean age of the 26 patients for whom the ARI Smart Form was used was 44 (SD±15) years old and included 15 (60%) women. Of these patients, 17 (65%) were white, 2 (8%) were Latino, and 7 (27%) had unknown race and ethnicity. Twenty-four patients (92%) spoke English as their primary language.

Antibiotic prescribing

Overall, during the pilot period, clinicians prescribed antibiotics to 35% (9 of 26) of patients when using the ARI Smart Form and 38% (15 of 39) of patients when not using the ARI Smart Form for ARI visits (**Table 1**). During the previous influenza season, these same clinicians prescribed antibiotics in 30% of ARI visits. For antibiotic-appropriate diagnoses, clinicians prescribed antibiotics in 6 of 6 visits (100%) when using the ARI Smart Form, 9 of 10 visits (90%) when not using the ARI Smart Form and in 154 of 367 visits (42%) during the previous cold and influenza season. For antibiotic-inappropriate diagnoses, clinicians prescribed antibiotics in 3 of 20 visits (15%) when using the ARI Smart Form, 6 of 29 visits (21%) when not using the ARI Smart Form, and 269 of 1027 visits (26%) during the previous cold and influenza season.

Use of other ARI Smart Form features

Clinicians prescribed non-antibiotic medications in 4 visits and recommended over the counter medications in 17 visits. Clinicians printed patient handouts in 3 visits and an excuse from work note in 1 visit.

Visit duration

The mean duration of ARI Smart Form use (calculated from the time the Smart Form was opened to the time the Smart Form was completed) was 7.5 minutes (SD±4.5), ranging from 2.0 minutes to 18.7 minutes (**Table 2**). The duration of use appeared to generally decrease with the number of uses by clinicians though there was notable variability within and between clinicians and 3 clinicians only used the ARI Smart Form one time.

Survey results

The 10 pilot clinicians responded to the post-pilot survey. Three clinicians felt the ARI Smart Form was marginally timesaving, 5 felt it was time-neutral, 1 felt it marginally increased work, and 1 felt it significantly increased work. Six clinicians would recommend that other clinicians use the ARI Smart Form unmodified and 3 would recommend it with some minor modification, such as increasing flexibility with more "freelance choices" and the feeling that the final note did not "flow naturally."

Table 1 – Antibiotic Prescribing by Diagnosis

*NA is not applicable

Discussion

In this pilot, we demonstrated the feasibility of conducting a larger study to evaluate the ARI Smart Form. We found that the ARI Smart Form has the potential to decrease inappropriate antibiotic prescribing for ARIs and improve workflow. The antibiotic prescribing rate for all ARIs did not change, but clinicians appeared to increase antibiotic prescribing for antibiotic-appropriate diagnoses and decrease antibiotic prescribing for non-antibiotic-appropriate diagnoses. This is in line with a major objective of the ARI Smart Form decision support: to get the antibiotic treatment of ARIs to match the diagnosis. Achieving such a goal could have a major impact on

reducing overall antibiotic prescribing in the United States.[2]

Table 2 – ARI Smart Form Use Duration by Clinician and Number of Uses

Clinician	Uses of the ARI Smart Form					
	1st	2nd	3rd	4th	5th	6th
	Time (minutes)					
1	10.2					
2	14.8	7.0	4.9	8.7	5.0	
3	4.1	10.5				
4	6.3	7.9	8.5	14.5		
5	4.1	3.6				
6	8.3	7.6				
7	13.2					
8	7.0					
9	8.6	18.7				
10	3.5	3.8	4.4	3.3	2.0	3.8
Mean	8.0	8.4	5.9	8.8	3.5	3.8

A major barrier to the adoption of EHRs is the perception that they interfere with workflow. Encouragingly, pilot clinicians generally felt that the ARI Smart Form was time-neutral or timesaving. This perception is in agreement with the measured results of local time-motion studies.[9] It is especially promising that 9 of 10 pilot users who used the ARI Smart Form with actual patients would recommend the ARI Smart Form to their colleagues.

The ARI Smart Form should provide additional benefits by standardizing documentation for ARIs. Some structured data elements are required for ARI Smart Form decision support at the time of use, like the signs and symptoms for calculating the probability of streptococcal pharyngitis. In addition, structured information can be used for quality reporting and quality improvement initiatives. Indeed, we are implementing an ARI "Quality Dashboard," with which clinicians review their antibiotic prescribing rates for ARIs compared to colleagues and national averages.

Limitations

This pilot study has several limitations that should be considered. First, and most obviously, this study was small with few participating clinicians using the ARI Smart Form with actual patients. This limited our ability to perform more meaningful comparisons between groups and statistical testing. Second, apparent improvements in appropriate antibiotic prescribing may simply reflect learning by clinicians to better match diagnosis codes with prescribed treatments. Third, not all of the invited clinicians used the ARI Smart From. Clinicians who are more inclined towards applications like the ARI Smart Form might assess it more favorably, leading to response bias in our satisfaction measures. Fourth, though we have previously found that administrative diagnoses have good positive predictive value for identifying ARI visits,[10] in this pilot, there was not a 1:1 relationship between the administrative diagnosis and the diagnosis from the ARI Smart Form. Fifth, participating clinicians did not use the ARI Smart Form for all of their ARI patients. There could be systematic differences between patients and visits at which clinicians do and do not chose to use the ARI Smart Form. The fact the pilot users did not use the ARI Smart Form in all patients with ARI suggests potential limitations in its design (e.g., difficulty using it with patients who have other active medical problems).

Future directions

The ARI Smart Form requires further evaluation with a larger sample of clinicians and patients in a randomized controlled trial. Such a trial could include a broader range of outcomes, such as re-visit rates, antibiotic costs, use of broader-spectrum antibiotics, and quality of documentation. In assessing the appropriateness of antibiotic prescribing in a larger study, we need to be aware of the potential for increasing the use of antibiotic-appropriate diagnoses and inadvertently increasing antibiotic prescribing for ARIs. For this reason, the primary outcome should be the overall antibiotic prescribing rate for all ARIs combined. Within this primary outcome, one can detect "diagnosis-shifting" from non-antibiotic-appropriate diagnoses to antibiotic-appropriate diagnoses.

Further changes to the application are also planned, including better integration of the ARI Smart Form into a visit in which multiple medical problems are addressed, increasing the flexibility of the form, and improving the readability of the generated note.

Conclusion

In this pilot study, we found that the ARI Smart Form did not appear to change the overall antibiotic prescribing rate. We did find the ARI Smart Form has the potential to decrease the antibiotic prescribing rate for non-antibiotic-appropriate diagnoses. We also found that pilot clinicians felt that the ARI Smart Form was time-neutral or timesaving and would generally recommend it to colleagues. Decision support applications for acute problems must provide clinicians with self-evident benefits at the time of the visit (e.g., saving time, improving patient education) or they will go unused. The ARI Smart Form requires further evaluation, but has the potential to improve workflow, reduce inappropriate antibiotic prescribing, and standardize documentation.

Abstract

The Indian healthcare sector is going through a period of significant transformation; moving from paper-based systems to electronic solutions. In order to be accessible to the current population and be able to cope with societal and technological advances, the new system has to be guided by present well-established medical practices in India and be designed and engineered to adapt and interoperate with other systems, both local and international. At the core of such a system has to be a well-designed data network. In this paper, we present our work on building such a network. We also highlight our design imperatives, which include the ability to address the issues of interoperability, scalability, privacy, security and extensibility in a very large data system.

Keywords:

India, Healthcare Systems, Healthcare Delivery, Healthcare Reform

Introduction

A safe and scalable information system is the essential backbone for building a nation-wide healthcare system to improve the quality of care, maximize operational efficiency, enhance planning & research and introduce cost-effective channels for delivering healthcare. The system needs to be able to evolve incrementally, build on the current traditions of medical practice and being able to explore new opportunities to eliminate inefficiency and reduce operational costs. In this paper, we describe the design of such an information system for the healthcare industry in India. We start off by discussing the current state of Healthcare in India and by presenting the factors driving the adoption of the National Health Data Network.

Method: The National Health Data Network

Most of the healthcare records in India are on paper and the health transactions are managed manually, with the exception of a few private hospitals. Manual data management invites error, inefficiency and significantly reduces the possibility of timely analysis of data to detect health-related emergencies such as an outbreak of a communicable disease in a particular city or state. The manual practice for exchanging the health data outside the enterprise introduces errors and inefficiencies into the system. The IT infrastructure in the private-sector hospitals cannot be utilized effectively for information exchange with the agencies having limited or no IT support.

The lack of data standards for integration and communication under-utilize the investments; as the health data will lie un-leveraged and fragmented across the primary, secondary and tertiary health institutions. The fragmented data continues to add to errors and duplication and will in the future demand higher technology investments to integrate diverse systems hosting data. Thus, it became clear that it is crucial to establish a standards-based, safe and secure IT backbone that can naturally enable the collaboration of health institutions nationwide and could virtually tie together a network of providers so that operational, clinical, and financial synergies can be realized.

Keeping the unique attributes of the Indian health industry in mind, IBM submitted a report in early 2005 entitled "Improving India's Healthcare System through Information Technology" to the President of India. This report made three principal recommendations:

- Adoption of electronic storage of data at all stages (including health records)
- Adoption of standards for communication and storage
- The construction of a nationwide health data network for sharing health information

These recommendations were expected to benefit the Indian society in the following areas:

- Operational efficiency (insurance, drug supply chain processing improvements, etc)
- Planning and management (disease surveillance, resource mapping etc)
- Education and research
- Cost effective and improved healthcare delivery

Our work takes an initial step towards addressing the recommendations in the IBM report to the president of India. The IT backbone infrastructure that we have designed facilitates sharing of information among heterogeneous data sources. The health institutions can use the infrastructure as an underlying network to collaborate in a safe, secure, scalable and fault-tolerant environment.

Discussion

Deployed over the Internet, NHDN is a special-purpose network to facilitate collaboration among health enterprises in a safe, secure, scalable and extensible environment based on the healthcare industry standards. The healthcare application service providers (HASP) can deploy their applications and services over this *virtual private health network* in the same way ASPs deploy their e-commerce applications on the Internet. In the healthcare sector, examples of such applications include Hospital Information System, Electronic Health Record and Claim Processing applications.

Applications deployed over the health data network, naturally gain the ability to establish collaboration among healthcare enterprises and their IT infrastructure. The collaboration is based on *hub-and-spoke* architecture that is better than point-to-point communication that lacks scalability and extensibility. The hub-and-spoke model is organic in design and deployment and allows enterprises to adapt to business transformations, new partnerships, vendors and business expansion.

The following are the key design considerations for NHDN:

- The network should be ***safe and secure***
  - Only authorized entities should connect to the network
  - All communication on the network should be encrypted
  - All communication on the network should be delivered to the targeted entity and should not be accessible to other entities. Effectively, network should prevent any sniffing.
  - The network should allow data privacy policies and enforce them
- The network should be ***standards-based***
  - Industry standards should be used to write and read information from the network.
  - The network should be specific to the healthcare industry and should use industry standards to represent information packets on the network.
- The network should integrate with legacy systems and should provide data ***integration and federation*** from disparate systems
- The network should be ***scalable and fault-tolerant*** for a nation-wide deployment

A **NHDN Access Point** is designed and developed to include all the above considerations and enable the healthcare enterprises and application service providers to connect to the NHDN. The technical details of NHDN access point for each of the above considerations are described below:

- **Security**
  - The health data network is deployed over Virtual Private Network technology that offers authentication and data encryption over the network.
  - Authentication technology prevents any unauthenticated access and retrieval of information
  - Hippocratic Database technology is used to specify fine-grained disclosure policies based upon the role of the user, purpose of access, intended recipient.
- **Standards**
  - Structured Query Language (SQL) is adopted to read and write information on the network.
  - Clinical Document Architecture (CDA) is adopted to represent health information on the network.
- **Integration and Federation**
  - IBM WebSphere Information Integrator (WS-II) is deployed to perform data integration and federation and enable the network to integrate with the legacy and disparate information systems.
- **Scalable and Fault-tolerant**
  - Grid technology is used in the design and development of Health Data Network that offers scalability and discovery to integrate disparate health data repositories available on the network.

Healthcare software vendors can package and deploy applications (ex: claim processing application) on NHDN access point and leverage the safe, secure and scalable collaboration among healthcare enterprises on the health data network. The generic data federation and integration capability of NHDN access point offloads the applications from the need to integrate data from disparate systems. The grid capability of the data network transparently enables the healthcare applications to adapt the business transformations of a healthcare enterprise as new customers, vendors join the network or the existing ones drop off the network. The applications coded for and deployed over NHDN, can naturally adapt to the entities connected on NHDN without the need of redeployment.

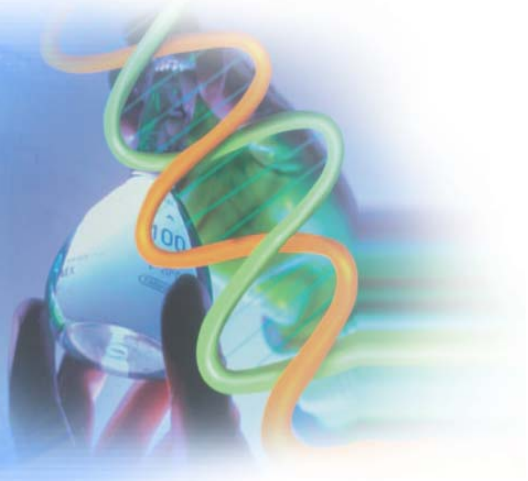
Conclusion

India is undergoing massive change in the healthcare market. There is a push towards transforming all the paper-based system to their electronic equivalents. Obviously, there are obstacles in the way of this renovation. One of the biggest hurdles is to ensure that all these electronic systems can collaborate seamlessly and securely in an effort to reduce transaction cost, increase quality of care, increase efficiency and lower administration overhead. To enable this, a safe and

scaleable data network is critical. In this paper, we present the National Healthcare Data Network (NHDN), which enables secure and privacy-preserving collaboration, while being scaleable and fault-tolerant. NHDN is standards-based, extensible and is able to evolve as the healthcare landscape changes.

IBM Healthcare & Life Sciences

A National Healthcare Data Network for India



IBM
Vishal Batra,Tyrone Grandison ,Sumit Negi, Ashwin Srinivasan

India's Healthcare System: Positive Things

- Eradication of diseases like small-pox
- Increased life expectancy (about 65 in 2000)
- About 5× more hospitals and 10× more doctors now than in 1951
- World-class pharmaceutical industry
  - About 20% of all (legal) drugs entering the US are from Indian pharmaceutical companies
  - Other than the US, Indian pharmaceutical companies have the highest number of drug filings with the FDA
- Some very good high-end hospitals

India's Healthcare System: Issues

- Money
  - Stagnant public spending (bottom 20% of countries)
  - 75% - 90% of government spending is made by state governments, which in turn consists largely of salaries
  - Large variance between states – Kerala spends twice as much as Bihar per capita
- Almost 80% of all health spending is private (largely unregulated)
- Number of hospital beds per 1000 population: 0.7
  - Comparable number is 1.4 for low income countries and 7.4 for high income countries
- India accounts for 17% of world population and 20% of disease burden

India's Healthcare System: Issues

- Nearly all private spending is "out-of-pocket"
  - About 25% of hospitalized individuals fall below poverty line as a result
  - Less than 15% of the population is covered through some form of pre-payment
- Poor still depend on public services for majority of major healthcare services
- Significant inefficiency and fraud in the distribution of drugs and supplies

Background: The Presidential Report

In early 2005, an IRL-led team submitted a report entitled "*Improving India's Healthcare System through Information Technology*" to the President of India

This report made 3 principal recommendations:

1. The construction of a nationwide health data network for sharing health information
2. The adoption of electronic storage of data at all stages (including health records)
3. The adoption of standards for communication and storage

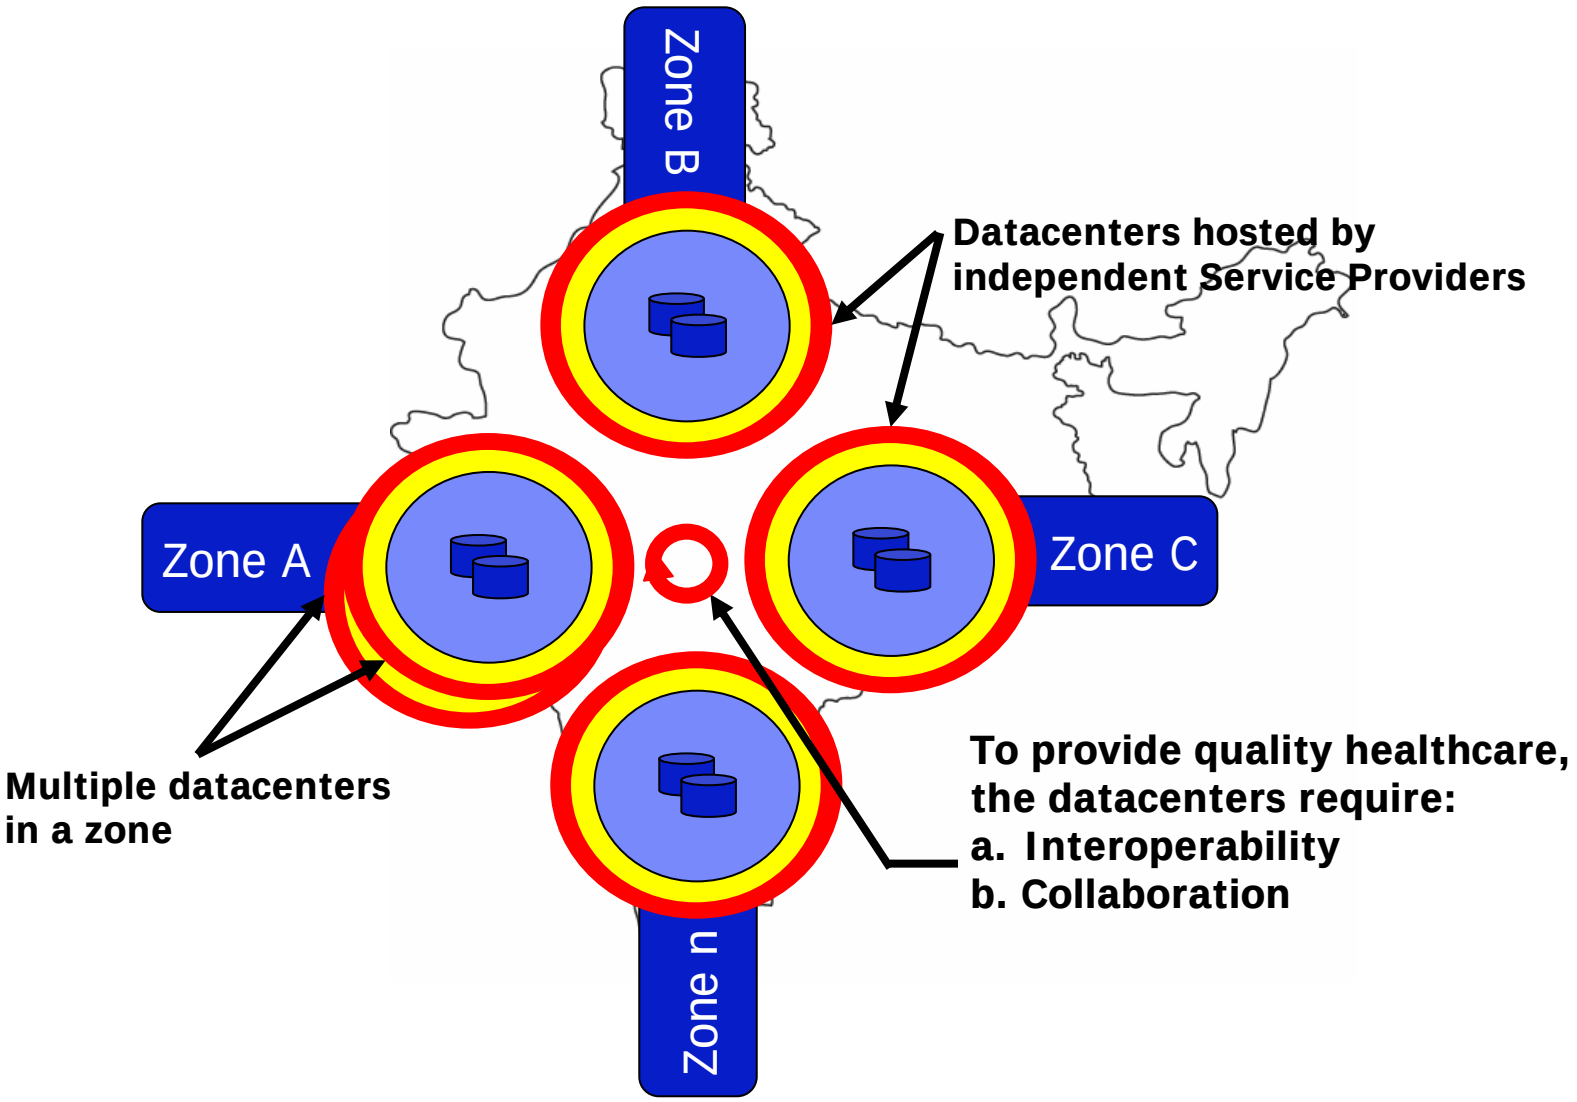
4 areas were expected to benefit

1. Operational efficiency
2. Planning and management
3. Education and research
4. New models of health delivery

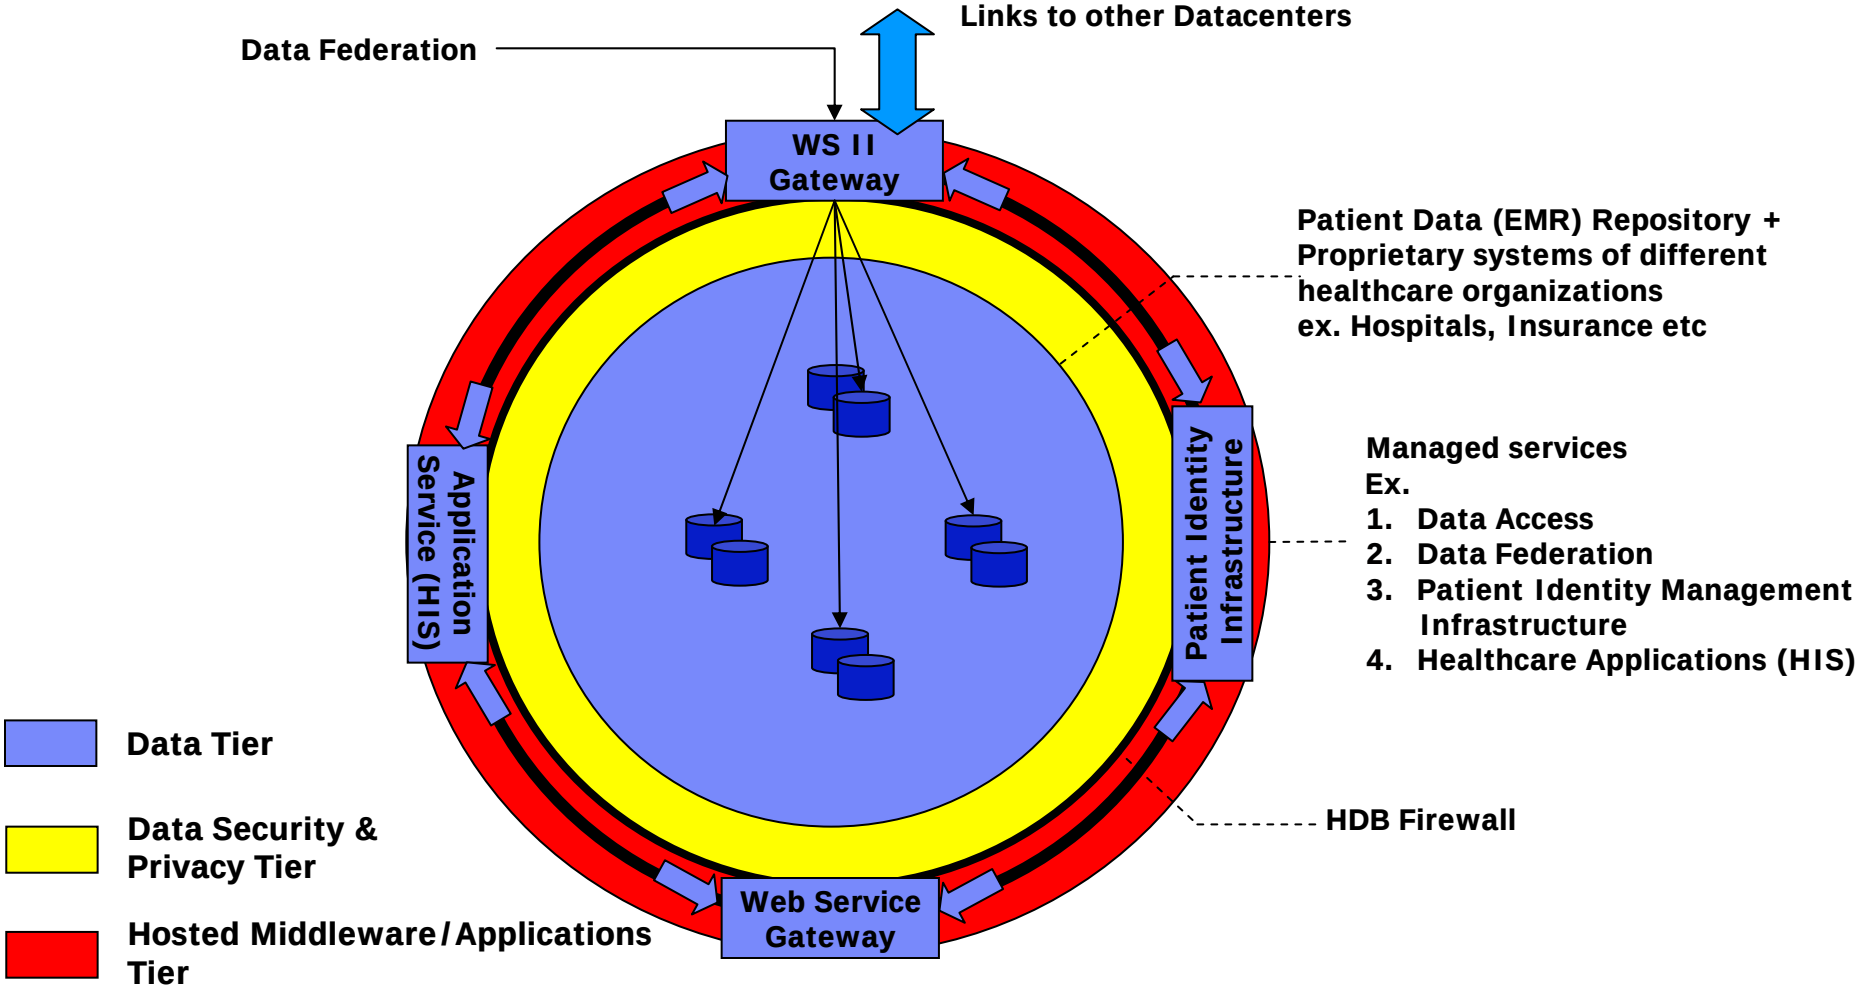
Background: India Healthcare Hyper-growth plan

- The Executive Summary in a hyper-growth plan for Healthcare in India makes the following points (from a draft document dated February 2005)
  - Health insurance is on the rise, and is creating incentives for driving efficiency and quality improvements in hospitals
  - Professionally managed private hospital chains have emerged, and are growing
  - Innovative high-volume business models are emerging around specialty care
  - Healthcare is high on the National agenda
  - Success in healthcare in India will have global implications for IBM
    - Medical BTO, pharma clinical BTO, and medical tourism to India are on the rise
    - There is strong demand for proven global solutions, e.g., clinical ISV applications, standards-based healthcare middleware, data warehousing, *etc*.
    - Successful models for hospitals and insurance will provide strong references for other developing markets
  - Suggests three market experiments with key customers early in 2005-2006:
    1. Insurance claims connectivity pilot with one or more insurance companies and TPAs
    2. EMR pilot with Apollo and other hospitals
    3. Hospital BPTS offering pilot with a hospital partner

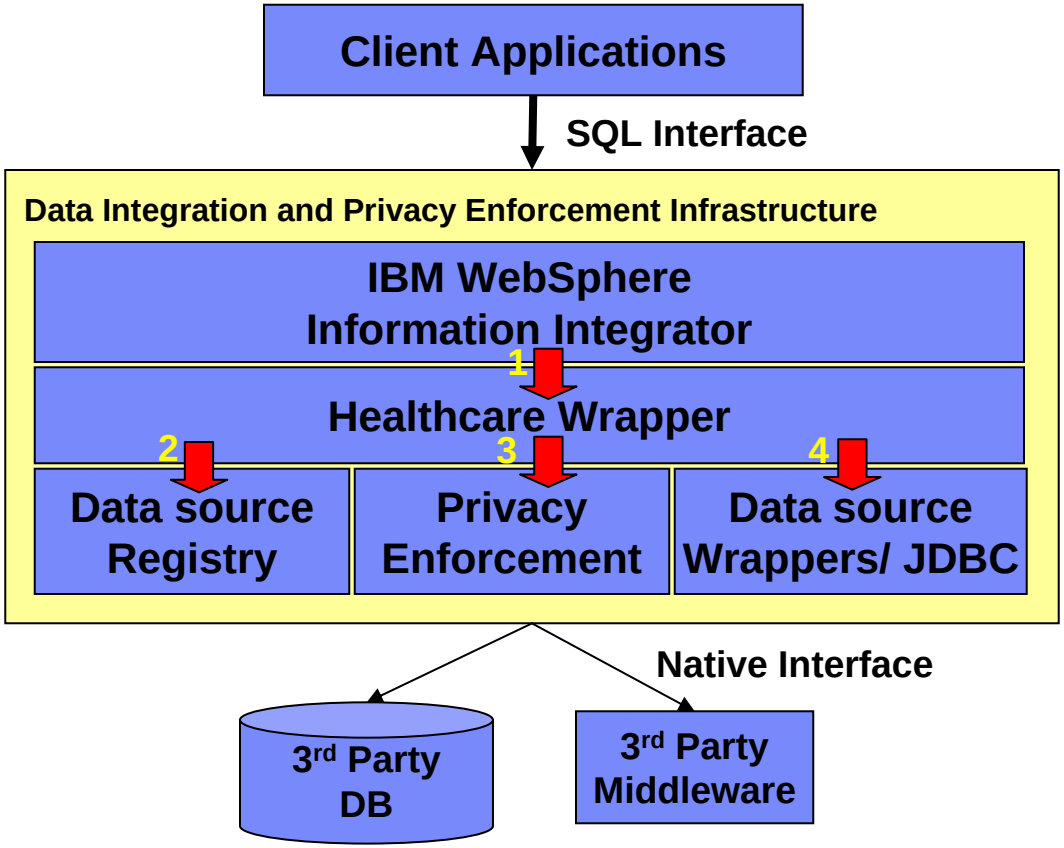
Distributed Healthcare DataCenter Overview



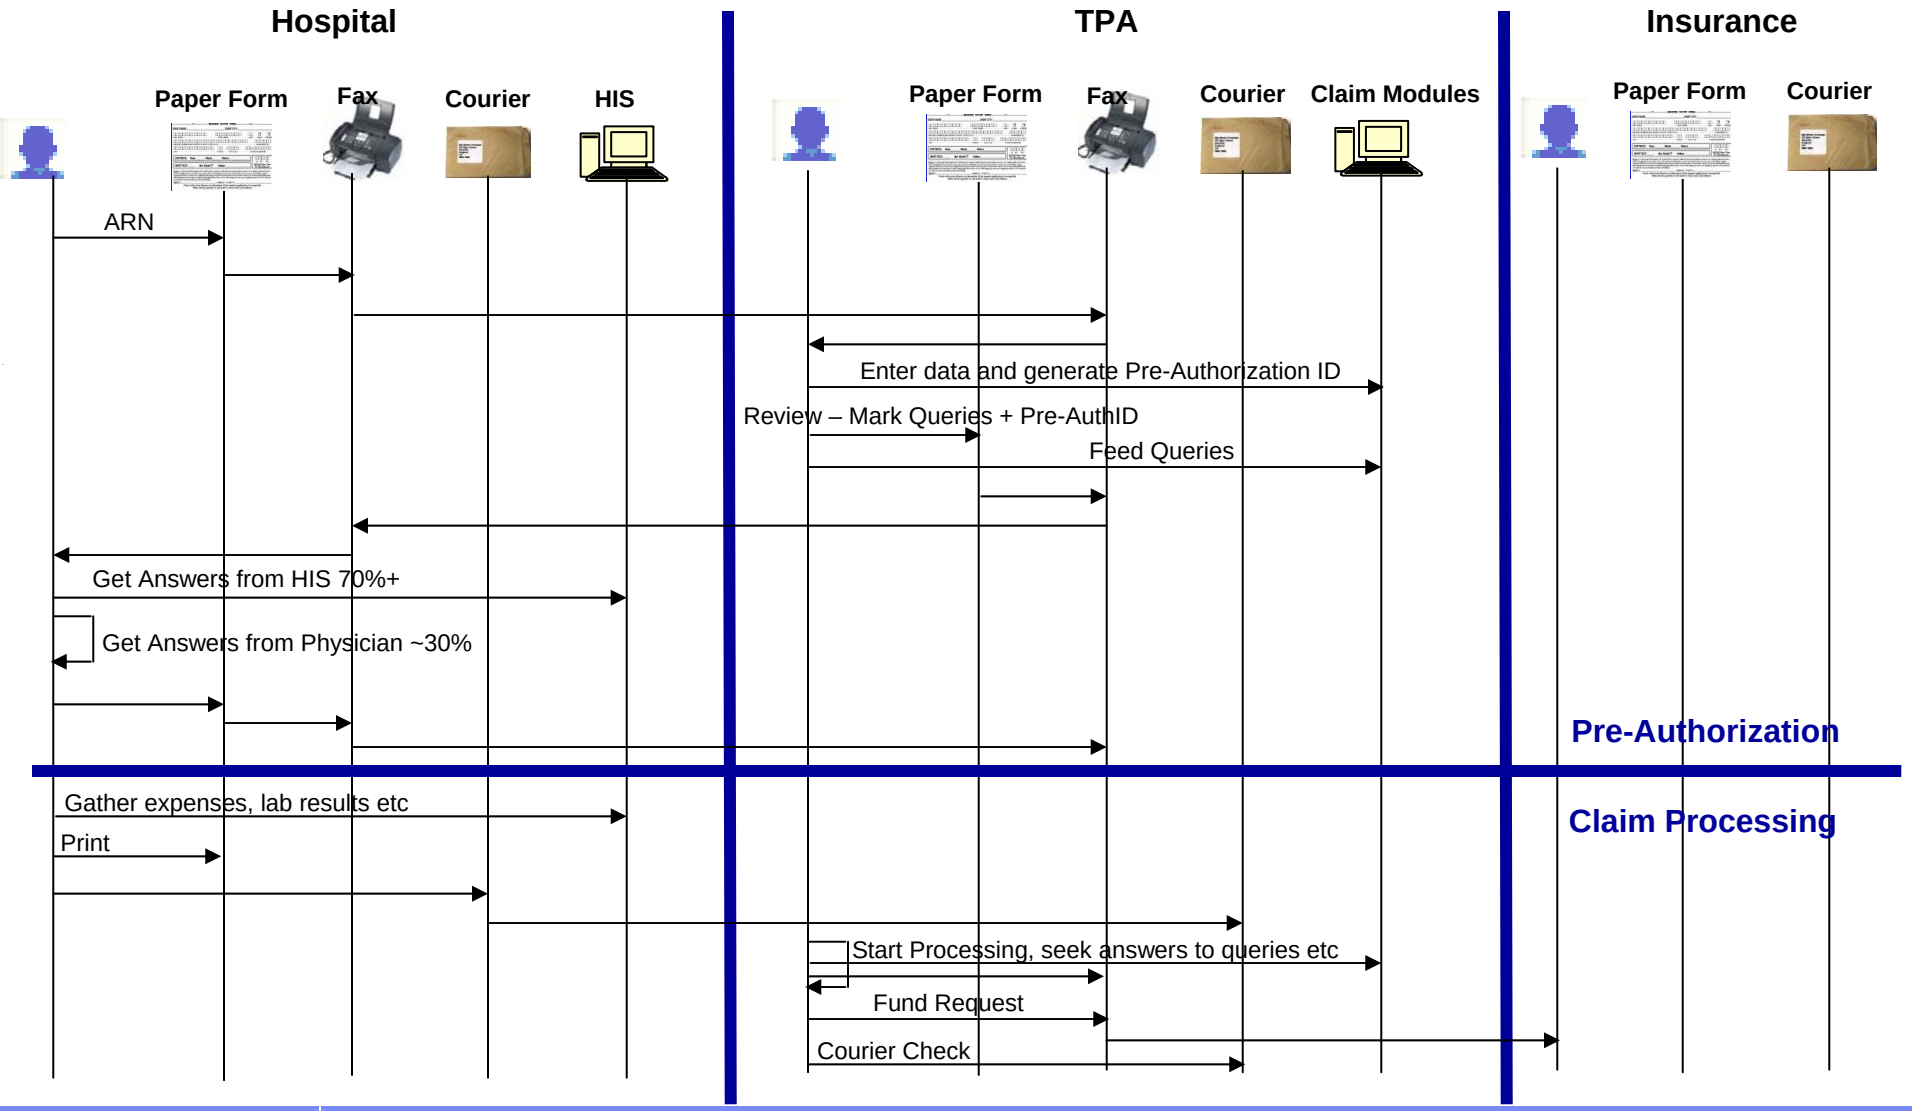
Healthcare Datacenter Stack



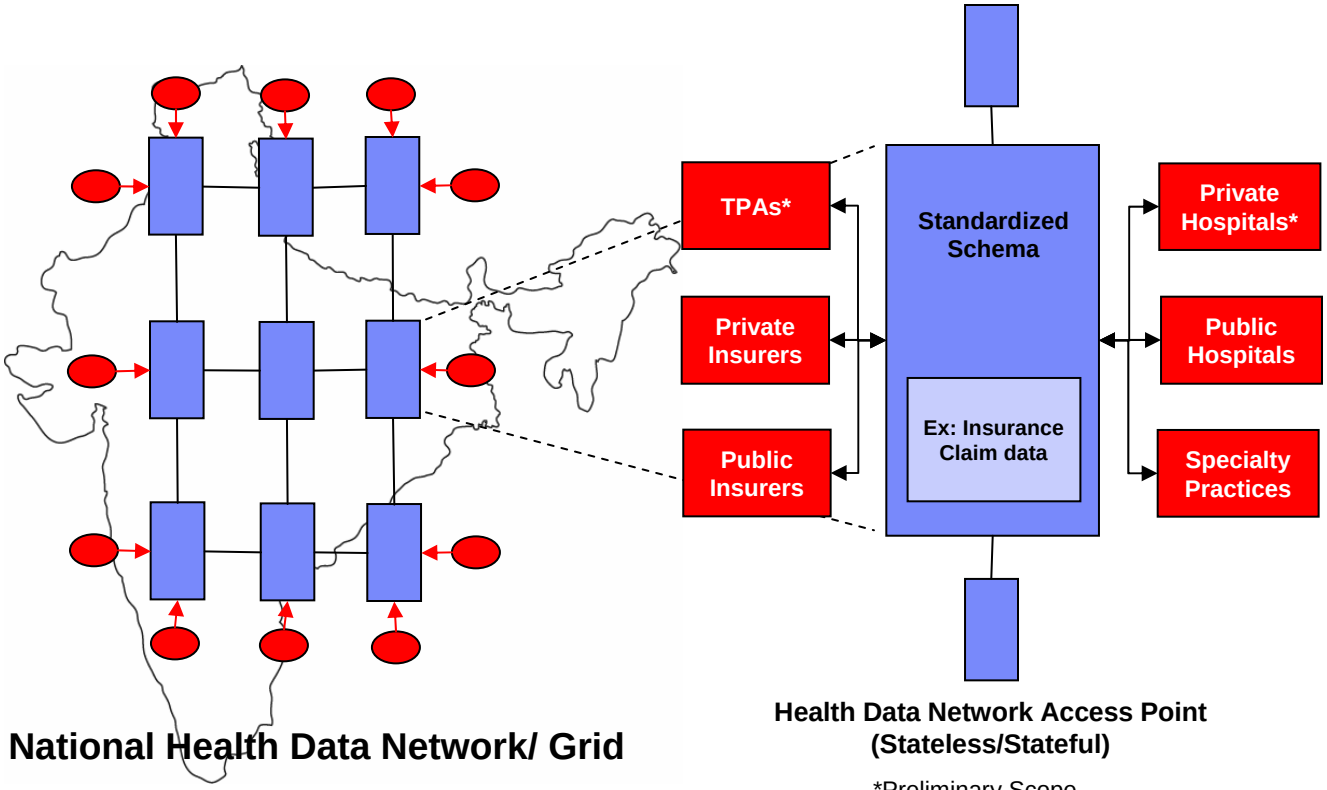
Data Integration & Privacy Enforcement Architecture



Claim Processing Sequence Diagram



Repository Based Architecture



Health Data Network Access Point (Stateless/Stateful)

*Preliminary Scope

Health Data Network Offers:

1. Standard data model over relational Schema.
2. SQL interface and query capability to aggregate data across desperate data sources allowing easy & rapid EAI.
3. Flexible (persistent/non-persistent) communication channel among multiple health care entities.

Strategic Information Management in Integrated Care – a Systematic Approach

Nils Hellrung

Institute for Medical Informatics, Technical University of Braunschweig, Germany

Abstract

Integrated care is an important element in achieving more efficient and effective health care. Information technology plays a vital role in implementing integrated care. In this paper, specific challenges of strategic information management in integrated care are approached.

Methods: Based on literature, two opposite organizational forms of integrated care are described: integrated care networks and hierarchies. A literature analysis concerning information management in integrated care was performed. The publications were indexed with regards to discussed scope of information management. Publications, that were assigned to strategic information management were analyzed with respect to their perspective (national/ regional or integrated care organization). In closing, specific conditions of strategic information management in integrated care are discussed.

Results: 56 of 88 publications could be assigned to strategic and/ or tactical information management. Information strategies were mainly formulated from a regional or national perspective. 3 publications described strategies for hierarchical forms of integrated care. It is concluded, that the absence of centralized authority in integrated care networks requires specific methods of strategic information management.

Keywords:

information management, integrated care,
medical informatics

Introduction

Improved coordination of health care is seen as a key issue in enhancing efficiency and effectiveness [1]. Given the degree of differentiation in health care regarding professionals, units and organizations which leads not only to complex coordination problems, but is also a great strength of the system, integration should be increased [2, 3]. The term “Integrated care” characterizes an organizational status, in which shared care, continuity of care and seamless care are achieved, tailored to individual needs [4-6].

Information technology is often regarded as a prerequisite for integrated care [6-9]. Equivalent to institutional information systems, transinstitutional information systems that support integrated care should be managed systematically. In this paper, we focus on strategic information management, which aims at translating strategic goals into information strategies [10]. While strategic information management is well described for institutional settings, e.g. [10, 11], it is not clear, how it can be implemented in transinstitutional situations [12], such as integrated care.

To approach this problem systematically, the following research questions are addressed in this paper:

Q1 Which organizational forms of integrated care are currently observable?

Q2 Which scopes (strategic or tactical) of information management in integrated care are discussed in current publications?

Q3 What can be concluded by the results of Q1-Q2 regarding strategic information management in integrated care?

Methods

Q1 is answered by applying a framework for systematizing organizational relations in general, e.g. [13, 14] and in health care, e.g. [15-17] with regards to the arrangement of institutions and management within integrated care.

To answer Q2, a literature research was conducted. The study design was designed as retrospective and prolective [18]. Using the pubmed database, we searched for publications with the following limitations: only journal articles were allowed that were published between 2001/10/01 and 2006/10/01, an abstract had to be available and the language had to be English. The queries were conducted on 2006/11/06.

Our goal was to identify publications that deal with the role of medical informatics, information systems or information management in integrated care. In order to generate comprehensive results, we combined each of the MeSH terms “Medical Informatics”, “Information Systems” and “Information Management” with each the following terms related to integrated care: "Delivery of Health Care, Integrated" (MeSH), "Continuity of Patient Care" (MeSH), “integrated care”, “seamless care”, “shared care” and “health networks”. Thus, 18 queries were performed. The relevant publications were indexed with respect to their scope, i.e. assigned to strategic and / or tactical information management [10]. Publications assigned to strategic information management were classified regarding their perspective (national/ regional or integrated care organiza-

tion). The indexation was performed based on the abstracts. If the information contained in an abstract was regarded as not sufficient for indexing, the full article was analyzed. Q3 is answered in the Discussion section by arguing with respect to results of Q1 and Q2.

Results

Q1 Organizational Forms of Integrated Care: hierarchies and networks

Organizational aspects of integrated care can be analyzed at an external level, management level, institutional or patient level [16, 19, 20]. In this paper, we focus on the management and institutional level. Integrated care means division of labour across professionals, units and institutions. This requires coordination [2, 21].

Two basic coordination mechanisms define the boundaries of a range with different organizational forms [13, 21, 22]. One approach is to establish hierarchical organizations, i.e. integrating health care providers of the same level in the value chain (horizontal integration) and of different levels (vertical integration) under unified ownership. Here, division of labor is coordinated through authority [21]. This approach has been pursued in the United States, where large Health Maintenance Organizations (HMOs) have been founded. As summarized by Wijngaarden et al [2], HMOs have been criticized for integrating structures without improving the alignment of care processes to patient needs.

In opposite to hierarchies, another coordination mechanism is to coordinate division of labor through formalized cooperation and exchange relationships between legally independent institutions [16, 17]. We refer to these forms of collaboration as integrated care networks (ICNs). It has been shown in different countries, that ICNs can be successful in providing integrated care across professions, functions, sites and over time [1, 2, 23].

Between the two basic forms hierarchy and ICNs, many different organizational arrangements can occur which possess characteristics of both hierarchies and ICNs. These intermediate forms can therefore be termed “hybrids” [24]. Regarding management, hybrids can be organized from completely independent and decentralized management units to centralized management units with high level of authority, [24], as illustrated in Figure 1.

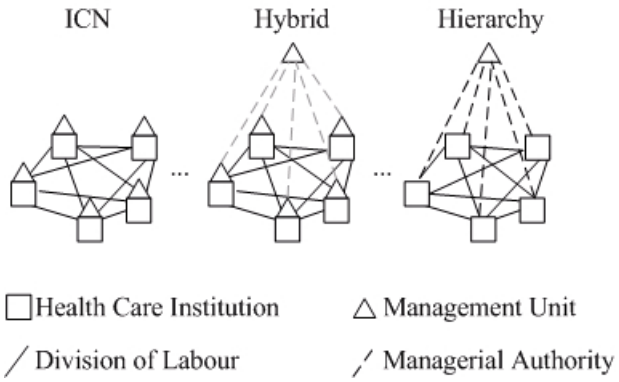

Figure 1 – The organizational continuum of management in integrated care

Q2 Current scopes of Information Management in integrated care

Our pubmed queries returned 269 different publications. 181 publications were excluded, because they discussed either ICN OR issues of medical Informatics/ information systems/ information management, but not both. Of the remaining 88 publications, 56 publications could be assigned to strategic and/ or tactical information management.

Table 1 – Assigned scopes of information management

Scope of Information Management	
Strategic	15
Tactical	48

Most of the publications were assigned to tactical information management. Hence, the focus was on specific technological issues of transinstitutional information transfer. Some publications presented concepts, in which transinstitutional information systems were seen as enablers for integrated care or related concepts, e.g. [25-28]. Another group of publications specified their concepts by describing technological approaches. Here, interoperability and security were the predominant subjects. With regards to interoperability standards such as HL7 respectively CDA were discussed in order to support transinstitutional information exchange, e.g. [29-31]. Security was discussed mainly from the view of access control and authorisation, e.g. [38-41], as well as information transfer, e.g. [32, 42, 43].

Beside the conceptual papers, pilot projects of electronic transinstitutional information transfer were described, e.g. [32-37]. Some publications presented evaluations, e.g. [45-47].

15 publications engaged information strategies or at least approached the topic. As Table 2 summarizes, 12 of these publications formulate strategies to enhance transinstitutional information sharing on regional or national level. Three publications could be identified, that present information strategies for organizational forms that aim to provide integrated care. These three publications refer to hierarchical health care organizations in the United States such as the Veterans Health Administration and PeaceHealth, e.g. [56, 58] [57].

Discussion

As presented, integrated care can be achieved through different organizational arrangements. In many countries a trend towards the ICNs is observable [2, 21].

The conducted literature analysis revealed that information technology plays a central role in implementing integrated care. However, it also revealed, that strategic information management is an unsolved issue in non-hierarchical organizational forms of integrated care. Most research focuses on technological challenges, such as security and standardization. Without denying the complexity and relevance of this research, we see a research gap with regards to how align transinstitutional information systems to organizational settings in integrated care. Information strategies are formulated exceptionally on regional/ national levels or with respect to hierarchical organizations.

The specific feature of ICN with regards to strategic information management is, that an ICN on the one hand is a conglomerate of different institutions, whose strategic goal systems overlap only in a limited scope and that on the other hand possesses no centralized management that could implement an information strategy by authority. In hybrid organizations it is also unclear, how a centralized information management is related to institutional information management.

For future research, we aim at constructing a framework for describing organizational forms of integrated care more precisely. Furthermore, we want to systematize specific requirements on information management in integrated care in order to develop adequate methods. Here, a key issue will be the balancing of different strategies within ICNs or hybrid forms in order to develop comprehensive information strategies.

Abstract

Bed shortage is a growing world problem and affects health care endangering patient safety, increasing length of stay, costs and morbimortality rates. The objective of this paper is describe a local solution centered on nurses and clerks work on intrahospital patients' transfer. Hospital Italiano of Buenos Aires gives on line support to the hospital census of 650 beds. There are 3000 inpatients admissions per month, with approximately 9500 transfers. This is possible due to an integrated Electronic Medical Record and ADT System (Admission, Discharge, and Transfer). In spite of transferring patients on line , with low beds availability setting, nurses depend and rely on telephone calls, wasting time on arranging a transfer in extreme situations, occupy beds without checking the Admitting Coordinator causing problems to others actors whom were waiting for that bed. As a solution to this problem the ADT System will be improved with a traffic light system with a bed waiting list, in which bed ordering from ICU and operating rooms are prioritized, with a bed differentiated display on the Nurse Control Chart establishing an asynchronic but effective communication.

Keywords:

bed occupancy, admitting department, hospital, patient transfer, inpatients

Introduction

Shortage of beds is a problem that affects all hospital system decreasing productivity and efficiency. This situation is a direct consequence of patient-flow problems[1]: in a hospital environment, a patient is admitted to the hospital, transferred and discharged when leaving the hospital.[2]

Trustworthy and on time updated the information where inpatients are as knowing availability of non occupied beds, is a critical aspect in daily hospital resources management. Since bed occupation information is not always well documented on information systems , the lack of correlation results in several complications such as cancellation of the admission of patients due to not having an accurate number of vacant beds[3] or employ human resources in nonessential functions like nurses calling to different hospital areas looking for non occupied beds [4]

Low availability of beds occurs during seasonal peaks, in this case reliable information of hospital census becomes critical [5], as well as to avoid bottle necks on passage of patients from one ward to another, commonly observed in the intensive care unit (ICU) and anesthetic recovery rooms

The objective of this paper is to propose a solution to this point being centered on nurses and clerks working on inpatients transfer.

Materials and methods

Setting

Hospital Italiano of Buenos Aires is a Hospital with 650 beds allocated in levels such as, general in-patients areas, intermediate and intensive care units. There are 3000 inpatient monthly admissions, with approximately 9500 transfers.

Hospital Italiano has been integrating several informatics systems in clinical layer with an Electronic Medical Record (EMR) that runs on web platform. The nurses work on a Nurse Control Chart (NCC) in which they organize human resources for each inpatient area and follow their assigned patients. In the field of Admission and Discharges patients, a software for their management was developed and called ADT system (Admission, Discharge, Transfer) This application made it possible to health care providers (nurses, doctors), stretcher-bearers (orderlies) and Admitting Department staff to make maintenance of Hospital census on line. But with the Online Census, bed occupancy information management was ameliorated but we realized that although all of the transfers were done through the system, disagreements with real bed occupation continued. A description of the issue is explained below and different situations will be described.

Two settings are related to intrahospital patient transfer:

- Appropriate beds availability: meaning there is an appropriate obtainable amount of beds.
- Low beds availability: means that there is not an appropriate obtainable amount of beds.

When the nurse needs to transfer a patient with appropriate beds availability, she chooses and allocates a vacant bed on

the EMR for this patient. If the transfer of the patient requires a stretcher bearer she asks for him through the system. When the patient leaves the bed, a housemaid prepares this room for the next patient. ***With low beds availability*** she **has to telephone** the Admitting Coordinator asking for a non occupied bed. When it is accomplished, a **Synchronic Communication between Nurse-Coordinator** occurs. If there are not "ready for use" beds, the Admitting Coordinator reserves ones.

These activities have these disadvantages: dependency on telephone call that not always can be achieved, causing delays, in extreme situations, nurses occupy beds without the Coordinators reply causing problems to others actors whom were waiting for that bed; in addition, it must consider wasted time on the arrangement of this transfer.

Considering these situations, and for **optimizing resources,** improvements are developed. The changes include : reorganization of the inpatients section on the system and introduction of "traffic light" concept with a Bed waiting list so as to increase the availability of beds.

Results

Modification developed on the ADT System, EMR and Nurse Control Chart (NCC)

The improvements on ADT system will be: inclusion of *Bed Manager* for the Admitting Manager, addition of *Stretcher Bearer Manager* for Stretcher Bearer Coordinator and inclusion of *Housemaid Manager* for Housemaids.

Hospital map will be redefined on ADT system as *Non Centralized Units* (ICU and operating rooms) and *Centralized Units* (Adult, Pediatric and Geriatric Areas) Inpatient areas from our Hospital were reorganized and combined in Sectors Admitting Units (SAU), and each of one is coordinated by an Admitting Manager using a *Bed Manager*. Admitting Manager with Bed Manager can have a quick view of inpatient episodes with discharges in progress, save beds for scheduled admissions for the following days is enlisted and the reservation can be done in accordance with each patient, administrate non-scheduled Admission (emergencies) and save beds for intrahospital transfer. Depending on number of occupied beds (higher than 85%) SAU Admitting Manager sets up on Red or Green for each SAU on the system.

When nurses need to transfer a patient to a SAU "in Red" (low availability) asks for a bed through the EMR. The solicitation is automatically enlisted in the Admitting Manager waiting list while the nurse continues working on their activities establishing an **Asynchronic communication between Nurse-Admitting Managers.** The system prioritizes ICU and operating rooms. When a bed is granted by the Admitting Manager, the system indicates an active reservation on the Nurse Control Chart: color bed changes *and* shows patients beds in four different colors. Depending on this color nurses can quickly identify who of their assigned patients have a pending transfer or is being discharged. Nurse continues with the transfer, with a reserved bed. A reserved bed has an expiration time, it has to be accepted within 3 hours by the nurse or the reservation is lost.

Discussion

Bed shortage is a growing world problem and affects health care endangering patient safety, increasing length of stay, costs and morbimortality rates. [1] As a solution to this problem a traffic light system with waiting list and asynchronic communication is presented. This work was merely descriptive and we consider it as limitation of this paper. This is an only an approach and our intention is compare how long every actor involved on Patient Flow spends on his work and how long every actor, mainly nurses, would save with changes introduced, as to show the efficacy of our implementation. We estimate that allocate beds and transfer patient task would be performed faster, and on the other hand , with a low beds availability setting, the improvements applied would give an opportunity for better bed management.

Introduction

- Shortage of beds affects all hospital system decreasing productivity and efficiency
  - ⟶Factors that contribute to this situation
    - inappropriate nurse-patient ratio
    - delay in rooms cleaning after discharge patients
  - ⟶Direct consequence of patient-flow problems

- Bed shortage affects health care
  - ⟶Endangers patient safety
  - ⟶Increases length of stay, costs and morbimortality rates.

Introduction (cont.)

- Bed occupation information not well documented on information systems produces
  - ⟶cancellation of the admission of patients
  - ⟶employ human resources in nonessential functions
- Low availability of beds occurs during seasonal peaks
- Bottle necks exist on passage of patients from one ward to another

This work

- Describes a possible solution centered on nurses and clerks working on inpatients transfer.

- Approach to a plan of two parts.

  →compare how long every actor involved on Patient Flow spends on his work and how long every actor would save with changes introduced, as to show the efficacy of our implementation.

Materials and Methods: Setting

- **Hospital Italiano de Buenos Aires**
  - ⟶Academic Medical Hospital with 650 beds
  - ⟶3000 inpatient admissions monthly, with 9500 transfers
  - ⟶Electronic Medical Record (EMR) that runs on web platform.
  - ⟶The nurses work on a Nurse Control Chart (NCC)
  - ⟶ADT system (Admission, Discharge, Transfer) made possible to make maintenance of Hospital census on line.
  - ⟶Hospital census had a 14% error on information before implementation Census on line. Two cross-sectional studies demonstrated a 5% decrease on global error
  - ⟶Bed occupation information was better documented on the system due to online support.

Materials and Methods: Necessity

- When the nurse needs to transfer a patient:
  - ⟶With low beds availability
    - She **has to telephone** the Admitting Coordinator asking for a non occupied bed.
      - **Synchronic Communication between Nurse-Coordinator**

- Disadvantages:
  - ⟶Dependency on telephone call
  - ⟶Nurses occupy beds without the Coordinators reply.
  - ⟶wasted time on the arrangement of this transfer.

- For **optimizing resources,** improvements were developed on ADT system, EMR and Nurse Control Chart.

Results: Modifications

- Inpatient areas reorganized in Sectors Admitting Units (SAU) on ADT
- ADT System: Inclusion of Bed Manager for the Admitting Manager

  →when his SAU has bed occupancy higher than 85% can define it as “in Red”.

Color	Condition : bed occupancy
Green	lower than 85%
Red	higher than 85%

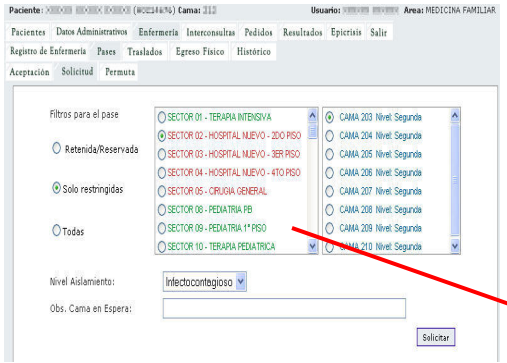
- EMR :Bed ordering System
  - bed ordering is enlisted in the Admitting Manager waiting list.
  - This solicitation is done on the EMR where nurses can visualize the SAU in Red or Green.
- Nurse Control Chart (NCC): Nurse Bed differentiated display

Results: Change on Nurse Workflow

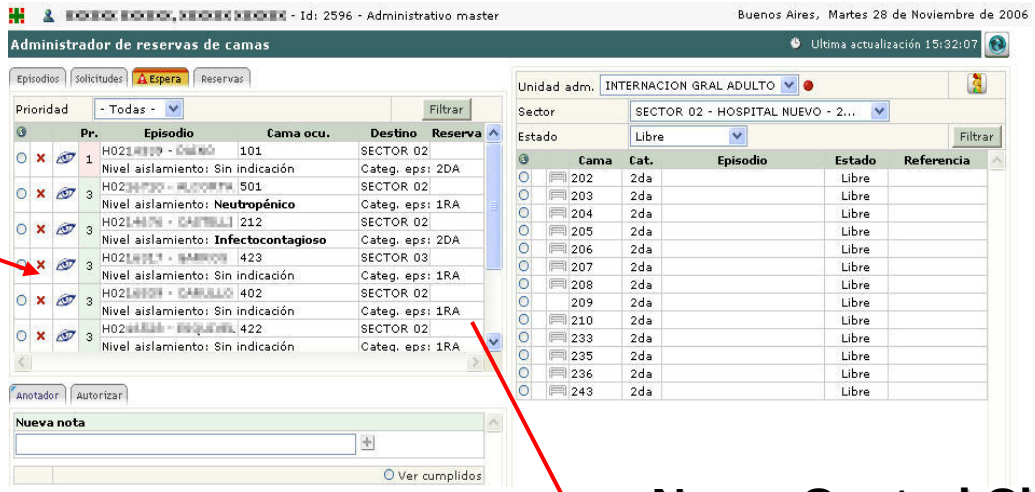
- When the nurses need to transfer a patient to a SAU “in Red” (low availability)
  - ⟶Asks for a bed through the EMR
  - ⟶The solicitation is automatically enlisted in the Admitting Manager waiting list (ADT) establishing an **Asynchronic communication between Nurse-Admitting Manager.**
  - ⟶When a bed is granted by the Admitting Manager, the system indicates an active reservation on the Nurse Control Chart (color bed changes) nurse continues with the transfer, with a reserved bed which has an expiration time

Results (cont.)

EMR



ADT System: Bed Manager



Waiting List

Bed Solicitation

color bed changes

Green	Patient, who occupies this bed, is being discharged from the hospital.
Yellow	Patient, who occupies this bed, has another one already reserved for him. Transfer can be done ***without delay*** due to be a vacant reserved bed.
Red	Patient who occupies this bed has another one already reserved for him. Transfer can be done ***with delay*** because is an occupied reserved bed.

Building Care Delivery Systems for Patient Value: Adding Nursing to Evidence-Based Practice

Norma M. Lang[a], Tae Youn Kim[a] , Sally Lundeen[a], Amy Coenen[a], Sue Ela[b], Judy Murphy[b],Charlotte Weaver[c]

[a]University of Wisconsin, Milwaukee, Milwaukee, Wisconsin, USA
[c]Aurora Health Care, Milwaukee, Wisconsin, USA
[b]Cerner Corporation, Kansas City, Missouri, USA

Abstract

Healthcare organizations in every country are exploring how to develop clinical best practices to guide delivery of safe, effective and appropriate health care as rapidly as possible. This paper reports on the innovative work of a major collaborative evidence-based practice (EBP) research initiative that adds nursing knowledge into team care protocols for the full life cycle of specific health conditions, e.g. congestive heart failure and nurses' clinical adoption of these new tools and practices.

Keywords:

nursing knowledge, best practices, evidence-based practices, nursing standard terminology; nursing data sets, data infrastructure, patient value

Introduction

Numerous efforts have been made to fill the quality chasm stemming from wide variations in practice patterns and access to healthcare providers. There have been intense efforts to develop and apply the best possible science to inform healthcare delivery [1-3]. Surprisingly, even though nurses are considered "knowledge workers," much of what nurses contribute to the care process and outcomes of care is not visible. This invisibility also extends to the data captured and stored in local, regional and national EHR systems [4]. In 2002, Aurora Health Care, Inc., a large Wisconsin-based integrated health system, prepared to implement plan of care clinical documentation across its delivery system. Aurora encountered a near total absence of evidence-based nursing content available to use within its clinical information systems (CIS). The research project reported here emerged from discussions on how best to address that void [5]. The scope included the redesign of care protocols to cross the full care continuum using evidence-based content for the care team. The decision was made to adopt a rigorous research methodology to generate best practice content in view of the many barriers that impede healthcare professionals in obtaining and applying best evidence. These barriers include a lack of clinician competency for literature searches, study evaluation and implementation, unfavorable attitudes toward EBP, and less supportive external environments [6].

Methods

The methodology used addresses the following three research aims:

1. to discover and generate the evidence-based nursing knowledge related to major clinical conditions
2. to define a framework for representing that knowledge to clinicians to use in clinical practice
3. to provide structured data using standard nursing terminologies for quality measurement, outcomes and research

The team started the knowledge generation process by working with clinical nurse experts to "name" and rank the "phenomenon of concern" that most commonly occurred in the care of their patients with major health conditions. Once identified, the research team used a systematic search and critical appraisal process to discover, synthesize, and organize the knowledge content to align with the nursing process. The second step in this process is the translation of the synthesized content into nursing knowledge for clinician application at the point of care into the work flow, decision support rules engine. The nursing knowledge is embedded in the assessment documentation content, decision support rules engine and into pre-built plans of care.

The EBP content was divided into two types of nursing knowledge for representation within the CIS - referential and actionable knowledge. Referential knowledge can be accessed as a point of information by any team member through a reference knowledge database that provides descriptions of the given problem, interventions Actionable knowledge refers to the actions that are programmed into the clinical rules engine for the system in response to the given documented value or result. Thus, the actionable knowledge is available at a screen level linked to a given procedure, topic or data element.

Concept representation

Since the ability to communicate, transfer and compare nursing data is essential to meeting the aims of this collaborative project, a dedicated terminology task group was built into project activities from inception. This team has focused specially on concept representation and the application of terminology standards to the nursing data embedded under the categories of assessment, diagnosis, interventions and outcomes. The terminology task group used international standards to guide the concept representation work, including (a) International Organization for Standardization ISO 18104:2003 Health Informatics – Integration of a reference terminology model for nursing [7], (b) International Classification for Nursing Practice (ICNP®) [8], and (c) Systematized Nomenclature of Medicine Clinical Terms (SNOMED-CT) [9].

Results and findings

To date 15 nursing "phenomenon of concern" have been developed into EBP recommendations for assessments, problem identification, plans of care, and outcomes evaluation. An initial pilot test was conducted at a 72-bed acute care site and focused on one phenomenon - Activity Tolerance. The pilot evaluation aimed to assess the extent to which the embedded knowledge pertaining to Activity Tolerance was utilized by nurses at the point of care. The sample of 773 adult patients (age 18) admitted from July 1 to October 31 2006 was used for this preliminary analysis. All the subjects projected for the analysis were medical patients and admitted for emergent services (72%) with a mean length of stay of 5 days (SD =4.6). The majority of patients were female (57%). Mean age of subjects was 59.3 years (SD = 19).

Table 1 - Summary of Nurse-Sensitive Outcomes

- **Activity level tolerated appropriate to level required in discharged setting (85.3%)**
  - **Met: 61.3%, Not Met: 24%, Missing: 14.7%**
- **Functional status maintained or improved relative to baseline ADL Index score (84.7%)**
  - **Met: 64.2%, Not Met: 20.5%, Missing: 15.3%**

Basic Descriptive Correlations: Activity Intolerance

Medical Patients (*n* = 773)	Mean Age	Mean Functional Score	Mean LOS	Readmission (Mean days)
Patients w/o Activity Intolerance (n = 494)	53.7 ± 18	11.17 ± 1.7 (*n* = 29)	3.8 ± 2.4	10.1% (*n* = 50) (34.8 ± 30.8)
Patients with Activity Intolerance (n = 279)	69.2 ± 16.8	6.1 ± 3.6 (*n* = 133)	6.0 ± 3.6	19.4% (*n* = 54) (27.7 ± 24)

Table 1 shows the significant differences in age, functional activity score, length of stay and readmission rates for those medical patients without activity intolerance (n=494) and those medical patients assessed as having activity intolerance (n=279). Nurses' documentation indicated that functional goals were documented as "met" in a little over 60 percent of the time with missing documented values for about 20 percent of discharged patients. The poorer health indicators for the patient group assessed as having activity intolerance also shows almost double the readmission rate as compared to the patient group without activity intolerance. We will continue to track these outcomes as our analyses evolve and we expand our integration of evidence based nursing in all aspects of nursing operations and culture.

Table 2 presents our approach to the descriptive analyses for nurses' compliance to the evidence-based recommendations within the ACW conceptual framework: general assessment,

focused assessment, nursing intervention, and outcome measurement. Focused assessments were to be performed if further assessments were necessary for a patient based on the findings of the initial general assessment. For example, if a nurse identifies that a patient needed "assistance" for Activity of Daily Living (ADL) prior to the admission, a decision support rule is triggered by the system. Additional assessment factors are then presented for the nurse to examine the level of functional status of the patient.

Table 2 - Nurses' compliance to the evidence-based recommendations related to activity tolerance

Care Component	Percentage of Compliance
Patient Assessment (General)	(*n* = 773)
• ADL's prior to admission	86%
• ADL activity	99%
Functional Assessment (Focused)	(*n* = 279)
• ADL Bathing	48%
• ADL Continence	48%
• ADL Dressing	48%
• ADL Feeding	48%
• ADL Toileting	48%
• ADL Transferring	48%
• ADL Index Score	48%
Plan of Interventions Established	(*n* = 773) 89%
Outcome Measurement	(*n* = 773)
• Activity level tolerated appropriate to level required in discharged setting	85%
• Functional status maintained or improved relative to baseline ADL Index score	85%

These findings show that the nurses were doing initial assessments at nearly 100 percent but completed follow-up assessments at only 48 percent of the time. In addition, while nurses took the next step of activating interventions and documenting against outcome measures at a rate of 85 percent compliance, they predominantly choose to work from a common universal plan of care rather than the specific problem plan of care. Use of the universal plan of care reflected the care approach prior to implementing the EBN plans of care. Thus, we view these behaviors as indications of incomplete clinical adoption by nurses. In summary, lessons learned regarding nurses' clinical adoption indicate a need to reengage with the next rollout phase and give a more concentrated focus on the people and processes portion of the implementation over the technology.

MedInfo 2007

Introduction

- In an ubiquitous healthcare domain, mobile computing system using mobile devices such as mobile phones, personal digital assistants (PDA) are carried nearly everywhere by excellent mobility and ease of accessibility.
- Web services now support a single uniform method for application integration through the Internet at distributed computing environments.
- In this paper, we suggest a healthcare information system that provides medical information on both wired and wireless networks with the following functions.
- First, the system provides medical information used for desktops on wired networks. Second, the system has a mobile context server that reconfigures web contents according to the mobile device.
- The mobile context server applies context to the contents by using styles, an attribute override, and templates according to the resources of a given mobile device.
- In this manner the system support reconfigured web contents to the mobile device.

Materials and Methods

- When a user requests medical information through a wired network, the web server serves the information by connecting to the databases of the web server.
- The mobile context server optimizes web contents according to the type of mobile device. The mobile context server was developed by Micro-soft and is called the Mobile Internet Toolkit. The Mobile Internet Toolkit filters mobile devices and creates “Device Specific/Choice” structure.
- The Device Specific/Choice filter can describe a style according to the browser type by using style sheets. In this system, a page is divided and made up of the select/result structure.

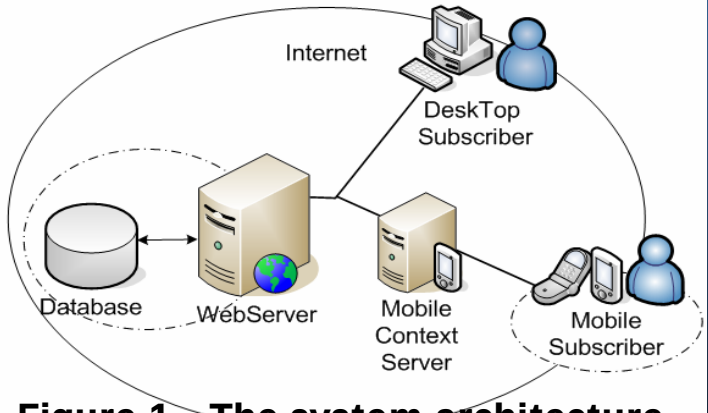

Figure 1 - The system architecture

- The system is conceptually composed of five main components: the web server, medical information database, mobile context server, mobile user, and desktop user.

Materials and Methods

- Using a tightly coupled application development approach provides certain safeguards from quality-of-service, security, privacy, data integrity, and complex transaction processing perspectives as compared to the Web Services architecture .

- After the system evaluates a mobile device's computing capacity, the system serves the web contents based on the context chosen by the mobile context server.

- When a user requests medical information through a wireless network, the mobile context server divides the con-tent pages according to the screen size of the mobile device. It also filters the pages according to mobile devices and then browses the adopted contents from the context server to the mobile web browser.

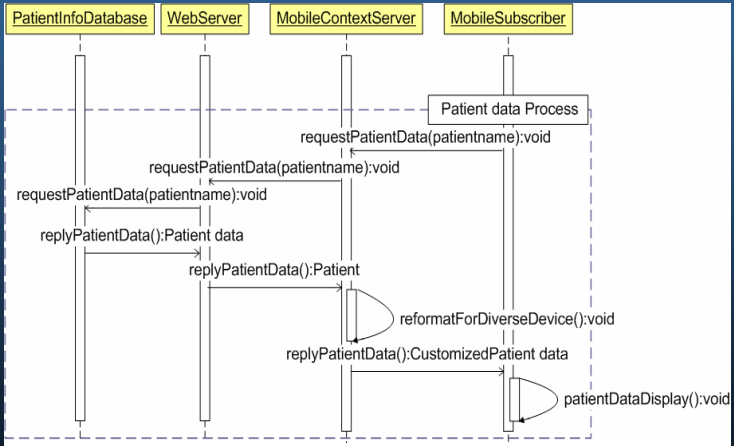

Figure 2 - Web service sequence diagram of a mobile device

- Figure 2 shows web service sequence diagrams of a mobile device.

- The mobile context server reconfigures contents offered by the web sever.

Results

- The web server was served using Microsoft IIS 5.1 and Microsoft Windows XP Professional. Server application was developed by Microsoft ASP.NET based on C# .
- The medical information database was served by Microsoft SQL-SERVER 2000. The context server connected to the web server acted as the web server. The user system served on the wired network was browsed by Microsoft Internet Explorer 6.0.
- The mobile web browsers used in the wireless network were a Microsoft MME 3.0 emulator, Microsoft Pocket PC 2003 PDA, HP i-PAQ H2200, or LG SC8000.

Results

- Figure 3 shows the contents that are displayed on the web browser using a wired network.

- The desktops shown have an adequate screen size, so web contents can be displayed on one screen. In this case, the content consists of the date, patient list, diagnosis, patient information, symptoms, and patient images.

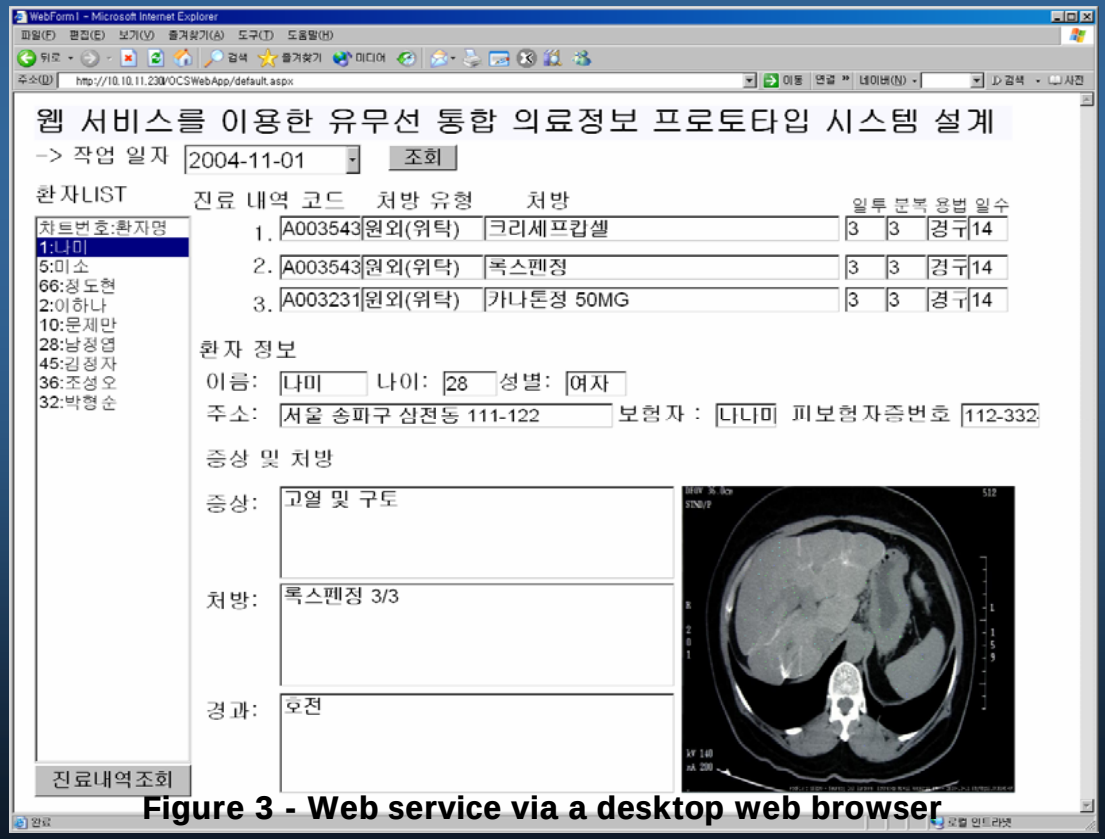

Figure 3 - Web service via a desktop web browser

Results-Experiment I

- This system is suggested to aid in faster diagnosis using medical information on both wired and wireless networks. It displays optimized web contents according to the user's browser resources.

- Figure 4 show the results displayed on a MME 3.0 emulator and HP i-PAQ H2200. This system can display optimized contents on mobile devices determined by the context server.

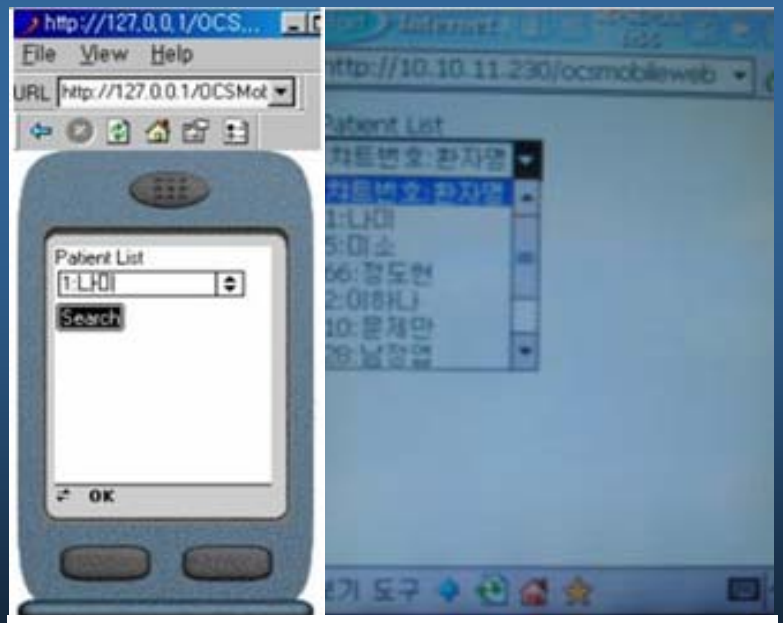

Figure 4 - Patient list page of various mobile browsers

Results-Experiment I

- Figure 5 shows the patient image. This application can enumerated the patient names using combo box control. Because each mobile device has its own screen size, the amount of information that can be displayed differs in each model.

Figure 5 - Patient image information

Results-Experiment II

- Figure 6 shows a divided web page for a mobile web browser. Our system divides the discharged web page into one “choose” page and eight “result” pages with considering the user friendly interface,

- C1 is a choose page of date and patient number. R1 is a result page of diagnosis confirmation. R2 is a result page of past history and present illness. R3 is a result page of physical exam. R4 is a result page of laboratory findings. R5 is a result page of result and plan. R6 is a result page of drug discharged. Finally, R7 is a result page of an MRI image

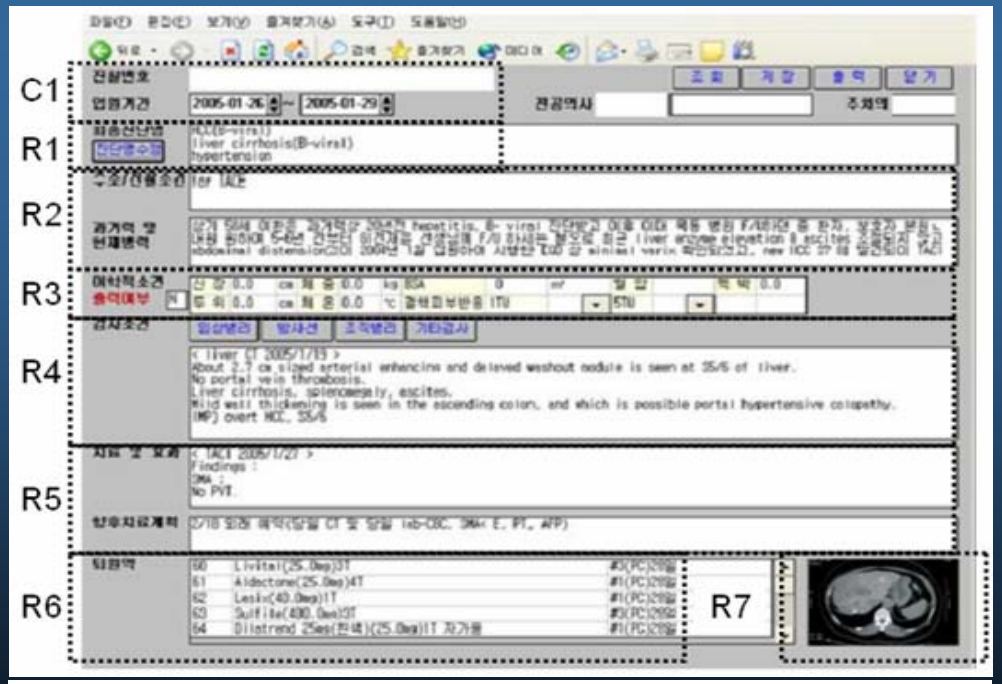

Figure 6- Discharge web page on the Order Communication System

Results-Experiment II

- As a result, the web service is considered an important technology to the healthcare system.
- Our proposed system solves some limits of mobile web services by using a mobile context server that applies context and serves information based on the type of mobile device.
- To develop this system from a prototype to a total healthcare system, additional patient information and research is needed, and a greater compatibility with divisions in dynamic web pages.

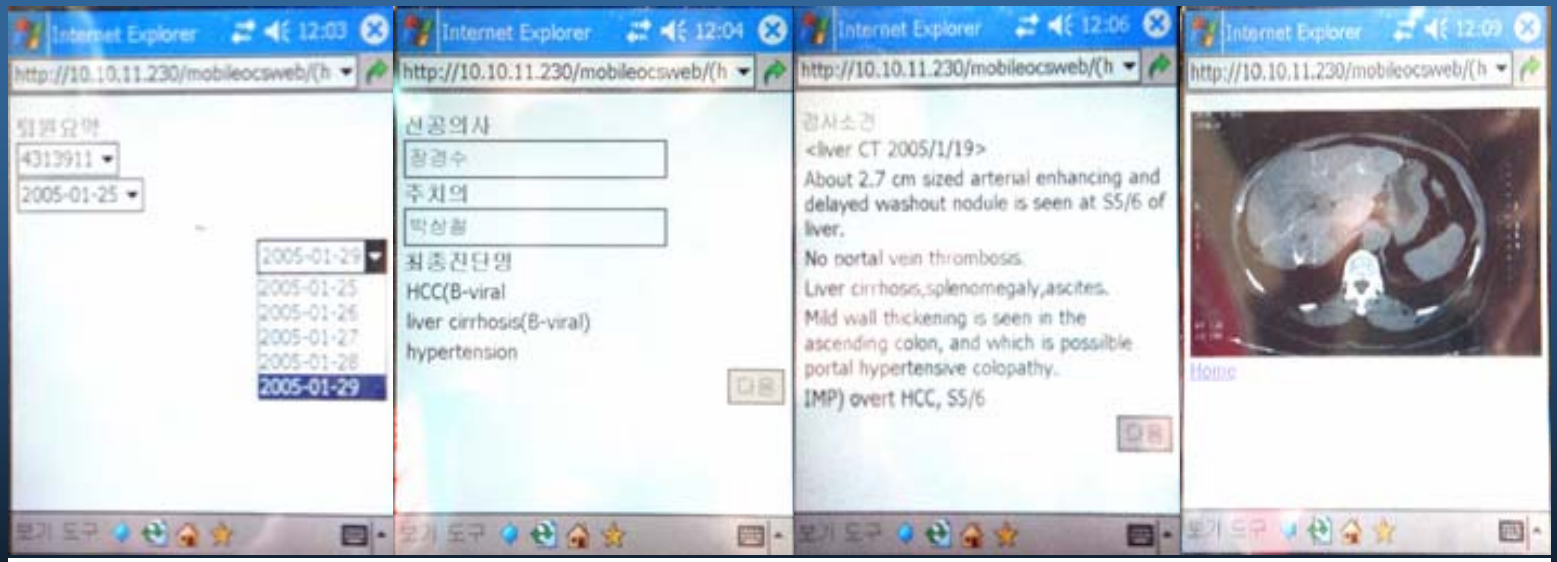

Figure 7. a) Date and patient number, b) Confirmation of diagnosis, c) Laboratory finding, d) MRI image

Discussion

- At present, there are not enough content applications to meet user requirements. Available existing web contents are mainly used for desktops on wired networks, but are not yet compatible with mobile web services.
- This paper suggested a healthcare information support system using Web services for wired/wireless integrated services according to the resources of a given device.
- This system solved some limits of mobile web services by using context server that applies context, and served information based on the type of device. So these results will help to implement effective web based healthcare information system at wired and wireless network environments.
- However, further complement research will be necessary. When regarding particularity of medical information system, enhanced security methods and healthcare information standard have to considered. Maybe HL7 can be one of alternative plan.

Abstract

In an ubiquitous healthcare domain, mobile computing system using mobile devices such as mobile phones, personal digital assistants (PDA) are carried nearly everywhere by excellent mobility and ease of accessibility. This paper suggests a Web Services based healthcare information support system using portable device over wireless and wired network according to the resources of a given device. When a mobile device requires web services, a mobile context server reconfigures and offers the equivalent contents provided by the web server to suit the required device's resources.

Keywords:

healthcare, wireless, mobile, web service

Introduction

Web services now support a single uniform method for application integration through the Internet at distributed computing environments. In particular, they provide a model for accessing software systems over the web by pointing to their web address (URI), while their public interfaces and bindings are defined and described using an XML standard format. Mobile web services have the following features: interoperability of web services for desktop, internet compatibility, convenient use with small mobile devices, and mobility.

Materials and methods

We presented an overview of the system architecture and the healthcare web service processes at Figure 1. The system is conceptually composed of five main components: the web server, medical information database, mobile context server, mobile user, and desktop user. The web server served medical information for mobile devices on both wired and wireless networks using WSDL (Web Service Description Language) to describe functions and protocols. Figure 2 shows web service sequence diagrams of a mobile device. The mobile context server reconfigures contents offered by the web sever.

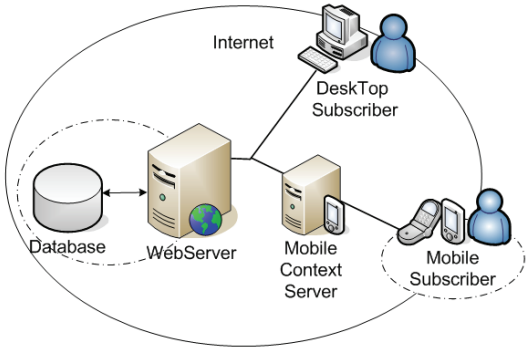

Figure 1 - The system architecture

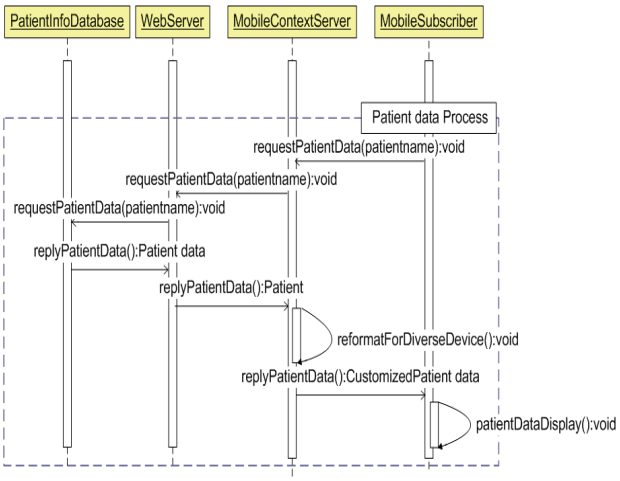

Figure 2 - Web service sequence diagram of a mobile device

The proposed system is not based on loose coupling that is open to UDDI (Universal Description Discovery and Integration) sending and receiving SOAP messages, but rather a tight coupling of a client and server. Using a tightly coupled application development approach provides certain safeguards from quality-of-service, security, privacy, data integrity, and complex transaction processing perspectives as compared to the Web Services architecture. After the system evaluates a mobile device's computing capacity,

the system serves the web contents based on the context chosen by the mobile context server. When a user requests medical information through a wireless network, the mobile context server divides the content pages according to the screen size of the mobile device. It also filters the pages according to mobile devices and then browses the adopted contents from the context server to the mobile web browser.

Results

This system is suggested to aid in faster diagnosis using medical information on both wired and wireless networks. It displays optimized web contents according to the user's browser resources. Figure 3 shows the contents that are displayed on the web browser using a wired network. The desktops shown have an adequate screen size, so web contents can be displayed on one screen.

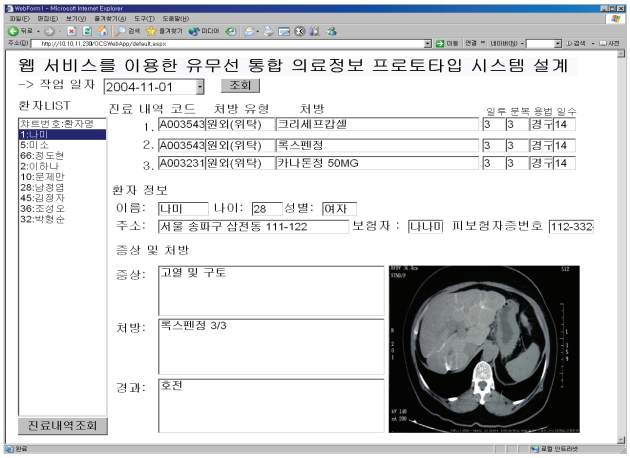

Figure 3 - Web service via a desktop web browser

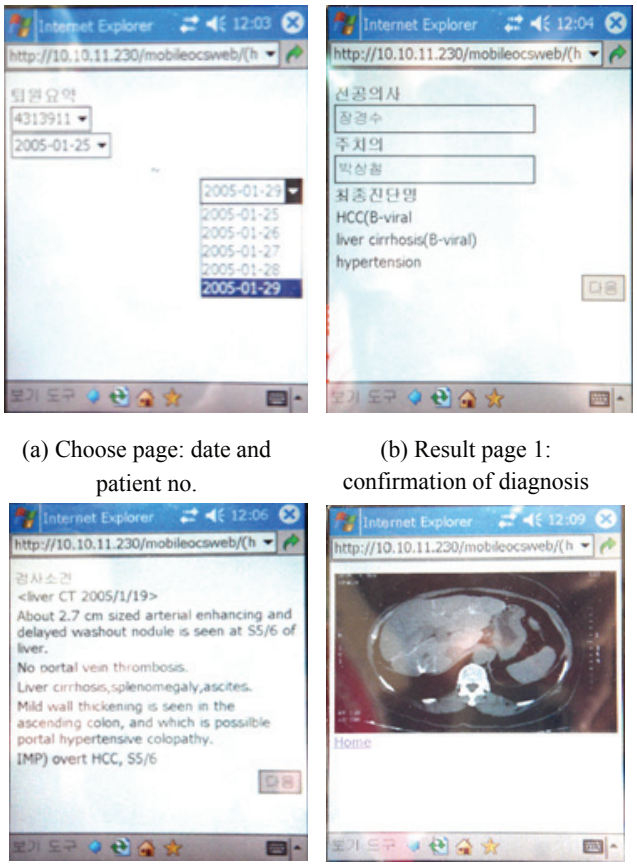
The web server was served using Microsoft IIS 5.1 and Microsoft Windows XP Professional. Server application was developed by Microsoft ASP.NET based on C#. The medical information database was served by Microsoft SQL-SERVER 2000. The context server connected to the web server acted as the web server. The user system served on the wired network was browsed by Microsoft Internet Explorer 6.0. The mobile web browsers used in the wireless network were a Microsoft MME 3.0 emulator, Microsoft Pocket PC 2003 PDA, HP iPAQ H2200, or LG SC8000.

Figure 4 shows the discharge mobile web pages displayed on a HP iPAQ H2200. This paper suggests an healthcare information support system using Web services for wired/wireless integrated services according to the resources of a given device. The web service is internet friendly, interoperational, and compatible with fire walls. As a result, the web service is considered an important technology to the healthcare system. Our proposed system solves some limits of mobile web services by using a mobile context server that applies context and serves information based on the type of mobile device. Our proposed system is a prototype based on a wired/wireless network. To develop this system from a prototype to a total healthcare system, additional patient information and research is needed, and a greater compatibility with divisions in dynamic web pages.



(a) Choose page: date and patient no.

(b) Result page 1: confirmation of diagnosis

(c) Result page 4: Laboratory finding

(d) Result page 7: MRI image

Figure 4 - Discharge mobile web pages on a mobile device

Discussion

This system solves some limits of mobile web services by using context server that applies context and serves information based on the type of device. So these results will help to implement effective web based mobile health care system. But we think that further research will be necessary.

When regarding particularity of medical information system, security and information standard problem is very important things. Therefore, point of further research must be medical information standard and security. HL7 could

be one of alternative plan. Although security problem was considered in this research, we think that web security must be intensified. Because patient's personal information and other medical data's secrecy is very important. So we will perform aggressive research about web security problem.

To develop this system from a prototype to a total medical care information and research is needed. The system requires greater compatibility with divisions in dynamic web pages.

The Mobile Phone and Health – Results from a Literature Survey

Günter Schreier

Austrian Research Centers GmbH – ARC, Biomedical Engineering, eHealth systems, Graz, Austria

Abstract

Due to its ubiquitous availability and rapid technological advancement the mobile phone (MP) has been considered and evaluated for many applications beneficial to health. On the other hand, MP use has raised concerns related to possible adverse health effects like interference with and exposure to electromagnetic fields or distraction during driving. The aim of the present study has been to elucidate and quantify the relationship between research on potentially beneficial and adverse effects of MPs on health by means of a literature survey. Results show that relevant publications increased steadily since the 1990's, initially dealing mostly with potentially adverse effects. Publications on beneficial effects started to increase since the late 1990's and amount to approximately 20% of all publications since 2004. Upcoming technologies and still rapidly increasing numbers of MP users are likely to further increase research within the full spectrum of supposedly beneficial and adverse health effects of MP use.

Keywords:

mobile phone, eHealth, telemedicine, health risk

Introduction

Patient empowerment is one of the top priorities among the many hopes and chances the eHealth era is expected to bring for future healthcare [1]. Placing patients in the center of the healthcare system and providing them with tools and knowledge to manage their health and health related data is considered to be essential in facilitating prevention and improving the outcome of treatment.

Due to its ubiquitous availability and rapid technological advancement the MP is poised to be the universal information and communication toolbox for a steadily increasing portion of the worlds population, both in the developed and the developing parts of the world. MPs have, therefore, the potential to serve as a universal eHealth terminal.

As a consequence, MPs have been used and evaluated for health applications by numerous authors. Likewise, we demonstrated the benefits of MP use for the management of patients with chronic diseases [2] and cardiological teleconsultations [3] together with clinical partners.

On the other hand, MP technologies have also raised concerns related to possible adverse health effects. Initial research occurring during the early 1990's assessed health risks in the following categories:

1. distraction during using and handling MPs, e.g. traffic accidents,
2. the impact of electromagnetic fields on medical devices, i.e. electromagnetic interference (EMI),
3. exposure of humans to electromagnetic fields associated with MPs.

A systematic comparison of both, adverse and beneficial effects of MP technology, however, is lacking. The aim of the present study has been to elucidate and quantify the relationship between research on potentially beneficial and potentially adverse effects of MPs on health by means of a literature survey.

Methods

The impact of MPs with respect to health related issues was assessed by querying the PubMed database [4] with the following search phrase:

"(mobile [ti] OR cellular [ti] OR cell [ti]) AND (phone [ti] OR phones [ti] OR telephone [ti] OR telephones [ti])"

so as to find any citation containing at least one of the various expressions for "mobile phone" in the title string.

The received citations were classified based on the title and - if necessary and available - the abstract as belonging to one of the following main categories:

1. **Adverse**: article clearly deals with potentially adverse effects of MPs on health
2. **Beneficial**: article clearly deals with potentially beneficial applications of MPs to improve health
3. **Other:** Undefined (title and abstract are inconclusive), Irrelevant (article not specifically associated with health), and Duplicate (article relates to a preceding article which had already been classified)

Results

A total of 814 citations have been obtained and examined (last PubMed access update on Nov. 28th, 2006).

The evolutions of the frequencies of articles over time are depicted as histograms for citations on adverse and beneficial effects in Figure 1.

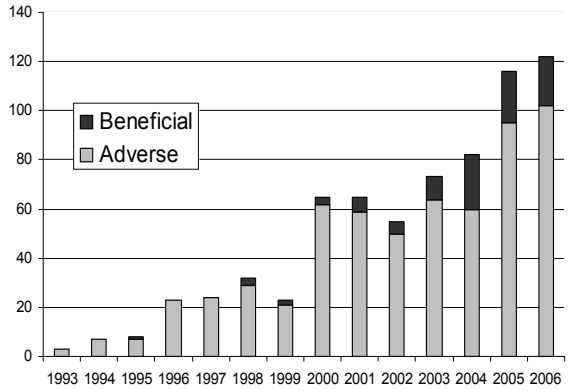

Figure 1 - Annual numbers of citations dealing with adverse (lower and light part of the bars) and beneficial effects (upper and dark part of the bars) of MPs on health

Discussion

Figure 1 indicates that Publications on the health impact of MPs actually started in the early 1990's and increased in a more or less linear way during the subsequent years. Initially, there were mostly publications on potentially adverse effects. Consistent publication activities on beneficial effects started in the late 1990's, increased until 2003 moderately and leaped to higher levels beginning with 2004. In recent years such publications amount to approximately 20% of all publications considered by this survey.

The presented survey includes only articles listed on PubMed. There are – of course – additional articles dealing with this issue, e.g. articles being associated with the author [3], including articles that would actually have satisfied the search phrase but are not listed on PubMed [5]. Hence, the list is far from being complete and no conclusions can be drawn in terms of absolute numbers.

Since the survey was concluded at the end of November 2006, the numbers for the year 2006 do not yet include December and are therefore underrepresented.

It has to be emphasized that this survey did not attempt to assess details of the outcome of the many articles, neither with respect to adverse nor beneficial effects. Other than a review, this survey did not intend to answer questions like "what is the odds ratio of using MPs with respect to a certain cancer?" or "does MP based home monitoring reduce the frequency of hospital admissions in heart failure patients?". Since for many – in particular older – articles only the title is available on PubMed, a detailed analysis with respect to the outcome would require an additional (probably enormous) effort.

This survey specifically aimed at assessing the interest of the scientific community in all health related effects of MP usage, not only in a particular class or sub-class of effects. To the author's best knowledge such a survey has not yet been performed. This notion is supported by the fact, that in the present sample, no article has been found which covered both, adverse and beneficial aspects of MP use.

Conclusions

Today's MPs provide a large portion of the world's population with an ever more powerful communication tool. With respect to health, MPs were already shown to have both adverse and beneficial aspects – as can be expected from any kind of effective technology. After initial research focused mainly on the risk aspects of MP use, during the last years an increasing number of investigations concentrated on potential benefits.

Upcoming technologies and capabilities and a still rapidly increasing number of MP users will warrant continued and new research within the full spectrum of possible risks and benefits of MP use with respect to health.

Identifying Visually Lossless Image Compression Levels For A Regional Scale Digital Radiological Image Distribution

WN Wong[a], NT Cheung[a], ACH Sek[a], V Fung[a], A Tong[a], William Chan[b], Amber Lam[b], CP Wong[c]

[a] Health Informatics Section, Hong Kong Hospital Authority, HKSAR
[b] Information Technology Department, Hong Kong Hospital Authority, HKSAR
[c] Clinical Informatics Program Executive Group, Hospital Authority, HKSAR

Abstract

This experimental study determined visually lossless image compression levels for 3 common digital radiological image modalities: Xrays, computerized tomography (CT) and magnetic resonance imaging (MRI). Compressed images of 17 different radiological pictures using JPEG lossy compression algorithm at different compression quality factors were rated by 160 clinicians from various clinical specialties using original-revealed side-by-side comparison method. Image quality of each testing image was rated as compared with the original image. The visually lossless compression level of each testing image was identified by the threshold of visible image quality deterioration. This study demonstrated that most radiological images could be moderately compressed with image quality well preserved. Visually lossless image compression levels for different image modalities were: Xray: Q10 (1:34-1:89); MRI: Q50-40 (1:6-1:14); CT: Q80-50 (1:8-1:13). The knowledge of visually lossless compression helps to reduce the data volume and network loading, which were critical for effective enterprise-wide radiological image distribution.

Keywords:

compression ratio, visually lossless,
image compression, JPEG, PACS

Introduction

Image compression has been advocated for effective large scale PACS implementation [1-2]. This study aimed at identifying the visually lossless image compression levels of three common radiological image modalities using JPEG compression.

Methods

This study evaluated the image quality of 17 radiological images including 6 Xrays (2 PA Chest Xray; 2 Lateral lumbosacral spine Xray; 2 AP abdominal Xray), 7 computerized tomography (CT) (2 Horizontal slice CT brain; 2 Horizontal slice CT thorax, 3 Horizontal slice CT abdomen) and 4 magnetic resonance imaging (MRI), 3 Horizontal slice MRI brain; 1 Saggital slice MRI spinal cord) at different JPEG (12-bit) compression ratios in a clinical environment by 160 clinicians from different specialties. Image quality of each compressed image was evaluated by original-revealed side-by-side comparison method [3]. Relative image quality of each testing image as compared to the "original" image was rated on a 4 point scale (3=no visible difference; 2= slightly poor; 1=moderately poor; 0=significantly poor). The image evaluation interface is shown in Figure 1. The mean image quality score of each was calculated. Any difference in the image quality between the original and testing image was identified by ANOVA post hoc analysis. Visually lossless image compression levels of various image modalities were identified by comparing the relative image quality of images compressed at different compression levels and identifying the thresholds of visible image quality deterioration.

Results

Relative image quality of different image at different compression levels are presented in Figures 2 to 4**.**

For Xrays, the difference of image quality was not statistically significant even up to maximum compression of Q10 quality factor (p=0.35-1.0) with a corresponding compression ratio of 1:32-1:89. For MRI, the image quality of images was maintained until reaching Q10-Q20 quality factor with compression ratio 1:7-1:18 ($p<0.001$). The image quality of all CT images dropped significantly past compression Q30-Q70 ($p<0.001$-0.02) with compression ratio 1:9-1:14.

Visually lossless image compression level thresholds for different image modalities were: Xray: Q10 (1:32-1:89); MRI: Q30(1:6-1:12); CT: Q80 (1:7)

Discussion

Clinically acceptable compression levels have been the focus of many studies worldwide. It has been shown that image quality deterioration can be tolerated without affecting diagnostic accuracy [4]. Similar studies using receiver

operating characteristic analysis have shown that diagnostic performance can be well preserved despite noticeable compression artifacts [5-8]. Although high level of compression could allow substantial cost savings, it has seldom been applied in real clinically situations and the presence of perceivable artifact reduces acceptance amongst skeptical clinicians and radiologists. In this study, another approach was adopted to determine more conservative thresholds - "visually lossless" compression levels. Although the identified visually lossless compression ratios were dependent on the images selected and the image viewing condition, monitor grade and size, they provide practical information for applying image compression in clinical settings.

Conclusion

Most radiological images could be moderately compressed with image quality well preserved. The knowledge of the visually lossless image compression of various images allows a great reduction in data volume and network loading to an affordable level for effective image distribution on a regional based network

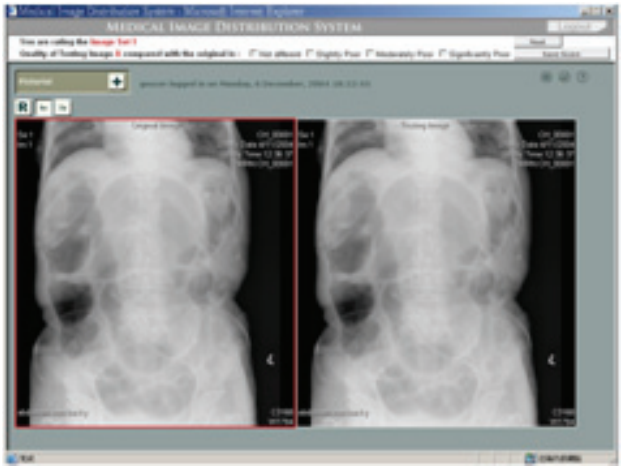

Figure 1 - Showed the image web browser for image quality evaluation. Original uncompressed image was shown on the left while testing image on the right

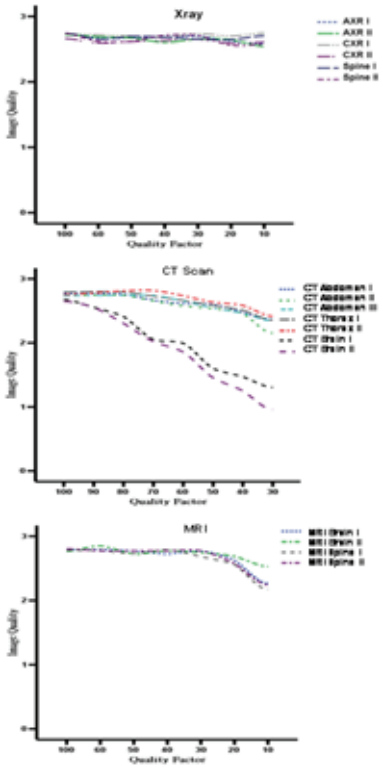

Figure 2 - Showed the image quality of Xrays, CT scans and MRI scans at different quality factor compressions. Image quality of different testing images compressed at different quality factors was evaluated on 4 points scale (3=not different, 2=slightly poor, 1=moderately poor and 0=significantly poor)

Extraction of White Matter Connectivity in the Human Brain Using the Projected Diffusion-Tensor Distance

Tetsuo Sato[a], Kotaro Minato[a]

[a] *Graduate School of Information Science,Nara Institute of Science and Technology, Ikoma, Nara, Japan*

Abstract

Diffusion tensor imaging (DTI) has become a powerful tool for analyzing the structure of white matter. We have already developed a novel method to assess white matter connectivity using diffusion tensor distance between neighborhood voxels. Diffusion tensor distance is defined as the length from the center to the surface of the diffusion tensor. In the proposed method, we use directional diffusion measurements to infer regional white matter connectivity. To assess the connectivity, we investigate the method using the iterative algorithm. By the algorithm, we can segment typical white matter trajectories such as Corpus Callosum. Compared with other algorithms using eigenvalues of the diffusion tensor, our approach has flexibility in selecting connected regions by using basic characteristics of the diffusion tensor shape.

Keywords:

diffusion tensor, MRI, anisotropy, white matter, connectivity

Introduction

Recently, the study of brain function has received much attention and in vivo detection of the structure of deep brain white matter has become more important. Conventional Magnetic Resonance Imaging (MRI) methods, however, cannot detect them. With the development of the devices and techniques of MRI, we can measure the diffusion of water molecules. This technique is called Diffusion Weighted Imaging (DWI). In DWI, the area where the degree of diffusion is large shows as dark and where the degree of diffusion is small shows as bright. Using such images, we can obtain MR diffusion tensor maps. Particularly in white matter, the diffusion varies very much. The value and orientation of the diffusion are directly related to the interaction between nerve bundles and magnetic gradients. This is known as the diffusion anisotropy. Namely if the nerve bundles are perpendicular to the magnetic gradient, we can obtain the minor diffusion coefficient. Conversely if the nerve bundles are parallel to it, we can obtain the major one.

In this study, directional diffusion measurements are used to infer regional white matter connectivity. The connectivity is determined as a function of distance between the origin of the tensor and the surface for each voxel. With the iterative algorithm, we can segment typical white matter trajectories such as Corpus Callosum and Internal Capsules. This approach is different from other methods that use the principal eigenvector or full tensor. Here, a novel method for labeling and segmenting white matter connectivity using DT-MRI is described.

Methods

Diffusion tensor images are acquired on a 1.5 T Signa MRI system (GE). Echo planar images are acquired on a subject in the axial plane at 36 slice locations. The six dimension weighting was done and the maximum b value was 1014 sec/mm2. Other parameters were Echo Time (TE) =78 msec, Repetition Time (TR) =7000 msec, slice thickness=3 mm, image matrix=256x256 pixels (zero filling), in plane resolution=1 mm.

First, the algorithm is started from a specified point in a slice. Second, an iteration method is used to select multiple neighborhoods

We consider the normalized distance potential by multiplying the in-coming and out-going distance divided by trace (D),

$$\varphi_i = \vec{x}_i^{\,t} \boldsymbol{D}_i \vec{x}_i FA_i \vec{x}_j^{\,t} \boldsymbol{D}_j \vec{x}_j FA_j \Big/ TRACE(\boldsymbol{D}_i) TRACE(\boldsymbol{D}_j) \quad (1)$$

where i indicates the reference, j indicates the neighborhood.

In Fig. 1, the searching algorithm is performed for all eight 2-D neighborhoods (26 neighborhoods in 3D). In this case, we start from the center as a reference. Left-up, up, down, right-down voxels are the subsequent references. We continue searching until visiting the previous reference.

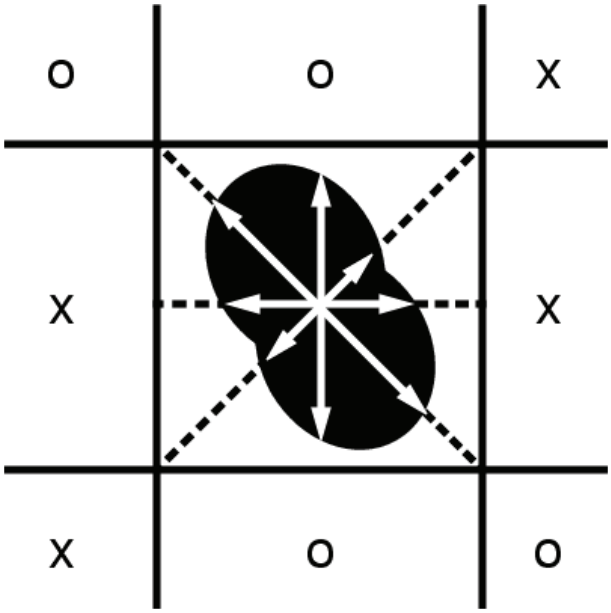

Figure 1 - Concept of threshold distance and iterative searching (o are candidates of next step (to be references) and x are discarded)

Results

In Fig. 2, we show the result of iterative algorithm superimposed on corresponding FA images for a single subject. The starting point is on major fiber trajectories such as Corpus Callosum and Internal Capsule.

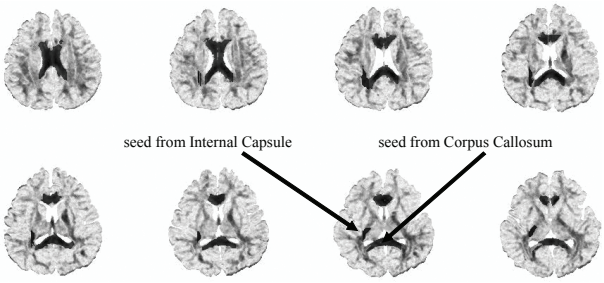

Figure 2 - Result of an iterative algorithm superimposed on corresponding FA images (8 contiguous slices: dark regions are seeding from Corpus Callosum and Internal Capsule)

Discussion

The result of the algorithm depends on the threshold value. For example, we used threshold 2.1 in Fig. 2. It is important to determine the value statistically and automatically. And the anisotropy of voxel size should also be improved. We are now investigating the effect of interpolation on the accuracy of the results.

We also have a plan to verify the feasibility of our method by way of adding noise simulation. The estimation of the effect of noise will be important before using the method in clinical studies.

These results are promising for connecting and segmenting specific white matter regions. The segmented volume may be used to constrain white matter tracking algorithms. The results here are preliminary and will require more work. We show that the iterative algorithm is refined further considering the interaction between the outgoing and incoming directions.

Conclusion

In this study, we propose methods to assess the white matter connectivity using projected diffusion tensor distance. This algorithm is different from other tracking methods and has potential to be used in combination with traditional tracking algorithm. The algorithm is iterative and consists of two steps. We can also use the result to analyze the connectivity quantitatively and statistically. Information derived from the result is important and necessary to obtain the structure of the white matter and it will enhance the study of human brain function.

Introduction

- MRI is important modality for imaging human brain function and structure
- With the development of devices, we can measure diffusion of water molecules (Bihan et al. 1986)
- Using diffusion tensor maps, we can obtain structural information of nerve bundles in white matter (Moseley et al. 1990)

Aim

- Obtain structural information of white matter trajectories
- Enhance and detect nerve bundles

Qualitative analysis of white matter trajectories

Apply the result to the statistical test of human brain function

Diffusion Coefficients

- Diffusion coefficients calculated from diffusion weighted images are reflecting the relative direction between diffusion gradient and fiber trajectories
  - Parallel measurements along a trajectory
    - High coefficient
  - Perpendicular measurements along a trajectory
    - Low coefficient

Diffusion Tensor

$$\begin{pmatrix} D_{xx} & D_{xy} & D_{xz} \\ D_{xy} & D_{yy} & D_{yz} \\ D_{xz} & D_{yz} & D_{zz} \end{pmatrix} \rightarrow \begin{pmatrix} e_1 & 0 & 0 \\ 0 & e_2 & 0 \\ 0 & 0 & e_3 \end{pmatrix}$$

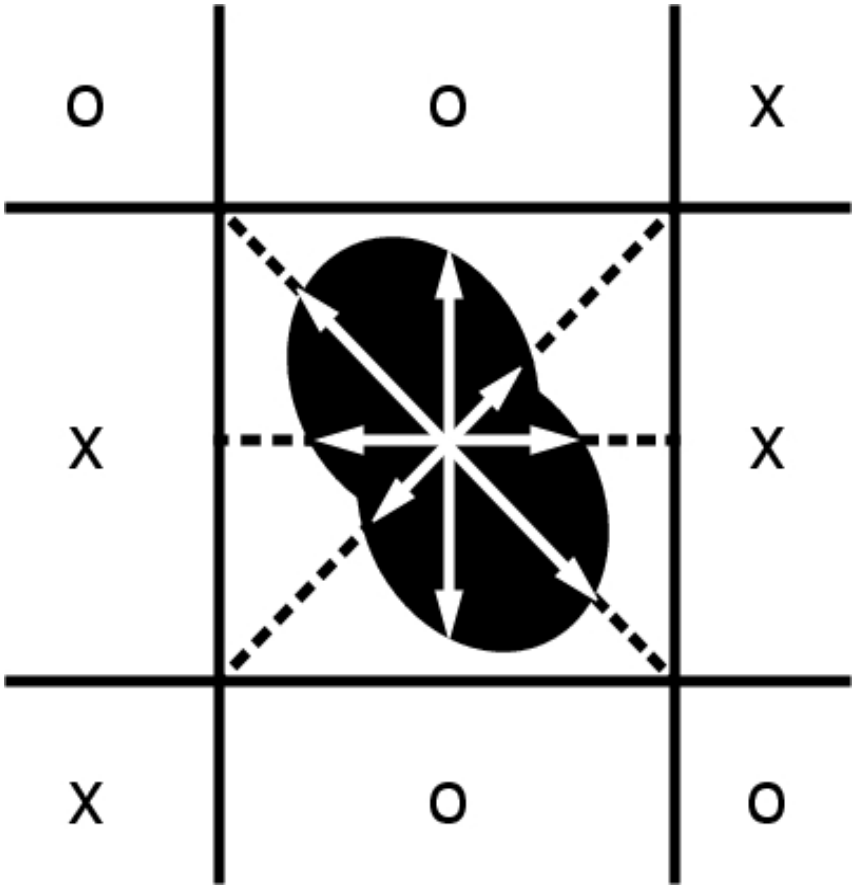
Diffusion tensor whose components are from diffusion coefficients

- Eigenvalues
  - Principal（e_1）, second（e_2）, third（e_3）
- Principal eigenvector
  - X, Y, Z components
- Fractional anisotropy（FA）

Diffusion Distance Analysis

- The connectivity is determined as a function of distance between the origin of the tensor and the surface for each voxel
- This approach is different from other methods that use the principal eigenvector or full tensor

Iterative Algorithm



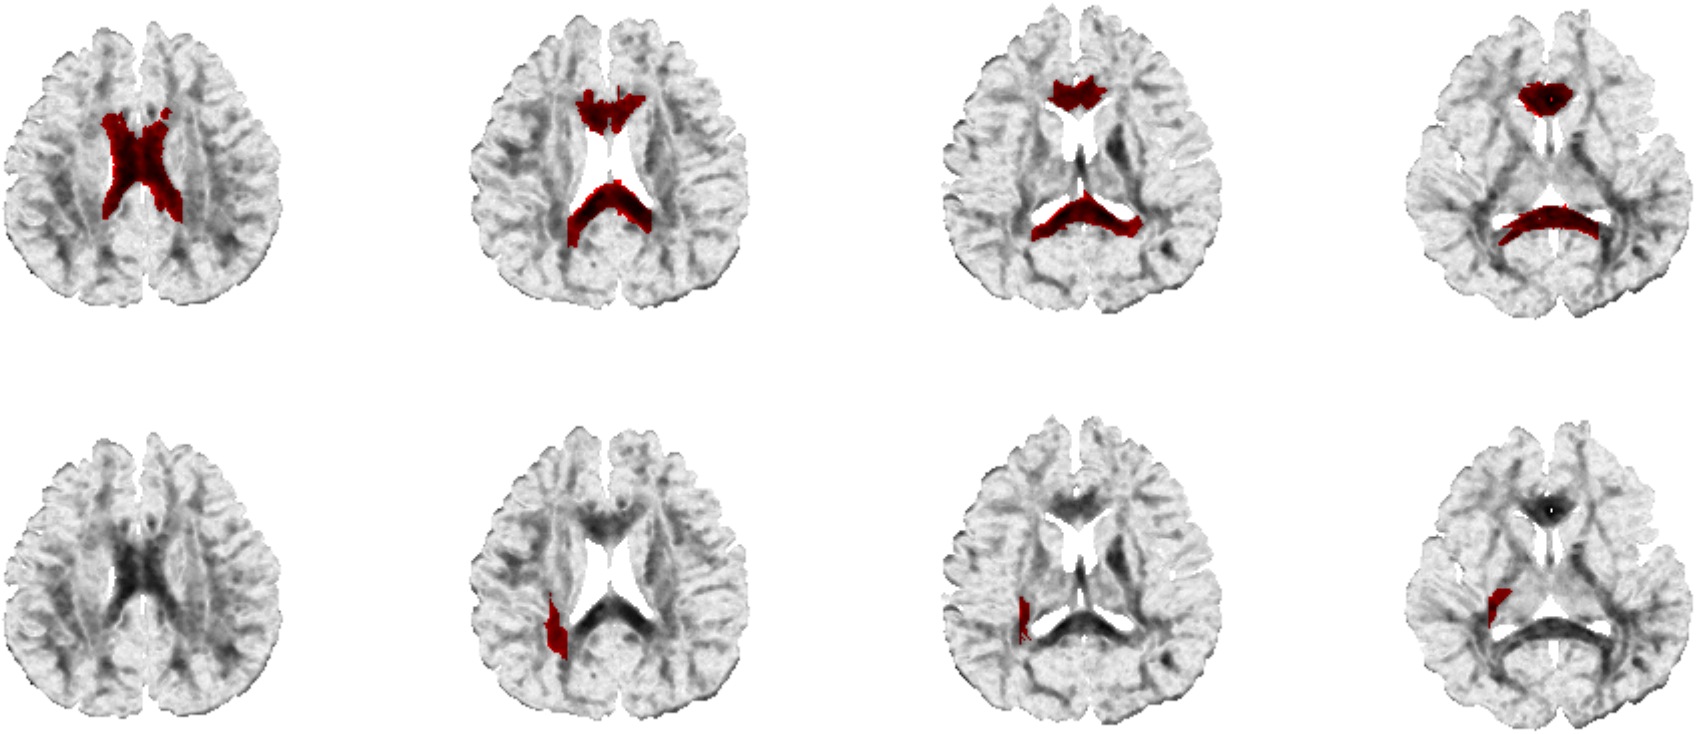
- Start from the center in the left, next check right-up, up, left-up, right-down, down, left-down iteratively
- Continue searching until visiting the already tracked voxel again

Distance Potential

$$\varphi_i = \{\vec{x}_i{}^t D\vec{x}_i / Trace(D_i)\}\{\vec{x}_j{}^t D\vec{x}_j / Trace(D_j)\}$$

- Consider the normalized distance potential combining by the in-coming distance and the out-going distance divided by its trace (D)
- Where i indicates the reference, j indicates the neighborhood

Result



Result of an iterative algorithm superimposed on cor-responding FA images

(8 contiguous slices: dark regions are seeding from Corpus Callosum and Internal Capsule)

Discussion

- The result of the algorithm depends on the threshold value
- To determine the value statistically and automatically is important
- To verify the feasibility of our methods by way of adding noise simulation will be important before using the method in clinical studies

Conclusion

- In this study, we propose a method to assess the white matter connectivity using projected diffusion tensor distance
- Proposed algorithm is different from other tracking methods and has potential to be used in combination with conventional tracking algorithm

[b] *Head and Neck Diagnostic, Department of Craniomaxillofacial Surgery, University Freiburg, Germany*

Abstract

Fractures of the orbital floor are within the most frequent in craniomaxillofacial surgery. For surgical reconstruction, the orbital volume must be restored exactly to maintain the vision abilities of the subject. In this paper, we present an automatic segmentation and volume determination of human orbit based on a general discrete contour model applied to CT volumes of the skull. The coefficient of variation for manually placed start points is below 2%. The system is evaluated based on six subjects, where the difference between left and right eye- assumed to be zero – is determined experimentally. Here, the mean variation is 1.52%. Therefore, our method is sufficiently robust and applicable for surgery planning and follow-up studies.

Keywords:

surgery planning, orbit reconstruction,
image processing, active shapes, segmentation,
quantitative measurements

Introduction

Just after fractures of the mandible and the zygomatic bone the fracture of the orbital floor is the most frequent one in craniomaxillofacial surgery [1]. It is often diagnosed as an isolated blow-out-fracture or in combination with a fracture of the zygomatic bone. As much as 40% of all midface fractures are associated with defects of the orbital floor. This leads to a descent of the orbital soft tissues and a consecutive increased orbital volume [2]. Moreover the bulb of the affected eye moves towards a more inferior and posterior position which leads to double vision or diplopia, which causes visual impairment and thus a high economic deficit [3]. According to our investigations, 58% – 86% of all blow-out-fractures and 13% – 20 % of all midface fractures seem to be associated with diplopia.

In most cases, the smallest fragments are not subject to a reposition via osteosynthesis. The medial wall of the orbit and the transition to the orbital floor are frequently affected. The current standard procedure comprises an insertion of an alloplastic foil or a titan mesh via a transconjunctival approach [4,5]. Regarding defects smaller than 2cm², the use of a resorbable alloplastic membrane is recommended [6].

The treatment of fractures of the orbital floor and the medial wall of the orbit is still a big issue in craniomaxillofacial surgery [7]. However, there is still no solution for an exact determination of the orbital volume in case of fractures of different orbital walls.

Automated segmentation of osseous structures of the midface from acquired CT data sets is yet unsatisfying, because typical partial volume effects according to the CT data lead to discontinuities in the virtual reconstruction. Further difficulties result from the distinct recalculation of an anterior and posterior border of the orbit, which is unavailable up to now. Only distinct borders can describe a self-contained volume which can be compared to the unaffected side or with standard values. The lack of reliable segmentation procedures becomes crucial if individual preformed titanium meshes are used for reconstruction of orbital fractures [8].

Unsupervised image segmentation is one of the major challenges in medical image processing [9,10]. In this paper, we apply an general discrete contour model [11] for automatic segmentation and measurement of orbit volumes. The method is evaluated based on six healthy subjects.

Materials and methods

Subjects and image data

Based on the image data obtained at the Department of Craniomaxillofacial Surgery, University Freiburg, Germany, six subjects without orbit fractures were selected and included in this study. Computed tomography was performed using a Siemens sensation 64 scanner (Siemens Medical Solutions, Forchheim, Germany), with 120 kV at 82 mA. Anisotropic volumes were obtained with 1 mm slice thickness and a spatial resolution of 512 x 512 voxel in $x - y$ direction. The number z of slices varied between 139 and 261 (Table 1).

The discrete contour model

For the segmentation of the orbit, a general contour model was applied to the three-dimensional (3D) data [11]. In two dimensions, the contour is represented by a simplex mesh, i.e. by vertices and edges. The segmentation proceeds iteratively, taking into account different powers to calculate the configuration of the next step. In each step, vertices

may be deleted, because they are located too close to each other, and others maybe inserted to reduce the distance between two vertices. In contrast to other active contour approaches, the vertices are not limited to positions within the slices.

The effecting powers are pressure, deformation and external influences. When these three powers reach an equilibrium a vertex is fixed.

- *Pressure* stays constant during the entire segmentation process and therefore constantly moves the vertices towards the searched edges. The start configuration of a contour can be a minimal sphere around a given starting point or a mesh along the outside border of the image space. In the first case, pressure is a positive power pressing vertices towards the outside, and in the second case, the pressure pulls vertices towards the inside.
- *Deformation* prevents the contour from accepting too sharp bends. It is calculated modeling the properties of biological membranes.
- *External influences* are derived from the individual CT data. In contrast to other active contour approaches, external influences regionally depend on the Hounsfield Units of the neighborhood of the considered vertex and the edges between the vertices.

This 3D model can be compared to a balloon, which is slowly blown up inside an image. For further details to this model, which was generally developed for two, three and four dimensions, see [1].

Segmentation of the orbit

When adapting the general model to the orbit, several difficulties occur. To facilitate further processing, images are smoothed (Fig. 1a) and binarized (Fig. 1b) such that only bone structures receive gray value 255 (white) and everything else gray value 0 (black). Resulting from the normilazed nature of CT Hounsfield Units, the perfect threshold varies only little between different image series and is regarded as constant.

The main problem is that the orbit is not cohesive. The front is completely open and it is not obvious where the segmentation should end. The images do not clearly display a limit between orbit and the surface of the face. Two methods have been applied to artificially insert a limit. Both work on the two dimensional slice images.

First, the orbit is closed by a straight line connecting the nasal bone with the cranial bone bordering the orbit (Fig. 1c). The nasal bone is identified as the first white pixel in the image when testing row by row from front to back. Then a straight line is tilted left and right from this point, until it touches another white pixel. The entire area above these lines is filled white to mark the new limit.

A second strategy applies two dimensional segmentation of cranial bones with the same active contour model as later used for the segmentation of the orbit. Here, however, the segmentation starts with a mesh on the outside image border and slowly encloses the cranium (Fig. 1d). The deformation power is high to prevent the contour from entering the orbit. The maximal distance between two vertices in the contour is small to assure that the thin bone structures around the orbit are recognized and cannot slip through between two vertices. The external influences are highly weighted, because in the binarized image a white pixel stands where bone was with high certainty and vertices near bone should be fixed immediately. Once the segmentation identified an area as the cranium, everything outside this area is filled white in the original binarized image.

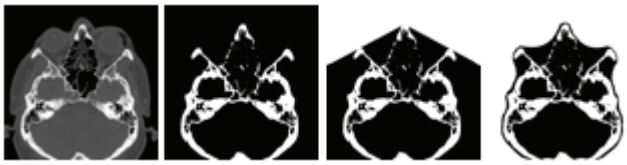

Figure 1 - Noise reduction, binarization, linear,and contour-based outer boundary of the orbit

The opening at the front of the orbit is not the only one, but there are several canals in the back of the orbit. Furthermore, the ethmoid bone between both orbits is extremely thin, and is not always visible cohesively. These difficulties must be overcome by suitable parameterization. Deformation cannot be chosen too high because the orbit becomes narrow to the back. The external influences must be set rather high to identify bone structures accurately. Pressure comes from the inside, but is of no relevance here. Far more important is the manual choice of a starting point, which is placed manually in the center of the orbit. However, this step can easily be easily performed automatically using the a-priori knowledge of the general geometry of the human skull.

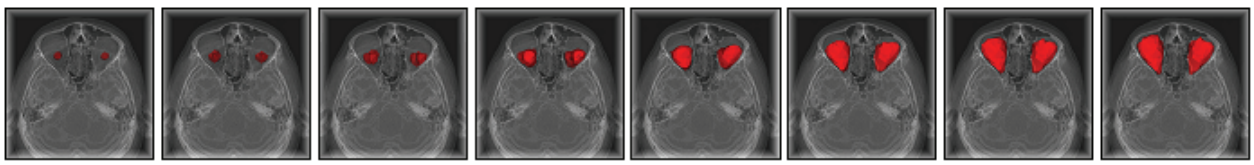

Figure 2 - Iterative orbit segmentation using a 3D balloon model

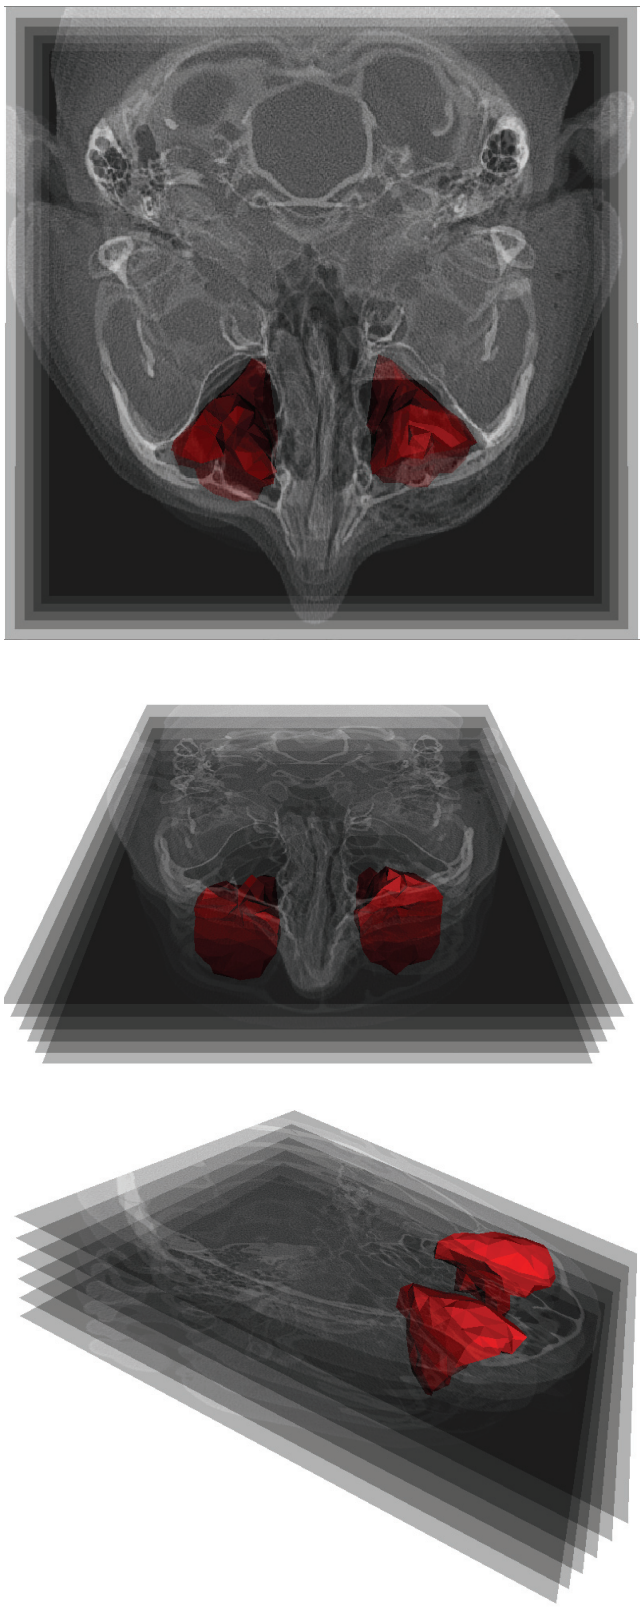

Figure 3 - Results on Subject 1

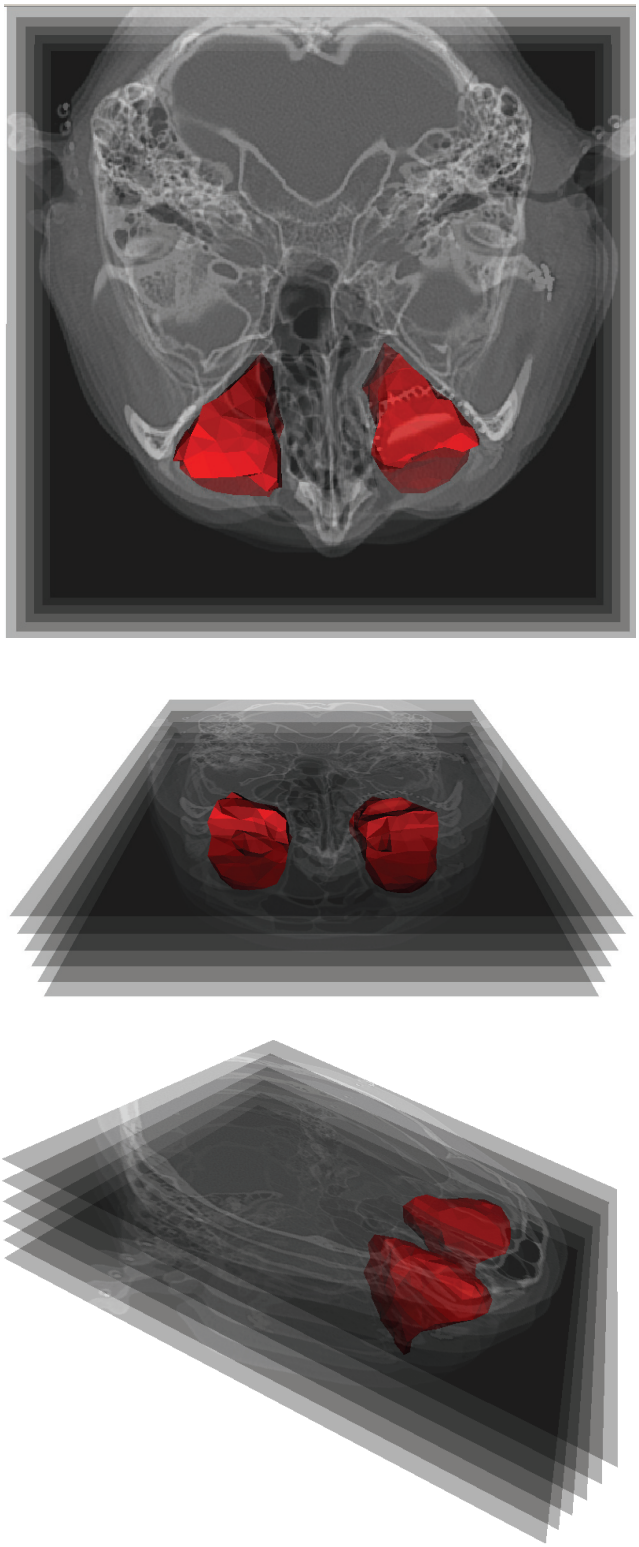

Figure 4 - Results on Subject 2

Results

A fixed set of parameters for the 3D active contour model was determined manually and applied to segment the six data sets selected arbitrarily from the clinical day-today routine.

Based on five segmentations on Subject 1 that were initiated with different starting points, the variation coefficients (standard deviation divided by the mean) of the volumes of left and right orbits were 0.98% and 1.28%, respectively. Since these coefficients are much smaller than 5 %, the method is considered as sufficiently stable.

The results of automatic orbit segmentation is visualized in Figures 3 and 4. For qualitative evaluation, the segmentation was confirmed by a skilled radiologist. The quantitative results obtained on the six patients are summarized in Table 1. The volume of left and right orbits are given by the number of segmented voxels. For all subjects, the relative differences

$$d = 100\frac{|l-r|}{l+r}$$

is below 5%, and the mean relative differences is $d_m = 1.52\%$.

Table 1 - Image data and results

Patient No	No of slices	Volume left *l*	Volume right *r*	Relative difference *d*
1	139	339819	350085	1.49 %
2	181	485792	491097	0.54 %
3	136	541376	521174	1.90 %
4	204	358029	365773	1.07 %
5	261	207250	221110	3.23 %
6	188	260264	255632	0.90 %

Discussion and conclusion

The general active contour model is applicable for automatic segmentation of orbits in CT data. The model consists of a membrane-like structure which is blown up from the interior of the orbit. Discontinuous surfaces caused by insufficient CT data are bridged with a defined surface tension of the membrane. The anterior border is defined as a vertical plane travelling along the infra-orbital rim. The posterior border is to be defined as a cone-like top of a pyramid.

The application of this virtual model to a real 3D model allows the exact pre-bending of a titan mesh for the surgical reconstruction of the orbital floor. First interventions with navigation guidance have shown that this mesh can be adapted with a geometric accuracy smaller than 1mm. Finally, in case of severe midface asymmetry, a preoperative transition of a virtual volume from an unaffected orbit to the affected side and consecutive integrative fusion with the mirrored orbital floor (morphing) can lead to an exact prediction of the reconstructed orbit. This will be evaluated in further studies.

Automatic Volumetry for Surgical Reconstruction of the Orbit

Thomas M Deserno, née Lehmann
Melanie Kleiner, Dirk Schulze, Pit Jacob Voss

RWTH Aachen University, Germany
University Freiburg, Germany

Relevance

- Fracture of orbital floor is frequent in cranio-maxillofacial surgery
- Double vision or diplopia results from
  - 58% – 86% of all blow-out fractures
  - 13% – 20% of all midface fractures
- Surgical treatment [1]
  - Preformed titanium mesh
  - Exact reconstruction of orbital volume (same volume on each side)

Goal

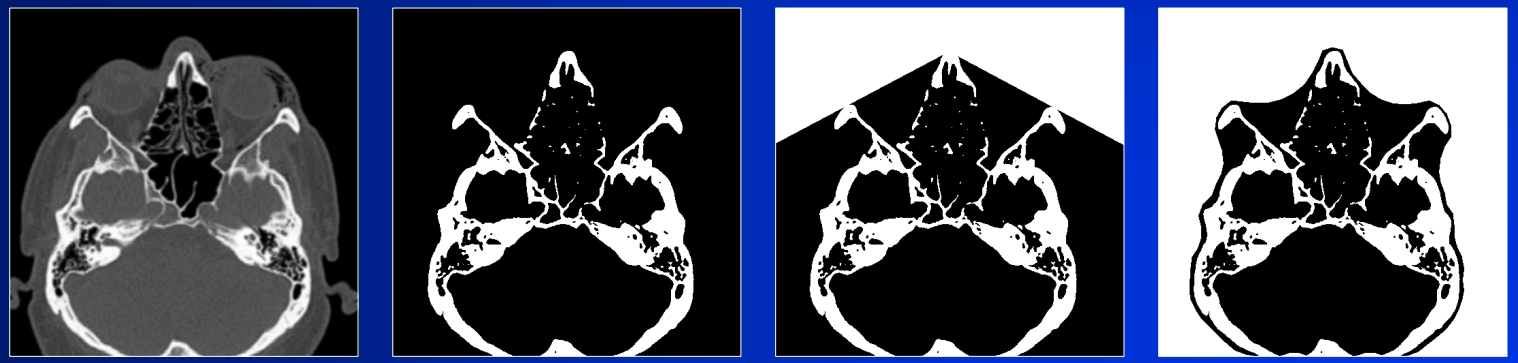
- Support of treatment planning
  - Automatic orbit segmentation in CT volumes
  - Orbital volume measurement
- Robust and reliable image processing scheme
  - Find suitable algorithm
  - Find robust parameterization
  - Evaluate on real data

Materials & Methods

- Selected subjects
  - A: 2 normal cases
  - B: 3 with fracture before treatment
  - C: 6 after mesh-based reconstruction
- Siemens Sensation 64 CT scanner
  - 120 kV at 82 mA
  - 512 x 512, 1mm slice thickness
- General discrete contour model [2]
  - Constant pressure moves towards edges
  - Biological membrane behavior avoids sharp bends
  - External influences regionally based on HU

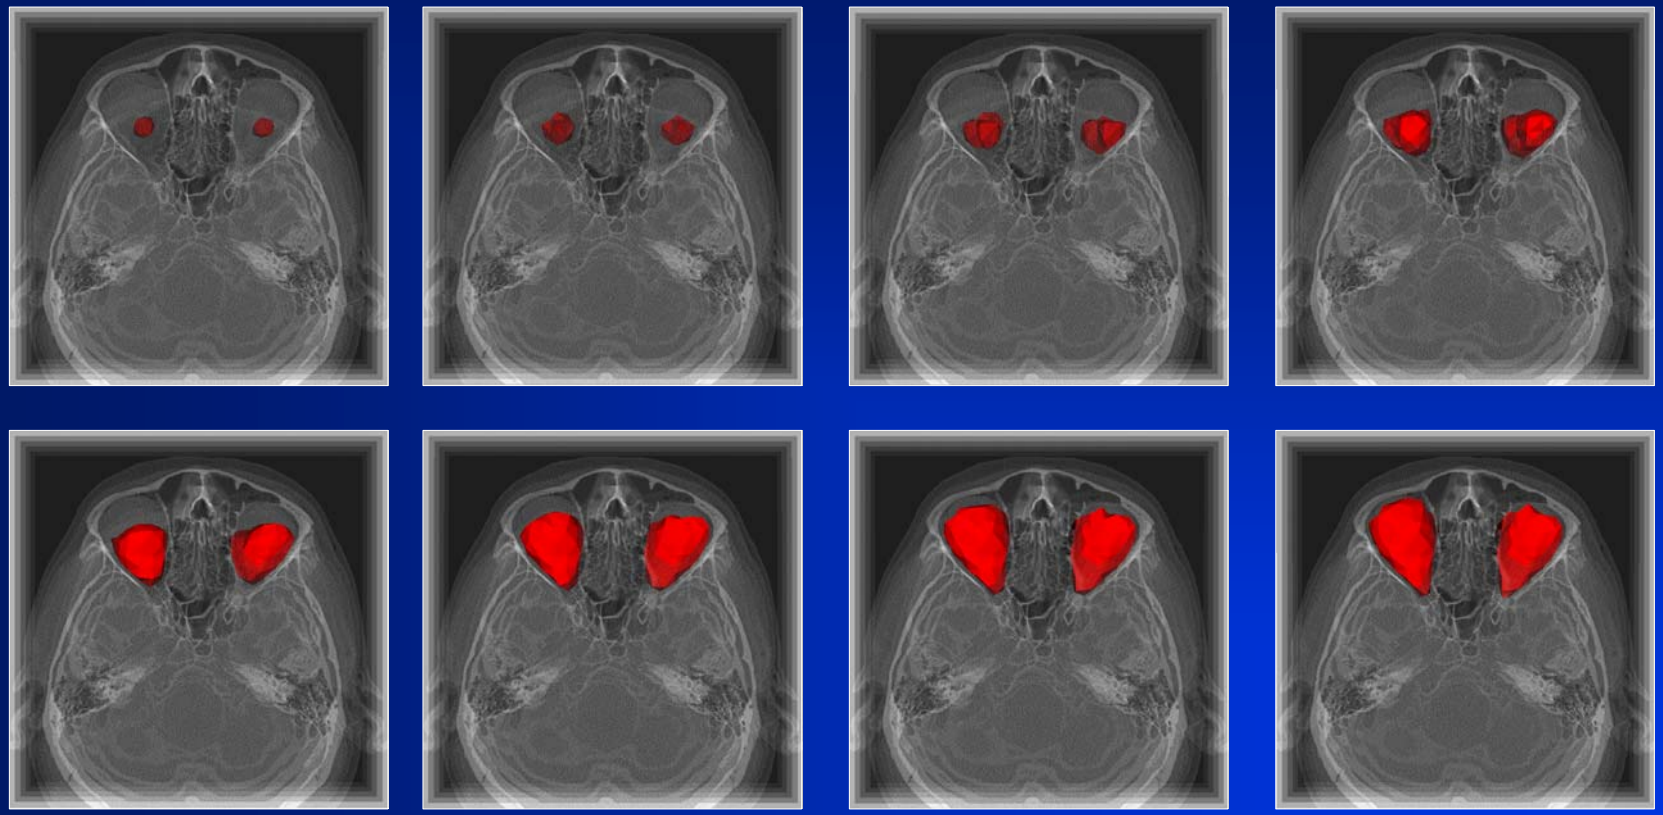
Preprocessing

- Problem: open orbit
- Solution
  - Noise reduction
  - Binarization
  - Linear boundary
  - Contour-based boundary using same balloon model



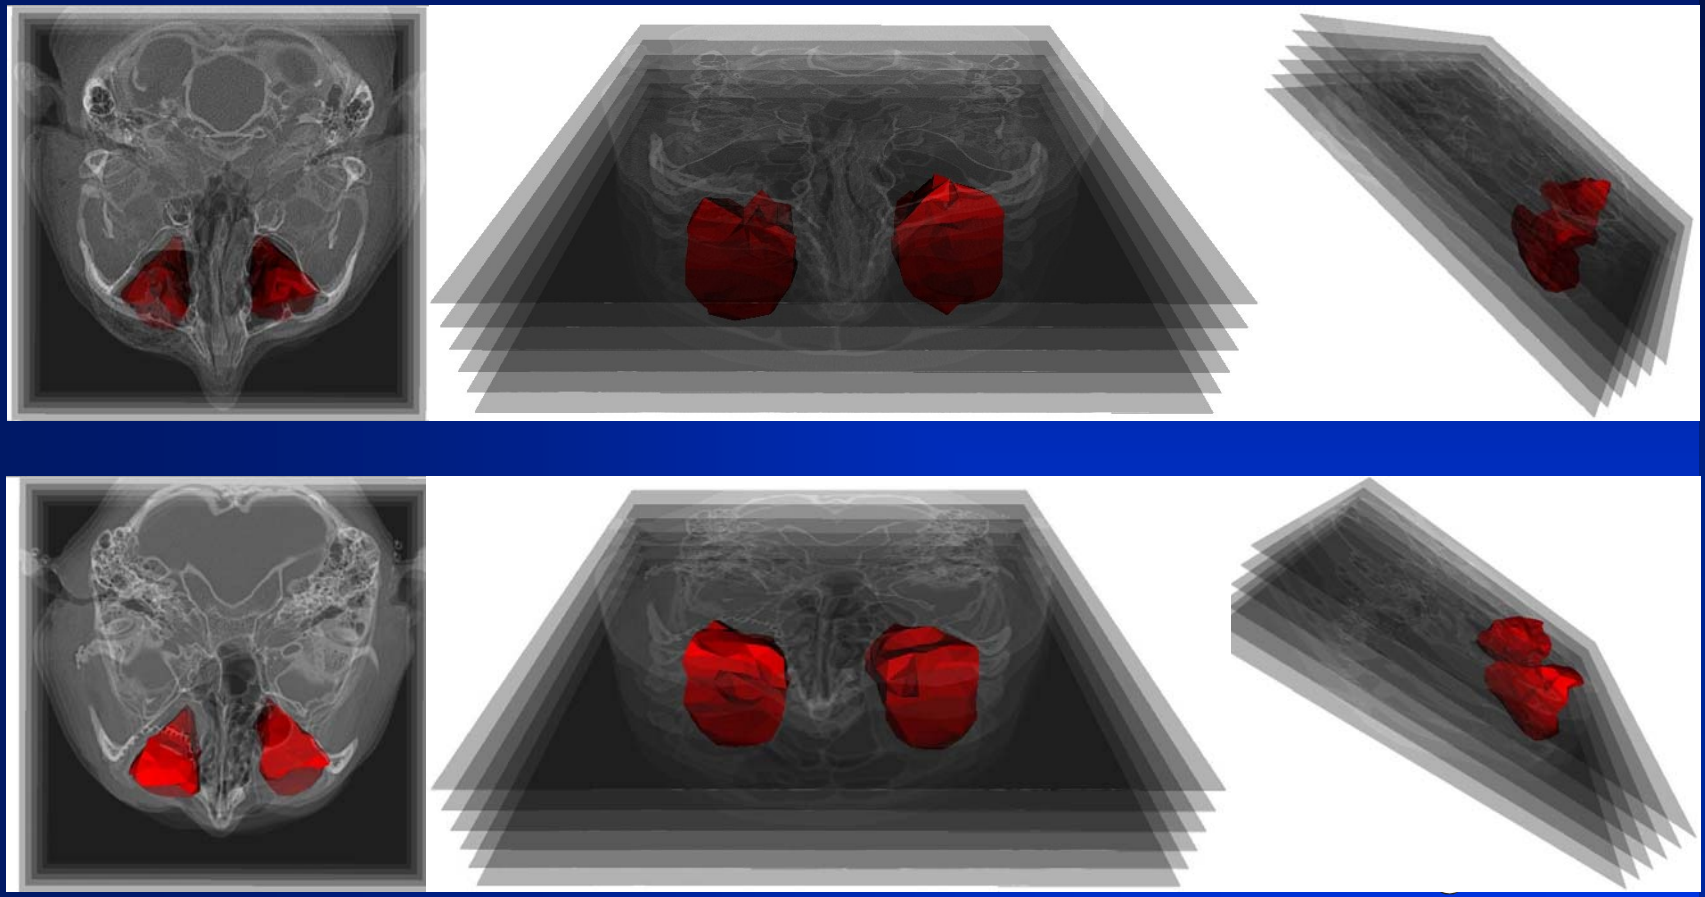
Example

- Iteration



Example

- Orbit segmentation



Evaluation

- Healthy patients
  - Left side equals right side
- Measurements
  - Volume of left orbit: l
  - Volume of right orbit: r
- Relative difference: d
  - Assumed to be zero

$$d = 100 \frac{|l - r|}{l + r}$$

IRMA

Results

Group	ID	No of slices	V_l	V_r	d
A	3a	136	541376	521174	1,90%
A	6	226	89395	87841	0,88%
					1.39%
B	1	139	339819	350085	1,49%
B	4	261	207250	221110	3,24%
B	10	191	506487	544712	3,65%
					2.79%
C	2	181	396430	390265	0,78%
C	3b	204	358029	365773	1,07%
C	5	244	469642	527664	5,82%
C	8	188	260264	255632	0,90%
C	9	216	151774	153774	0,65%
C	14	192	381866	320753	8,70%
					3.58%

Discussion & Conclusion

- New method for CT orbita segmentation
  - Membrane-like balloon structure
  - Shrunk from image border to close orbit
  - Blown from the orbit center for volume measurements
- Robustness
  - Mean variation below 5% for
    (A) healthy, (B) fractured, (C) reconstructed subjects
- Applications
  - Surgery planning
  - Follow-up studies

Abstract

According to the World Health Organisation, breast cancer is the second leading cause of cancer deaths in women today and is the most common cancer among women, excluding nonmelanoma skin cancers. Several studies have proved that the early detection of breast cancer can reduce mortality rates and improve the chances that the patient is diagnosed at an early stage and treated successfully. Mammography is widely used as the primary method for breast cancer detection.

Breast microcalcifications usually appear in the form of clusters and sometimes can be easily detected on mammografic films due to their high clustering density. An approach in the classification of microcalcifications has been presented by Ligomenides et al. and it is based on detailed analysis and evaluation of seven features of individual microcalcifications and of formed clusters. The proposed system is now in clinical trial in an Athens University Hospital's Breast Unit. The results from the first 51 cases (all biopsy tested) that were processed are presented in this paper and indicate that all malignant cases were classified correctly.

Keywords:

computer aided diagnosis, mammogram,
microcalcifications, breast cancer, clinical trial

Introduction

Breast cancer is the second leading cause of cancer deaths in women and is the most common cancer among women, excluding nonmelanoma skin cancers. According to the World Health Organization, more than 1.2 million people will be diagnosed with breast cancer every year worldwide. The chance of developing invasive breast cancer during a woman's lifetime is approximately 1 in 7 (13.4%). The death rates from breast cancer also declined significantly during the last years, with the largest decreases among younger women. This is attributed to earlier detection and more effective treatments.

Breast microcalcifications are considered a very useful index of malignancy, which helps in the early detection of breast cancer. Malignant calcifications may occur with or without the presence of a tumor mass and are typically clustered, varying in size and shape. Mammography is accepted as the most effective method to detect breast cancer. However, interpreting a mammogram is not easy for not experienced radiologists. The aim of computer aided detection techniques in breast cancer is to improve the chance that a malignant region is detected and appropriately evaluated. It is very important for the success of the treatment that any malignant area is detected as early as possible. Furthermore, the ability to discriminate benign cases (specificity) is a major issue in computer-aided diagnosis.

Breast microcalcifications are viewed as bright spots with diameter varying from 0.1 to 0.3 mm and usually appear in the form of clusters that can be detected on mammographic films due to their high clustering density. Nevertheless, the existence of microcalcifications in breast tissue is not always a clear evidence of malignancy. Many research efforts have been made to segment medical image findings and specifically to classify breast microcalcifications as benign or malignant, based on computer-aided analysis of their structural and photometric characteristics as those appear in mammographic images.

A computer aided diagnosis (CAD) system, called Hippocrates-mst, has been developed and is based on detailed analysis and evaluation of related features of individual microcalcifications and of formed clusters. The output of the system is considered to be very useful to the radiologists, giving them extra input before reviewing each case.

After an initial evaluation that was done in the laboratory with a set of 200 mammograms, the system is now been tested in a Breast Unit of an Athens University Hospital. The system's integration and ease of use within the unit's workflow as well as the results are examined closely as they may indicate future developments.

Methods

Microcalcification detection and analysis is carried out with the use of an algorithm based on the processing of

three image data sets: a) the application of a high pass filter b) the variance normalization c) the application of an adaptive filter. Similar techniques have been successfully used to process medical and astronomical images.

The proposed methodology for microcalcification classification uses a four-way projection method and examines each microcalcification cluster from four different viewing angles in order to process all possible variations of each view. Seven characteristics are extracted for each microcalcification including size, circularity, existence of sub dense center, brightness level, anomaly of shape, existence of apophyses and branches and existence of windings.

The workstation of the system comprises of a modern IBM compatible personal computer, a printer and a high quality film scanner unless a digital mammographic device exists.

Each case is processed as follows: each mammogram has to be digitized using certain parameters and then the doctor/user enters the patient's demographic data and medical history in the system's digital patient record. After those initial steps the doctor has the option to examine the mammogram(s) using the provided digital tools. These tools include modules as the 'digital lens', which helps users to zoom in an area of interest, or the brightness, contrast and -value adjustment tools that help the user reveal anomalies in a selected area of the mammogram. At the next step, the doctor can use the system's microcalcification detection algorithms and reveal the microcalcifications of a selected area. The microcalcifications of this area are counted and categorized using a color-based categorization.

The final results of the Hippocrates-mst system are presented in a risk percentage scale from 0 to 100. Percentage lesser than or equal to 35 means there are not enough evidence to support sending the patient for a biopsy test. Percentage from 35 to 55 declares benign state and a biopsy test is suggested, while percentage greater than 55 indicates malignancy and a biopsy test has to be made as soon as possible. It must be stated that the system only makes suggestions to the doctor and it is the doctor that makes the final decision whether a case has to be sent for a biopsy test or not.

As from February 2006 the Hippocrates-mst system is used on a daily basis in the Hippocratio Hospital Breast Unit. The Breast Unit belongs to the 1st Propaedeutic Surgical Clinic of the University of Athens Medical School and is fully equipped with: Mammography system (Siemens Mammomat 3000 Nova), Ultrasound system (Siemens Sonoline), Fischer's Table, Vacuum assisted Breast Biopsy (Mammotome), and Ductal endoscopy.

Hippocrates-mst is used following a specific clinical evaluation protocol. Our goal, in this initial clinical trial phase that will last for 6 months, is to achieve integration within the Breast Unit's workflow and make sure every case that would be Mammotome examined would also be processed with the CAD system. During this initial phase of the clinical trial protocol, the system's results must be compared versus the corresponding biopsy results.

The clinical workflow of a typical case involving Hippocrates-mst is as follows: the woman/patient undergoes breast clinical examination along with a mammographic examination. Depending on the mammogram and the clinical examination results, there are a number of options. In case the mammogram shows signs of suspicious microcalcifications or in case there are findings suggesting malignancy, the patient undergoes a Mammotome examination.

When a case is processed with Hippocrates-mst CAD system, the doctor (usually one of the Unit's radiologists) selects the mammogram(s) that must be digitized and scans it/them using the system's scanner. Then adds the resulted image files to the patient's digital record and begins to process each mammogram using Hippocrates-mst's digital image tools and classification modules. At the final step of the computer-aided examination, the system provides the doctor with the overall risk estimation for the selected region of interest. After reviewing a case, the doctor has the option to save the results, along with any notes on the case, to the system's hard disk drive or to a cd. The whole process from the film digitization to the final results takes no more than 6 minutes.

The sample images set contained 51 mammograms, of both craniocaudal and mediolateral views, with microcalcifications collected in a period of five months, from March 2006 to mid July 2006. Each case was accompanied with the patient's demographic data and medical history as well. Indications for mammography could be routine check up, screening or follow-up.

The mammoraphic images obtained through digitization using UMAX 1000XL scanner, with a resolution of 300 dots per inch (DPI), 16 bit greyscale colour depth and .tiff unzipped as the image format. The image size for each image was 2048X2048 while the size in megabytes was approximately 10 MB for each image.

Results

So far 51 cases have been reviewed and biopsy tested, following the clinical trial workflow mentioned earlier.

It must be stated that all these cases would have gone either to surgery or biopsy using Mammotome so every successful indication of a benign case from the CAD system would save this woman from an unnecessary surgery or biopsy.

The initial results have shown that 17 out of 51 patients that underwent biopsy with Mammotome had an actual -

tissue biopsy proven- malignant finding. The system successfully identified all malignant cases showing no false negatives. Furthermore, regarding the benign cases, Hippocrates-mst was able to identify that eighteen of them were benign or possibly benign assigning them a percentage between 0 and 55.

Discussion

The clinical trial protocol worked flawlessly as there were no problems in the CAD system's integration in the Breast Unit's workflow. The doctors were tutored on how to use the system and were able to quickly review each case using Hippocrates-mst's digital image tools as well as the microcalcification detection and classification module.

The laboratory's as well as the first clinical evaluation test results of all malignant cases were encouraging, since no malignant cases were falsely classified as benign. It must be stated here that the correct categorisation of malignant cases was our primary goal during the proposed system's development.

Clinical Trial of a CAD System for microcalcification detection and classification.

The Hippocrates-mst

Is a computer aided diagnosis system (CAD) that uses:

- Image processing techniques
- Artificial intelligence methods

In order to help in early breast cancer diagnosis

Methodology

- Image Processing
  For microcalcification detection
- Image Analysis
  To export and quantify the microcalcifications' characteristics
- Classification Algorithms
  For the microcalcifications' classification
- Diagnosis Model
  To evaluate the findings and to propose a diagnosis

Image Analysis for the export and quantification of characteristics

Microcalcifications' measured characteristics:

- Size
- Sub dense Center
- Circularity
- Brightness
- Anomalies in shape
- Branching
- Windings

Classification Algorithms

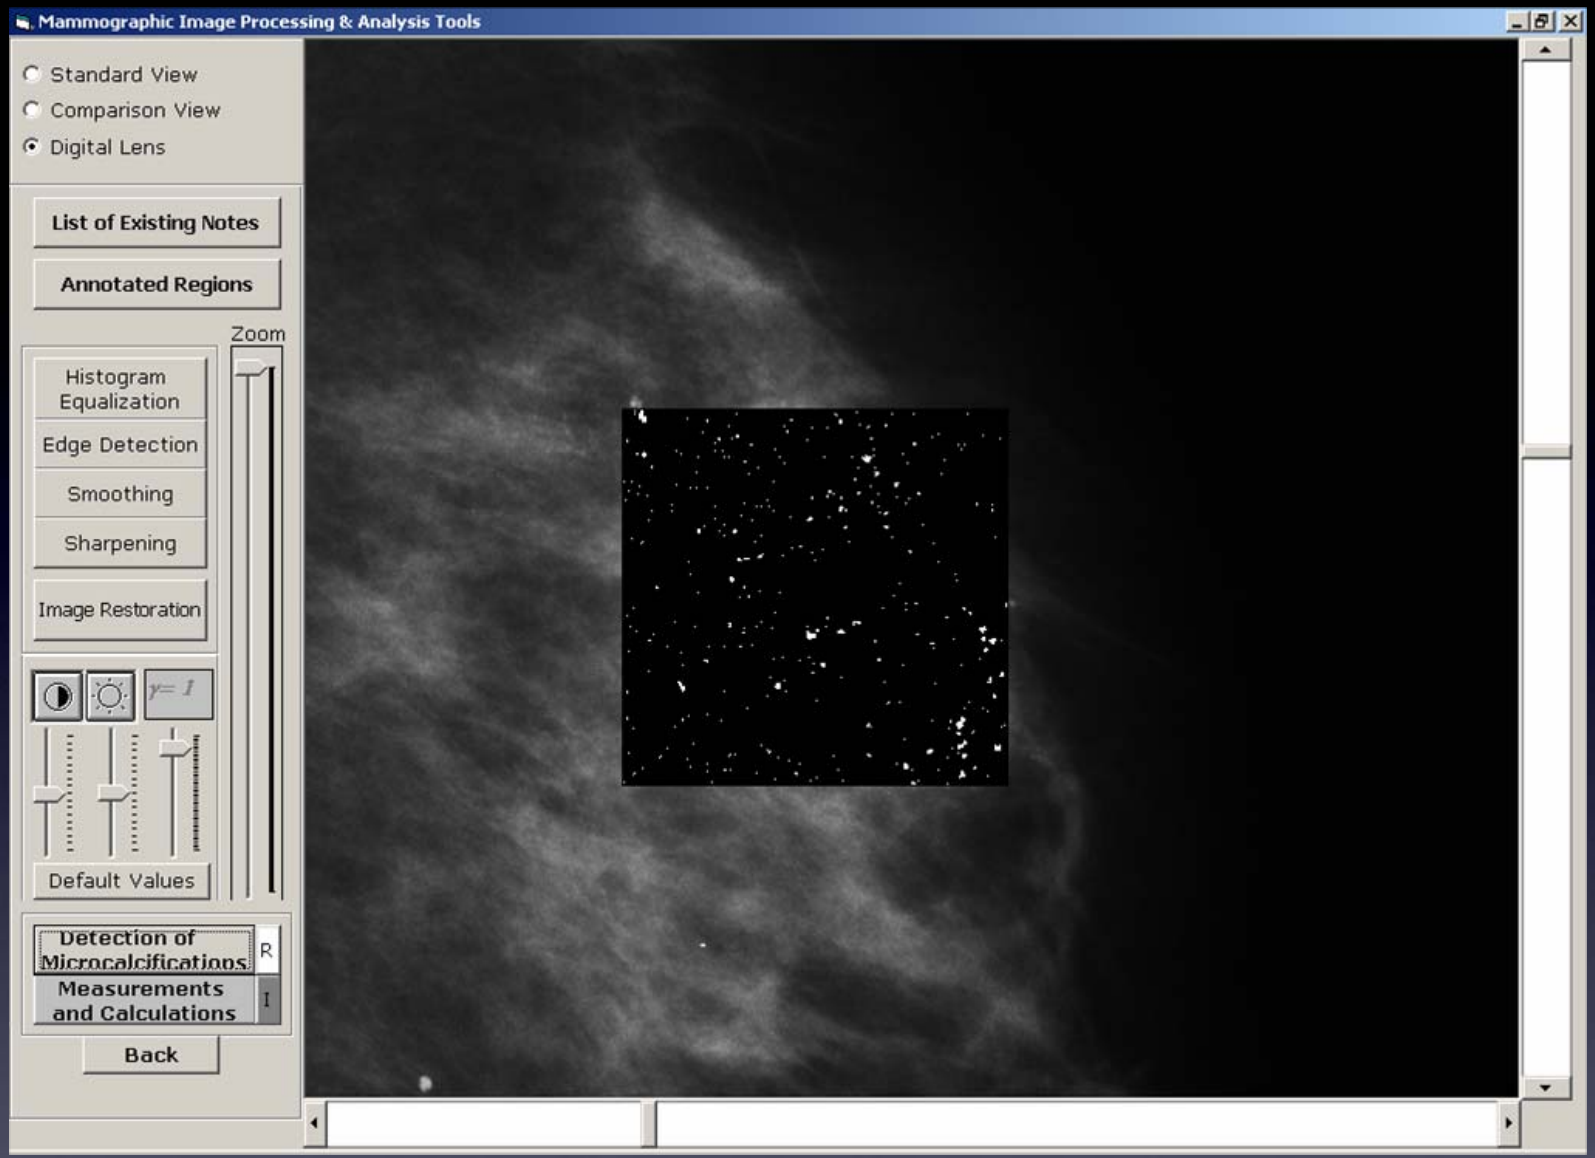
Consist of modeled empirical rules based on :

- Information given by specialized clinical doctors
- Relevant Medical Bibliography

Diagnosis Model

Mathematical model based on the following parameters :

- Risk from total number of microcalcifications
- Number of high risk microcalcifications
- Polymorphy of microcalcifications
- Position and direction of the microcalcification cluster
- Patient’s age and medical history



Microcalcification Detection

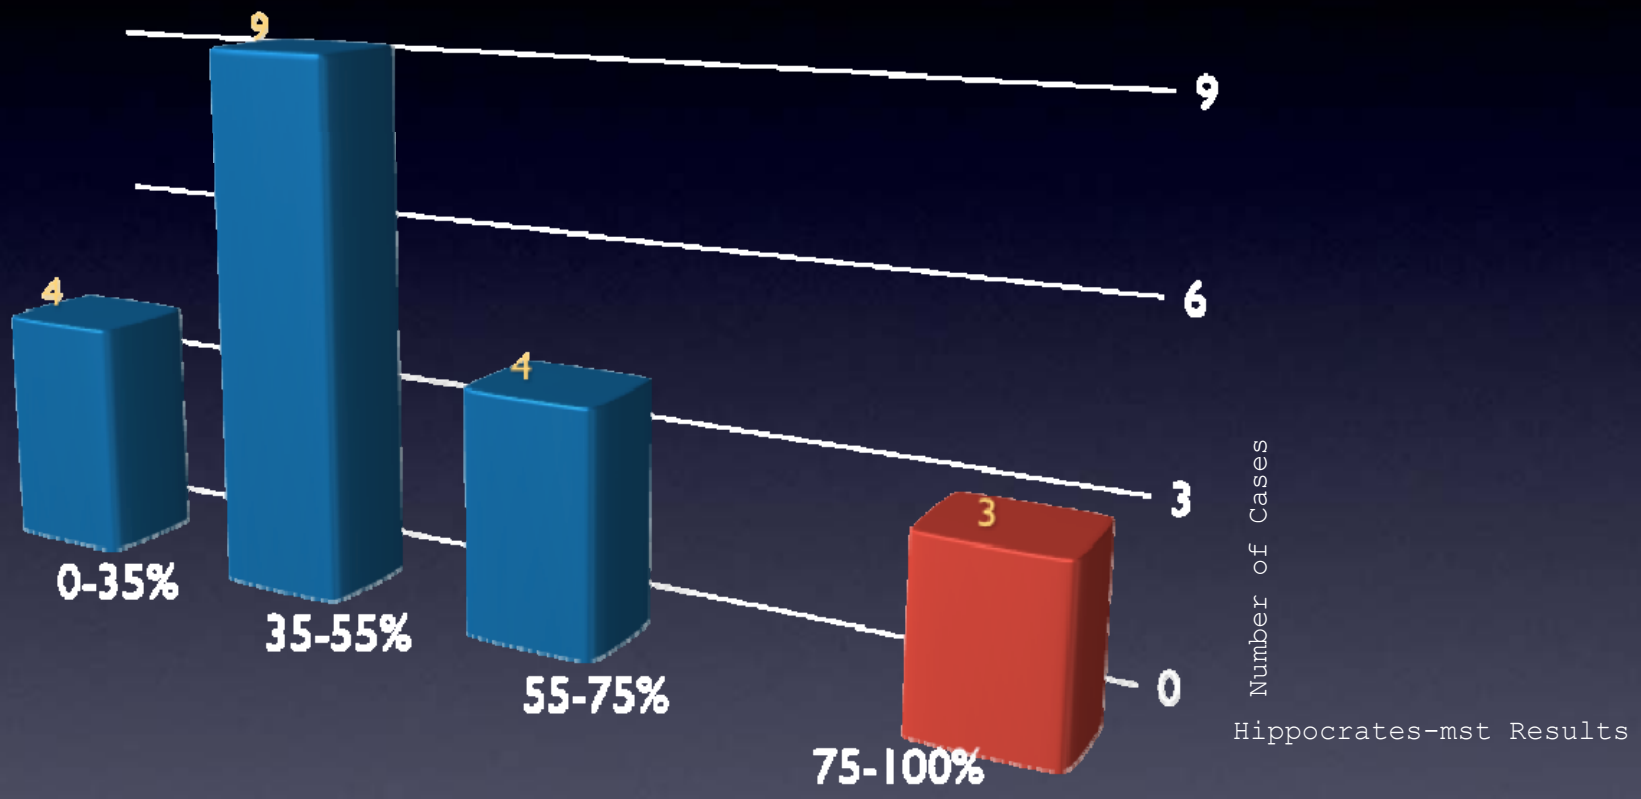
Results

- The sample images set contained 20 mammograms, of both craniocaudal and mediolateral views, with microcalcifications collected in a period of two months, from mid February 2006 to mid April 2006. Each case was accompanied with the patient's demographic data and medical
- 3 out of 20 patients that underwent biopsy with Mammotome had an actual -tissue biopsy proven- malignant finding. The system successfully identified all malignant cases showing no false negatives.

Results

- Hippocrates-mst was able to identify that eight of them were benign or possibly benign assigning them a percentage between 0 and 55.
- Every successful indication of a benign case from the CAD system could save this woman from an unnecessary surgery or biopsy.

Clinical Trial Results



Discussion

- The clinical trial protocol worked flawlessly as there were no problems in the CAD system's integration in the Breast Unit's workflow.
- The first week the doctors seemed unfamiliar with the system's interface but after a number of tutorials and some hours of hands-on experience they were able to quickly review each case using Hippocrates-mst's digital image tools as well as the microcalcification detection and classification module.

Content Based Image Retrieval of Glioblastoma Multiforme

Shishir Dube, Suzie El-Saden, Timothy Cloughesy, and Usha Sinha
UCLA Medical Imaging Informatics

Introduction

- Glioblastoma multiforme brain tumors have a variety of MR image presentations
- Mean time to survival of patients diagnosed with GBM who have undergone standard treatment protocols is 18 months
- Time to survival, within the GBM subgroup of malignant brain tumors, is highly variable

Background

- Several studies have been done to find relationship between imaging variables and prognosis
- Imaging variables that negatively correlated with survival were: presence of edema, necrosis, satellites, and multifocality
- Previous literature uses qualitative descriptors of imaging findings or simple quantitative indices, such as bi-linear measurements

Methodology

- **T1 post-contrast SPGR sequences, prior to surgery, from 40 patients diagnosed in GBM made up the data set.**
- **All patients underwent gross total resection and subsequent radiation and chemotherapy regimen.**
- **Quantitative features extracted from T1 post contrast study, but the T2 sequence was used to accurately delineate the edema region (Figure 1)**

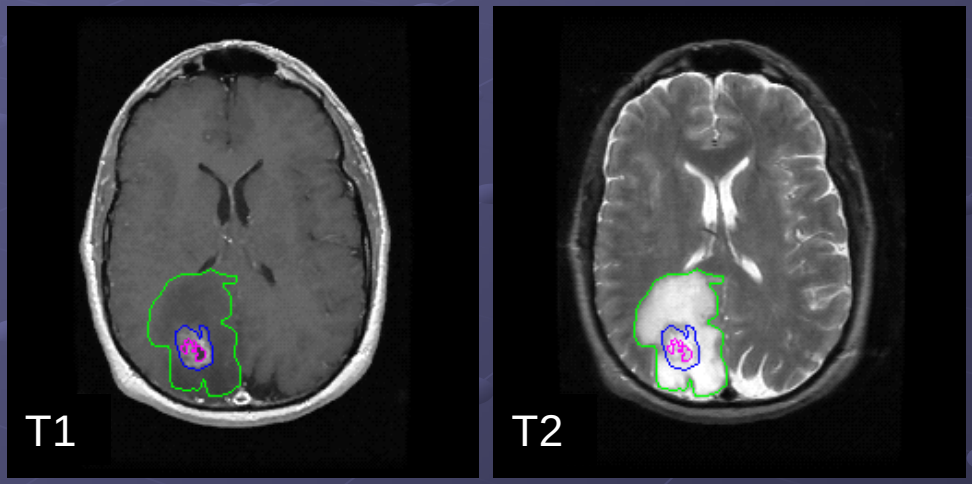

Figure 1. The left and right images are the T1 post contrast and respective T2 with the labeled regions that were segmented for quantitative analysis. The edema boundary is outlined by green, contrast enhancement by blue, and necrosis by magenta.

Image Conditioning

- Images were pre-processed to improve image quality
- The steps consisted of:
  1. Denoising (FSL)
  2. Brain Extraction (FSL)
  3. Image Alignment (FSL)
  4. Image Intensity Standardization via Normal Hemisphere Histogram Matching

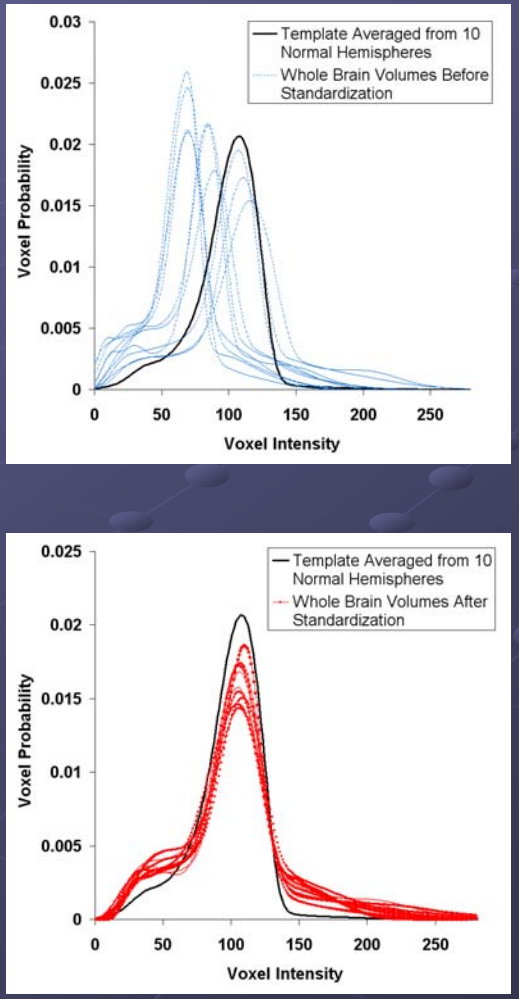

Figure 2. a) Histogram plots of $h_{template}$ and patient data before standardization b) Histogram plots of $h_{template}$ and patient data after standardization

Features

Table 2: Results of the stepwise multivariate linear regression model applied to the quantitative imaging data. Each model shows the variables involved, their weighting coefficients, and the resulting correlation coefficient to describe how well the model fits the data.

Edema Features:

- **The value of the invariant shape descriptor chosen for edema has a trend to increase the more irregular a shape becomes and in the presence of holes (i.e. tumor/necrotic regions)**

Necrotic Features:

- **For the necrotic shape descriptor, higher irregularity also leads to an overall lower estimate of survival, indicating the malignant nature in the morphology of the necrotic region**

Contrast Enhancing Tumor Features:

- **Kurtosis of CET reflects the peakedness of the intensity histogram, which is narrower for CET regions that had high TTS**
- **Mean intensity of the CET regions corresponds to average voxel uptake of the tumor. Thus, a higher uptake could indicate a higher degree of infiltration**
- **The two invariant shape parameters indicate that CET regions with a higher irregular structure accompanied with larger presence of necrosis yield an overall lower survival time estimate**

Future Work

- Expansion to a larger patient population
- Inclusion of more quantitative and qualitative (i.e. age, multifocality presence) features
- Correlations to other outcomes (i.e. time to tumor progression)
- Glioma molecular subtype characterization
- Application of an AdaBoost cascade methodology

Content Based Image Retrieval of Glioblastoma Multiforme

Shishir Dube[a], Suzie El-Saden, Timothy F. Cloughesy[b], Usha Sinha[a]

[a]*Department of Biomedical Engineering, University of California at Los Angeles,CA,USA*
[b]*Department of Neurology, University of California at Los Angeles,CA,USA*

Abstract

We propose a Content Based Image Retrieval system, for patients diagnosed with Glioblastoma Multiforme that will predict of time to survival and allow a neuroradiologist to modify treatment procedures based on quantified features explicitly extracted from segmented regions of the tumor. Our proposed system has two components: a preprocessing scheme to improve the image quality and provide consistency and a multivariate linear model. The multivariate linear model applied to the training data had a correlation coefficient of 0.848, which indicated a strong association of the selected features to time to survival. Future work will involve expanding the training set and incorporating additional features not explicitly extracted from the segmented tumor regions.

Keywords:

content based image retrieval, imaging informatics, image data mining, image processing, disease modeling

Introduction

Medical image databases have grown immensely in the past few years. Imaging studies, such as magnetic resonance (MR) and computed tomography (CT) result in a large volume of data. The ability to query large image databases can form the basis of a decision support system. However, a large number of existing image databases are indexed by text annotations that routinely contain patient demographic or study information. Manual methods to extend this with more comprehensive text annotation that capture image content are both tedious and time-consuming. We propose a CBIR system for GBM tumor cases for the purposes of visualizing the variety of different disease presentations that can exist given similar features as well as prediction of time to survival given a query volume (for the purposes of treatment modification). Our proposed CBIR system includes a fast and automated segmentation component with the ability to allow a radiologist to modify the pertinent regions segmented, as well as a multivariate linear regression model predicting time to survival based on particular features (extracted only from the T1 post contrast enhanced studies) of the tumor region.

Materials and methods

Two important components are required in order to have an accurate and efficient CBIR system of brain tumor images: I) preprocessing of images to reduce variability resulting from differing MR scanner conditions; II) an accurate model relating time to survival to extracted quantified features. Our proposed methods for the three areas are discussed below.

Preprocessing scheme

The following steps were performed to improve SNR, register the two image channels of a given subject, and to obtain consistent image intensities across all subjects for a given channel: Denoising –FSL nonlinear filter [3], Registration – For image alignment [3], Intensity Standardization – Performed via a histogram matching method (Figure 1) [4].

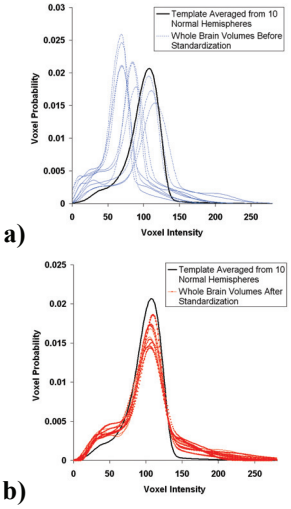

Figure 1 - a) Histogram plots of $h_{template}$ and patient data before standardization b) Histogram plots of $h_{template}$ and patient data after standardization

Quantitative feature modeling

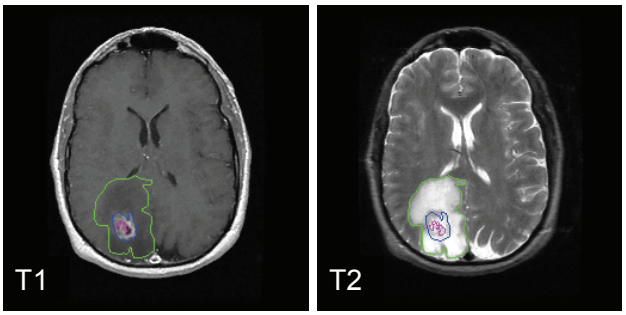

Figure 2 - The left and right images are the T1 post contrast and respective T2 with the labeled regions that were segmented for quantitative analysis. The edema boundary is outlined by green, contrast enhancement by blue, and necrosis by magenta

Imaging data from 34 subjects with GBM were included in the analysis for training purposes, and an additional 4 patients' images were kept aside for querying purposes. The quantitative features were extracted from only the T1 post-contrast study, but the T2 sequence was used to accurately delineate the edema region (Figure 2). Table 1 is a list of the shape, texture and intensity histogram features extracted for each tumor sub-region. A stepwise multivariate linear regression model was applied to the quantitative data to determine the quantitative variable (or combination of variables) that best predict time to survival.

Table 1 - List of the different features extracted for each sub-region. The features consisted of texture parameters derived from 3D co-occurrence matrices, 3D shape moments, and histogram parameters

	Correlation of Edema	**747.286**	
	3rd order SM of Edema	**6.85E-07**	
	Kurtosis of CE	**64.09**	

Table 2 shows the results of the stepwise multivariate linear regression model. Each model corresponds to the number of variables used to predict survival and the respective correlation coefficient. For a given model n (where n represents the number of variables), the variables (along with their respective weighting coefficients) that gave the best correlation with time to survival are listed.

Discussion

As can be seen in Table 2, the shape and texture of edema show strong correlations to time to survival. Edema presumably follows the white matter tracts, and a higher infiltration of the tracts may be captured in the shape indices as structures of high morphological anisotropy. The correlation texture feature is related to the inhomogeneity of intensity in the edema sub-region. Infiltration of tumor cells into edema could potentially result in inhomogeneous intensities of the edema sub-regions. Greater infiltration into the surrounding peri-tumoral edema has a poor prognosis and this could be the basis for a correlation between the edema texture feature and time to survival. The correlation of the shape of contrast enhancing tumor region to survival time may also have its origin in the infiltrative nature of tumor. Kurtosis of the intensity histogram primarily reflects asymmetry and the presence of a long tail in the high intensity end of the histogram. This heterogeneous intensity profile may arise from some voxels

showing a high uptake of the contrast agent, which in turn may reflect tumor aggressiveness.

Future work will involve expanding the multivariate model training set to 100 patients and including features not derived explicitly from the segmented volumes (i.e. age, presence of multifocality) that have been shown to have some correlation with survival.

On Classification of Otoneurological Cases Based on Vestibulo-ocular Reflex Signals

Martti Juhola[a], Heikki Aalto[b], Timo Hirvonen[b]

[a]*Department of Computer Sciences, University of Tampere, Tampere, Finland*
[b]*Department of Otorhinolaryngology, Helsinki University Central Hospital, Helsinki, Finland*

Abstract

According to signal analysis and pattern recognition results earlier computed by us, we distinguished a set of patients from the healthy subjects. Classification was executed on the basis of machine learning methods to explore, which methods are the most efficient to identify the two classes from each other. We implemented programs for nearest neighbour searching, clustering, decision trees, Bayesian decision rule, multilayer perceptron networks and Kohonen networks. The last method was better than the others and obtained total accuracies as high as 94 %.

Keywords:

vestibulo-ocular reflex, eye movements, classification

Introduction

In otoneurology diseases entailing vertigo and other balance problems are investigated, among others, with signal analysis techniques applied to various measurements recorded from subjects. We began our research on this topic already in the 1980s by using syntactic pattern recognition methods for saccades, nystagmus, sinusoidal tracking eye movements and vestibulo-ocular reflex.

We constructed a computer program developed from our earlier research to recognize vestibulo-ocular reflex responses. In this research we continue the work by testing and surveying several classification methods to identify patients from healthy subjects along with the signal analysis results given by our syntactic pattern recognition technique.

Methods

In order to yield vestibulo-ocular reflex, head movements have to be made. We have developed a computer-controlled mechanical device to produce carefully guided horizontal head movements of a subject. For this purpose, a subject sat in a fixed chair and a boxer's helmet was tightly set on the subject's head. Two push rods controlled by an electronic DC motor and connected to the boxer's helmet moved the head from the centre to the left or right and back after an interval of 0.7-1.2 s.

During the measurement the subject was due to keep the gaze toward a fixed object. Each head movement stimulates a rather symmetric eye movement response in the opposite direction. Head movements were recorded with a potentiometer. Both signals were measured at the same time at 400 Hz and lowpass filtered to dampen noise above approximately 70 Hz. Signals of 22 healthy subjects and 22 patients were measured for 80 s.

We applied our syntactic method to recognize stimulation head movements and their eye movement response from each signal pair. Latency and gain values between stimulations and responses were computed. We computed three gain estimates. The first one, g_1, was computed according to linear regression. Second, we applied the ratio g_2 of the maximum velocity values of the response and stimulation and the ratio g_3 of their mean angular velocities. All three gains were computed on the basis of the 100 ms duration immediately after the beginning of a vestibulo-ocular reflex.

We computed average gain and latency values for the group of the 22 randomly selected healthy control subjects and similarly for the 22 patients, who suffered from unilateral otoneurological dysfunctions caused primarily by an operated acousticus neuroma. We separated their intact sides from those of the dysfunction since the intact side should be almost normal.

Results of machine learning methods

Our goal was to distinguish the healthy subjects from the patients by means of algorithms implemented in Matlab. They were run to compare their efficacy in the classification based on eye movements of vestibulo-reflex. We applied ten-fold crossvalidation by dividing the stimulation-response pairs of both subject groups (483 from the healthy and 371 from the patients) into ten subsets. If a method was such as neural networks that had some random initialization values, ten runs were still performed for each crossvalidation situation. Sensitivity, positive predictive value and total accuracy were computed for both classes.

Tests of *k*-nearest neighbour searching (Table 1) and *k*-means clustering in the Euclidean variable space (Table 2)

were run. We tested decision trees (Table 3), Bayesian decision rule (Table 4) and multilayer perceptron neural networks (Table 5).

92.5±7.0	82.7±11.3	87.9±7.3	89.8±8.8	88.3±7.1

Table 5 - Means and standard deviations [%] of classification results with multilayer perceptron neural networks

Hidden nodes	Sensitivity		Positive predictive value		Total accuracy
	healthy	disordered	healthy	disordered	
4	94.3±6.7	80.6±14.5	87.1±7.8	91.0±12.5	88.4±7.5
8	93.4±7.9	82.0±11.4	87.5±7.1	91.1±9.5	88.5±7.3
16	93.4±8.2	82.9±11.6	88.1±7.1	91.2±9.3	88.8±7.3

Kohonen networks were tested with ten runs with hexagonal neighbourhood pattern used with link distance (Table 6). Networks including 36 or more nodes reached 3-11 % higher outcomes than those in Tables 1-5.

Table 6 - Means and standard deviations [%] of classification results with Kohonen neural networks

Nodes	Sensitivity		Positive predictive value		Total accuracy
	healthy	disordered	healthy	disordered	
3 × 3	94.4±4.8	83.5±9.6	88.6±6.3	92.3±6.4	89.7±4.9
5 × 5	94.8±2.2	89.5±9.6	92.5±6.4	93.0±2.9	92.5±4.4
7 × 7	98.1±2.3	90.0±7.2	93.0±4.8	97.5±3.1	94.6±3.4

Using Wilcoxon matched-pairs signed-ranks test, the efficiency of the methods are compared to each other. Because the *k*-nearest neighbour searching method, Bayesian decision rule and Kohonen networks were tested with ten and the others with 100 test settings, we compare inside these two method groups. The results of Kohonen networks of size 7 × 7 significantly differed from those of the *k* nearest neighbour searching of k=3 at the significant level of 0.001 and from those of the Bayesian decision rule at 0.01. The results of the perceptron networks of size 16 hidden nodes highly significantly differed from those of the *k*-means clustering with k=2. Further, the results of the decision trees highly significantly differed from clustering results and perceptron networks at 0.001.

Discussion and conclusion

The methods of *k*-nearest neighbour searching and *k*-means clustering produced average total accuracies of 84-86 %, the Bayesian decision rule evolved 88 % and the decision trees gave as high as 90 % total accuracies. Per-

ceptron neural networks obtained 88 % total accuracies. Thus, the nearest neighbour searching and clustering were the weakest, the multilayer perceptron networks followed with the Bayesian decision rule, the decision tree method was the next best, and the Kohonen neural networks were the best. The running times (with the 3 GHz processor) expectedly favoured the first three simple methods. The approximate durations were 7 s for the 10 nearest neighbour searching tests, 3 s for the 100 k means clustering tests, 1 min 13 s for the 100 decision tree tests. The Bayesian decision rule was the fastest, with clearly less than 1 s. For the 100 tests of the multilayer perceptron networks they were approximately 4 min 25 s for two hidden nodes and 6 min 23 s for 16 hidden nodes. For the 10 tests of the Kohonen neural networks they were 2 h 15 min for 2×2 nodes and 2 h 21 min for 7×7 nodes. These durations show how more effective but also complicated methods require considerably more time. On the other hand, the training process of the networks only once run engulfed most of the running time.

On Classification of Otoneurological Cases Based on Vestibulo-ocular Reflex Signals

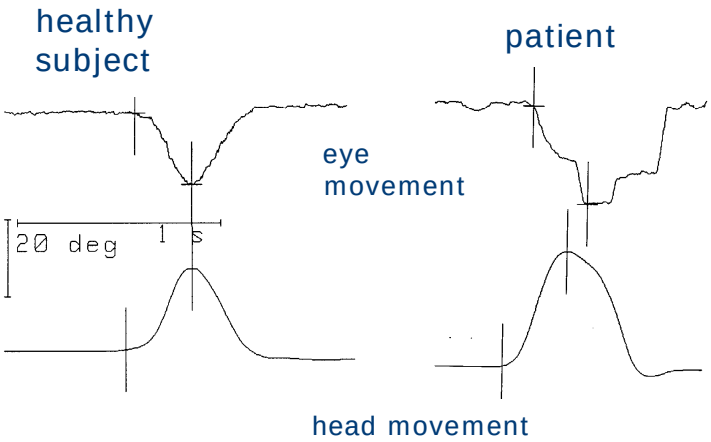
Introduction

In otoneurology diseases entailing vertigo and other balance problems are investigated, among others, with signal analysis techniques applied to various measurements recorded from subjects. Earlier we began our research on this topic by using syntactic pattern recognition methods for saccades, nystagmus, sinusoidal tracking eye movements and vestibulo-ocular reflex [1,2].

We constructed a computer program developed from our earlier research to recognize vestibulo-ocular reflex responses [3,4]. In the present study we continue the work by testing and surveying several classification methods to identify patients from healthy subjects along with the signal analysis results given by our syntactic pattern recognition technique.

Methods

In order to stimulate vestibulo-ocular reflex [5-7] (upper fig.), head movements are made. We have developed a computer-controlled mechanical device [8] to produce horizontal head movements of a subject. A subject sat in a fixed chair (lower fig.) and a boxer's helmet was tightly set on her head. Two push rods controlled by an electronic DC motor and connected to the boxer's helmet moved the head from the centre to the left or right and back after an interval of 0.7-1.2 s.



We applied our syntactic method to recognize stimulation head movements and their eye movement response from each signal pair. Latency and gain values between stimulations and responses were computed. We computed three gain estimates: g_1 was computed according to linear regression, the ratio g_2 of the maximum velocity values of the response and stimulation, and the ratio g_3 of their mean angular velocities. All three gains were computed on the basis of the 100 ms duration immediately after the beginning of a vestibulo-ocular reflex.

We computed average gain and latency values for the group of the 22 randomly selected healthy control subjects and similarly for the 22 patients, who suffered from unilateral otoneurological dysfunctions caused primarily by an operated acousticus neuroma. We separated their intact sides from those of the dysfunction since the intact side should be almost normal.

Results of machine learning

We distinguished the healthy subjects from the patients with algorithms implemented in Matlab. We applied ten-fold crossvalidation by dividing the stimulation-response pairs of both subject groups (483 from the healthy subjects and 371 from the patients) into ten subsets. If a method had some random initialization values, ten runs were still performed for each crossvalidation situation. Sensitivity, positive predictive value and total accuracy were computed for both classes.

Tests of *k*-nearest neighbour searching (Table 1), *k*-means clustering in the Euclidean variable space (Table 2), decision trees (Table 3), Bayesian decision rule (Table 4) and multilayer perceptron neural networks (Table 5) were performed. Kohonen networks were tested with ten runs using hexagonal neighbourhood pattern used with link distance (Table 6). Networks including 36 or more nodes reached 3-11 % higher outcomes than those in Tables 1-5.

Background

Photoplethysmography (PPG) is a noninvasive test that uses a light-emitting diode and a photoelectric cell to detect changes in skin blood volume. Blood volume of the skin can be changes, so too does the amount of light reflected back to the sensor.

We developed multi-channel PPG systems and tested the reproducibility of the system to measure the volume pulse from healthy subjects.

Method

Twenty healthy volunteers were studied (M:F = 6:14) The PPG sensor was applied to the 2nd finger tip of subjects Pulse acquisition was done for 3 min and repeated again with 3 min interval (Sampling rate of 400 Hz). Acquired pulses was synchronously averaged into one representative pulse (only including the pulses with pulse duration of average ± 1 SD)
Pulse averaging was performed using Visual C++ & Matlab on PC.

Results

In 11 subjects, pulse parameters were calculated and correlation coefficients were r=0.68 for PT1, 0.48 for PT2 and 0.58 for augmentation index

Conclusion

Parameters of digital PPG did not showed reasonable reproducibility. However, further studies including more subjects & advanced devices is warranted.

Abstract

Traditionally the time it took researchers to collect high-quality data through experimentation was longer than the time it took to formulate theories that explain them. In recent years, high-throughput data gathering methods have reversed this. Advances in computer technology and a systems approach to biology has led to the adoption of computer models as a means to formulate and test theories in silico faster and more cheaply than previously possible. This has led to a proliferation of model representations and ontologies, creating a complexity that is unwieldy to its human authors. Based on these trends and state-of-the-art practices evidenced in the literature, a new trend of computer-generated, integrated models of high complexity is predicted. In this paper we explain the trend and the challenges that it is likely to raise.

Keywords:

computer aided knowledge discovery, multi-models, multi-scale models, multi-method models

Introduction

In recent years, changes have been emerging in the way life-scientists make novel discoveries. New high-throughput measurement technologies such as mass spectrography, flow cytometry, microarray chips and biobanks are so widespread that more data is gathered than can be analysed [1]. Computer models are nowadays well established as tools required for gaining profound insights from data. The amounts of data and complexity of models is becoming a research area [2-5].

Another emerging research area, in which models are used in scientific discovery, is called "hypothesis generation". Briefly, an algorithm generates models that don't contradict known data [6,7]. In this paper we explain and give examples of two integrated biomedical models. We then discuss the requirements for computer generated integrated biomedical models.

Materials and methods

Many distinct methods have been shown to be effective in modelling life science systems. Some of the more common methods are differential equations [8], numerical methods [9], system dynamics [10], Bayesian networks [11], -calculus [12] and petri-nets [13].

Computer aided knowledge discovery is a relatively new sub-discipline of Machine Learning that is concerned with supporting the discovery of scientific theories. In biomedicine, machine learning has only been used for about 15 years [6,7,14-18]. The on-line Journal of Biomedical Discovery and Collaboration, the first peer-reviewed journal dedicated to biomedical knowledge discovery, was launched in March, 2006 [19].

Multi-modelling

Model construction is a tedious manual task even when assisted by authoring software. Recently, automatic generation of models was shown to be a promising way of constructing hypotheses and suggesting experiments that can falsify them and thus lead to new discoveries [15,20]. These successes exemplify a potentially substantial change in the way we discover natural phenomena.

Complex models are generally limited by several factors. The following issues are of interest to this paper:

- *Two or more modelled interacting systems might not have a common representation suitable to all of them.*
- *The data available for different modelled systems or even different parts of a system are collected in a variety of experimental settings and can't easily be consolidated.*
- *Models' complexity is hindering their intelligibility.*

These limitations can usually be alleviated by modelling each system independently and then interchanging information between the models. We call this method **multi-modelling**.

We distinguish between two kinds of multi-models: multi-scale models, and multi-method models.

Multi-scale models

These are multi-models in which at least one pair of interacting systems operate in different spatio-temporal scales (*e.g.* a cell model integrated with a tissue model) or ontologies *(e.g.* a protein model integrated with a metabolic model). While the models need not be spatial themselves, the interaction crosses scales.

Multi-method models

These are multi-models in which at least one pair of interacting systems are simulated using different representations. Many representations are agnostic to scale. The representation method determines how modelled systems are simulated, visualised (or otherwise explained) and how the model interacts with- or is compared to other models.

Typically, multi-models are either multi-scale, multi-method or both. It is possible to construct multi-models that are neither, assembling components at the same scale and using the same representation. A model of the interactions between two separately developed metabolic pathway models that use the same representation is an example of a multi-model that is neither multi-method nor multi-scale.

Model integration through spatial representation

A representation that is to interchange data between models that vary in method and scale will need one or more mathematical entities to be present in both models. Since spatial relationships are very common in biomedical modelling across all scales, we created a spatio-temporal representation language called the Field Representation Language (FRL)[21] to facilitate interchange of spatial information between different models.

FRL is a representation of algebraic fields which are constructs that vary over a domain defined in space and/or time. The language uses analytic expressions in predefined spatio-temporal coordinates (*e.g.* X, Y, Z) to define fields analytically, represent new interpolation methods and define field domains. FRL supports fields that are composed of one or more other fields. The composition is defined by mathematical relationships given as analytic expressions.

To facilitate integration between different simulation environments we created the Abstract Field Layer (AFL) – a mathematical library that can read and manipulate FRL files and perform numeric interpolation, derivation and integration on them. AFL is released under the General Public Licence (GPL) and is available from http://visiome.sourceforge.net.

Results

Multi-method model example

The work presented in this section was previously published [22]. This section summarises the work for completeness. The emphasis here is on the interchange of information between models of different representations. The interchange is illustrated in Figure 1.

The multi-model described is for treatment planning of progressed liver cancer. Ferromagnetic microspheres are introduced locally and then lodge in tumour capillaries. When the patient is subjected to an alternating magnetic field the microspheres emit heat, preferentially heating and destroying tumour tissue.

We developed a three-dimensional fractal model of microvasculature within the peripheral shell of a tumour (Figure 2a). Our model construction starts with four initial cylindrical segments representing arterial vessels. These initial segments then branch into smaller daughter segments according to probabilities derived from the literature. The segments are further constrained to a spherical shell. In turn, each segment branches and the process is repeated until the segments are too thin to allow microspheres through. The resulting vasculature covers more than an octant of the tumour.

We constructed 21 different vasculature models using different random seeds. We simulated microsphere infusion into the four initial segments of each model and recorded the proportional size and location of each cluster of microspheres in the vasculature in a FRL field. One of these fields is shown in Figure 2b.

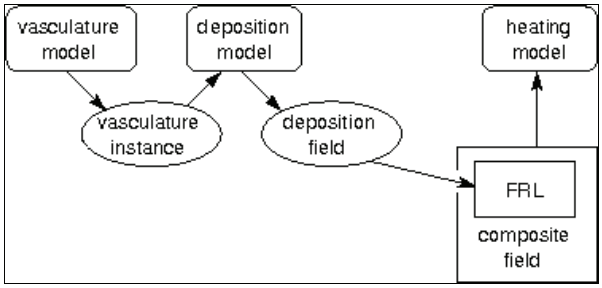

Figure 1 – Interchange between the three component models of the liver cancer treatment multi-model

Separately, we modelled an octant of the tumour with tetrahedral finite elements and assigned a volumetric heat generation rate (VHGR) to each element. The values for each element's VHGR are calculated based on the number of microspheres lodged in that element's space.

We used a composite field to scale and orientate the microsphere probabilities models so that the modelled regions were aligned. We then used AFL to compute the integral of the probabilities field over each tetrahedral element of the heating model. Listing 1 is a part of the FRL representation of the composite field that transforms the coordinate systems of the microsphere deposition field "depo5", the fifth instance of the 21 model instances generated.

The integral for each element of the composite field gives the proportion of microspheres lodged in the volume of the element and from that we computed the VHGR. The temperature field resulting from the heating simulation is shown in Figure 2c.

Listing 2 is a pseudo-code illustration of the algorithm that assigns the VHGR to each element. The integral of the field gives a number between 0 and 1 that represents the fraction of the microspheres in the entire tumour that are lodged in the volume of the current element. The VHGR is linearly proportional to that fraction.

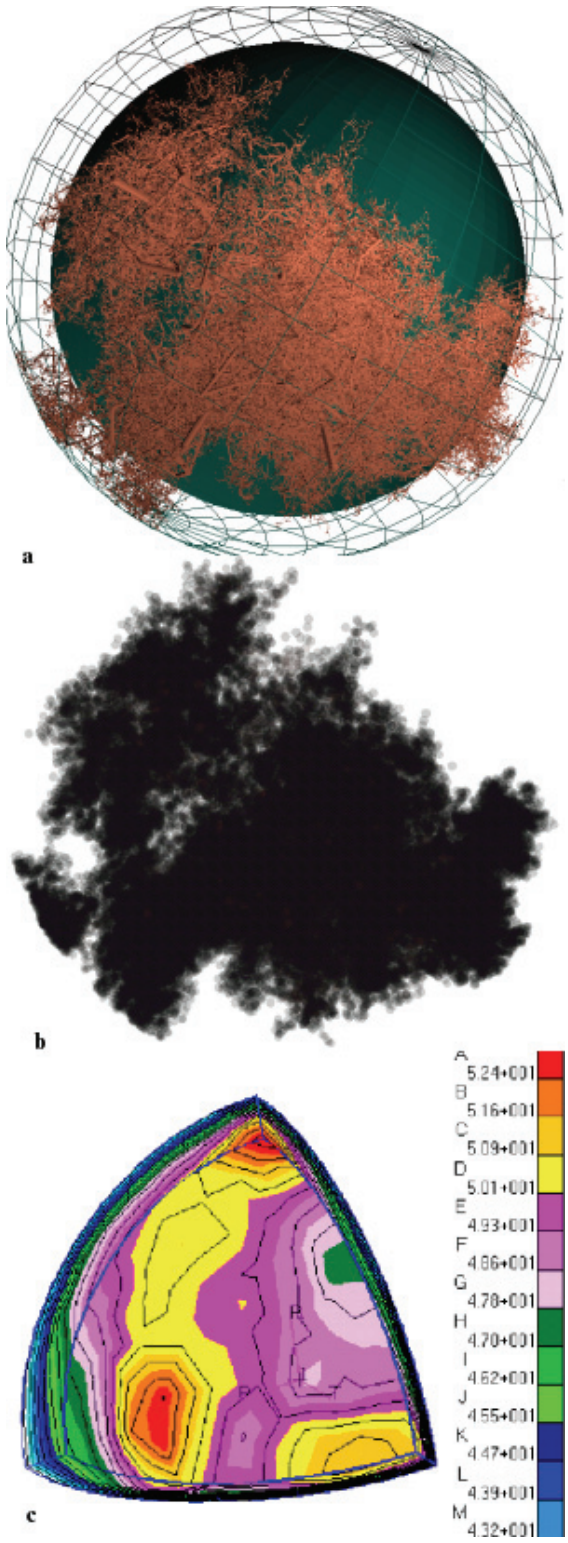

Figure 2 - Four arterial trees constrained to the spherical shell of the tumour periphery (a), their corresponding microsphere distribution field (b) and the resulting temperature field showing a heterogeneous heating pattern (c)

```
<composite name="depo5c">
  <fieldref uri="file:///depo5.xml"/>
  <function>
     depo5( -81.65*(X+Y) + 163.3*Z,
            -115.47*(X+Y+Z) + 11.25,
            -141.42*(X-Y) - 30)
  </function>
</composite>
```

Listing 1 – The composite FRL field that scales and reorientates the field "depo5" from the coordinates system of the deposition model, to that of the heating model. The coefficients were worked by hand

```
depo := load AFL field ("depo5c")
for each element e in mesh do:
    Tetrahedra t := e.getVertices()
    fraction f := depo.integral(t)
    e.assignVHGR(totalVHGR * f)
```

Listing 2 – a pseudo-code of the algorithm that assigns the VHGR to each element in the heating model based on information obtained from the composite field shown in Listing 1

Multi-scale model example

The work summarised in this section was previously presented in [23]. We created a 2D finite-difference model of activation propagation in a rabbit sinoatrial node (SAN). The model was composed of two models of specialised SAN myocytes and 231 spatio-temporal models of the extra-cellular environment (which can be thought of as the extra cellular fluid or ECF) of the tissue (*e.g.* a field of membrane potential). The myocyte models were developed separately [24] as a series of ODEs. The environment models were represented as FRL fields, of which 29 change over time as part of the interaction between individual myocytes. Individual cells interact with each other through a feedback mechanism embedded in their models. The feedback process is facilitated by changes to the ECF. For example, if one cell emits Ca^{2+} ions to the ECF, the Ca^{2+} concentration level around it goes up and this affects nearby cells.

Figure 3 illustrates the interaction between three myocytes and the environment. At each iteration T of the simulation, each myocyte reads the membrane potential's spatial derivative from the ECF at the end of T-1 (B) uses an ODE solver to compute the state of the cell at T, and updates the ECF (A). Listing 3 shows the algorithm that controls this process.

The result is a tissue model in which activation of individual myocytes was synchronised through the extra-cellular environment (Figure 4).

Discussion and conclusion

Coming up with new hypotheses is still normally done manually and is often called "model identification", "system identification" or the "inverse" problem. Existing hypothesis generation algorithms search through a space of unknown variables and identify points in the space that are consistent with the known data and first-principle rules.

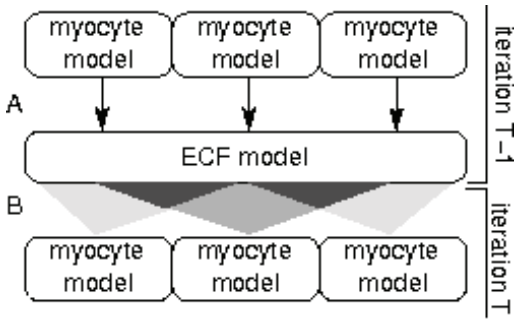

Figure 3 – Interactions in the SAN multi-model. The values set by each arrow in A is at a particular point in the ECF but affects larger regions (in grey) in B of the next iteration

```
ECF_T := set of AFL fields
ECF_T-1 := set of AFL fields
for each iteration T do:
    ECF_T-1 := ECF_T
    clear(ECF_T)
    for each myocyte m do:
        m.read(ECF_T-1)
        m.solveToNextIteration()
        m.update(ECF_T)
```

Listing 3 – Pseudo code of the algorithm that causes the cells to interact and thus drives the simulation

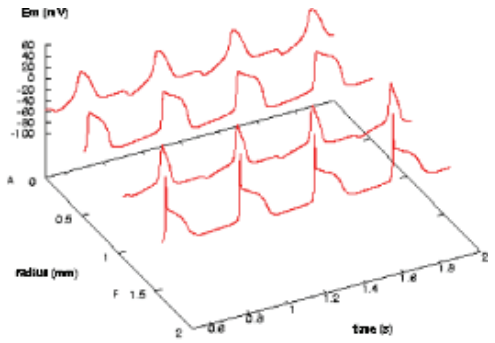

Figure 4 – A plot of membrane potential (Em) at 4 points along a radial slice of the membrane potential field in the SAN tissue model. The regular activation pattern indicates that the cells are interacting through their environment

To be able to search through knowledge spaces of multiple scales and using multiple methods, model-generating algorithms would need to be able to consider several representation languages, use a variety of modelling methods and present complex models in a human-readable fashion [25].

In addition to spatio-temporal interchange we argue for a **logical** setting for model integration in hypothesis generation and propose a machine learning approach based on inductive logic programming (ILP) [26]. Consider, a multi-model composed of three

for example, the problem of discovering metabolic networks in eukaryotic cells. Normally this process relies on quantitative methods such as flux analysis [27]. King *et al.* [17] demonstrated for the first time a successful ILP multi-model that integrated metabolic pathways from KEGG [28] with data from auxotrophic growth experiments in the budding yeast *S. cerevisiae.* Hypothesis generation in this case was the search for new experiments to maximize the refutation rate of potential genetic regulatory interactions in a multi-stage process, at the end of which a robot scientist had converged on a network to explain the data.

In a hypothetical model of pheromone response: the hypothesis space would contain a model of the cell membrane sensors, a protein interaction pathway, a transcriptional regulatory network and a set of metabolic pathways. These different types of models all have to be integrated to generate a hypothesis. ILP is the *only* machine learning approach that can integrate arbitrary background knowledge and hence different model types. A logical interface in AFL could facilitate this integration.

Standard representation languages are essential for interchange between models developed independently. However, machine learning algorithms that can reason in multiple scales and interact with other algorithms require a more profound solution, of which representation is only a part.

The current research in the area of multi-modelling is predominantly limited to standardisation of representation languages. Among those, quantitative languages seem to be leading the charge [21,29,30]. However, as of yet, there are no standard representation languages that are recognised by *any* international standards organisation.

In contrast with the current model identification algorithms which are constrained to a particular modelling method, multi-method hypothesis generation algorithms should be capable of choosing appropriate modelling methods. For this task, ontology of the available methods is required [4].

Given this ontology, a calculus of model interactions based on their model type would allow intelligent algorithms to decide which methods to use and how to construct the interactions between the modelled systems. Finally, with an ontology and a calculus, new machine learning techniques need to be formulated that are able to deduce knowledge in multiple representations, using multiple methods and support a variety of inter-model interaction models.

High-throughput biological methods necessitate high-throughput analysis methods. Computer aided knowledge discovery is an emerging field that shows promise in interpreting information from large volumes of complex data. Computational multi-modelling techniques are relatively new techniques that make complex models wieldy. As theories become more detailed, supported by more data and harder to formulate, an amalgamation of computer aided knowledge discovery and computational multi-modelling will become necessary.

In this paper we presented two examples of manually constructed multi-models and referred to several discoveries in the life-sciences that were directly aided by computer generated hypotheses. Finally, we identified several enabling areas of computer generated multi-models that are still deficient.

Guideline-based Visualization of Medication in Chronic Disease

Ján Stanek, Michelle Joy Davy

Advanced Computing Research Centre, University of South Australia, Australia

Abstract

Chronic disease management at the General Practice level is a challenging task requiring synthesis of information across time and possibly several practitioners. Sparsity of data, lack of structure, lack of time are limiting factors of computer use in this domain. Authors are exploring the concept of visualization of individual patient's medication using a clinical guideline to provide some structure to the problem by creating a state-transition model. This approach was shown to be promising at the practice level in previous research [1,5] where an overall synthesis of practice decisions was created and alerts were generated on the basis of individual transactions or states - current focus is on individual patient and the sequence of states describing his/her medication history.

Keywords:

general practice, visualization, decision support, guideline

Introduction

In managing chronic diseases, the information on the past course of the disease can be important - but many practitioners see reviewing of past data as a (necessary) evil to be done as quickly as possible [2]. With more and more general practitioners (GPs) using a computer in their everyday practice [3] it is more than tempting to use the existing data to provide support for quality and continuity of care. Typically the data is rather unstructured, with highly variable quality in terms of completeness or adherence to some coding standards. In a comprehensive review it was shown, that prescription data is the one most complete and reliable [4]. Assuming, that medication reflects significant proportion of decision-making about a case a guideline-based state-transition model was created and used for analysis at the practice level, as well as for generation of patient-related alerts [1]. While this approach shows promising results, information on patients as drawn from the model does not take into account patient-specific sequences of states. In the current work we explore the visualization of these sequences as well as generating alerts based on sequential patterns for particular patients in line with the ideas of Aigner and Miksch [9].

Materials and methods

The backbone of the study was a state-transition model focusing on treatment of hypertension in diabetes mellitus based on an American Diabetes Association guideline [1]. The data used in the study were de-identified extracts from a general practice in rural Australia holding age, gender, visit dates, problem codes, blood pressure measurements and drug prescriptions. The extracts covered 6 years and contain more than 70000 prescriptions. Two sequences of events/states were generated for each patient: prescription path and treatment path.

Treatment path

According to methodology described in [1] medications were clustered into 6 groups (group B has 3 subgroups):

- Group A: Angiotensine converting enzyme inhibitors (ACEi) - ATC codes C09A and C09C
- Group B1: -blockers (BB) - ATC codes C07AA, C07AB
- Group B2: Diuretics - ATC codes C03AA, C03CA or C03D
- Group B3: Non-dihydropyridine Ca-channel blockers (NCCB) - ATC code C08D
- Group C: Dihydropyridine Ca-channel blockers (DCCB) - ATC code C08CA
- Group D: -blockers, hydralazines, clonidine - ATC codes C02CA, C02DB, C02AC

To simplify the model-building process we deviated slightly from standard ATC coding - combination drugs were coded as if a set of separate drugs was given.

Based on prescription data states were generated, using the amount and the daily dose of prescribed drug to calculate duration of treatment with a particular drug group. In this calculation we assumed, that patient starts the medication on the same day as it was prescribed, that the dosage is unchanged throughout the time covered by a particular prescription (and the patient adheres to the dosage).

All methods were implemented using Cache and Ensemble (Intersystems Inc.), graphs were generated using GraphViz software (www.graphviz.org).

Prescription path

A prescription is a sequence of prescription instances. A prescription instance is a drug, or combination of drugs as

prescribed on a particular day, disregarding dosage or quantities prescribed.

Results

A prescription path and a treatment path are shown simultaneously and provide different views on what was done. E.g. if a drug containing a BB and diuretic was prescribed and at the same time a potassium-sparing diuretic was prescribed the prescription instance is shown as B1+B2+B2; while the treatment path will show B1+B2 combination. (Figure 1).

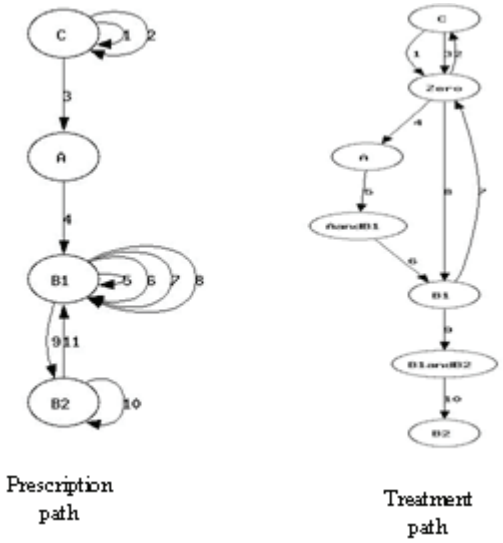

Figure 1 - Prescription path vs. Treatment path

Alerts

Visualisation of the paths should be in most cases enough for an experienced GP to see any unusual patterns. Analysing treatment paths allows to create an additional class of alerts, taking into account more than just one state or one transition Eventually the whole path can be taken into account in launching an alert - e.g. a cyclic repetition of transition tuple (A to B1 followed by B1 to A) for more than **n** (usually 2-4) times may be considered an unusual pattern and an alert should be launched.

Discussion

Guideline can be utilized at two levels in data analysis. First approach is to use the guideline to structure the problem space and then fit the data into the resulting of structure. Several authors applies such approach in hospital settings [6, 7, 8]. The guideline context make it easier for physicians to recognise and appreciate the rationale behind the graphs and alerts.

Alternate approach is to use data mining techniques to raw data and then compare the results to a guideline (e.g. [10]) This approach can be exploited either to improve the guideline or to detect exceptions in clinical workflow.

Conclusion

Authors extended the scope of previous research [1] by adding visualizations for individual patients as well as new types of alerts taking into account more than just one transition or just one therapeutic state. This approach is to be validated by a clinical study in next future.

Acknowledgments

Special thanks to Lubims Pty. Ltd. for providing the datasets and to Intersystems Inc. for providing licenses for Cache® and Ensemble.

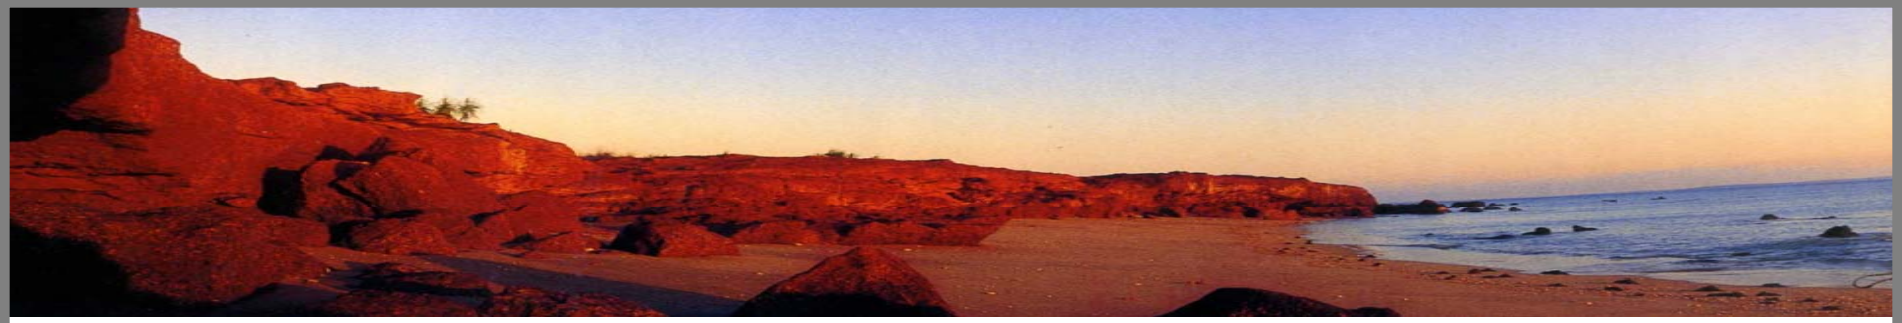
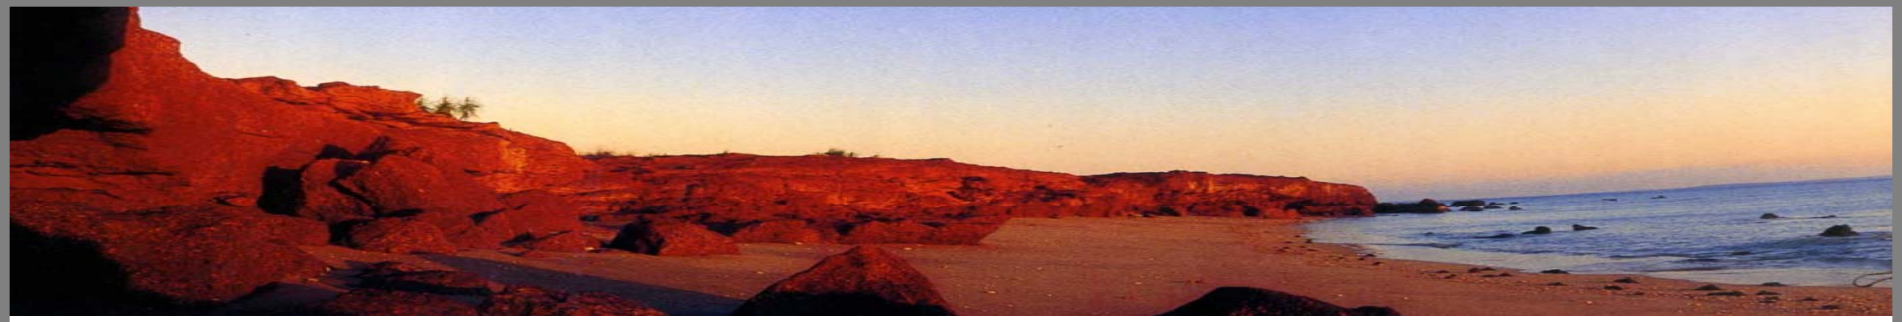
Guideline-based visualization of medication in chronic disease

Jan Stanek, Michelle J. Davy
University of South Australia
ACRC



The problem

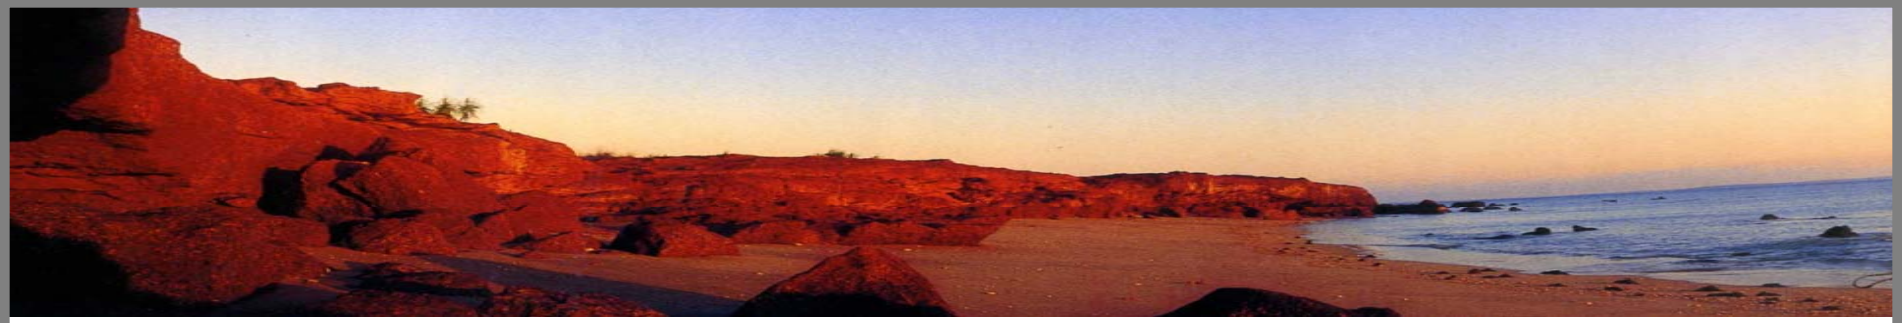
- Growing complexity of medicine
- Growing pace of change
- Growing focus on evidence and *demonstrated* quality of care
- Restricted budget – especially at GP level



Opportunity

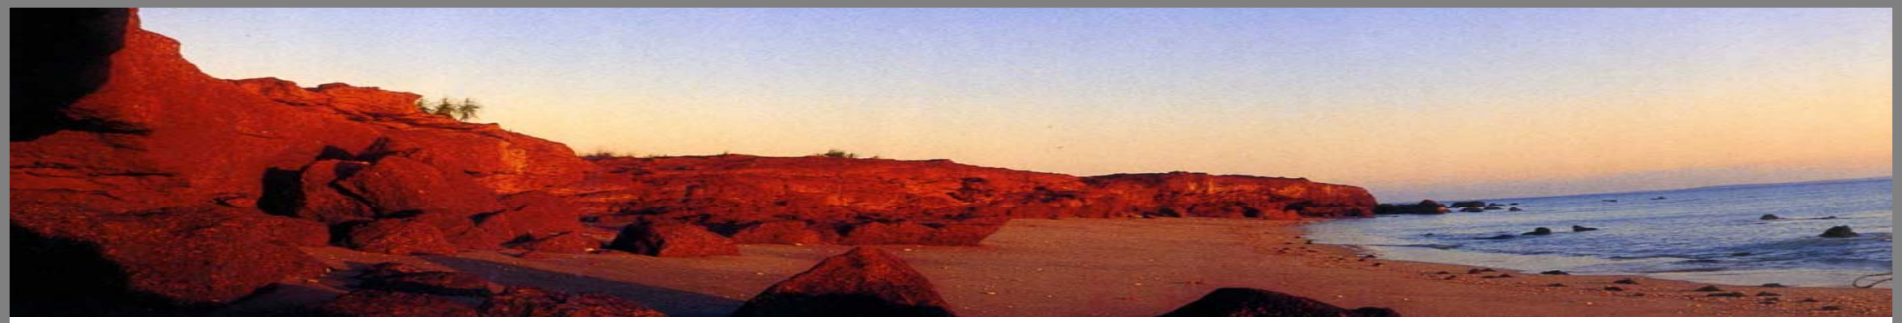
- Over 96% of Australian general practitioners (GPs) use computers
- Prescription data is the best data at GP level *)
- Treatment guidelines are available

*) Thiru K, Hassey A, Sullivan F, Systematic review of scope and quality of electronic patient record data in primary care. BMJ 2003; 326: 1070-80.



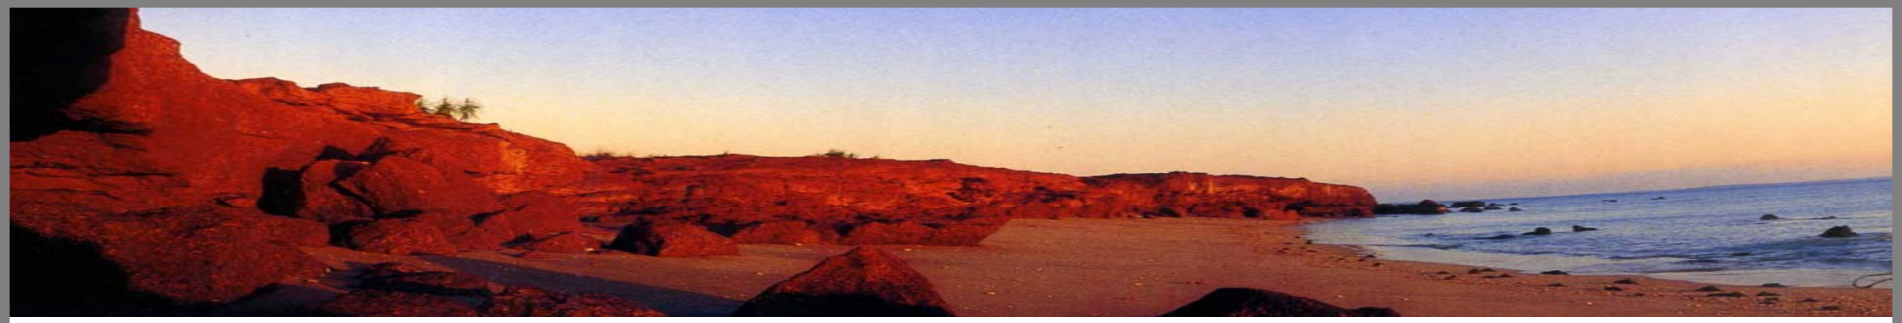
Hypothesis

1. Additional significant information can be extracted from routinely collected data in general practice
2. Feeding this information back to GPs is useful
3. This information can be presented in a way which does not require extensive user training of clinicians



The Project

1. Use guideline to structure the problem space (create state-transition model based on a guideline)
2. Fit relevant data from the GP electronic records into the model
3. Use the model for information syntesis and feedback to the practice

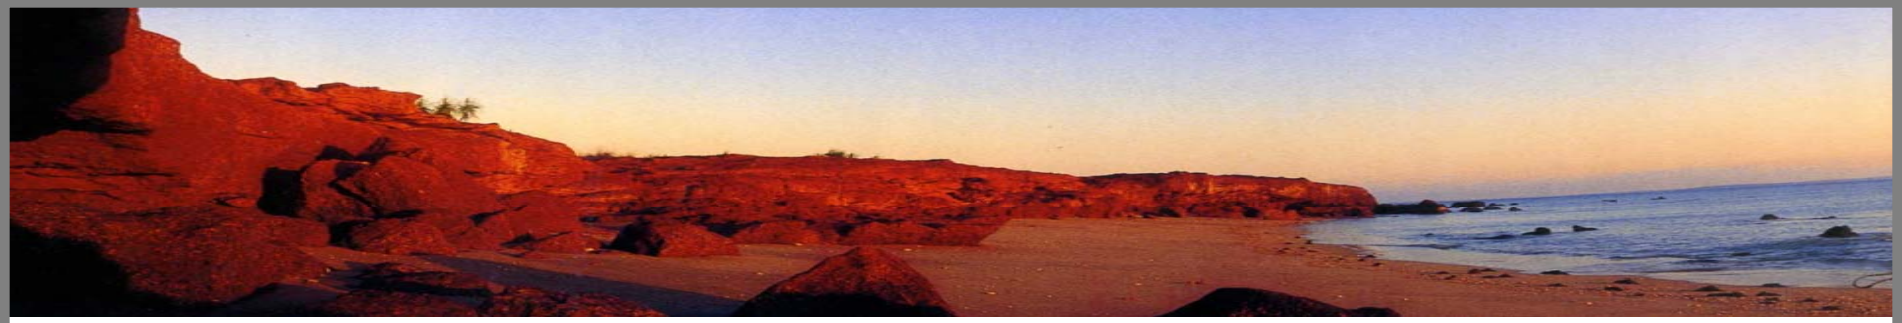


Project components

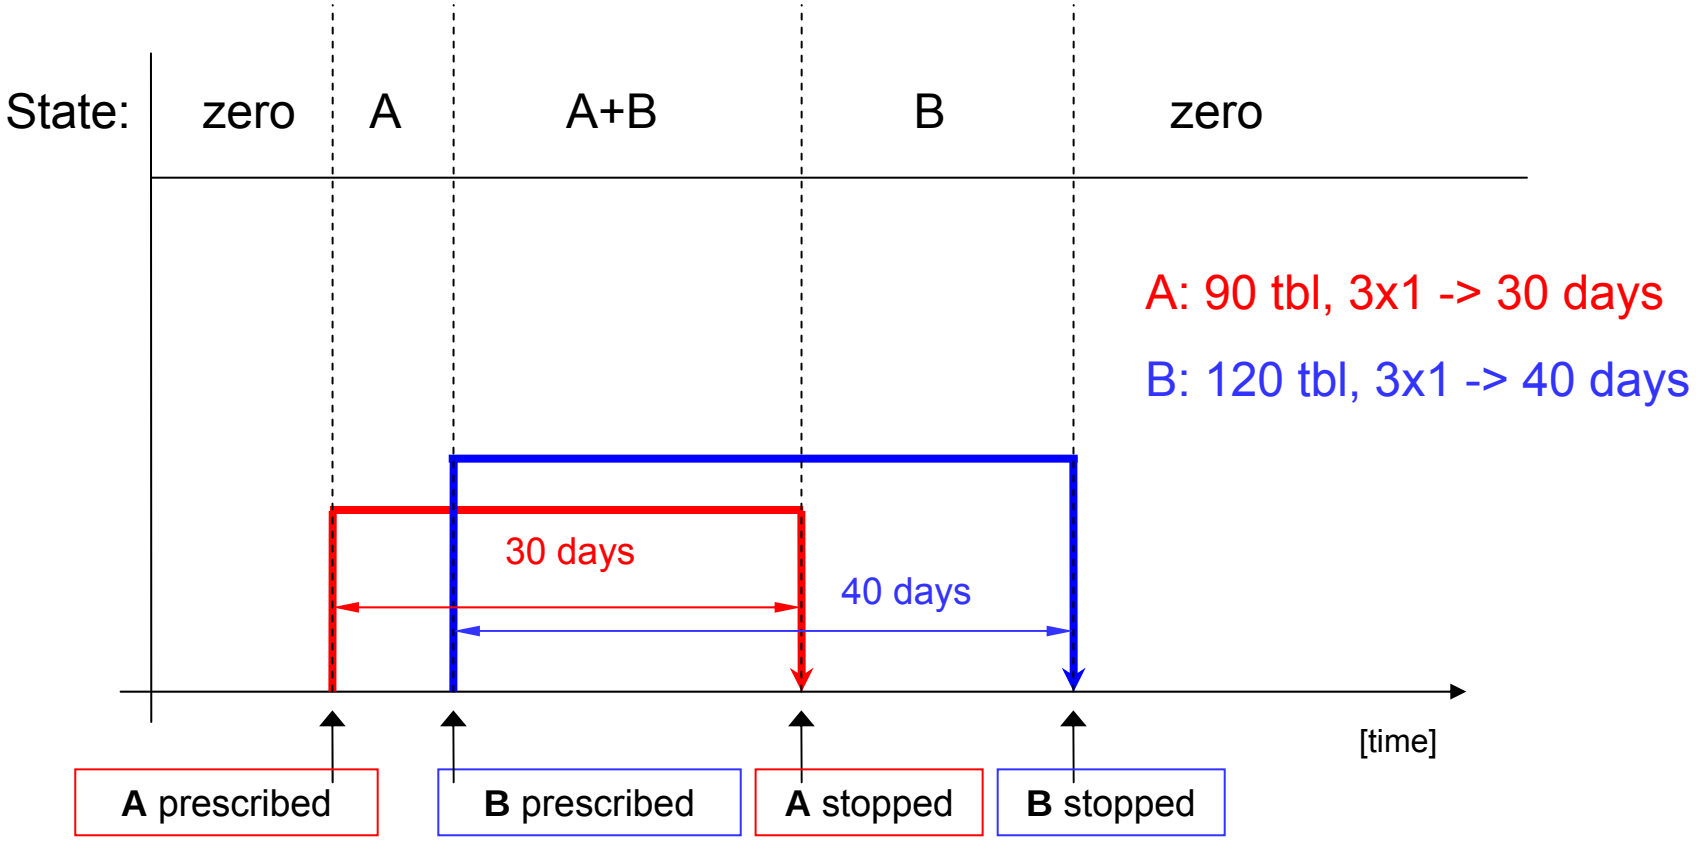
- Guideline: Treatment of hypertension in diabetic patients *)
- Prescriptions – drugs classified according to ATC and organised into groups reflecting the guideline**)
- Data extracts form GPs (70000 prescriptions across 6 years)

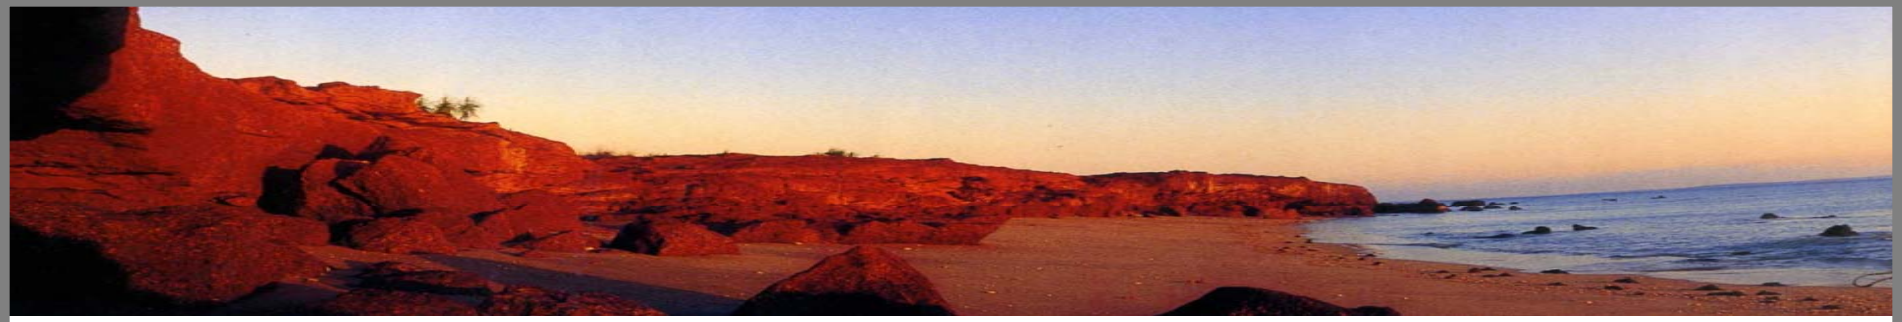
*) American Diabetes Association, Hypertension management in adults with diabetes. Diabetes Care 2004; 27:S65-S67.

**) Gadzhanova, S. et al.: Developing High-Specificity Anti-hypertensive Alerts by Therapeutic State Analysis of Electronic Prescribing Records. JAMIA, 2007;14, pp 100-109.



Converting prescription events into states:





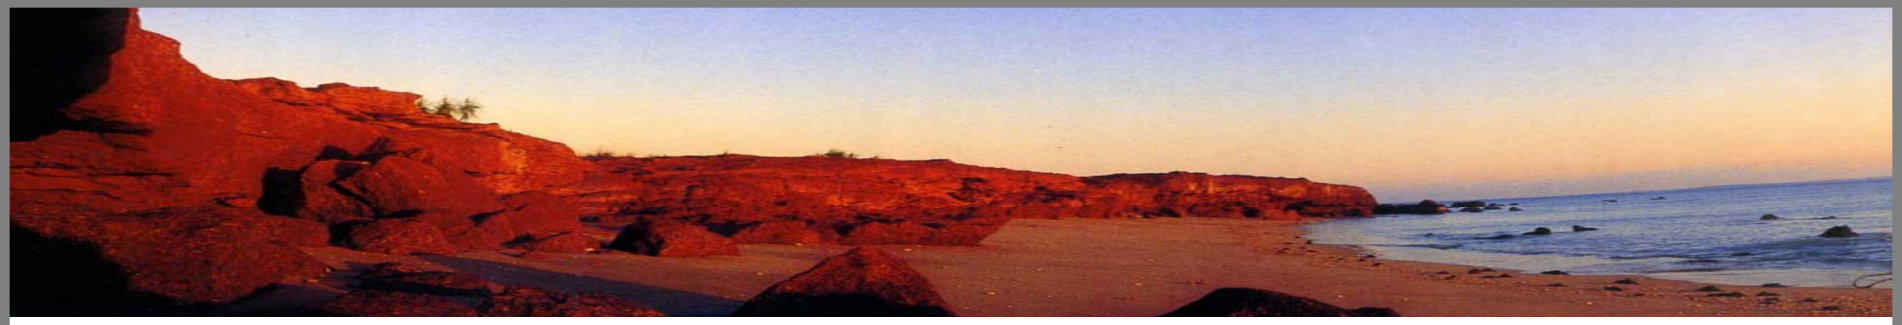
Results

Prescription path = showing the sequence of prescription events (**A** - **B**)

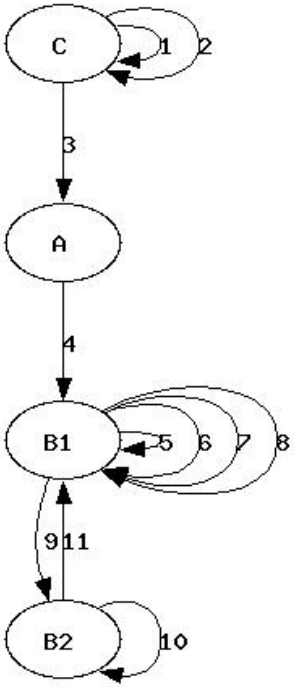
Treatment path = showing the sequence of guideline-derived states

(zero → A → A+B → B → zero)

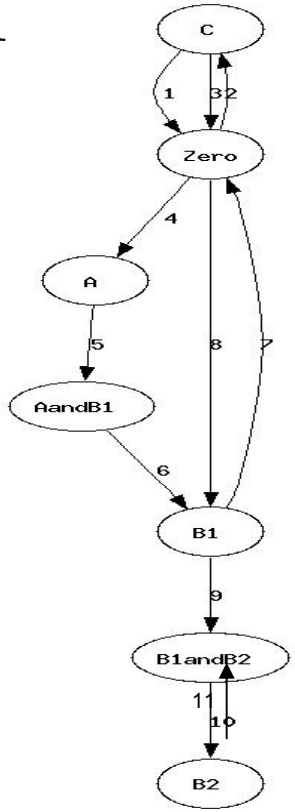
Zero indicates the patient does not appear to have any medication



Visualisation

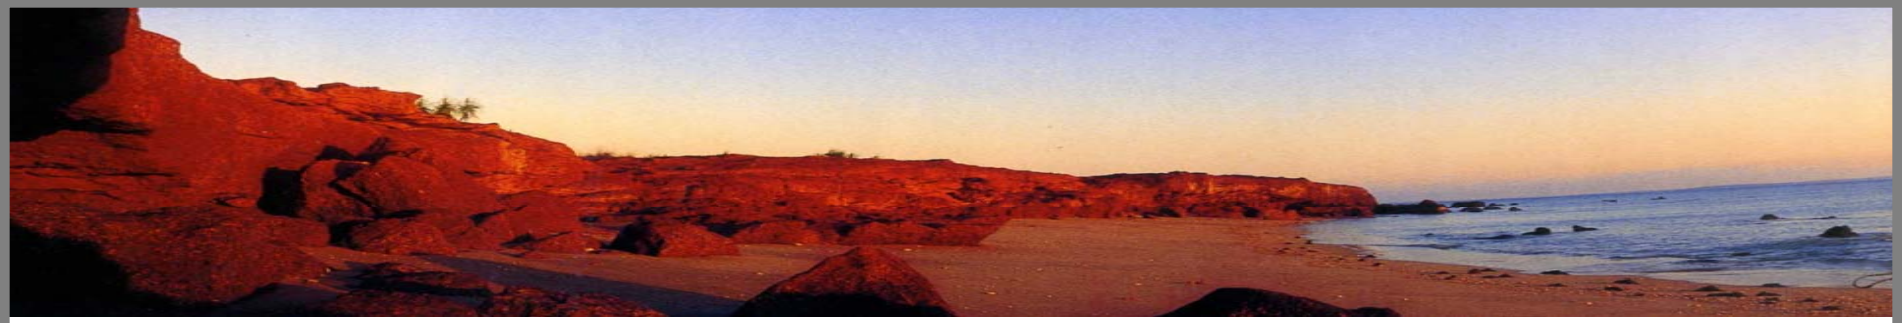


Prescription path



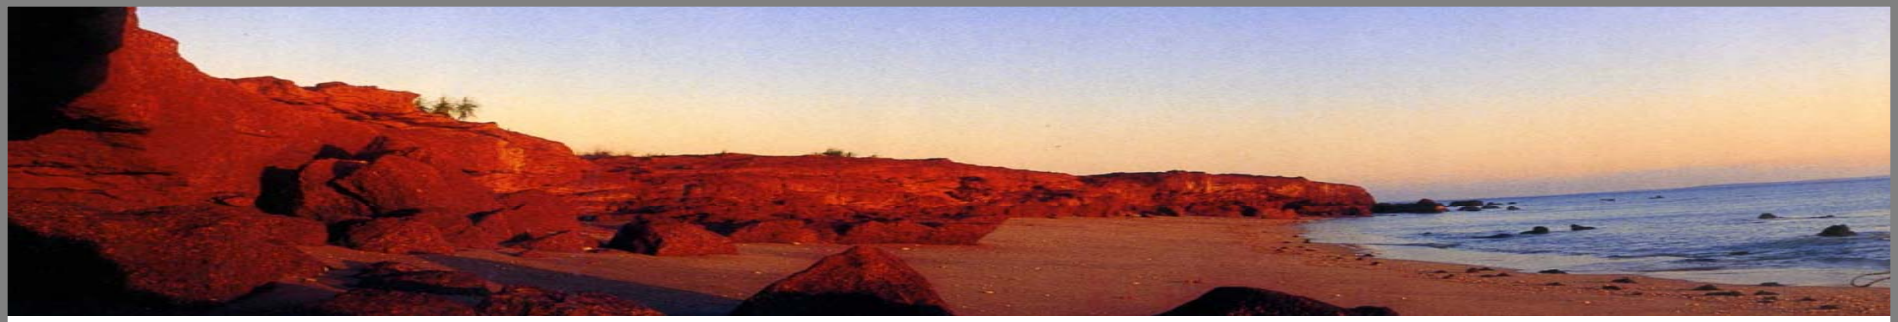
Treatment path

Group A: Angiotensine converting enzyme inhibitors (ACEi) - ATC codes C09A and C09C
Group B1: β-blockers (BB) - ATC codes C07AA, C07AB
Group B2: Diuretics - ATC codes C03AA, C03CA or C03D
Group B3: Non-dihydropyridine Ca-channel blockers (NCCB) - ATC code C08D
Group C: Dihydropyridine Ca-channel blockers (DCCB) - ATC code C08CA
Group D: α-blockers, hydralazines, clonidine - ATC codes C02CA, C02DB, C02AC



Use of the paths

1. Direct use:
   - both paths are directly related to the practice and (given the GPs know the guideline) readily understandable
   - Unusual paths can be picked from the image itself
2. Indirectly
   - both types of paths can be used to generate alerts (e.g. unusual states, transactions, cycles) – serving as a possible screening of unusual cases.



Related work

- Probably closest to our approach were authors*) using a guideline to lead their data-mining exercise, although on a smaller sample of patients in hospital setting
- Others**) too worked in a hospital, data rich setting and focussed more on intentions, guideline compliance and quality control.

Geographic and Management Information Systems Join Forces: Delivering More than the Sum of their Parts

Thomas Ganslandt[a], Stelios Gikas[a], Ronald Grolik[a], Katharina Diesch[a], Hans-Ulrich Prokosch[a]

[a] *Department of Medical Informatics, Friedrich-Alexander University Erlangen, Germany*

Abstract

Management and Geographic Information Systems have coexisted in the medical field with clearly defined boundaries. Recently, geovisualization toolkits like GoogleMaps™ have introduced freely-available high-resolution imagery and standardized APIs, lowering the barrier for a seamless integration of MIS data and GIS functionality. In this project, an existing MIS was extended by geovisualization functionality based on GoogleMaps. Sustainable usage scenarios were identified, including visualizations of patient origins, distributions of bacteria and drug-resistance patterns. It could be shown that geovisualization is suitable for location-based MIS queries.

Keywords:

Geographic Information Systems,
Management Information Systems, Data Warehouse,
visualization

Introduction

Management Information Systems (MIS) have been applied in the medical field since the early 1980s, providing consolidated data and analyses with an emphasis on administrative information needs, e.g. service performance and utilization or cost structures. Geographic Information Systems (GIS) have been increasingly mentioned in medical literature since 2000, with applications focusing primarily on the support of epidemiological studies at a regional or national level[1-4]. Early GIS development was hampered by a lack of freely available high-resolution map imagery as well as the necessity to implement proprietary application programming interfaces (APIs). With the advent of Google Earth™ and Google Maps™ in 2005, a simple-to-use API was made available together with high-quality digital satellite and map imagery under a license that permitted free non-commercial use. The simplicity of the API led to a rapid worldwide uptake, including the medical field[5;6]. As a virtue of this commoditization, GIS methods can now be leveraged to add a new dimension to MIS data analysis: visualizing service cost and utilization data geographically can further support management decisions on a regional or local level. Clinical users may also benefit by integrating workflow or infection surveillance data with a geographical representation. Erlangen University Hospital, Germany, has built an extensive MIS based on a data warehouse platform, integrating information from various administrative and clinical sources[7]. As the hospital is also distributed among several locations within the area, it would profit especially from a comprehensive geographic visualization of its MIS data. The goal of this project is to integrate the existing Erlangen MIS with GIS functionality and evaluate sustainable usage scenarios.

Materials and methods

The Erlangen MIS is based on the Cognos BI™ platform and imports data from all connected source systems on a nightly schedule. The reporting platform provides both standard relational and OLAP paradigms as well as the locally developed workflow visualization system *Pathifier*[8]. The geovisualization functionality was implemented as an extension of the *Pathifier* application. Geocoding of transactional data (e.g. patient addresses) occurred at run-time by means of freely available geocoding databases (OpenGeoDB, GNIS, GEONAMES), whereas coordinates for hospital locations were geocoded manually and permanently stored as additional attributes to the organizational dimension of the data warehouse. The geovisualization implementation was based on the GoogleMaps API, using a standard AJAX (Asynchronous Javascript and XML) pattern. Data warehouse-based measures (e.g. amount of cases selected, distribution of diagnostic tests ordered or antibiotic resistance) were dynamically rendered and overlaid on the maps. Detailed information on a specific icon was provided through pop-up windows. Icons were clustered dynamically depending on the chosen map zoom level.

Results

The GIS extension has been operational since mid 2006. Integration with the *Pathifier* application is seamless and delivers an intuitive graphical representation of fact data from the MIS. By clustering image elements on lower zoom levels, visual clutter is avoided. Geocoding worked reliably for full German address records including ZIP-codes. For records without ZIP-codes or international records it was necessary to rely on the less detailed GNIS and GEONAMES datasets which are susceptible to mis-

spellings as well as homonymous or synonymous location names.

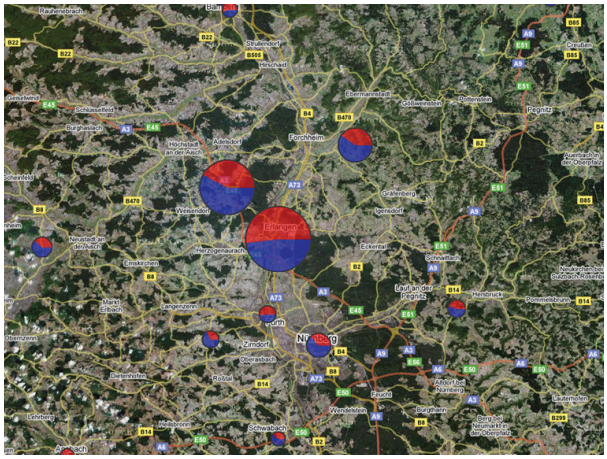

Figure 1 - Origin of Diabetes patients (2006) differentiated by sex (red=female, blue=male) on a regional level

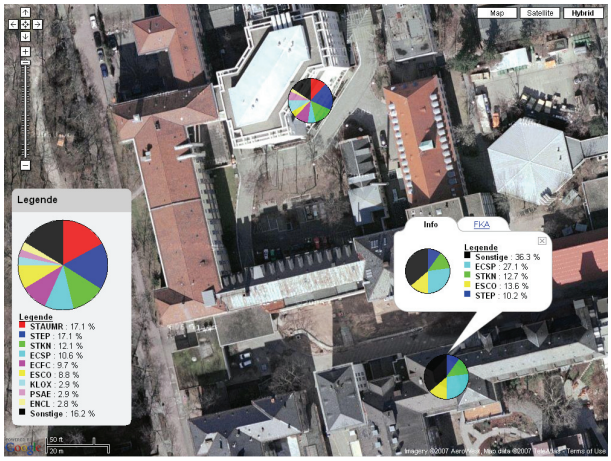

Figure 2 - Top 10 resistant bacteria strains at a standard care versus an intensive care unit

Discussion

In this project, we were able to achieve seamless integration of geovisualization functionality into an existing MIS by using freely available, standardized tools. Only limited effort was necessary to manually geocode hospital organizational units. Geocoding of address data was fully automated, but manual interventions might be necessary to disambiguate international or incomplete records with multiple or no matches in the respective geo-databases. Making use of the established GoogleMaps API and user interface provided users with a well-known navigational concept, making special training for the system unnecessary.

Preliminary feedback from users indicates that the new GIS functions are providing answers to common questions like "Which areas do my patients come from?", "At which wards are MRSA-infected cases?" or "What are the drug-resistance patterns throughout the hospital?". Data and corresponding tabular reports for all of these questions were available in the MIS previously, but the new visualization mode provides a faster overview and more intuitive. In comparison to epidemiological visualization projects published previously, using MIS data opens up a new field of view towards local developments occurring within organizational units, as well as providing detailed data updated on a daily basis. Data confidentiality is a concern, as an external service provider (Google) is taking part in the geovisualization process. However, geocoding takes place locally, and only aggregated iconic data is displayed within the map.

Conclusions and outlook

The synthesis of MIS data and GIS functionality is providing a valuable tool for both administrative and clinical users to visually explore location-based data in a way not possible previously. By being based on freely available standardized tools, the approach used in this project should be portable to other sites with a comparable infrastructure. Further development will include a formal evaluation of the system as well as further extensions of its visualization functionality. Areas of special interest will include infection surveillance and visualization of workflow patterns.

Visualization of Preterm Birth Health Disparities

Karen L. Courtney[a], Christina Baktay[a], Sara Stewart[b], Mihail Popescu[c], Linda K. Goodwin[d]

[a] *School of Nursing, University of Pittsburgh, USA*
[b] *Independent Researcher, USA*
[c] *School of Medicine, University of Missouri - Columbia, USA*
[d] *School of Nursing, Duke University, USA*

Abstract and objective

Preterm birth is one of the leading causes of infant mortality in industrialized countries. There is a growing body of literature that suggests socio-economic and socio-demographic factors may be causal factors that either explain or confound birth outcome disparities. Understanding differential patterns in birth outcomes is necessary to develop effective interventions designed to decrease birth outcome disparities amongst pregnant women. This project used geographic information systems and publicly available birth records to explore geographic disparities in birth outcomes in North Carolina. Building on prior statistical and computational models, this poster presents the visualization of geographic variation in birth outcomes as associated with the following maternal demographic predictor variables: race/ethnicity; age; education level; and marital status. Birth outcomes associated with health history variables of cigarette smoking and the Kotelchuck Index are also visualized. Data visualization is an important step in exploring patterns and understanding the context of preterm birth. This research will help to identify target areas for future preterm birth prevention interventions.

Keywords:

premature birth, geographic information systems, population characteristics, health services research, informatics

Methods

The purpose of this study was to use geographic information systems (GIS) to explore geographic variations in birth outcomes associated with selected demographic and health history variables. This study is a retrospective, secondary analysis of de-identified, 2003 North Carolina birth record data.

Data source

This data set contained approximately 120,000 live births and included maternal, paternal, infant and health care system variables. When filtered for out-of-state births, induced or stimulated labor and multiple births, the data set contained approximately 73,000 birth records.

Data analysis

Both statistical and computational methods were used to investigate a parsimonious preterm birth prediction model based solely on birth certificate data. Methods included: logistic regression, neural networks, classification and regression trees, Support Vector Machines and Bayesian classifiers for model comparison. Receiver Operating Characteristics curves were used to compare results across methods. Individual predictor variables were visualized using GIS for geographic variation in preterm birth outcomes.

Results

Data visualization demonstrated wide geographic variation in preterm birth outcomes in the selected maternal demographic variables and selected medical history variables. Noticeably different patterns emerged for each variable. Descriptive variable pattern maps will be presented on the poster.

Conclusion

Data visualization is an important step in exploring patterns and understanding the context of preterm birth. The geographic variation in the demographic and medical history variables illustrates the need for incorporating context into prediction models. GIS visualization enhances researchers' abilities to discover patterns across variables that may not be readily apparent within numeric tables.

The next step in this research is to apply spatial statistics to the individual variables and to assess the geographic variation in the full statistical and computational model. This research will help to identify target areas for future preterm birth prevention interventions.

A Pilot Evaluation of Fall Prevention Rooms in a Hospital Facility

J. Turley, RN, PhD [a]; R. Vogler, RN, DSN [a];
P. Willson, RN, PhD [b]; L, Eriksen, RN, DSN [c], A, Dains
a

[a] The University of Texas, Health Science Center, School of Health Information Sciences, Houston, Texas, U.S.A.

[b] Prairie View A&M University, College of Nursing, Graduate Program, Houston, Texas, U.S.A.

[c] The University of Texas, Health Science Center, School of Nursing, Houston, Texas, U.S.A.

Background

- *Falls continue to be a major safety problem for hospitalized patients.*
- *Measures for patients at risk for falling have been directed towards: prevention by identifying patients at risk & safer room design.*
- *The majority of reported falls and near falls are un-witnessed so data are not available to characterize these un-observed falls.*

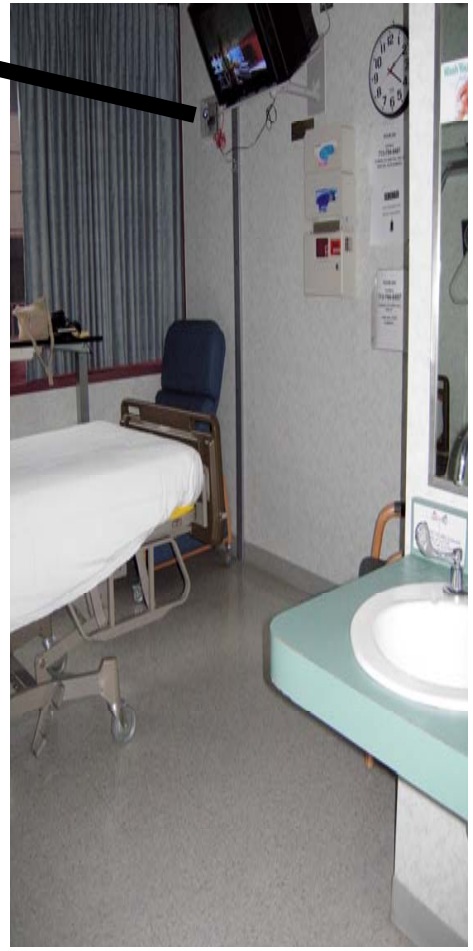
Problem

- *Some evidence indicates that patients may repeat circumstances or characteristics of the initial fall in subsequent falls.*
- *Since the majority of falls or near falls are un-witnessed there is no rigorous research available to provide data and/or support allegations concerning subsequent falls.*

Objectives

- *To evaluate the effectiveness of dedicated fall prevention patient rooms.*
- *To monitor patients identified at risk for falling using video cameras*
- *Establish a methodology to record and analyze falls that usually go un-witnessed.*

Methods



- Two rooms specifically designed for fall prevention were outfitted with video-cameras to record patient ambulation.
- Video surveillance of consenting adult patients occupying two fall prevention designed hospital rooms was maintained on a 24/7 basis.

Methods

- Video-images stored on hard drives were routinely collected and screened for any fall or near-fall incidents.
- Video recordings of fall or near-falls would then be subjected to further software analysis
- Any fall events would be documented and characteristics of the recorded falls and/or near-falls would be determined.

Results

- *Although no fall or near-fall events were recorded during the 1680 hours of video surveillance*
- *The equipment and methodology proved effective in monitoring patients*
- *The video quality was sufficient for further software analysis of fall events*.

Discussion

- Although fall prevention rooms are available for hospitalized patients identified at risk for falling the patients admitted to the rooms may not met the at risk criterion.
- The use of video surveillance for patients at risk for falling in hospital rooms with fall prevention measures can provide needed data to evaluate both the fall prevention rooms as well as determine the characteristics of usually un-witnessed patient falls or near falls.

Conclusions

- This pilot evaluation proved successful for establishing methodology for video monitoring of patients at risk for falls during hospitalization in rooms dedicated to fall prevention.
- Further monitoring of at risk patients is needed in order to record actual falls or near-fall events and submit the video observations to further video software analysis.

Implications

- The use of video technology can provide data concerning the effectiveness of identifying patients at risk for falling & the rooms designed for these at risk patients.
- Video technology can also provide data concerning the characteristics of falls or near falls and subsequent events.
- If it is determined that patients repeat circumstances and characteristics with subsequent fall events then an education/therapy program could be developed for these patients.
- Further studies may increase the ability of health care agencies to provide a safer environment for patients at risk for falling as well as result in a possible reduction in the incidence of falls.

The Development of an Information System and Installation of an Internet Web Database for the purposes of the Occupational Health and Safety Management System

I. Mavrikakis[a,1], J. Mantas[a,1]

[a]*Department of Public Health, Faculty of Nursing, University of Athens, Greece*

Abstract

This paper is based on the research of the possible structure of an information system for the purposes of occupational health and safety management. We initiated a questionnaire in order to find the possible interest on the part of potential users in the subject of occupational health and safety. The depiction of the potential interest is vital both for the software analysis cycle and development according to previous models. The evaluation of the results tends to create pilot applications among different enterprises. Documentation and process improvements ascertained quality of services, operational support, occupational health and safety advice are the basics of the above applications. Communication and codified information among intersted parts is the other target of the survey regarding health issues. Computer networks can offer such services. The network will be consisted of certain nodes responsible to inform executive persons on Occupational Health and Safety. A web database has been installed for inserting and searching documents. The submission of files to a server and the answers to questionnaires through the web help the experts on their activities. Based on the requirements of enterprises we have constructed a web file server. We submit files so that users can retrieve the files which they need. The access is limited to authorized users and digital watermarks authenticate and protect digital objects.

Keywords:

occupational health and safety, workflow management, computer networks, World Wide Web, file submission, questonnaries

Introduction

The management of occupational health and safety constitutes a field which concentrates the interest of enterprises. Particularly the enterprises with a modern concept of management, not only care to comply with the legal obligations as far as it concerns the occupational health and safety, but also they implement a health and safety management system, in order to improve the work conditions. Quality management systems are developed and implemented to enterprises following some standards. For health and safety management, ISO 18001 is widely applied. For the development of such systems the workflow and information management between experts and enterprises is very important and interesting. The use of computer networks and the whole infrastructure is significant for this purpose. Such a system can be administered via the WWW. An external expert can handle the information in a way to correct and to intervene to improve the quality of occupational health and safety services. We have developed such a system in order authorized users, of each enterprise, mainly the responsible for the occupational health and safety, can communicate and submit files. On the other hand, we can use comments for each submission to explain in a more executive way the files and retrieve them. For the purpose of managing and detecting some very important workflows we use questionnaires; the processing of which are very useful for management and decision making in this field. The depiction of interest is important because we adopt new technologies and methods in order to accommodate the procedures for the occupational health and management system.

The interest of the potential users responsible of the occupational health and safety is included on the analysis cycle of the software. At the second phase we are searching about the requirements of the enterprises analyzing the answers of the questionnaires. The evaluation of the results by the experts will lead us to create pilot based applications for communication between enterprises and selected branches.

At the second phase of the implementation work we are developing a system which will be responsible to inform the interested parties about the subjects of occupational health and safety management system. On the other hand

1 Health Informatics Laboratory, Faculty of Nursing, University of Athens, 123 Papadiamantopoulou street, 11527 Athens, Greece,
email mavrik@csd.uoc.gr, jmantas @cc.uoa.gr

this system is going to store information about educational issues. A relational database is a scientific tool for the purposes of storing and retrieving useful information.

We insert new technologies to depict the daily situations on the working conditions and in order to support the work of the administration and the work of the employees. We initialize a measuring system based on ISO 18001 in order to evaluate and shape new working conditions. The instability at the working conditions forces us to initiate some rules to protect and promote health and safety of the employees. We are trying to develop a system which will be useful to the users. Such a system after the frequent use must be improved in order to keep the practical features and be more operational. The improvements of such a system is not an easy task. We must find the principle components which support our system and follow some equations to intervene to improve the state of the system. We should pose some limits for the states of the system. In case we exceed them we must enable some actions to correct and to prevent the unsafe conditions. We should restore to the initial regular state the system in case we find that we have exceeded the initial parameters.

In order to achieve the above ideas we should install some means of communication between enterprises. The internet support this communication. The protocol which the internet is based is the TCP/IP[9]. The address IP is a 32-bit number fundamental to Internet addressing and routing. It is also used for addressing the servers and clients. The TCP/IP provides a realiable transport service which is used by most Internet Applications. Examples of applications are the electronic mail (e-mail), the File Transfer Protocol (FTP) and the access of Web Pages through the World Wide Web via HTTP. The evolution of the e-mail was the incorporation into the web.

Some issues on computer networks

Interconnection networks play a major role in the performance of modern enterprise management. There are a lot of factors which can differentiate the design of each network.

- Performance requirements (on time and reliable decisions from the informations we collect): All operations are usually performed by explicit message passing or by accessing shared variables. To reduce the message latency, we reduce the idle time of processes and memory access time to remote memory locations [6]. The delay of information trasmission between two points is a very important aspect in case we take some useful decisions. The validity of information is also important, if we can collect information from all the enterprises we have reliable data, otherwise the latency of communication between the enterprises and the experts may cause an unreliable source of information.
- Scalability: As we add more enterprises in the network, we should proportionaly increase the network bandwidth, the I/O bandwidth and the memory bandwidth. If we are not able to use a scale factor for all the above requirements, at the network, it may become a bottleneck for the rest of the system decreasing the overall efficiency accordingly[6].
- Incremental expandability (example of ISPs): Customers are unlikely to purchase a computer network with a full set of computers and other electronic devices. More enterprises may be involved in the network until a system's maximum configuration is reached. We should find a way that the new nodes we add, do not decrease the performance. For example if we have 10 enterprises and we want to install an internet service provider we may not use a provider exactly for 10 enterprises, we should predict that after a long time we may provide our services to 15 enterprises, so we must use a provider with incremental expandability in order to reach the new requirements.
- Partition ability: It depends on the work we want to do. We devide the work in several partitions and then we dedicate certain tasks to computers of network [7]. This partition is very efficient for the performance of the network. We can use it also for the design of the network, we configure a network for the requirements of our work and we do not configure the work to the requirements of the network. For example we can use one node of the network as file server, another as database server, another as network server etc. Partition ability may also be required for security reasons[6].
- Simplicity: It is useful for the customers who understand the design and can easily exploit their performance. Otherwise the network may not be so efficient [6].
- Distance span, Locality: There are appropriate mechanisms which can reduce the noise during the transmission of the data, but there are a lot of constraints mainly on the distance between nodes on this domain. The use of optical links solve these problems equalizing the bandwidth of short and long links up to a much greater distance than when copper wire is used[6]. The locality is a very importat parameter, we must know where the enterprises are placed in a map in order to design a network.
- Physical Constraints: The operating temperature control, the wiring length limitation and the space limitation are constraints for the network design. We must be careful in case we put together a lot of wires, the overheating may cause damages to the wires [6].
- Reliability and Repairability: It should be able to transmit information reliably. In addition interconnection

networks should have a modular design allowing upgrades and repairs [6].

- Expected Workloads: The network design should be robust. The performance should be efficient independently of the wide range of traffic conditions [6].

Cost Constraints: We should find an optimal solution between the cost of the implementation and the performance of the network. A solution which is probably expensive it is not necessery and efficient [6].

Interconnection networks

At the design of a network we should predict its connectivity with other networks, such as wide area networks [17]. We may need to connect our network with a network of an enterprise and to communicate with an establishment of the enterprise, in order to find useful informations for our work. We can connect our network with leased lines of the telephone network, in order to use services such as voice over ip, teleconference, video conference etc. Interconnection networks exist between parallel and distributed systems[3], [4], [7]. In general purpose the usage of the above systems is the efficient solution of a problem. The network design help us to devide our work into small tasks and try each computer to solve these small tasks. Then we combine the solution of each node to the final[7]. For those systems the network should reduce the message latency in order to be efficient[3]. A decomposition technique based on interconnection network should care for the load balancing of the work between computers. A central unit can recursively divide the work, sending partition of work to nodes and control the overall work.

Meanwhile an application can not use general rules, the services we want the network offer to their users and the quality of services determine the parameters of a network. There are a lot of issues in network design[6], [25], [26]. First issue is how many routers we are going to use. Having a topological map of the whole network where shall we put them? The connections are going to be wireless (data links), which routing algorithm we are going to use, Dijkstra or smth else. There are also some challenging issues such as the network bandwidth and the time delay of packets. Computer networks individual for enterprises are crucial for their speeds in transfering data and for the internal communication.

Programming and configuring an internet web database

For the purpose of installing a web database we used the Apache Server Program and a Database Management System. The apache server enables some files of the host computer to be accessible from the Internet via the HTTP. For the communication of the database we use some script programs written in PHP language. The accessible files via HTTP are HTML forms which communicate with PHP programs[27]. For safety reasons we used some global variables (sessions) on php scripts in order only experts and executive persons from enterprises could administer the internet web database. The information on the Internet Site is accessible to everyone. On the site we can find which enterprises are interested on the domain of Occupational Health and Safety. We can find the executive persons of each enterprise which are responsible to communicate with us. We install a communication between the database and one program in java [8] in order to compute some interesting statistical values from the dataset. The internet web site which host a part of our work is located at the address http://healthandsafety.nurs.uoa.gr/sdyaergasia.php.

In order to construct an Internet Web Site, we find the system requirements and the users requirements. Then we design the web site in order every user to find easily whatever he wants on the domain of occupational health and safety. Then we configure the web site in order to achieve a communication between the site and the database. The updates for news on research in occupational health and safety are appropriate. The updates on the software are also important. The file management we present[27], uses the classic way of FTP. We insert documents, files, data and multimedia[20] in a directory which is structured in such a way for displaying into the www. Using some additional attributes to the above attributes we can cluster the data into groups[19]. The development of an Internet Web Site for efficient storing and indexing documents is a pioneering research work on the domain of Occupational Health and Safety. These attributes help the users to retrieve the data easily. They are inserted by the system administrator or by the composer of digital data. The metadata are all the appropriate elements which describe the uploading documents. Some operations that a system administrator can do are the uploading of a document and the updating of metadata using a simple web interface.

We develop this internet web site in order the executive person of an enterprise be informed about the issues of Occupational Health and Safety.

We are heading the semantic web[16]. This means that the internet can support workflow models. Workflow models are abstractions revealing the most important properties of the entities participating in a workflow management system. The workflows are 3 types, Human – Oriented (a person is responsible to execute a workflow), System – Oriented (we use databases and decision support systems,[15],[21] in order to find answers to our queries) and Transactional workflows (consisted from a mix of tasks, some performed by humans, others by computers and support selective use of the transactional properties for individual activities or for the entire workflow). The workflow models consist from entities which interact with

others in an Interconnection Network and they are participate in a management system[1], [16].

Administration by authorized users

The administration of internet web site could be performed via the web. The web interface is quite familiar to everyone who want to use it. We use html forms to upload documents. We insert metadata and documents in a database using php scripts. Experts on the domain of Occupationl Health and Safety are responsible to update the site with news and with the latest scientific research. The web interface which supports the administration can be seen at figure 1.

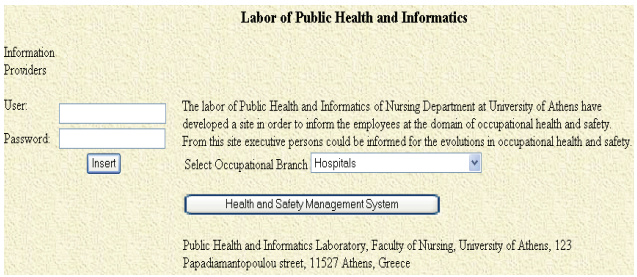

Figure 1 - Web Interface for administrating and presenting information on Occupational Health and Safety

There are some constraints at the insertion of data. We can insert only text documents, Microsoft Word Documents, and documents which can be read by the Adobe Acrobat Reader. Meanwhile we may need to insert files for educational reasons, such as power point files, video and images. On multimedia files we can insert a digital watermark in order to authenticate the constructor of the object [14]. We can insert a list of notes for each document in order to have a dialogue about certain ideas[27]. This dialogue is important for improvements in work.

The data we insert at the internet site are peer reviewed in order to be reliable. We also protect the authenticity of the digital objects inserting to them digital watermarks resistant to attacks such as compression, smoothing and geometric transforms[14] (mainly for multimedia data).

In the web site http://healthandsafety.nurs.uoa.gr/sdyaergasia.php, figure 1, developed in the Department of Public Health in the Nursing Department, University of Athens, we have configured the server to be able to find all the relevant information useful to this task. We can search the documents[19] placing keywords. There is also the possibility of browsing in all data lists.

Services provided by the system and applications on distant learning

The transmission of multimedia data in real time is critical for designing this system. We also search the number of clients a video server can serve with certain criteria of quality of services. The video on demand has as target to inform enterprises about the subjects of common interest. The subjects will be registered electronically among all the speakers and finally the revised lectures will be inserted in the information system in a corrected form. Meanwhile there are some difficulties on the transmission of multimedia data: firstly the subject about the quality of service second the decompression of the data and finally the removal of the jitter.

Another issue is that the system can provide training packages for the protection and promotion of health at the workplace and the implementation of safety procedures[24]. These packages are disseminated through the network or applied by e-learning techniques[2]. The function and the effectiveness of those packages will be evaluated at the ability of installing integrated solutions and applications to support experts on Occupational Health and Safety.

Conclusion

At this paper we have described a web application, which is administrated by authorized persons only. We intend to inform executive persons of each enterprise for the evolutions in Occupational Health and Safety. This site will inform and allow communication among enterprises. Documents and data based on ISO 18001 will be submitted, processed and presented in appropriate format in order to be useful to the interested executive persons. The corrections and the control of the whole infrastructure is significant to our work. Our target is to improve occupational health and safety, to find new policies, to design new systems, to control new procedures and finally to review the whole structure in order to be comprehensible to the users. An application has already been installed at hospital "Agios Savvas". The application will be evaluated continuously in order to achieve the standards of ISO 18001.

Conducting Time Series Analyses on Large Data Sets: a Case Study With Lymphoma

Vojtech Huser[a,b], Roberto A. Rocha[b], Martin Huser[c]

[a] *Intermountain Healthcare, Salt Lake City, Utah,* [b]*University of Utah, Department of Biomedical Informatics*
[c]*Obstetrics and Gynecology Clinic, Masaryk University Hospital, Brno, Czech republic*

Abstract

We describe the application of our previously developed analytical infrastructure called RetroGuide to conduct an observational retrospective cohort study using a clinician friendly flowchart approach.

Keywords:

time series analysis, retrospective observational study, Hodgkin lymphoma, workflow technology

Introduction

Retrospective observational studies can provide important background knowledge for preparing expensive clinical trials. Our main purpose is to demonstrate the use of a suite of medical informatics tools called RetroGuide. The problem of investigating the pregnancy rate in women who underwent toxic therapy for Hodgkin lymphoma is used as a case study.

Methods

Intermountain Healthcare's Enterprise Data Warehouse (EDW) was used as the data source. It contains a lifetime Electronic Health Record (EHR) for each patient and it includes encounters from multiple healthcare facilities. RetroGuide was used to create graphical scenarios representing a temporal sequence of events of interest associated with analytical questions. RetroGuide uses a workflow engine to execute the modeled process on real retrospective data and produces a series of analytical reports about how well the model fits the data from EDW.

Women with a diagnosis of Hodgkin lymphoma between the age of 18 and 40, and with at least 5 years of follow up data were included in the study (140 subjects total).

Results

A simplified version of the executable flowchart addressing the main question about the pregnancy rate is shown in Figure 1. Arrows represent transitions and may contain a condition: e.g. "previous event found" (black) or "not found" (grey). The variables inside brackets show that the engine can remember the timestamp of a previously identified event. After the execution of this scenario, the resulting RetroGuide

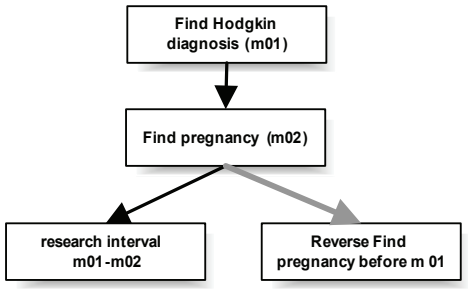

Figure 1 - RetroGuide Scenario (simplified version)

summary report showed that 22.9% of the patients treated for Hodgkin's lymphoma successfully completed a pregnancy within 5 years of the diagnosis (32/140; 95% CI 15.5-30.2).

Discussion

We found only one observational study investigating pregnancy after treatment for Hodgkin's lymphoma (prospective). Our results are comparable to this study, however the retrospective design is cheaper and faster to conduct, with results directly relevant to our local population. Additional advantages of RetroGuide when compared to traditional SQL-based database tools are: (a) user-friendly flowchart model as a shared logic formalism between the data analyst and clinicians; and (b) support for extensive "drill down" capability into available EHR data via a hierarchy of customizable reports. We have used RetroGuide to investigate 13 additional clinical questions relevant to lymphoma therapy and pregnancy.[1] We have also initiated a controlled study to evaluate the suitability of RetroGuide's methodology to empower champion clinicians to effectively utilize a large EDW. The value of our graphical tool will increase with a more widespread adoption of longitudinal and detailed EHRs.

RetroGuide

clinician-friendly flowchart alternative to SQL !

Problem

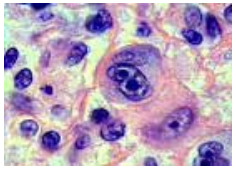
```
SELECT rownum, VAL_NUM2, T2TXT, times
FROM
(
SELECT  empi, VAL_NUM2, T2TXT, count(*) as times
FROM sandbox.ev9
WHERE VAL_NUM2 is not null
group by empi, val_num2, T2TXT
)
order by VAL_NUM2
```

- Amount of EHR data stored in databases grows exponentially
- SQL is currently predominant way of analyzing it
- Clinicians need extra analyst person in order to run advanced queries
- Clinicians can not review SQL code and effectively collaborate with the analyst
- SQL has limitations (e.g. temporal queries, GUI, learning curve)

RetroGuide

- internally developed analytical suite based on workflow technology
- uses standard process modeling language (XPDL)
- re-uses workflow editor as the modeling application
- provides set of external libraries called by the flowchart nodes

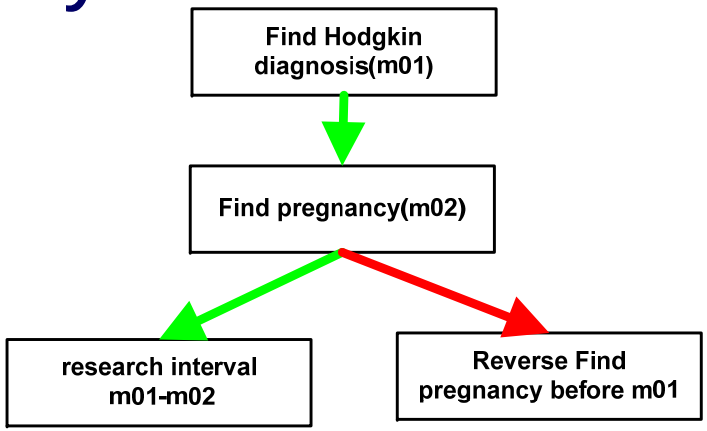
Lymphoma case study



- problem in cancer domain chosen as a case study to demonstrate features of RetroGuide
- retrospective observation study with 140 cancer subjects followed for 5 years
- primary outcome: rate of completed pregnancy after toxic cancer therapy

RetroGuide methodology

- 4 phases (data extraction, scenario creation, scenario execution and reports review)
- RetroGuide scenario has 2 layers
  - flowchart layer
    - (user-friendly to clinicians)
  - code layer
    - (makes the flowchart executable)



Analogy to manual chart review

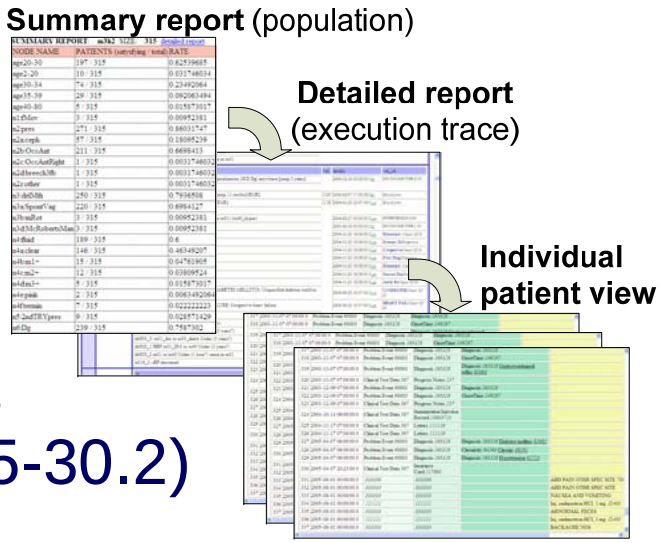
- RetroGuide scenario resembles instructions for manual chart review
- RetroGuide uses procedural approach as opposed to a declarative SQL code
- Analytical problems can be formulated having single patient in mind
- Ability to use constructs like “Time Jump” and remember values or timestamps by using variables

Intermountain's EHR data

- 3.2 TB large EDW covering 3+ million patients
- integrated lifetime EHR
- clinical data (lab, medication, clinical) combined with administrative data
- only coded data was utilized

Intermountain℠ Healthcare

Results



- 22.9% of the patients treated for Hodgkin's lymphoma successfully completed a pregnancy within 5 years of the diagnosis (32/140; 95% CI 15.5-30.2)
- Other clinical factors were investigated with RetroGuide scenario but necessary EHR data elements were present only in limited subset of patients
- Comparable prospective study with 85 subjects with 8.5 years follow-up time found 36.9% rate of pregnancy [1]

[1] Franchi-Rezgui (2003) "Fertility in young women after chemotherapy with alkylating agents for Hodgkin and non-Hodgkin lymphomas

Conclusion

- RetroGuide is a user friendly modeling and analytical approach based on established technology (Bussines Process Management)

- We have demonstrated the use of RetroGuide for conducting a retrospective observational study in cancer domain

RetroGuide advantages

- graphical element of the analytical model (middle layer)
- drill-down capabilities via linked reports
- ability to run code not covered by the query language
- combine multiple queries into one model
- single patient execution model resembling decision support mode of operation

Future

- RetroGuide use and potential will grow with more detailed EHR data and longer time-span available
- RetroGuide functionality is intended to be an exploration and feasibility study of alternative analytical approach to current code-only based methods

Collaborative Atlas in Upper Digestive Endoscopy

Jean-Michel Cauvin[a,c], Judith Logan[b], Franck Cholet[a,c], Clara Le Guillou[c]

[a] *Medical Information Department. University Hospital, Brest, France*
[b] *Medical Informatics and Clinical Epidemiology Department, Oregon Health and Science University, Portland, USA*
[c] *Medical Information Processing Laboratory (LATIM U650), Brest, France*

Abstract

With this project about endoscopic images of the upper digestive tract, the matter is to build a collaborative atlas and a learning tool for junior endoscopists, to participate in the standardization of terminology in digestive endoscopy and to explore new ways to investigate the medical reasoning process. Previous work on endoscopic image indexing and retrieval has led to the development of a reasoning model of endoscopic diagnosis along with a determination of features to be used in finding and case descriptions. We present a web platform, based on this previous research, which creates a collaborative environment for indexing of endoscopic images. This is currently implemented using the 1500 endoscopic images collected from the data warehouse of the Clinical Outcomes Research Initiative (CORI) as published online in the OHSU Digital Resource Library. In addition, we describe our early investigations on similarity and the art of diagnostic reasoning.

Keywords:

endoscopy, gastrointestinal - image interpretation,
computer assisted indexing,
collaboration problem-based learning, internet

Introduction

Since its widespread use began in the late 1960's, endoscopic examination of the upper gastrointestinal tract (esophagus, stomach and duodenum), with its careful inspection of the mucosal surface, has expanded the understanding of numerous gastrointestinal diseases and has thus greatly improved patient care. During this time, advances in digital imaging have simplified the sharing of still images or video sequences. Collections of these images into atlases and, more specifically, their integration into a learning environment, presents new issues such as optimal indexing, communication, interactivity and collaboration. The aim of the Project is the development of collaborative tools for creating and sharing atlases and for teaching endoscopy.

In previous works [1], inspired by medical practice, we have defined a bi-leveled – disease and lesion – description language of diagnostic information in endoscopy in order to unify the representation of pathologies and of cases. Upon this analysis of the diagnostic reasoning process, all the elements were joined to a system of decision aid which suggests consistent diagnostic hypothesis and relevant cases according to the problematic case description. This system leans on two bases, one defines the endoscopic knowledge and the second corresponds to a case iconography. To identify potential cases within the same class than the problematic case, the similar case retrieval consists in a classification process upon the endoscopic knowledge. Potential cases are then sorted according to their similarity with the problematic case.

Now, it is the matter of presenting a web platform, based on these previous researches, allowing a collaborative symbolic indexing of the 1500 endoscopic images collected from the data warehouse of the Clinical Outcomes Research Initiative (CORI) - published online in the OHSU Digital Resource Library [2] – by using 150 already indexed pictures, excerpt of the Normedia atlas [3] - and allowing some experimentations to investigate the similarity and the diagnosis reasoning. The goal is to develop a learning tool, based on a previously limited and defined set of training scenarios that could be used in real conditions for demonstration and for evaluation with endoscopists.

The following section will describe the structure and processing of endoscopic information, the construction of knowledge and case bases, and their use for similar case retrieval. Next, in the 3rd section, the collaboration framework is sketched with the web platform allowing collaborative indexing and experimentations. After a discussion about investigations on similarity and reasoning, the proposed future works will conclude the paper.

Materials and methods

In order to help the endoscopist faced with a complex case, previous work [1] has been done in developing an “intelligent” endoscopic atlas. Such an atlas proposes consistent diagnosis hypothesis and relevant cases according to the endoscopist description of the case. At the same time this development has imposed to analyze the cognitive processes that underlay the medical decision making.

Endoscopic information structuration

Physician's reasoning [1] in endoscopy emphasizes, in the diagnostic process, two decision levels which refer to two information spaces: the endoscopical findings, i.e. the lesions, and the diseases. An interaction connects these two decision levels because the diagnosis of endoscopical findings meddles with the disease diagnostic decision. Inconsistencies in the final decision according to other information (medical context, other endoscopical findings) must lead to doubt about the validity of endoscopical finding diagnoses. At the disease level, the decision of assigning a diagnostic class also depends on the prevalence of this diagnosis in the current practice and on the endoscopist experience for rare cases.

The analysis of the medical context leads to distinguish two reasoning approaches. In one hand, the medical context is not specific. A systematic exploration of the organ permits to focus on lesions, according to abnormal variations of color, relief or anatomical repairs. Medical knowledge of lesion characteristics leads to the diagnosis of these elementary objects. The association of lesions compared with the knowledge of the endoscopic aspects of diseases induces to the generating of diagnostic hypothesis. In the other hand, a specific context earlier prompts to formulate diagnostic hypothesis and to consider endoscopic lesions whose association would confirm the diagnosis. Moreover, the endoscopist closely explores the regions where these lesions are usually found. During endoscopic examination, the two schematic approaches are not exclusive.

Information structuration

Drawn from the physician reasoning and from the Minimal Standard Terminology of the European Society of Gastro-Enterology (ESGE) [4], a bi-leveled description mode of the endoscopic imaging and of the gastro-enterology pathologies is illustrated by the concept of Scenes with Objects whence three types of Scenes with Objects.

Physical Scene: the file of an image or of an image sequence It visualizes an interesting part of the endoscopic exam, showing anomalies, that is the Objects.

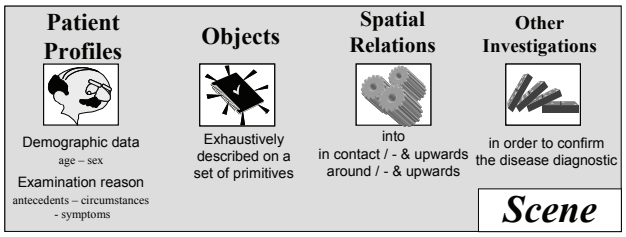

Figure 1- Logical and Conceptual Scene Information

Logical Scene: a medical interpretation of endoscopic imagery, i.e. an endoscopical diagnosis, which associates a peculiar patient context, one or several endoscopic Logical Findings or Objects and their eventual spatial relations (*Figure 1*).

Conceptual Scene: as abstraction of Logical Scene, the extended definitions of the upper digestive tract pathologies. Patient context, reasons for the endoscopy, one or several Conceptual Objects with their eventual spatial relations, and the complementary procedures to be advised, constitute the medical knowledge of these Scenes (*Figure 1*).

In these three kinds of scene, lesions or any element of interest, i.e. the "endoscopic findings", constitute the objects that can be depicted through an exhaustive description mode. To each descriptor or feature is associated a set of choices, representative of all possibilities and judiciously defined by the expert as shown *Figure 2*.

Knowledge and case bases

The Minimal Standard Terminology (MST) constitutes the framework for the identification and organization of endoscopic information and decisions while the basic concepts of the terminology imply the incompleteness of the description. However, the syntactic descriptors of endoscopic findings and the set of values for each descriptor can not be retrieved in MST while the terminology does not detail all the features of the endoscopic lesions. The finding descriptors refer to a lower implicit description level whose knowledge has to be acquired by endoscopic learning and training.

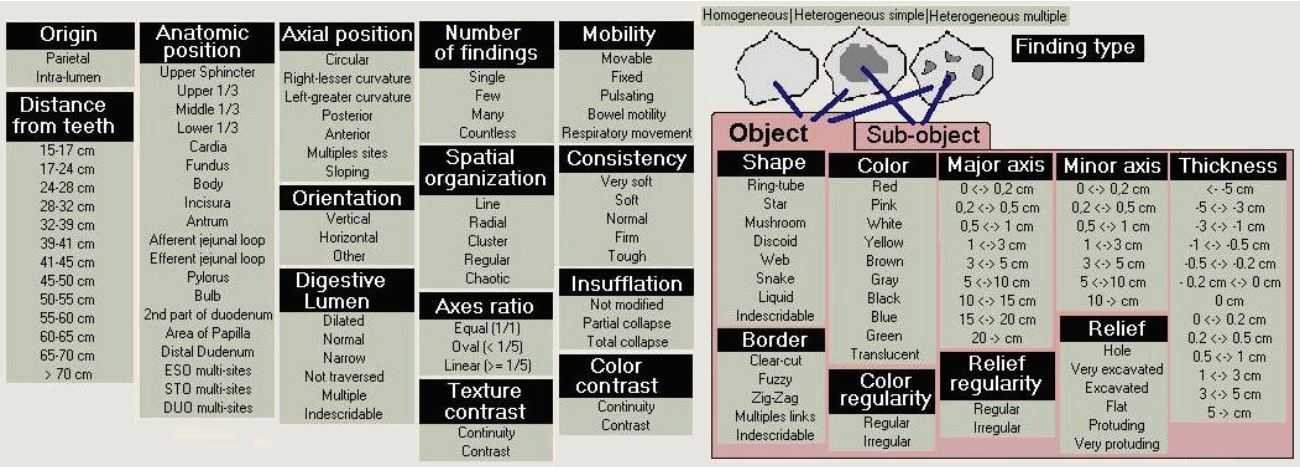

Figure 2 - Features and items of finding description

This approach leads to an a priori description of 150 Conceptual Scenes (diseases) and 100 Conceptual Objects (endoscopic findings).

The expert squeezes out his knowledge, using Linguistic Valuations (LV) instilling uncertainty or vagueness [5]. Each feature can be judged as without interest, impossible or of interest; in this last case, each feature item must be evaluated as *never, exceptional, rare, frequent* and *always*. A sixth level is also defined *doubtful* when the choice between never and exceptional cannot be stated: this level expresses the knowledge limits of the expert.

An object, identified with a code and a label is systematically described through 33 features as shown in *Figure 2*. To one feature corresponds several items which will be assigned a LV value. The actual number of considered items is 206. A scene is depicted by a patient profile (the sex and age prevalence features as well as a predefined whole of clinical contexts), by the objects (one of them must be "always") and by eventual spatial relations between objects.

The case base is constituted of indexed images; each of them represents an endoscopic diagnosis (Endoscopic Scene) with one or more findings, being described with one item by feature. The indexing is leisurely and fastidious task. Most of the images have been extracted from the Atlas of Digestive Endoscopy - Normed Verlag Editions (Homburg) [3] - with their authorization.

Reasoning with knowledge and cases

For a new situation, the similar case retrieval leans on the knowledge and case bases. Based on the knowledge base, the system looks for the potential finding and disease classes of the observed case. The retrieval is completed searching into these classes the more similar case according to similarity rules.

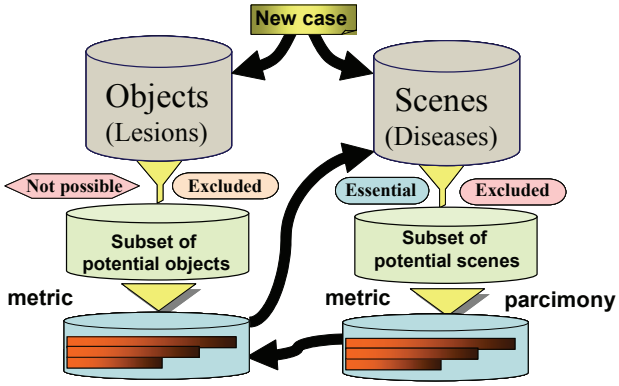

Figure 3 - New case classification

Lesion and Disease Classification, illustred by *Figure 3*, are the key points of the Scene analyze. With this intent, the questioning interface allows the user to depict an endoscopic exam, in other words the patient profile, the objects and possible spatial relations between objects. To avoid a boring description of objects, only 5 features (anatomical position, form, color, relief and type) are wanted at first; the other ones, according to their discriminating power, will be selected to refine the object recognition. After the object classification, the whole description of the exam is analyzed to identify one or several Logical Scenes - i.e. the diagnoses of diseases -. This analysis of scene still allows perfecting the classification of the lesions - i.e. objects-. Indeed, as the level of the image (or of the sequence) generally represents the endoscopic lesion level, the classification should especially insist on the objects in order to select a subset of candidate cases (the similarity playing upon those), while, from a medical point of view, the level of interest should surely envisage the pathology diagnosis.

The classification step having unveiled the objects and scenes potentially similar, it is a matter of illustrate them

by pertinent images. For this purpose, the new case is compared with selected cases according to three levels, characteristics, objects, and scenes. The Characteristic Similarity uses predefined tables for each feature with 5 values (incompatible - no similar - slightly similar - fairly similar - identical). Fusion of Object Similarities, of patient profile characteristic similarities and relation characteristic similarities complete the retrieval.

Such a system with evolved functionality is in keeping with the Pattern Recognition and Case Base Reasoning paradigms. A version of the endoscopic atlas is accessible via internet at http://i3se009d.univ-brest.fr/ -- Password medinfo2007. At the moment, then application contains around 150 endoscopic images (from Normedia) and 150 descriptions of 90 findings; it enables the user to describe an object or a scene in order to obtain the potential diagnoses and similar images. The reasoning model and the indexing criteria have been informally assessed by endoscopists with different levels of experience.

It is clear that the accuracy of the system to retrieve similar images depends strongly on the user's ability to analyze the endoscopic image. Faced with a diagnostically ambiguous image, it becomes difficult for the endoscopist to extract and describe the relevant features. This inherent weakness is common to other computer-assisted decision-making systems and limits their usefulness as real-time diagnostic aids. On the other hand, this work has demonstrated a method for precise description of the cases by experts, the flexibility of the research engine, the ability to store a large number of cases and to use web tools. With this background, we have continued to study the topics of similarity and reliability in the collaborative atlas Project.

Collaborative atlas project

The 1500 endoscopic images collected from the data warehouse of the Clinical Outcomes Research Initiative (CORI) as published online in the OHSU Digital Resource Library [2], constitutes a collection that may be sufficient for preliminary work, that is to say, to a reference atlas for further projects. This collection differs from the endoscopic case base described above, however, in that the images are not linked to patient information and are indexed with CORI terminology and not the MST-derived terminology described. Nevertheless, this collection allows us to explore issues in similarity such as the reliable assignment of indexing terms (including validation of images in the collection), comparisons of standardized vocabularities, metrics for similarities between images, and the technical and organizational requirements for collaboratively creating a shared, indexed case base for clinical care and education. Two projects have been initiated, the first in collaborative indexing, the second in development of educational scenarios for testing and education.

Collaborative indexing

In the setting of this collaboration, another web site http://i3se009d.univ-brest.fr/Collab - Email and Password: medinfo2007– is under construction and uses the 1500 endoscopic images from CORI as a base for collaborative image indexing and creation of a case base.

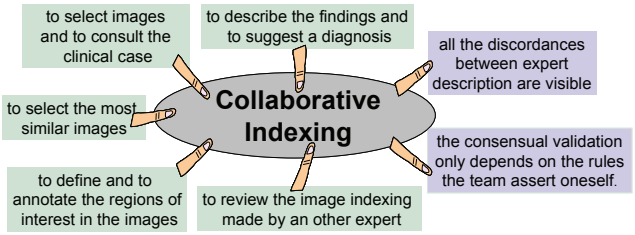

Figure 4 - Collaborative indexing

Already, the indexing module enables a domain expert to select images, to consult the clinical case, to describe the findings, to suggest a diagnosis, to select the most similar images from the atlas or to define the regions of interest in the images and to annotate them as seen *Figure 4*. The finding description is made easier by the ability to match the current image to a similar image already indexed - as shown *Figure 5* - and to adapt the description to its case; the validity is checked thanks to the Knowledge base; the expert can maintain a non valid description and, if necessary, the Knowledge base will be updated. Several experts can index the same picture and modify the descriptions. All of the discordances between experts are displayed; final validation of an image description depends on the rules which the team chooses.

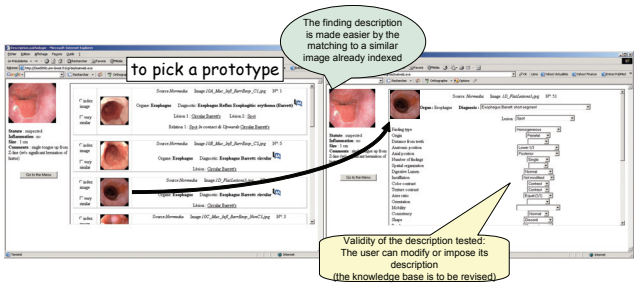

Figure 5 - Indexing thanks to previous cases

Educational scenarios

The educational/testing module is made up of HTML pages and combines images and test questions as presented *Figure 6*. For any learning scenario, the forms and their display order may be customized. Images within those forms can be displayed in a set order or randomly selected. The subject is given a scenario and one or more images

and answers questions about those images. In an educational mode, the subject may access the text description of the image and/or the case. In testing mode, following validation that all questions are answered, the responses are saved for subsequent analysis.

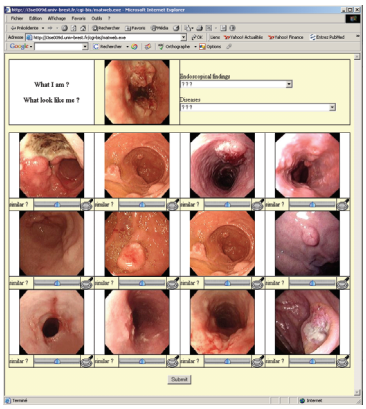

Figure 6 - Testing module

Preliminary work with this module suggests opportunities for development of some interactive tools and will enable to devise learning scenarios adapted to the reasoning methods of endoscopists and to the experience level of the apprentice.

Discussion

The difficulty by endoscopists in extracting relevant features from an ambiguous image and the interference of the diagnostic conviction in the description process leads to explore similarity in endoscopy.

Similarity exploration

A study of the similarity [6] in digestive endoscopy has been conducted first with endoscopists (both novice and experienced) and then with a group of college-level psychology students. The study used a library of 90 well-known endoscopic images and 3 study images. For each study image, the participants were asked to choose from the library the ten most similar images and, in addition, for the endoscopists, to list the most relevant diagnosis for each study image. A comparison of the subject responses according to diagnostic accuracy suggests there are correlations between the diagnostic accuracy, the perception of similar features, and the selection of images with the same expected diagnosis. One hypothesis could be that endoscopists choose images with similar diagnosis rather than in accordance with the aspect of the image. The choice of similar images would then depend predominantly on the diagnostic conviction of the endoscopist.

A comparison of the endoscopist and student responses suggests that similarity between endoscopic images can be perceived even by subjects who have no experience in the field of medicine. That is, similarity between images can be perceived based on intrinsic properties of image content but without requirements of knowledge and/or experience. A practical consequence of this finding might be that the search method for an endoscopic atlas could be based on a selection of similar images by the user, rather than on the verbal description of the case under investigation. Moreover, this study confirms the necessity of multi-expert in the image indexing task and validates the chosen collaborative approach.

Future works

As the verbal description or the query by similarity is influenced by the diagnostic conviction of the endoscopist, it will be indispensable to extract some features directly from the digital content of the images. A previous study with a global approach of the image numerical content did not have good results. But, with regions of interest in the picture defined by the experts at the time of annotation, some finding features will have to be obtained and interpreted by local numerical approaches. It will then be matter of developing new algorithms for the similar case retrieval, combining image analysis and text retrieval approaches.

In the future, the endoscopic e-learning could prepare resident to practice on real cases and thwart the inherent threefold weaknesses of the endoscopy teaching: “the unhappy patient, the unhappy student and the unhappy instructor”.

Abstract

We propose an extension of the standard DB model in order to support cooperative updates to clinical guidelines, as needed both in the acquisition phase and when guidelines are modified to capture new therapies.

Introduction and background

Modelling guidelines is a complex task, which may require a cooperative effort of several participants. Alternative proposals may be generated, and a team of "supervisors" is needed in order to validate and choose between them. Maintaining the authors of each proposal and the history of the different versions of the guidelines is very important (e.g., to support the retrieval of past version of the guideline, to justify decision taken in the past). A temporal extension of the standard DB models is thus needed to support such a cooperative and dynamic environment.

Methods

In order to devise a modular, general, and system independent approach to face the above issues, we propose a three-layered architecture, consisting of:

1. a data model layer, defining the data model and providing the basic operations;
2. a query language layer, supporting an SQL-like high-level manipulation and query language, based on layer (1);
3. an interface layer, based on the previous ones, that provides users with high-level functionalities, accessed through a user-friendly graphical interface.

For the sake of brevity, in the following only the data model layer will be sketched. The data model must support temporal tables, in which both the *validity* time of data (i.e., the time when data are true) and its *transaction* time (i.e., the time when data are inserted\deleted from the DB) must be considered. Two levels of tables must be distinguished: (i) "supervisor" tables, containing data which have been validated (accepted) by supervisors, and "proposal" tables, concerning user proposals. Specifically, for each supervisor table r, we use three tables: (i) a table *propose_insert(r)* with the proposal of insertions in r, (ii) a table *propose_delete(r)* with the proposals of deletion, and (iii) a table *propose_update(r)* with the proposals of updates. While the first two tables contain standard tuples (plus their temporal part), *propose_update(r)* will contain pairs of tuples, the former representing the tuple to be modified, and the latter the new tuple to be entered.

Different manipulation operations are provided. Specifically, standard users can *propose* the *insertion, deletion* or *update* of tuples. Such operations will modify the proper proposal tables, while they will not affect the supervisor tables.

On the other hand, supervisors have the possibility to *accept* and to *reject* user proposals. The acceptance of a proposal will affect the corresponding supervisor table. For instance, the acceptance of a proposal of update will lead to the practical execution of the update on the supervisor table.

Subtle semantic issues need to be faced in the definition of operations. For instance, proposals of update concerning the same supervisor tuple must be managed as alternative proposals, in the sense that only one of them can be accepted (to resperct such an intended semantics, the acceptance of an update must modify the transaction time of each alternative update proposal to state that such proposals are no longer valid).

Results

We have defined an extended approach to temporal DB in order to support cooperative updates to a guideline.

Such an approach supports different levels of users (supervisors vs simple users) and supply proper operations for them, as required in guideline applications.

Abstract

Parameters of a logistic model were studied when the descriptive variables are not mutually independent. For this purpose a generation algorithm of multiple test data with arbitrary sensitivity, specificity and correlation was developed, and the effect of correlation on the parameters of the model was investigated. Based on the results, the possibility of a new modeling framework for logistic analysis was proposed.

Keywords:

logistic model, correlation, generation algorithm

Introduction

A logistic model

$$y = \log(p/(1-p)) = b_0 + \sum b_i x_i \quad (1)$$

with dichotomous descriptive variables x_i are considered, where p designates the probability of an event such as a particular disease. If the variables are mutually independent, we have the relations

$$b_i = \log(\text{Odds ratio of the i-th variable}) \quad (2)$$

for the coefficients of the model. However, this relation does not hold when the variable x_i is correlated with some other variables. The purpose of this study is to examine how the correlation between the descriptive variables affects the values of coefficients b_i.

Methods

A generation algorithm of multiple test data with arbitrary sensitivity, specificity and correlation was developed [1], and was implemented using MATLAB 7.1 (The MathWorks, Inc.). Various numerical data were created, e.g. mutually independent tests with the same sensitivity and specificity, data with a positive correlation coefficient between two variables, data with a negative correlation coefficient, and data with correlations among many variables. Logistic analysis was performed on each case and the estimated model parameters,

Table 1 - Contingency table of test x_i and the diagnosis D (=1: positive, =0: negative)

	D=1	D=0
$x_i = 1$	α_i	$1-\beta_i$
$x_i = 0$	$1-\alpha_i$	β_i

b_i, were examined. For the estimation of the model, the "logistic procedure" of SAS 9.1 (SAS Institute Inc.) and the "glmfit" function of MATLAB were employed.

The relationship between disease D and its clinical test x_i can be presented by a contingency table, Table 1. Variable D represents the state of the patient, having the disease by D=1 and not having the disease by D=0. Variable x_i represents the result of the i-th test, e.g., positive by $x_i = 1$ and negative by $x_i = 0$. The sensitivity and specificity of the test are represented by α_i and β_i, respectively. When D=1 the correlation coefficient between test i and test j is r_{ij}^{+}, and when D=0 the correlation coefficient between tests is r_{ij}^{-} .

Results

Test data was created by the generation program [1] and precisely reconstructed the given conditions of sensitivity, specificity and correlation coefficients for arbitrary number of tests. Effect of correlation on the parameters of the logistic model was examined by using these data. In the following the number of variables in the model was set to 4, and the interaction model

$$y = \log(p/(1-p)) = b_0 + \sum b_i x_i + \sum b_{ij} x_i x_j \quad (3)$$

was assumed for SAS procedure.

A. All variables are mutually independent

We assumed the following conditions of sensitivities and specificities and no correlation among the variables:

$$\alpha = \beta = (0.80, 0.75, 0.70, 0.65).$$

By applying the logistic procedure we get the model parameters b_i's that satisfy the relation (2).

B. Positive correlations between two variables

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{12}^{-} = 0.3$. The result is that the coefficients b_1 and b_2 decrease due to the correlation between tests 1 and 2.

Parameter	Estimated value	SE	p
b_0	-2.991	0.142	<0.0001
b_1	1.288	0.123	<0.0001
b_2	1.288	0.123	<0.0001
b_3	1.702	0.120	<0.0001
b_4	1.702	0.120	<0.0001
b_{ij}	0.000	0.000	1.0000

C. Negative correlations between two variables

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{12}^{-} = -0.3$. The result is that the coefficients b_1 and b_2 increase due to the correlation between tests 1 and 2.

Parameter	Estimated value	SE	p
b_0	-4.444	0.207	<0.0001
b_1	2.760	0.167	<0.0001
b_2	2.760	0.167	<0.0001
b_3	1.685	0.131	<0.0001
b_4	1.685	0.131	<0.0001
b_{ij}	0.000	0.000	1.0000

Diagnostic performances with the four tests and with the same α and β were represented in Figure 1 by the ROC curves based on the three cases of logistic model obtained above.

D. More complex correlations

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{13}^{+} = r_{12}^{-} = 0.3$. The result is that the coefficients b_1 , b_2 and b_3 decrease due to the correlation between tests 1 and 2, and tests 1 and 3. Parameter b_1 was not statistically significant and the interaction terms are quite complicated.

Parameter	Estimated value	SE	p
b_0	-2.487	0.190	<0.0001
b_1	0.012	0.282	0.9664
b_2	1.508	0.242	<0.0001
b_3	0.936	0.236	<0.0001
b_4	1.612	0.221	<0.0001
b_{12}	0.227	0.256	0.3769
b_{13}	1.719	0.258	<0.0001
b_{14}	0.086	0.252	0.7336
b_{23}	-0.535	0.255	0.0360
b_{24}	0.037	0.251	0.8829
b_{34}	0.098	0.244	0.6868

In general, values of b_i and b_j decreased when x_i and x_j had a positive correlation coefficient, and increased when they had a negative correlation coefficient, compared with the other parameters with no correlation. When the correlation exists in

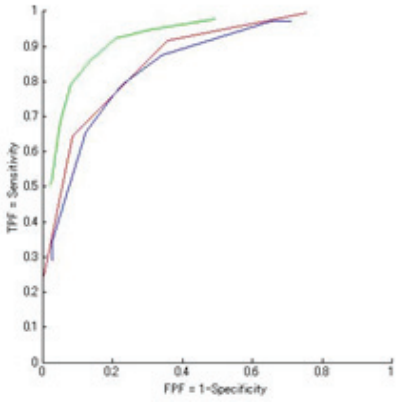

Figure 1 - ROC curve of diagnosis for cases A: independent (red), B: positive correlations (blue), and C: negative correlations (green). In all cases it was assumed that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$

more than two pairs of variables, no simple rule predicted the results. Introducing the interaction terms, $b_{ij}\, x_i\, x_j$, did not improve the situation.

Discussion

Our results indicate that there is a need for a new modeling framework of logistic analysis, if we wish to separate the effect of each variable from their interactions, and to use the model parameters b_i for the diagnostic or risk evaluation purposes. Based on the theory of joint probability of dichotomous tests with correlations [2], we could show how the bi's are affected by the correlation coefficients between xi's.

Conclusion

The effects of correlation on a logistic model with dichotomous variables were examined. Correlation between explanatory variables made the coefficients of logistic model difficult to interpret. Based on the results, we propose a possible new modeling framework for logistic analyses.

Abstract

Parameters of a logistic model were studied when the descriptive variables are not mutually independent. For this purpose a generation algorithm of multiple test data with arbitrary sensitivity, specificity and correlation was developed, and the effect of correlation on the parameters of the model was investigated. Based on the results, possibility of a new modeling framework for logistic analysis was proposed.

Keywords:

Logistic model, Correlation, Generation algorithm.

Introduction

A logistic model

$$y = \log(p/(1-p)) = b_0 + \Sigma\, b_i\, x_i \qquad (1)$$

with dichotomous descriptive variables x_i are considered, where p designates the probability of an event such as a particular disease. If the variables are mutually independent, we have the relations

$$b_i = \log(\text{Odds ratio of the i-th variable}) \qquad (2)$$

for the coefficients of the model. However, this relation does not hold when the variable x_i is correlated with some other variables. The purpose of this study is to examine how the correlation between the descriptive variables affects the values of coefficients b_i.

Methods

A generation algorithm of multiple test data with arbitrary sensitivity, specificity and correlation was developed [1], and was implemented using MATLAB 7.1 (The MathWorks, Inc.). Various numerical data were created, e.g. mutually independent tests with the same sensitivity and specificity, data with a positive correlation coefficient between two variables, data with a negative correlation coefficient, and data with correlations among many variables. Logistic analysis was performed on each case and the estimated model parameters, b_i, were examined. For the estimation of the model, the "logistic procedure" of SAS 9.1 (SAS Institute Inc.) and the "glmfit" function of MATLAB were employed.
The relationship between disease D and its clinical test x_i can be presented by a contingency table, Table 1. Variable D represents the state of the patient, having the disease by D=1 and not having the disease by D=0. Variable x_i represents the result of the i-th test, e.g., positive by x_i =1 and negative by x_i =0. The sensitivity and specificity of the test are represented by α_i and β_i, respectively. When D=1 the correlation coefficient between test i and test j is r_{ij}^{+}, and when D=0 the correlation coefficient between tests is r_{ij}^{-} .

Table 1: Contingency table of test x_i and the diagnosis D (=1: positive, =0: negative)

	D=1	D=0
$x_i = 1$	α_i	$1-\beta_i$
$x_i = 0$	$1-\alpha_i$	β_i

Results

Test data was created by the generation program [1] and precisely reconstructed the given conditions of sensitivity, specificity and correlation coefficients for arbitrary number of tests. Effect of correlation on the parameters of the logistic model was examined by using these data. In the following the number of variables in the model was set to 4, and the interaction model

$$y = \log(p/(1-p)) = b_0 + \Sigma\, b_i\, x_i + \Sigma\, b_{ij}\, x_i\, x_j \qquad (3)$$

was assumed for SAS procedure.

A All variables are mutually independent

We assumed the following conditions of sensitivities and specificities and no correlation among the variables:

$$\alpha = \beta = (0.80, 0.75, 0.70, 0.65).$$

By applying the logistic procedure we get the model parameters b_i's that satisfy the relation (2).

B Positive correlations between two variables

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{12}^{-} = 0.3$. The result is that the coefficients b_1 and b_2 were decreased due to the correlation between tests 1 and 2.

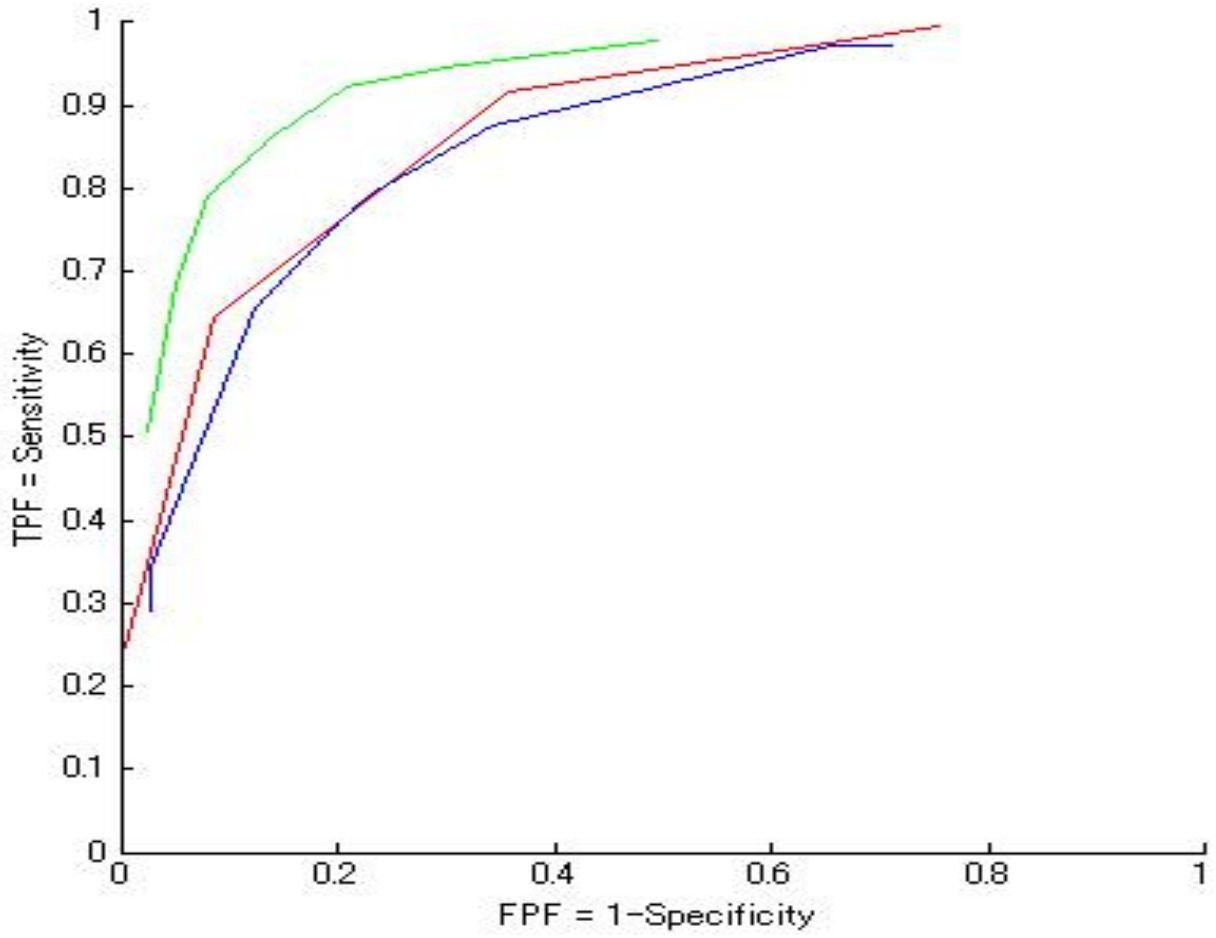
Parameter	Estimated value	SE	p
b_0	-2.991	0.142	<0.0001
b_1	1.288	0.123	<0.0001
b_2	1.288	0.123	<0.0001
b_3	1.702	0.120	<0.0001
b_4	1.702	0.120	<0.0001
b_{ij}	0.000	0.000	1.0000

C Negative correlations between two variables

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{12}^{-} = -0.3$. The result is that the coefficients b_1 and b_2 increased due to the correlation between tests 1 and 2.

Parameter	Estimated value	SE	p
b_0	-4.444	0.207	<0.0001
b_1	2.760	0.167	<0.0001
b_2	2.760	0.167	<0.0001
b_3	1.685	0.131	<0.0001
b_4	1.685	0.131	<0.0001
b_{ij}	0.000	0.000	1.0000

Fig.1 ROC curve of diagnosis for cases A: independent (red), B: positive correlations (blue), and C: negative correlations (green). In all cases it was assumed that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$.



D More complex correlations

We assume that $\alpha = \beta = (0.7, 0.7, 0.7, 0.7)$ and $r_{ij}^{+} = r_{ij}^{-} = 0$ except for $r_{12}^{+} = r_{13}^{+} = r_{12}^{-} = 0.3$. The result is that the coefficients b_1 , b_2 and b_3 decrease due to the correlation between tests 1 and 2, and tests 1 and 3. Parameter b_1 is not statistically significant and the interaction terms are quite complicated.

Parameter	Estimated value	SE	p
b_0	-2.487	0.190	<0.0001
b_1	0.012	0.282	0.9664
b_2	1.508	0.242	<0.0001

b_{12}	0.227	0.256	0.3769
b_{13}	1.719	0.258	<0.0001
b_{14}	0.086	0.252	0.7336
b_{23}	-0.535	0.255	0.0360
b_{24}	0.037	0.251	0.8829
b_{34}	0.098	0.244	0.6868

Discussion

Our results indicate that there is a need for a new modeling framework of logistic analysis, if we wish to separate the effect of each variable from their interactions, and to use the model parameters b_i for the diagnostic or risk evaluation purposes. Based on the theory of joint probability of dichotomous tests with correlations [2], we could show how the bi's are affected by the correlation coefficients between xi's.

Conclusion

The effects of correlation on a logistic model with dichotomous variables were examined. Correlation between explanatory variables made the coefficients of logistic model difficult to interpret. Based on the results, we propose a possible new modeling framework for logistic analyses.

A Method for Categorizing Continuous Prognostic Variables Based on the Overall C Index

Harukazu Tsuruta[a], Leon Bax[b]

[a]*Department of Medical Informatics, School of Allied Health Sciences, Kitasato University*
[b] *Department of Medical Informatics, Graduate School of Medical Science, Kitasato University*

Abstract

We propose a new method for categorizing continuous prognostic variables based on the overall discrimination index C introduced by Harrel. We show that this index is closely related to the area under the ROC curve for the original continuous prognostic variable and that the resulting categorized variables have predictive properties comparable to the original variable. However, like some existing approaches, the simple application of our method overestimates the predictive performance. To solve this problem, we propose a parametric method that minimizes this bias and assess its performance with the use of Monte Carlo simulation. The simulation shows that the parametric method is essentially unbiased for both the estimates of predictive performance and the cutoff points, and is a valid tool to create probability profile tables from prediction models for clinical practice.

Keywords:

projections and predictions, prognosis, cutoff point, sensitivity and specificity, categorization

Introduction

Multivariable regression models are useful for both diagnosis and prognosis. If we categorize all continuous independent variables, we can replace the risk function by a table of risks for all possible patient profiles, which is much easier to apply at outpatient clinic [1]. To achieve this, we need a way of optimal categorization. Although many methods have been proposed to dichotomize predictive variables, there has been no integrated method for polychotomization. In this study, we propose a theoretical and practical method for categorization of continuous independent variables.

Methods

For the categorization of continuous variables, we need to (i) define a measure for the predictive ability of prognostic variable with discrete values and then (ii) find the categorization in which the predictive ability is maximized.

We adopted the overall discrimination index *C*, or the pair consistency probability, introduced by Harrel [2] as a measure of the predictive performance of a categorized independent variable. The *C*-index is defined as the probability of the correct ranking of a normal-disease-pair. For instance, when we take a sample x_i from the normal group *N* and another sample y_i from the disease group *D* randomly; we can call this pair *concordant* if $r(x_i)<r(y_i)$, *tied* if $r(x_i)=r(y_i)$, and *discordant* if $r(x_i)>r(y_i)$, where $r()$ is the rank of the observed value among all values. The ranks are expected to be higher for the diseased cases. The *C*-index is then defined by

$$C = p_{\text{con}} + p_{\text{tied}}/2 \quad (1)$$

where

$p_{\text{con}} = \text{P}(r(x_\text{i})<r(y_\text{i}))$ and $p_{\text{tied}} = \text{P}(r(x_\text{i})=r(y_\text{i}))$

Let α denote the probability that x_i is greater than a cutoff point z for dichotomization, and let β denote the probability that y_i is less than z, i.e.

$$\alpha = \int_z^\infty f_N(x)dx = Fp \qquad \beta = \int_{-\infty}^z f_D(x)dx = 1 - Tp$$

Then the probability of the concordant case becomes

$p_{\text{con}} = (1 - \alpha)(1 - \beta)$,

and that of the tied case becomes

$p_{\text{tied}} = (1 - \alpha)\beta + \alpha(1 - \beta)$

Assigning these probabilities into (1), we have

$$C = 1 - (\alpha + \beta)/2 \quad (2)$$

Since sensitivity is $(1 - \beta)$ and specificity is $(1 - \alpha)$, the *C*-index becomes

$$C = (\text{sensitivity} + \text{specificity})/2 \quad (3)$$

Therefore the highest pair consistency probability is achieved when the sum of two kinds of errors, $\alpha + \beta$, is minimized, or the sum of sensitivity and specificity is maximized.

We can apply the definition of the *C*-index (1) for polychotomouse cases, and define the *ROC line graph* by joining the points (Fp, Tp) [3]. We can then proof that the *C*-index is equivalent to the area under the *ROC line graph* and the produced polychotomized variable's predictive

performance is comparable to the original continuous variable.

If we repeat the evaluation of the *C*-index to find optimal cutoff points, for instance by increasing the possible value of the cutoff point with a certain step (*repeated search method*), it overestimates the predictive performance. We therefore developed a practical parametric method in which

1. the distributions of the independent variable in healthy and disease groups are estimated;
2. the optimal cutoff points are found based on the estimated distributions;
3. the predictive ability of the categorized variable is evaluated based on the produced cutoff points.

We assessed its performance with the use of Monte Carlo simulation, both for cases where independent variables are normally distributed and cases where we cannot transform the distributions to normal distributions.

Results and discussion

The simulation shows that the parametric method is essentially unbiased for the estimates of the cutoff points and predictive performance (Figures 1 and 2). We repeated the simulations for various n_h and n_d (n_h=n_d) . Figure 3 shows that the estimation by the parametric method is almost unbiased even if the sample size is relatively small, whereas the naïve repeated search method shows non-negligible bias even when the sample size is large (n =300).

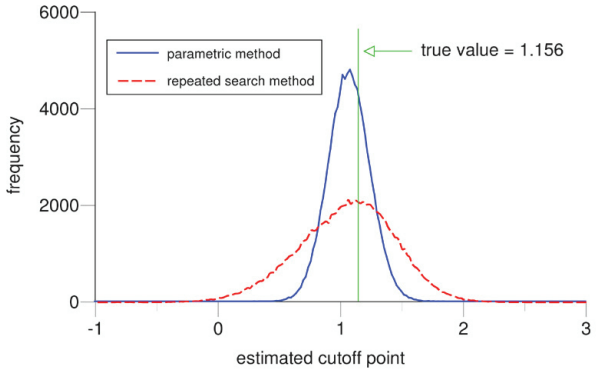

Figure 1 - The frequency distributions of the estimated optimal cutoff point in 100,000 simulations of dichotomization, with $f_h \sim N(0, 1^2)$, $f_d \sim N(2, 1.5^2)$ and n_h=n_d=30

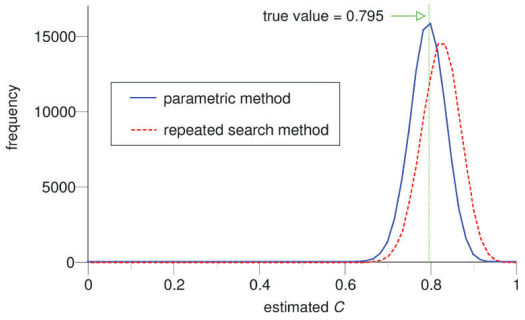

Figure 2 - Distributions of estimated pair consistency probability C in 100,000 simulations of dichotomization

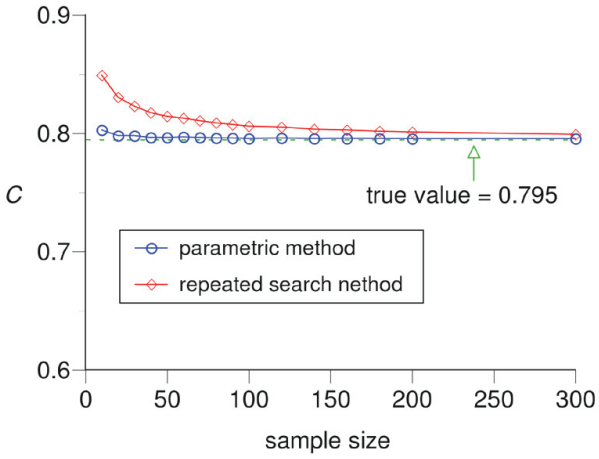

Figure 3 - Changes of estimated pair consistency probability C in dichotomization as a function of sample size

The results for trichotomization and categorization to four classes have a similar tendency for cases where independent variables are normally distributed [3] as well as for cases where we cannot transform the distributions to normal distributions [4].

If a certain type of distribution cannot be assumed, approximation of the distribution curve by a line graph or a restricted cubic spline function creates a workable situation.

Conclusion

We proposed a categorization method for continuous prognostic variables based on the overall discrimination index *C*. We evaluated a parametric method for this problem and showed that it performs well.

Pair Consistency Probability *C*

- Measure for the Predictive Ability of a Prognostic Variable -

Let x_i be a sample from the normal group *N*,

and y_i be a sample from the disease group *D*.

We call this pair

concordant if $r(x_i)<r(y_i)$,

tied if $r(x_i)=r(y_i)$,

discordant if $r(x_i)>r(x_i)$,

where r() is the rank of the observed value among all values and is expected to have a larger value for the diseased cases.

Pair Consistency Probability C is then defined by

$$C = p_{con} + p_{tied}/2 \qquad (1)$$

where

$$p_{con} = P(r(x_i)<r(x_i)) \text{ and } p_{tied} = P(r(x_i)=r(x_i)).$$

What we have to do next is to find a combination of cutoff points that maximizes the pair consistency probability *C*.

Optimal Cutoff Point for Dichotomization

Let α denote the probability that x_i is greater than a cutoff point z, and let β denote the probability that y_i is less than z, then the probability of the concordant case becomes

$$p_{con} = (1 - \alpha)(1 - \beta),$$

and that of the tied case becomes

$$p_{tied} = (1 - \alpha)\beta + (1 - \beta)\alpha.$$

Consequently,

$$C = (1-\alpha)(1-\beta) + ((1-\alpha)\beta + (1-\beta)\alpha)/2 = 1 - (\alpha+\beta)/2.$$

Since *sensitivity* is $(1 - \beta)$ and *specificity* is $(1 - \alpha)$,

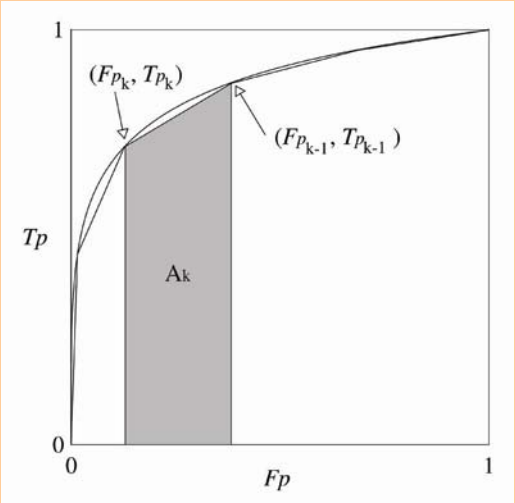
$$C = 1 - (\alpha+\beta)/2 = (sensitivity + specificity) / 2. \qquad (2)$$

Therefore, the highest pair consistency probability C is achieved when the sum of two kinds of errors, $\alpha+\beta$, is minimized, or the sum of sensitivity and specificty is maximized.

Extension to Polychotomization

We can also apply the definition of the *C*-index (1) for polychotomouse cases, and define "optimal" cutoff points by maximizing the *C*-index.

We then define the *ROC line graph* by joining the points (*Fp*, *Tp*), each corresponding to one of the cutoff points for polychotomization. We can then proof that the *C*-index is equivalent to the area under the *ROC line graph* and that the produced polychotomized variable's predictive performance is comparable to the original continuous variable [3].



NB: *Fp* = false positive fraction, *Tp* = true positive fraction

Parametric Method for Categorization

If we repeat the evaluation of *C* to find optimal cutoff points, for instance by increasing the possible value of the cutoff point with a certain step (*repeated search method*), it overestimates the predictive performance. To solve this problem, we developed a practical parametric method in which

(i) the distributions of the independent variable in healthy and disease groups are estimated;

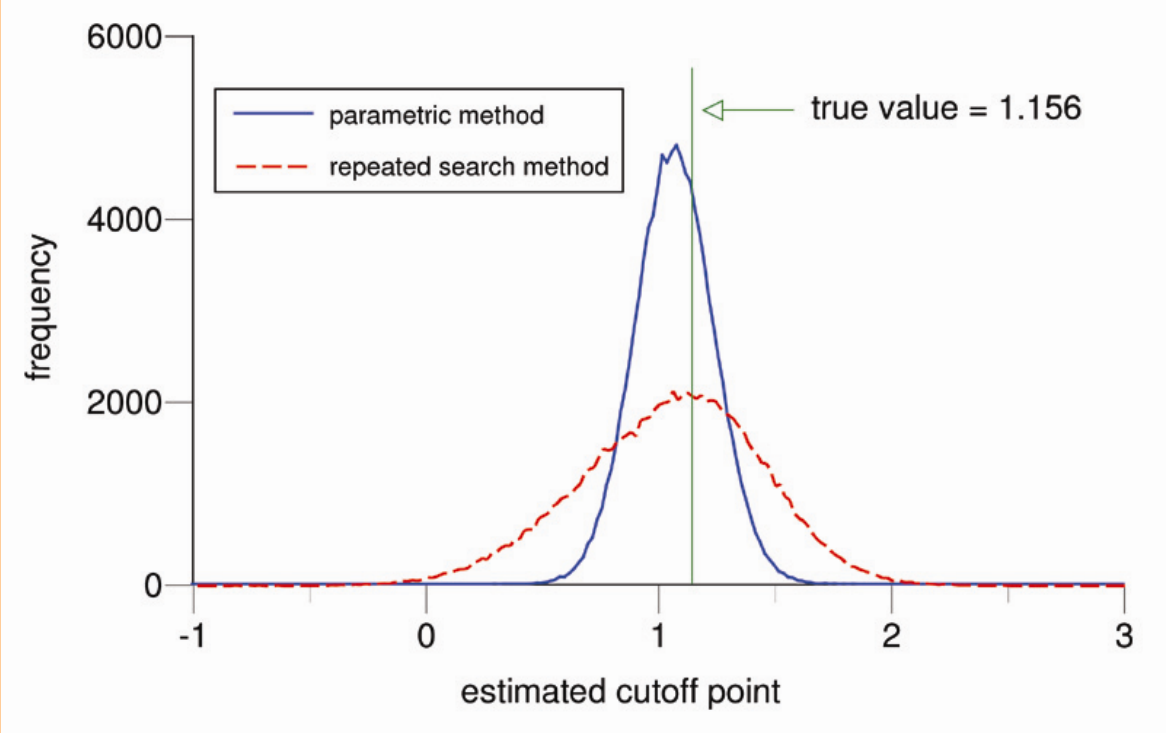
(ii) the optimal cutoff points are found based on the estimated distributions;

(iii) the predictive ability of the categorized variable is evaluated based on the produced cutoff points.

We assessed its performance with the use of Monte Carlo simulation, both for cases where the independent variables are normally distributed and for cases where we cannot transform the distributions to normal distributions.

Results

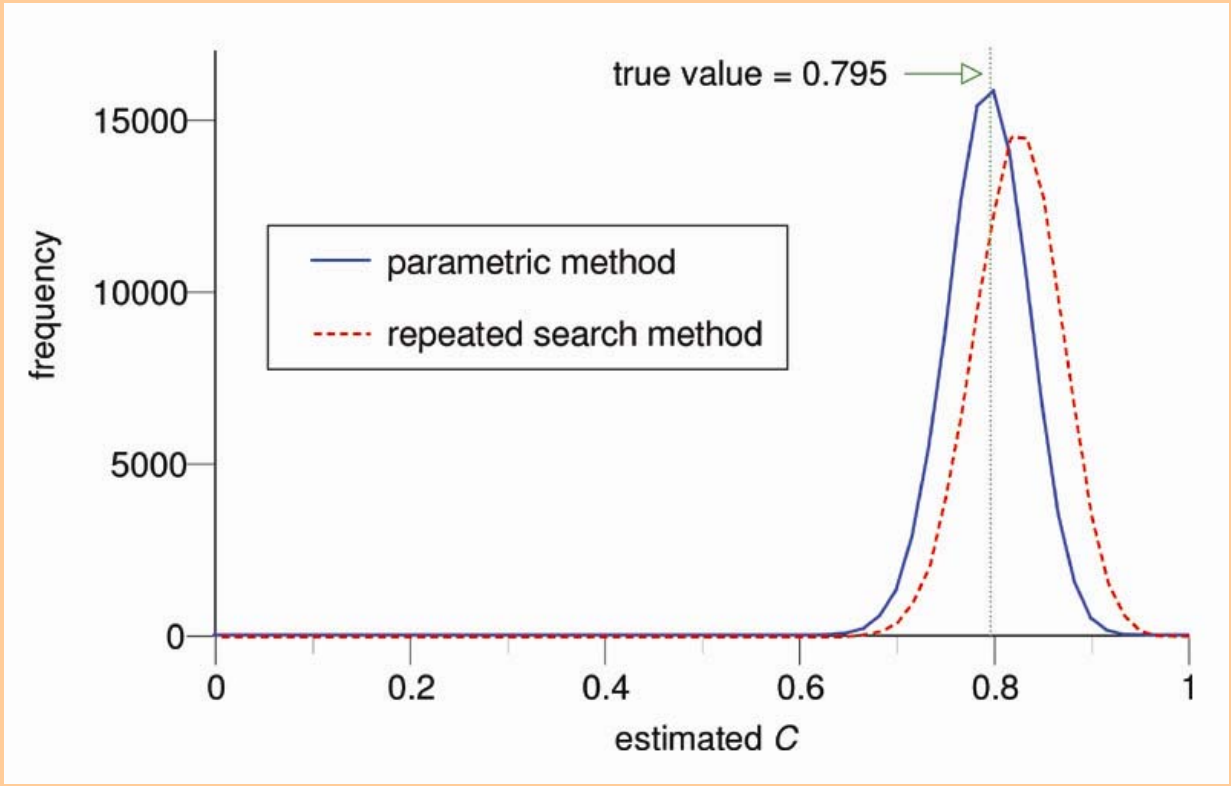
The frequency distributions of the estimated optimal cutoff point in 100,000 simulations of dichotomization



The parametric method provides a estimator for the cutoff point with higher precision.

($f_h \sim N(0, 1^2)$, $f_d \sim N(2, 1.5^2)$ and $n_h=n_d=30$)

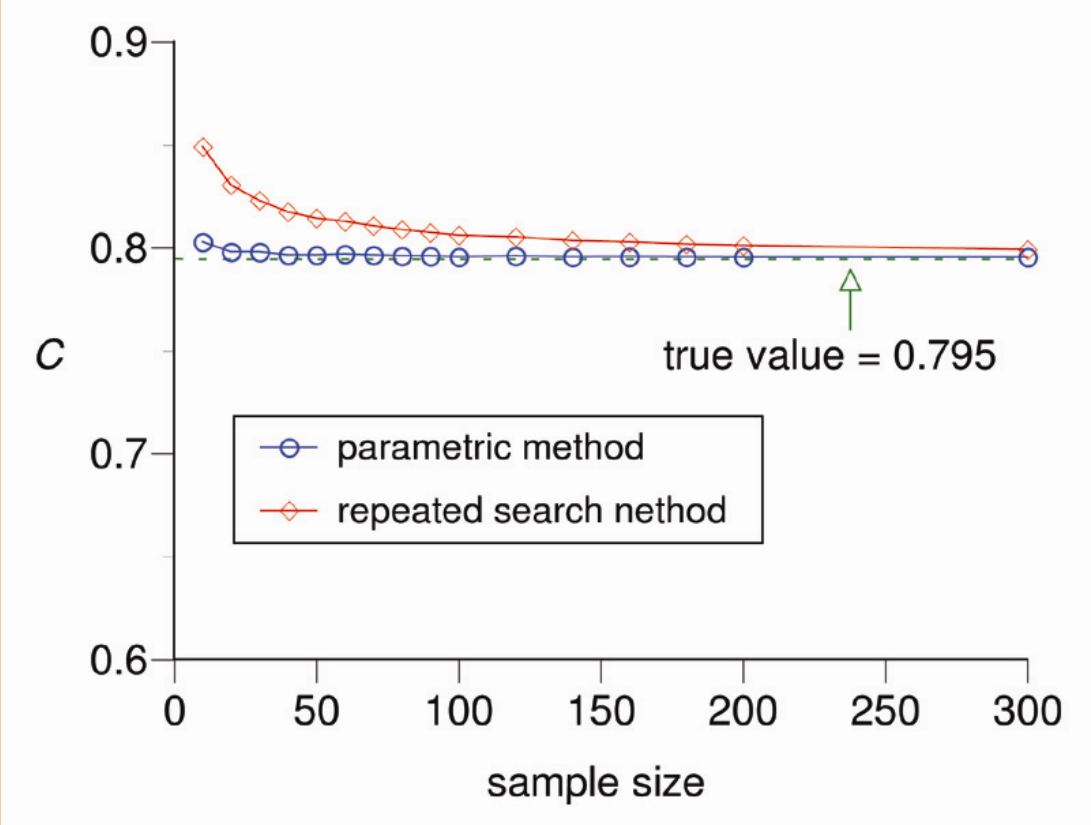
Distributions of estimated pair consistency probability *C* in 100,000 simulations of dichotomization



The parametric method is essentially unbiased for the predictive performance.

($f_h \sim N(0, 1^2)$, $f_d \sim N(2, 1.5^2)$ and $n_h=n_d=30$)

Changes of estimated pair consistency probability *C* in dichotomization as a function of sample size



The estimation by the parametric method is almost unbiased even if the sample size is relatively small, whereas the naïve repeated search method shows non-negligible bias even when the sample size is large (*n* =300).

Discussion

The results for trichotomization and categorization to four classes have a similar tendency, both for cases where independent variables are normally distributed [3] and for cases where we cannot transform the distributions to normal distributions [4].
If we cannot assume a certain type of distribution, approximation of the distribution curve by a line graph or a restricted cubic spline function creates a workable situation.

Conclusion

We proposed a categorization method for continuous prognostic variables based on the overall discrimination index *C*. We evaluated a parametric method for this problem and showed that it performs well.

Abstract

We aimed at developing an alert-system to decrease the inappropriate repetition of hepatitis B virus tests. We evaluated the impact of the alert by an interrupted time series of the proportion of repeated results and the physician's response to the alert by system execution traces archiving. The alert was successfully implemented. We validated our method for measuring expected outcomes. But the preliminary evaluation of the alert could not prove any effect on the HBV tests repetition.

Keywords:

Decision Support System, Laboratory Test Redundancy

Introduction

Several studies and systematic reviews have demonstrated the efficacy of computerized decision support systems, especially alerts and active reminders, for improving the quality of care and/or hospital practices [1, 2]. However, other studies have identified problems with the implementation of such systems in routine practice and with the accessibility of such systems to doctors [3].

The Georges Pompidou European Hospital is a university hospital with 880 beds [4]. It has a complete information system centered on the electronic health record, DxCare®, facilitating the computerized prescription of drugs, imaging and laboratory tests. During 2005, 216 (13%) of the hepatitis B virus (HBV) tests prescribed by the Cardiovascular Surgery Department were ordered less than 30 days after the previous order for the same patient. An active reminder system concerning the repeated prescription of HBV tests in this department was implemented as a mean of decreasing this redundancy. This paper presents the implementation of this intervention, and its evaluation.

Materials and methods

DxCare® permits both the prescription of laboratory tests and the viewing of their results. By default, the results shown are those for the current stay in hospital, but it is possible to search for all previous results for the patient. The alert system created in this environment triggers a new page concomitant with the prescription window, the moment of a HBV test is selected to be prescribed. This alert contains the date and complete result for the most recent last HBV test carried out for the patient (obtained less than 30 days previously and whether linked or not to the current hospitalisation). For the purpose of the evaluation, the system was developed so that traces of its execution be archived. They reflect the selection of HBV test for ordering, the display of any alert, and the time elapsed between any previous result and these events.

The impact of the intervention is measured by interrupted time series analysis of repeated HBV tests over a four-year period, with assessments at two-month intervals. As the system became functional at the end of June 2006, the "before intervention" period runs from January 2004 to June 2006 and the "after intervention" period from July 2006 to December 2007. The consequences of alerts on the repetition of serological tests are estimated from HBV results extracted from the DxCare® database. The corresponding indicator is the proportion of all HBV results that were repeated within an interval of less than 30 days (RT_{30}).

A trace is stored each time that the prescriber selects a HBV test, *i.e.* each time that he or she intends to prescribe that test. This makes it possible to estimate the proportion of all intentions to prescribe a repeated test within 30 days of the last one: RTI_{30}. Compliance with the alert is evaluated by comparing RT_{30} and RTI_{30}.

Results

During the "before intervention" period (January 2004 to June 2006), there were 3,671 results for HBV tests in 2,682 patients. 12.3 % (nb = 450) of the results were obtained within 30 days after a previous one (RT_{30}). During a preliminary "after intervention" period from July 2006 to April 2007, there were 1302 results for HBV tests

in 823 patients. 13.8% (nb = 180) results were obtained following the repetition of the test within 30 days (RT_{30}).

The preliminary segmented regression analysis of the time series for the rates of HBV repeated tests suggested no effect of the intervention. However, since only 5 bi-monthly rates were available for the post intervention period (and since neither seasonal variation nor autocorrelation of the data were observed), we preferred to perform nonparametric tests. Wilcoxon rank-sum test results showed no significant change in rates after the setting up of the alert-system (p-value=0.11)."

An analysis of the system's traces for the preliminary "after intervention" period revealed 1430 intents to prescribe, 165 (11.5%) of which corresponded to repeat tests within 30 days (RTI_{30}). The median interval between the previous test and the repeat test was 123 days, with an interquartile interval of 26.75 to 287 days. The comparison of RT_{30} and RTI_{30} showed a compliance with the alert of 8.3%.

Discussion

The alert was successfully implemented but its evaluation could not prove any effect on the HBV tests repetition. We hypothesized that doctors are not aware of the existence of a previous result at the time of prescribing. The effectiveness of the alert depended on the relevance of this hypothesis. Indeed, biological results are linked to a particular stay in hospital in our computerized information system. Consequently, a HBV test prescribed during a consultation is not visible during any subsequent hospitalization (considered as another hospitalization) unless the prescriber actively searches for previous biological results. Our hypothesis turned out to be insufficient and balanced by the fact that HBV tests have to be prescribed periodically according to predefined protocols. Moreover, there is no fully acknowledged delay for repletion of serology: the delay of 30 days was decided with the collaboration of one clinician of the Cardiovascular Surgery Department and a virologist. This was probably not sufficient to warrant a consensus of all prescribers.

Evaluation of the response of users to this support is based on the recorded traces of its functioning. The quality of these traces was ensured as part of the design of this support system, independent of the information system. Conversely, the impact of the alert on the repetition of HBV testing can only be evaluated using biological results extracted from the DxCare® database. The quality of the data used for evaluation depends entirely on the correct use of the information system. The interpretation of both indicators is therefore limited by the quality of their respective data sources.

Conclusion

The capacity of a computerized prescription system to alert the doctor to the unnecessary repetition of examinations and potential prescription errors is one of the characteristics included in evaluations of the quality of such a system [5]. However, although this type of intervention is generally effective [1], the implementation of alerts and the evaluation of their impact must be adapted to the local context. Indeed, it remains to be demonstrated that alerts are effective regardless of the context in which they occur.

Introduction

- Computerized Decision Support Systems (especially alerts and active reminders) could improve the quality of care and/or hospital practices [Garg 2005].

- However, some problems remain with the implementation of such systems in routine practice and with the accessibility of such systems to doctors [Aarts 2004].

Introduction

- During 2005, 13% of the hepatitis B virus (HBV) tests prescribed by the Cardiovascular Surgery Department at the European Georges Pompidou Hospital were ordered less than 30 days after the previous test result for the same patient.

- An active reminder system concerning the repeated prescription of HBV tests in this department was implemented as a mean of decreasing this repetition.

Materials and Methods: Intervention

- **HBV alerts**
  - are displayed as a new page (in the EHR) concomitant with the prescription window,
  - appear at the moment of a HBV test is selected to be prescribed,
  - contain the date and complete result for the most recent last HBV test carried out for the patient (obtained less than 30 days previously).

- **Alerts traceability to reflect**
  - the selection of HBV test for ordering,
  - the display of any alert,
  - the time elapsed between any previous result and these events.

Materials and Methods: Impact

- **Indicator:**
  Proportion of all HBV results repeated within an interval of less than 30 days (RT_{30})

- **Method of analysis:**
  Impact of the intervention on practices is evaluated by an interrupted time series of two-month periods
  - "before intervention": Jan 04 - Jun 06 (9 pts)
  - "after intervention" :Jul 06 - Dec 07 (5 pts)

- **Data collection:**
  Indicator estimated from HBV results extracted from the EHR database

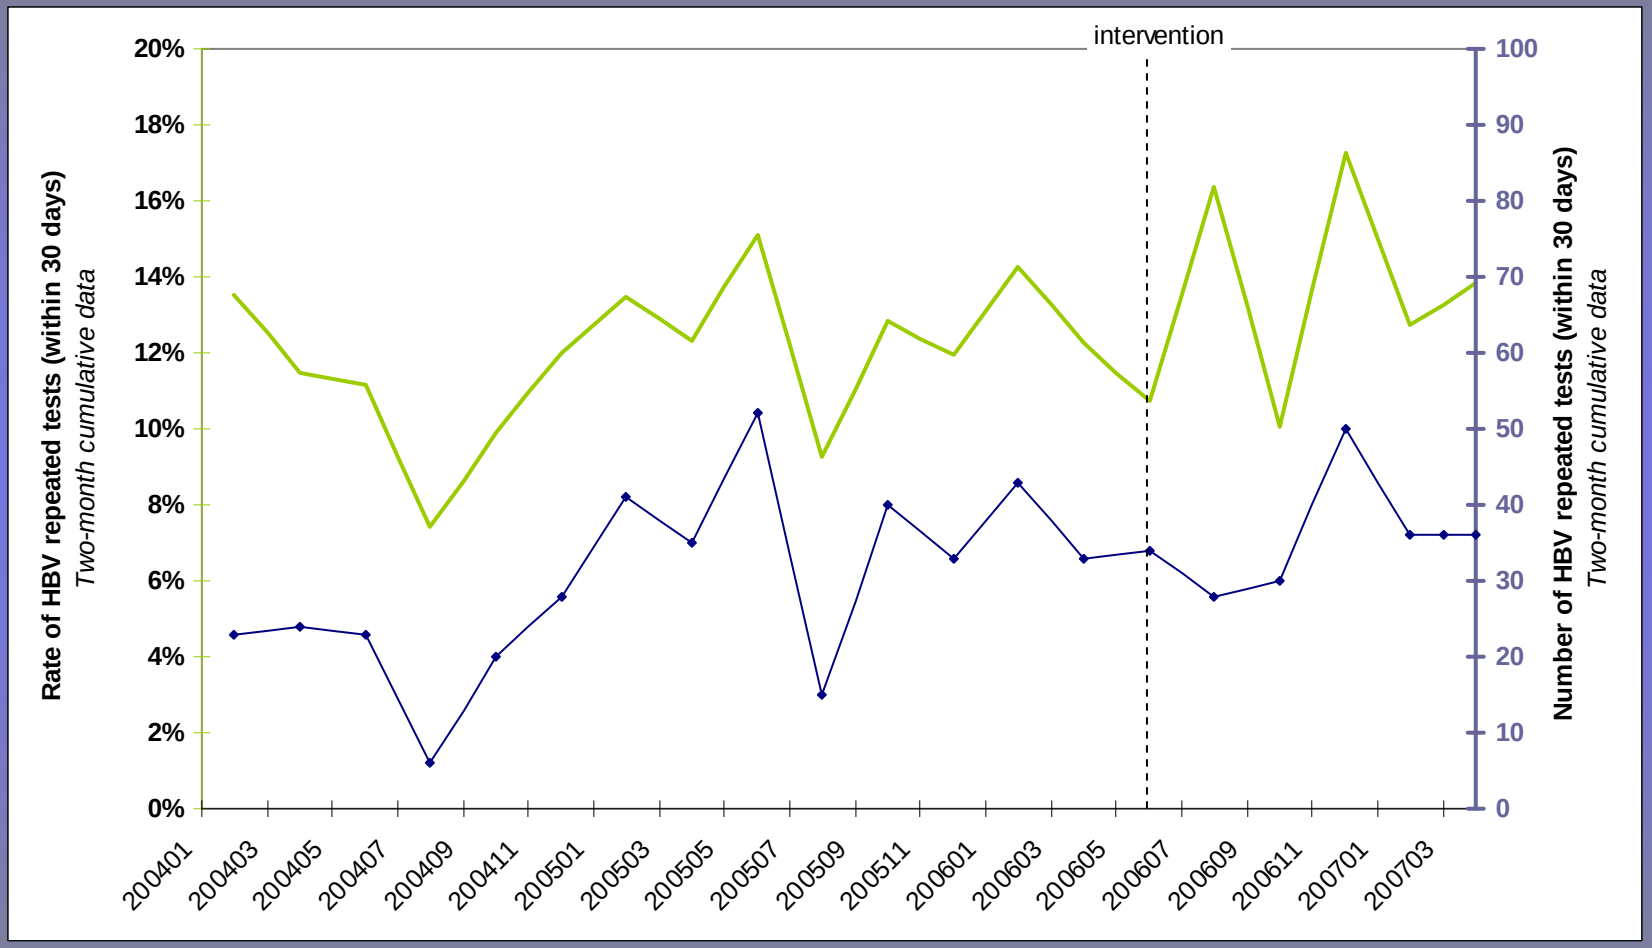
Materials and Methods: Compliance

- **Indicator:**
  Proportion of all intentions to order a repeated test within 30 days of the last one (RTI_{30})

- **Method of analysis:**
  Compliance with the alert is evaluated by comparing RT_{30} and RTI_{30} during the after intervention period

- **Data collection:**
  Indicator estimated from traces extracted from the decision support system database

Results: Impact of the intervention



Wilcoxon rank-sum test

no significant change in rates after intervention

p-value=0.11

Results: Compliance with the alert

- 1,430 intents to prescribe
- 165 (11.5%) intents to prescribe within 30 days after a previous HBV test result
- Interval between the previous test and the repeated test: median 123 days (interquartile range 26.75 - 287)
- 8.3% of compliance with the alert

Discussion

- Alert successfully implemented
- Data extraction from EHR database make possible decision support evaluation
- But the intervention seem to have no effect on the HBV tests repetition
- Disappointing results because this CDSS provides features of interest [Kawamoto 2005]
  - Automatic provision of decision support as part of clinician workflow
  - Provision of decision support at time and location of decision making
  - Promotion of action rather than inaction

Discussion

- Ambiguous source of knowledge used to provide the support?
  - no fully acknowledged delay exists for repletion of serology
  - 30 days-delay decided with the collaboration of one clinician and a virologist, probably not sufficient to warrant a consensus of all prescribers

- Next alert (HbA1C) based on incontestable arguments
  - indicated for diabetics patients follow-up
  - 3 months-delay of repletion due to HbA1C kinetic physiology

Conclusion

- The capacity of a computerized prescription system to alert the doctor to the unnecessary repetition of examinations and potential prescription errors is one of the characteristics included in evaluations of the quality of such a system [Kilbridge 2006].
- However, although this type of intervention is generally effective [Garg 2005], the implementation of alerts and the evaluation of their impact must be adapted to the local context.
- Indeed, it remains to be demonstrated that alerts are effective regardless of the context in which they occur.

[e] *ezCaretech Co.,Ltd, South Korea.*

[f] *Seoul National University Bundang Hospital, South Korea*

Introduction

- Background
  - Efforts for nationwide dissemination of standard CDSS in Korea
  - We developed a prototype MLM engine, MLMPlusX
  - Problems in dissemination of MLM engine
    - Widespread questions about
      - possibility of successful operation
      - Safety
      - Usefulness
- Purpose
  - Develop, apply, and evaluate an Arden Syntax based MLM engine for practical use to prevent medical errors
- Refined our previously developed MLM engine
- Applied and validated the MLM engine
  - Adopted to a development server of Seoul National University Bundang Hospital (SNUBH), for drug-drug interaction (DDI) domain

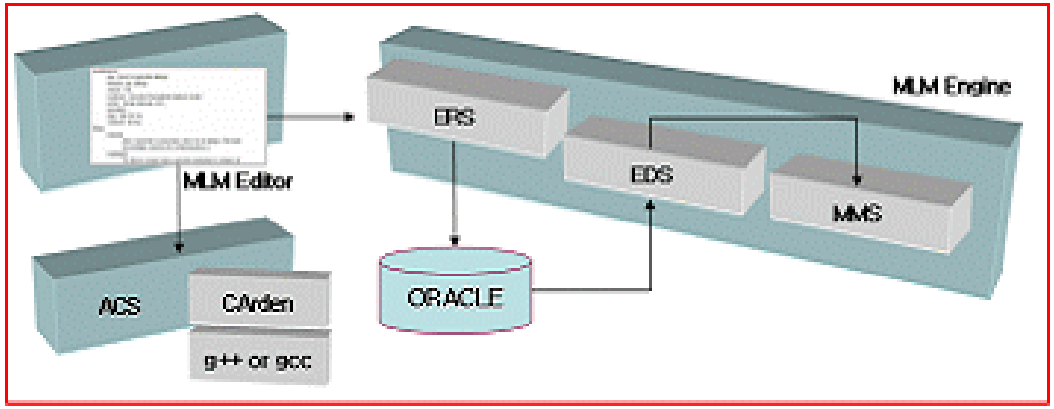
Preparation phase

- Focused on giving trust to the adopting institution and on understanding each other's system
- Tried to sufficiently communicate each other during nine months
  - Communication between MLM engine developers and system engineer group in SNUBH, ezCaretech Co. LTd.
  - Communication channel : temporal meetings, messengers, phone, and email
- Derived requirements
- Improved MLM engine design
- Decided to adopt our MLM engine to a development server in SNUBH

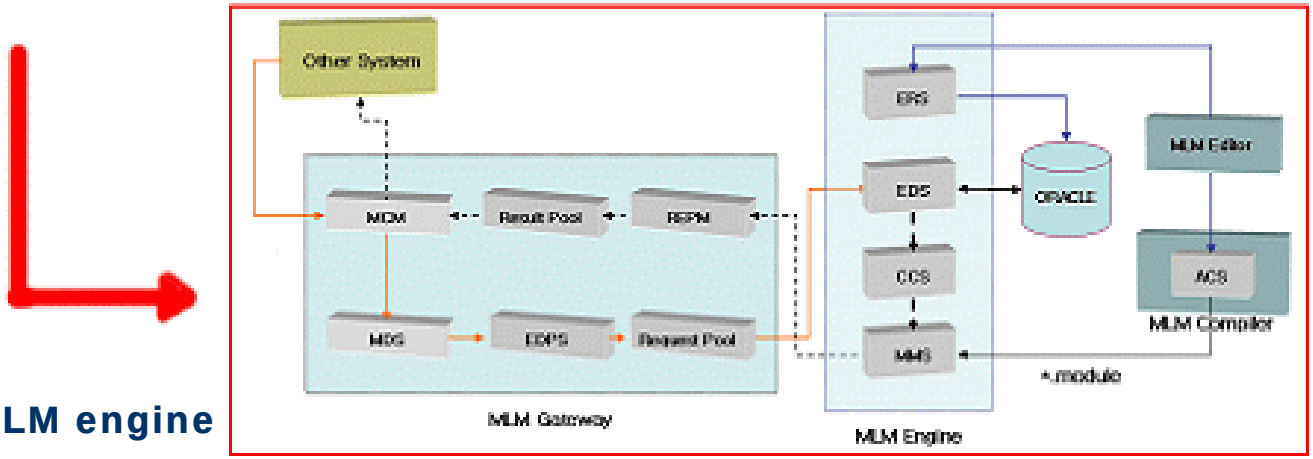
Refinement of MLMPlusX

- MLMPlusX
  - Our previous version of MLM engine
  - Core running environment for the Arden Syntax based decision supports
- Refined the MLMPlusX for practical use in HIS environment
- Improved interface to other systems it interacts
- Separated engine components independently
- Improved performance, accuracy, and reliability
- Simplified MLM system configuration setting work
- Added a MLMGateway
  - A middleware that handles HIS events between HIS and MLM engine
  - Added to minimize modification cost on the existing HIS application processes
- Changed event detection method

MLMPlusX and Refined MLM Engine



MLMPlusX



Refined MLM engine

Integration

- Integrated our improved MLM engine to development server in SNUBH
  - It was fast and simple work
  - Two person did it in three days
- Built DDI knowledge base
  - Converted 930 DDI rules used in SNUBH into 930 Arden Syntax MLMs

Evaluation

- Evaluated our MLM engine to validate possibility in practical use
- Method
  - Compared our engine with locally developed DDI system in SNUBH (local CDSS)
  - Metrics
    - Performance
    - Knowledge building and management cost
    - Integration and migration
    - Usability
- Evaluation environment
  - Zeon dual core 3.0GHz CPU, 4G memory, 80G SATA HDD

Evaluation Results : Performance

Input order	Avg. response time in MLM engine (ms/order)	Avg. response time in local CDSS (ms/order)
order -1	1.343	0.300
order -2	1.546	0.169
order -3	1.703	0.076
order -4	1.847	0.109
order -5	2.507	0.044
order -6	2.847	0.046
order -7	2.660	0.205
order -8	2.689	0.046

Evaluation Results : Knowledge Building and Management Cost

Measurement	Result	Evaluation
Knowledge building cost in MLM engine : time spent in building 980 DDI rules	1601 ms	low

Measurement		Result	Evaluation
Cost for Knowledge modification	MLM Engine	Directly modify the Arden Syntax by a domain expert Or, automatically converts to modified MLM if a domain expert enters modified information through DDI editing tool	low
	Local CDSS	A domain expert enters modified information through DDI editing tool	low
Cost for adding a new pattern MLM to knowledge base	MLM Engine	A domain expert directly writes a new MLM Or, an informatician writes a new MLM informed by a domain expert	low
	Local CDSS	A developer should program a new knowledge informed by a domain expert	**high**

Evaluation Results : Integration and Migration, Usability

- Integration and migration results

Measurement	Result
Time spent in integrating MLM engine to a development server of SNUBH	3 days
Number of persons participated in MLM engine integration work	2 persons
Modification list generated in MLM engine integration process	Only values of variables in a configuration file

- Usability results

Measurement	Result
Number of modifications in user interface when adopted MLM engine	0
Modification list in user interface when adopted MLM engine	none
Possibility of user interface improvements when adopted MLM engine	possible

Discussion and Conclusion

- Refined MLMPlusX for practical use
- Established the work process of integration process
- Applied the MLM engine to SNUBH development server of SNUBH
  - Built Arden Syntax knowledge base for DDI rules used in SNUBH
- Validated our system by comparing with DDI system used in SNUBH
- The evaluation showed promising results
  - Though performance was lower than local CDSS, it can be solved by modifying MLM engine design
  - Knowledge management cost was expected to be lower
  - There was no reduction in usability
  - The integration work was simple and fast
- Future work
  - Adoption of our system in real-time HIS

Abstract and objective

For nationwide dissemination of standard CDSS, we have developed a MLM engine for the Arden Syntax. As a first step of practical use of the MLM engine, we adopted it to a development server of Seoul National University Bundang Hospital (SNUBH), for drug-drug interaction (DDI) domain. We improved our previous version of MLM engine, and the work process of integration process was established. We evaluated the MLM engine to validate possibility of practical use. The overall evaluation results showed possibility that our system can replace existing DDI system and can reduce knowledge management cost.

Keywords:

Arden Syntax, CDSS, HL7

Methods

For successful integration of Arden Syntax based CDSS into an existing HIS, we had to give trust about our system that it is safe and give idea that this standard CDSS adaptation can be useful decision to the institution. And the MLM engine developers and system engineer group in SNUBH, ezCaretech Co. LTd., both needed to understand each other's system. We tried to sufficiently communicate each other via temporal meetings, messengers, phone, and email during nine months. From this preparation phase, we derived requirements, improved MLM engine design, decided to adopt our MLM engine to a development server in SNUBH.

We refined and improved our previous version of MLM engine, MLMPlusX. The MLMPlusX is a core running environment for the Arden Syntax based decision supports. In order to use the MLMPlusX in practical HIS environment, we improved interface to other systems it interacts, separated engine components independently, improved performance, accuracy, and reliability, and simplified MLM system configuration setting work. And to minimize modification cost on the existing HIS application processes, we added a MLMGateway, a middleware that handles HIS events between HIS and MLM engine, and changed event detection method.

We integrated our improved MLM engine to development server in SNUBH. It was fast and simple work that only two person did it in three days. And we also built DDI knowledge base. We converted 930 DDI rules used in SNUBH into 930 Arden Syntax MLMs.

We evaluated our MLM engine to validate possibility in practical use. Performance, knowledge building and management cost, integration and migration, and usability was measured by comparing our engine with locally developed DDI system in SNUBH (local CDSS). The evaluation environment was Zeon dual core 3.0GHz CPU, 4G memory, 80G SATA HDD.

Discussion & conclusion

We refined MLMPlusX that it can be used in practice. To validate our system, we applied the MLM engine to SNUBH development server of SNUBH and built Arden Syntax knowledge base for DDI rules used in SNUBH. The overall evaluation results were promising. Performance was lower than local CDSS but it can be solved by modifying MLM engine design. Knowledge management cost was expected to be lower when using our engine, and there was no reduction in usability. The integration work was simple and fast that it showed high migration property. For the future work, we plan to adopt our system in real-time HIS.

Assessment of a Prototype Diagnostic Nursing Decision Support System for Inpatients with Type II Diabetes Mellitus

Cho I.S. [a], **Chung E.J.** [b]

[a] *Department of Nursing, Inha University, Korea*
[b] *Department of Nursing, Bundang Seoul National Hospital, Korea*

Abstract

Nurses are often asked to make quick decision with incomplete information under time pressure. For clinical decisions, computerized clinical decision support system can be used as tools to help with these decisions when it is implemented appropriate. This study was performed to obtain opinions on a previously developed diagnostic nursing decision support system developed by these researchers in order to aid the further development of the system. Knowledge representation and the appropriateness of our approach were assessed based on user feedback of a prototype system. Twenty-five NANDA diagnoses and 145 clinical assessment variables were structured into a criteria table. Twenty-seven nurses from inpatient and ambulatory settings and a graduate course on nursing informatics were recruited, and a scenario-based preliminary evaluation was performed. Based on these opinions w described the advantages and disadvantages of the prototype system.

Keywords:

Decision Support System, nursing diagnosis,
user evaluation

Methods

To acquire the relevant knowledge, a systematic literature review was conducted iteratively to establish nursing diagnoses and clinical assessment criteria. Twenty-five NANDA diagnoses and 145 clinical assessment variables were structured into a criteria table as the knowledge base for a prototype Web-based stand-alone system. This system automatically generates a nursing problem list based on the input data and detailed explanatory information for each item on the list.

Feedback on the system was obtained from 27 volunteer nurses: 17 from inpatient units and 10 from ambulatory settings and a graduate course on nursing informatics. The nurses from inpatient units were using electronic nursing record system every day and providing diabetes mellitus care for more than 10 years. The nurses from ambulatory settings had specialties in educating diabetes mellitus patients.

We asked the nurses to read the scenario developed by researchers based on the case studies selected from the nursing textbooks, and to look at the results produced by the system. They then completed a questionnaire on their opinions on the functions and the nursing problem list generated by the system.

Results

The nurses' responses to the suggested nursing problem list were summarized below, categorized into advantages and disadvantages that were mentioned more than twice.

Advantages:

- Well organized, making it easy to determined patients' problems.
- Easy to understand due to the data-driven approach.
- Convenient to obtain the problem list automatically.
- Able to consider all the potential relevant problems (which can be used as a reminder).

Disadvantages:

- Insufficient expression of NANDA terminology.
- Tedious or difficult to input data.
- No suggestion of nursing actions for each problem.
- Discrepancies between the priorities of suggested and selected problems.

Conclusion

The feedback from the nurses was useful and qualitative insights on identifying the requirements of a CDSS for nurses. This information will be used when we consider designing and development issues of a diagnostic CDSS.

So far diagnostic DSS had been limited on being adopted in clinical settings due to several implementation issues such as data capturing and redundant data entry. However, the current movement toward an EMR or EHR systems encourages us to consider on how to design it more effectively in the manner of integrated with those systems.

Assessment of a Prototype Diagnostic Nursing Decision Support System for Inpatients with Type II Diabetes Mellitus

Cho IS, PhD., RN. Chung EJ. RN

Department of Nursing, Inha University, Incheon, South Korea

Bundang Seoul National Hospital, South Korea

Contents

Main goal of the study

- **To assess nurses' opinions on the prototype of Diagnostic Decision Support System designed for inpatient with Type II Diabetes Mellitus**

  - **Get feedback useful and qualitative insights on identifying the requirements of a DSS for nurses**
    - **Advantages**
    - **Disadvantages**
    - **Other concerns**

Background (1)

- For clinical practice, use of “Nursing Problem/Diagnosis”
  - There are inconsistencies in the way in which nurses use and state nursing diagnoses
  - There are the semantic ambiguity of the diagnosis language
  - Accuracy, Consistency, & Validating problems of diagnoses used by clinical nurses within units and hospitals EXIST
  - No consistently document a wide range of nursing diagnoses
  - Diagnostic expertise is a vital initial component of nursing practice

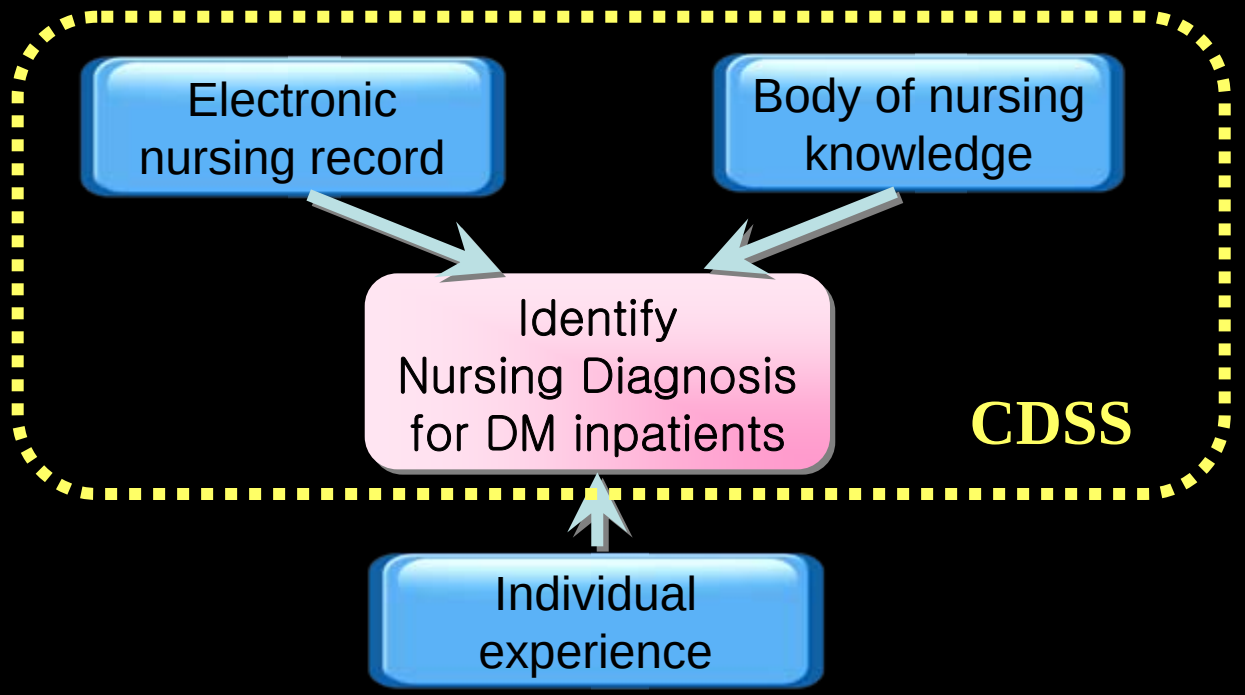
Background (2)

- Nursing Diagnosis needs critical thinking
  - "Judgment of conclusion that occurs as a result of nursing assessment"
  - Basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable
  - Diagnostic skill is one dimension of expertise and diagnostic expertise has a high priority on research
  - Expertise is needed to access an extensive, organized cognitive network of specialized knowledge

  ➔ The use of Nursing Diagnosis have been limited in practice

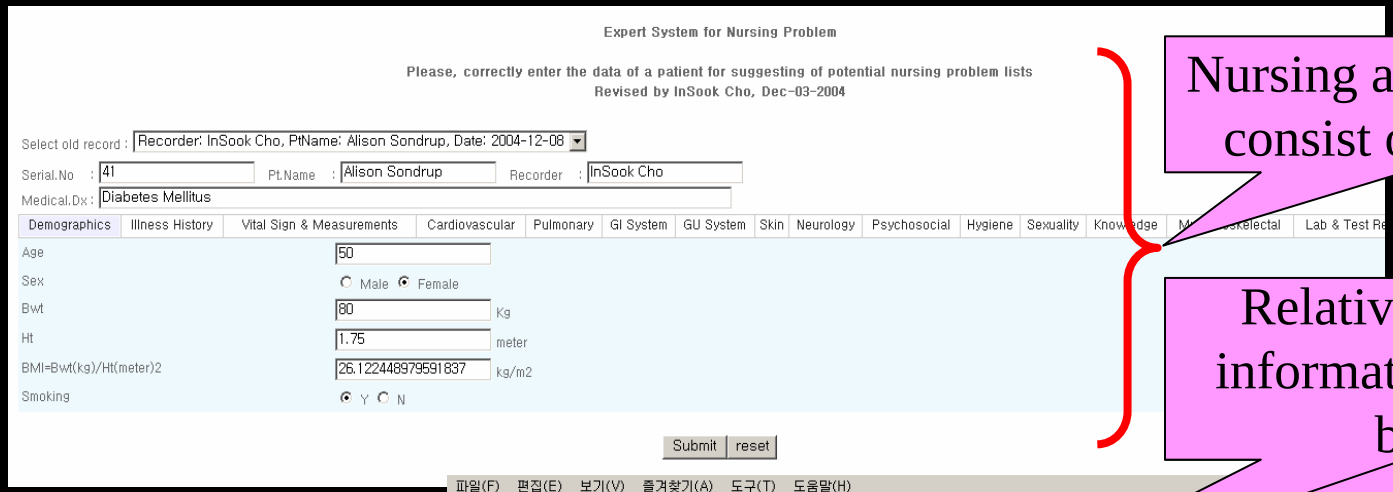
Conceptual Framework

- **Computerized Clinical Decision Support System**
  - **"…Current trend suggest that many of the formidable technological and conceptual challenges associated with representing nursing knowledge may be overcome and that decision support systems may significantly impact nursing practice…… "** (Ozbolt, 1988)



Materials and methods (1)

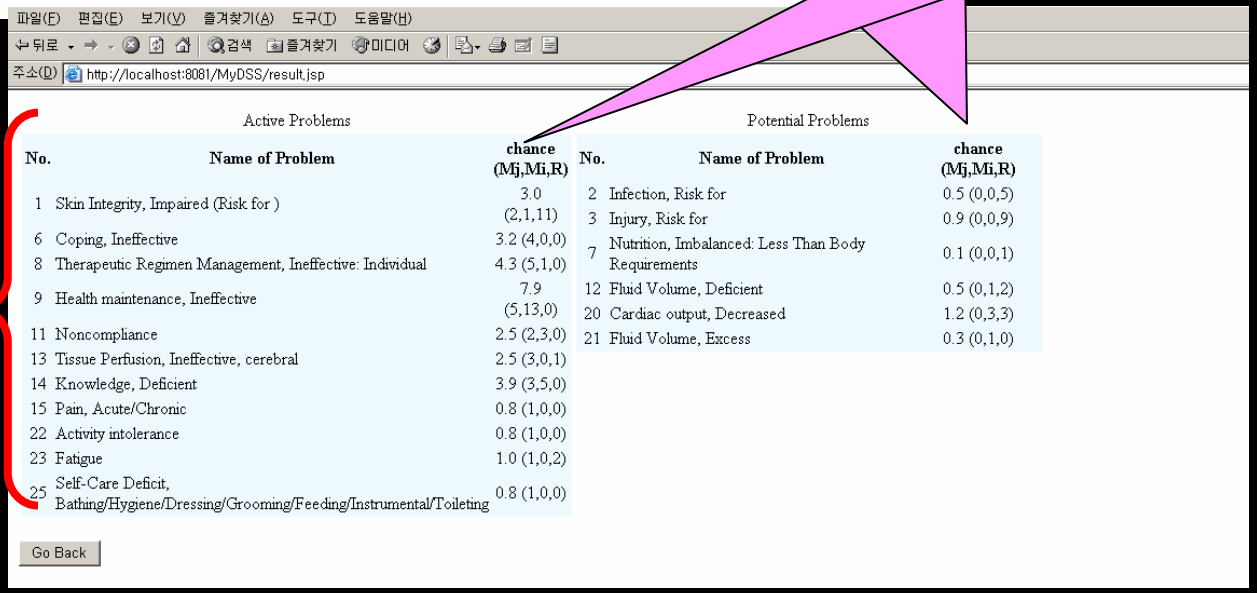
- **Web-based prototype**



Nursing assessment part: consist of 15 sub tabs

Relative probability information supported by data

The list of nursing problems suggested by system from the input assessment data



No.	Name of Problem	chance (Mj,Mi,R)
1	Skin Integrity, Impaired (Risk for)	3.0 (2,1,11)
6	Coping, Ineffective	3.2 (4,0,0)
8	Therapeutic Regimen Management, Ineffective: Individual	4.3 (5,1,0)
9	Health maintenance, Ineffective	7.9 (5,13,0)
11	Noncompliance	2.5 (2,3,0)
13	Tissue Perfusion, Ineffective, cerebral	2.5 (3,0,1)
14	Knowledge, Deficient	3.9 (3,5,0)
15	Pain, Acute/Chronic	0.8 (1,0,0)
22	Activity intolerance	0.8 (1,0,0)
23	Fatigue	1.0 (1,0,2)
25	Self-Care Deficit, Bathing/Hygiene/Dressing/Grooming/Feeding/Instrumental/Toileting	0.8 (1,0,0)

No.	Name of Problem	chance (Mj,Mi,R)
2	Infection, Risk for	0.5 (0,0,5)
3	Injury, Risk for	0.9 (0,0,9)
7	Nutrition, Imbalanced: Less Than Body Requirements	0.1 (0,0,1)
12	Fluid Volume, Deficient	0.5 (0,1,2)
20	Cardiac output, Decreased	1.2 (0,3,3)
21	Fluid Volume, Excess	0.3 (0,1,0)

Materials and methods (2)

- Participants
  - 27 volunteer nurses with agreement to participate
    - 17 from nursing units of inpatients
    - 10 from ambulatory settings or a graduate course on nursing informatics
  - Asked them to visit and make a trial with a written scenario
- Collection of data
  - Period: Oct. 2005 ~ Mar. 2006
  - Use a Web-based online self-report questionnaire
    - Demographics
    - three open questions

Results (1)

- **Demographic and professional experience of subjects**

Variables	Subjects (*n*=27)
Average age (SD)	35.1 (4.7)
Degree of education (%)	
Master	9 (33.3)
Bachelor	17 (63.0)
Diploma	1 (3.7)
Field of working (%)	
Inpatient care	17 (63.0)
Outpatient care or Nursing Informatician	10 (37.0)
Specialty (%)	
Yes	20 (74.1)
No	7 (25.9)
Mean years of clinical working (SD)	11.1 (5.3)
Mean years of computer experience (SD)	5.6 (2.2)

Results (2)

- Nurses' responses to a suggested nursing problem list automatically generated by the system

Advantages (n)
well organized, making it easy to determined patients' problems (10)
easy to understand due to the data- driven approach (8)
convenience of obtaining the problem list automatically (4)
are able to consider all the potential relevant problems (which can be used as a reminder) (4)
good being able to select the coverage of problems (1)
very helpful being given information on the likelihood of each item on the list of problems (1)
easy to use (1)

Results (3)

- Nurses' responses to a suggested nursing problem list automatically generated by the system

Disadvantages (n)
insufficient expression of NANDA terminology (6)
tedious or difficult to input data (5)
no suggestion of nursing actions for each problem (3)
discrepancies between the priorities of suggested and selected problems (2)
errors in data input may lead to incorrect diagnoses (1)
difficult to understand the likelihood score (1)
difficult to differentiate the major, minor, and risk factors (1)
not familiar with the use of English (1)
looks complex (1)

Conclusion

- **Implications of the advantages**

  A Diagnostic Nursing DSS has the potential for

  - **Stimulating the use of nursing diagnosis based on the data**
  - **Encouraging the use of critical thinking**

- **Implications of the disadvantages**

  A diagnostic Nursing DSS should

  - **Be integrated with an EMR necessarily**
  - **Consider the use of more expressive nursing terminology than only NANDA**

Needs Assessment for the Computer-interpretable Hypertension Guideline at Public Health Centers in Korea

EunJung Lee[a], SoYoung Kim[b], InSook Cho[c], JiHyun Kim[a], JaeHo Lee[d], Yoon Kim[b]

[a] *Center for Interoperable EHR, Korea*
[b] *Department of Health Policy and Management, Seoul National University College of Medicine, Korea*
[c] *Department of Nursing, Inha University College of Medicine, Korea*
[d] *Department of Emergency Medicine, University of Ulsan College of Medicine, Korea*

Abstract

Computer-interpretable hypertension guidelines can make for the improvement of blood pressure control rate by assisting clinicians at the point-of-service to behave according to the evidence-based guidelines. We surveyed 117 public health centers in Korea to evaluate current hypertension management status with clinicians' performance, and to analyze the needs for the computer-interpretable hypertension guidelines. Hypertension control rate was 57%, while clinicians overestimated it as 79.5%. 60.4% of patients were treated with 2 or more anti-hypertensive medications, and most frequently used drug class was calcium channel blocker. Inappropriate prescription rate of contraindicated patients was 2.6%. Two-thirds of clinicians agreed to implement the computer-interpretable hypertension guideline. Implementation of computer-interpretable hypertension guideline is considered as a way to improve the hypertension control rate and to reduce the inappropriateness of the therapeutic choice.

Keywords:

needs assessment, hypertension, guideline, practice guideline

Introduction

For the prevention of cardiovascular diseases, hypertension management takes important portion. Yet world-wide hypertension control rate is known to be less than one-third, especially in Korea, it is about 17%. Computer-interpretable guideline is suggested as an intervention tool for the quality improvement of patient care as modifying clinicians' behavior. This is a preliminary study for developing computer-interpretable hypertension guideline, which is designed to improve hypertension control rate in primary health care. We intended to analyze current hypertension management status, clinicians' performance and needs for the CIGs.

Materials and methods

We surveyed 117 public health centers and 154 clinicians in Gyeonggi province. We extracted medical records of hypertension patients from the centers' clinical database during a 10-month period. Data included blood pressure, medication, comorbid disease, and others. Questionnaire was answered by the clinicians to assess their adherence to hypertension guidelines and needs for the CIG program.

Results

38,474 patients' data and 41 clinicians' survey was analyzed. 61% of clinicians agreed to implement the computer-interpretable hypertension guideline. Hypertension control rate was 57%. Clinicians overestimated as 79.5% of patients had controlled blood pressure. Over 60% of patients were treated with 2 or more antihypertensive medications, and calcium channel blocker was the most frequently prescribed. Based on JNC7 report, inappropriate prescriptions, such as monotherapy for the stage hypertensive patient, beta blocker only for the diabetes patient, combination of beta blocker and non-dihydropyridine calcium channel blocker, thiazide diuretics for the gout patient, and beta blocker for the asthma patient, were 2.6% (N=1001).

Conclusion

Clinicians overestimated the proportion of their patients with controlled blood pressure. Implementation of computer-interpretable hypertension guideline is considered as a way to reduce the inappropriateness of the therapeutic

Making a Decision Support System with the Electronic Medical Record

Yoshinori Yamashita, Tatoku Ogaito

Department of Medical Informatics, University of Fukui, Japan

Abstract

We have been developed and used the electronic medical record system for 12 years. For integrate the text, data, and image, we have constructed the record that based on XML[1]. But, we had some problem for reporting and evaluation. We adopted the diagnosis and the unification of terminology for the common understanding. For the solution of these problems, we need the making the decision support system and the coding system. Thereupon, we make the model of the diagnosis process and make the preparation of the system. In this time, we did the evaluation of the system in the nursing region, because our database is established.

Keywords:

decision support, nursing process, medical record

Introduction

Our electronic medical record system has made the construction of the database by XML, for the purpose of that does information interchange. The correspondence to the tag of XML was a subject in the record of SOAP. The relation between the problem and goal are important in SOAP. Thereupon, it made to evaluate this relation.

We have made the nursing support system[2]. In its system, we had been needed the recognition of nursing diagnosis. So, we made the system of nursing process. In these ways, we think that the process state is important.

Thereupon, we tried that traces the changes of the process.

In the preparation of the plan, we make the goal corresponding to the problem. For example, we implement a plural plan while doing treatment. We evaluate the change in this process. As a result, we trace the problem and plan, and check the relation with the problem. The factor of judgment is analyzed from these relations.

We accumulate these analysis results as database and use to the support of the plan and assessment.

Methods

We made from patient information to SOAP that use as the record of the electronic medical record. However, it is difficult to trace the changes of the process with only this.

Thereupon, we added the part that registers the process of assessment, diagnosis and evaluation.

The flow of the system and data are shown in Figure 1.

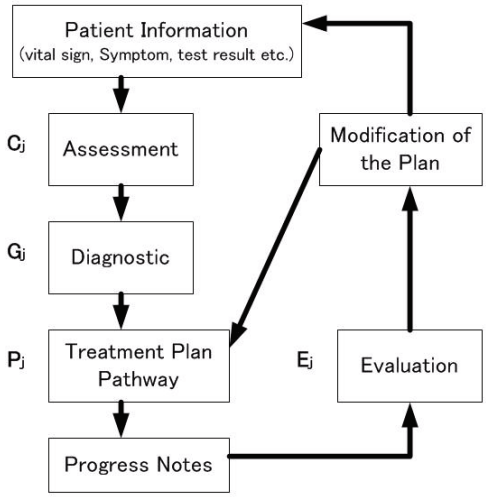

Figure 1 - System flow

The flow of the process is as follows.

1. It is making the problem list of patient information and summarized the symptom. (C_j)
2. It is making the goal corresponding to the problem. (G_j)
3. It is making the plan corresponding to the cause of diagnosis. (P_j)
4. It is making the evaluation to the plan. (E_j)

Where, G_j , P_j , E_j are recorded with the relation C_j.

We evaluate the change of this process by such a method. We make database this, from the result that evaluated. In such a period when treatment ends, it records the changes to these goals.

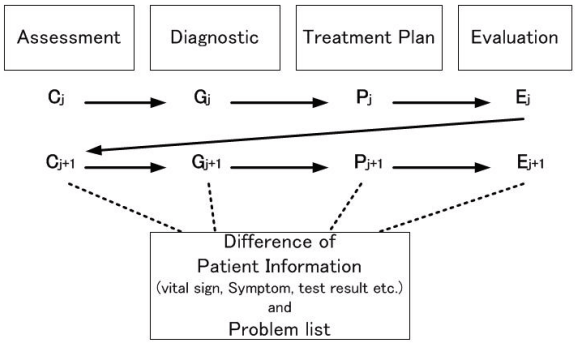

Figure 2 – Data Relationship

The data of this patient basic information are always held as even, the process of the diagnosis and plan are able to trace. Figure 2 shows the relation between the data and record in this system.

In addition to this, we record the skill and viewpoint of the user. These factor is used for the standard of the classification.

In this system, the candidacy of the diagnosis is selected from these data. These are not an automatic diagnosis in each process. Here is building a relation data of selecting and degree of preference.

Results

The system of the region of the physician is incomplete, although the system of the nursing region was finished. this reason is need the unification of terminology for using diagnosis.

However, It is possible to supports the process of the nursing diagnosis. The support of diagnosis and plan has obtained many satisfactions. As shown in this result, most users are answering this result as being that support was effective.

We are evaluating which item and template are effective in the critical pathway by using this system. This is useful for the preparation of the critical pathway.

This application effect of this system was investigated as a different viewpoint. This survey is classified by the experience years.

Furthermore, we are using to education and discussion such the analysis result.

Conclusion

In the nursing region, we are utilizing this system actually. By this system, we were able to unify the data on the record.

As this result, we ware able to analyze the condition of the branch on each problem list. By using this data, we are evaluating the diagnosis database.

However, the improvement is necessary about the user interface for the diagnosis support.

Making a decision support system with the electronic medical record

Yoshinori Yamashita, Tatoku Ogaito

Department of Medical Informatics,
University of Fukui, Japan

Introduction

- *We have been developed and used the electronic medical record system for 12 years.*
- *We adopted the diagnosis and the unification of terminology for the common understanding.*
- *We make the model of the diagnosis process and make the preparation of the system.*

What is necessary to us?

- Electronic Medical Record?
  - For data sharing?
  - For data exchange?
- What is the outcome corresponding to the effort?
  - Various searching?
  - Evidence
  - Evaluation of the process

Our trial system

- We made from patient information to SOAP that use as the record of the electronic medical record.
- We added the system that able to trace of the diagnosis process.
  - It is making the problem list of patient information and summarized the symptom. (Cj)
  - It is making the goal corresponding to the problem. (Gj)
  - It is making the plan corresponding to the cause of diagnosis. (Pj)
  - It is making the evaluation to the plan. (Ej)

Our Goal

- We intend the unification of terminology by using diagnosis.
- The plan should be able to be evaluated clearly.
- The clinical path should be able to be evaluated clearly.
- The physician and nurse are able to make a plan.
- Without relying on the experience years, the physician and nurse are able to collect at least necessary patient information in this system .
- By connecting problem information and the evaluation result in this system, we are able to evaluate the justifiability of diagnosis.

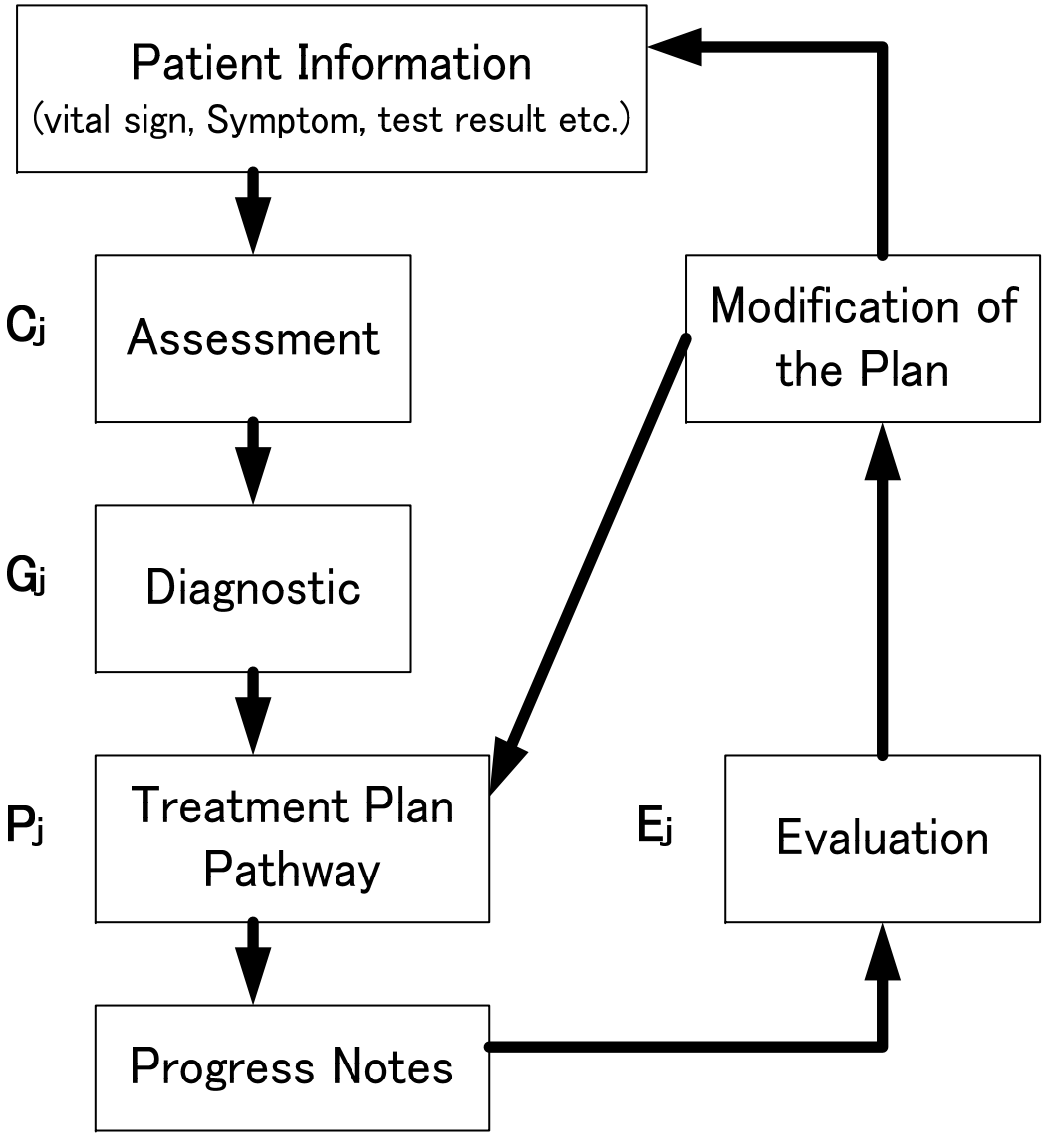

Figure 1 – System flow and Trace points

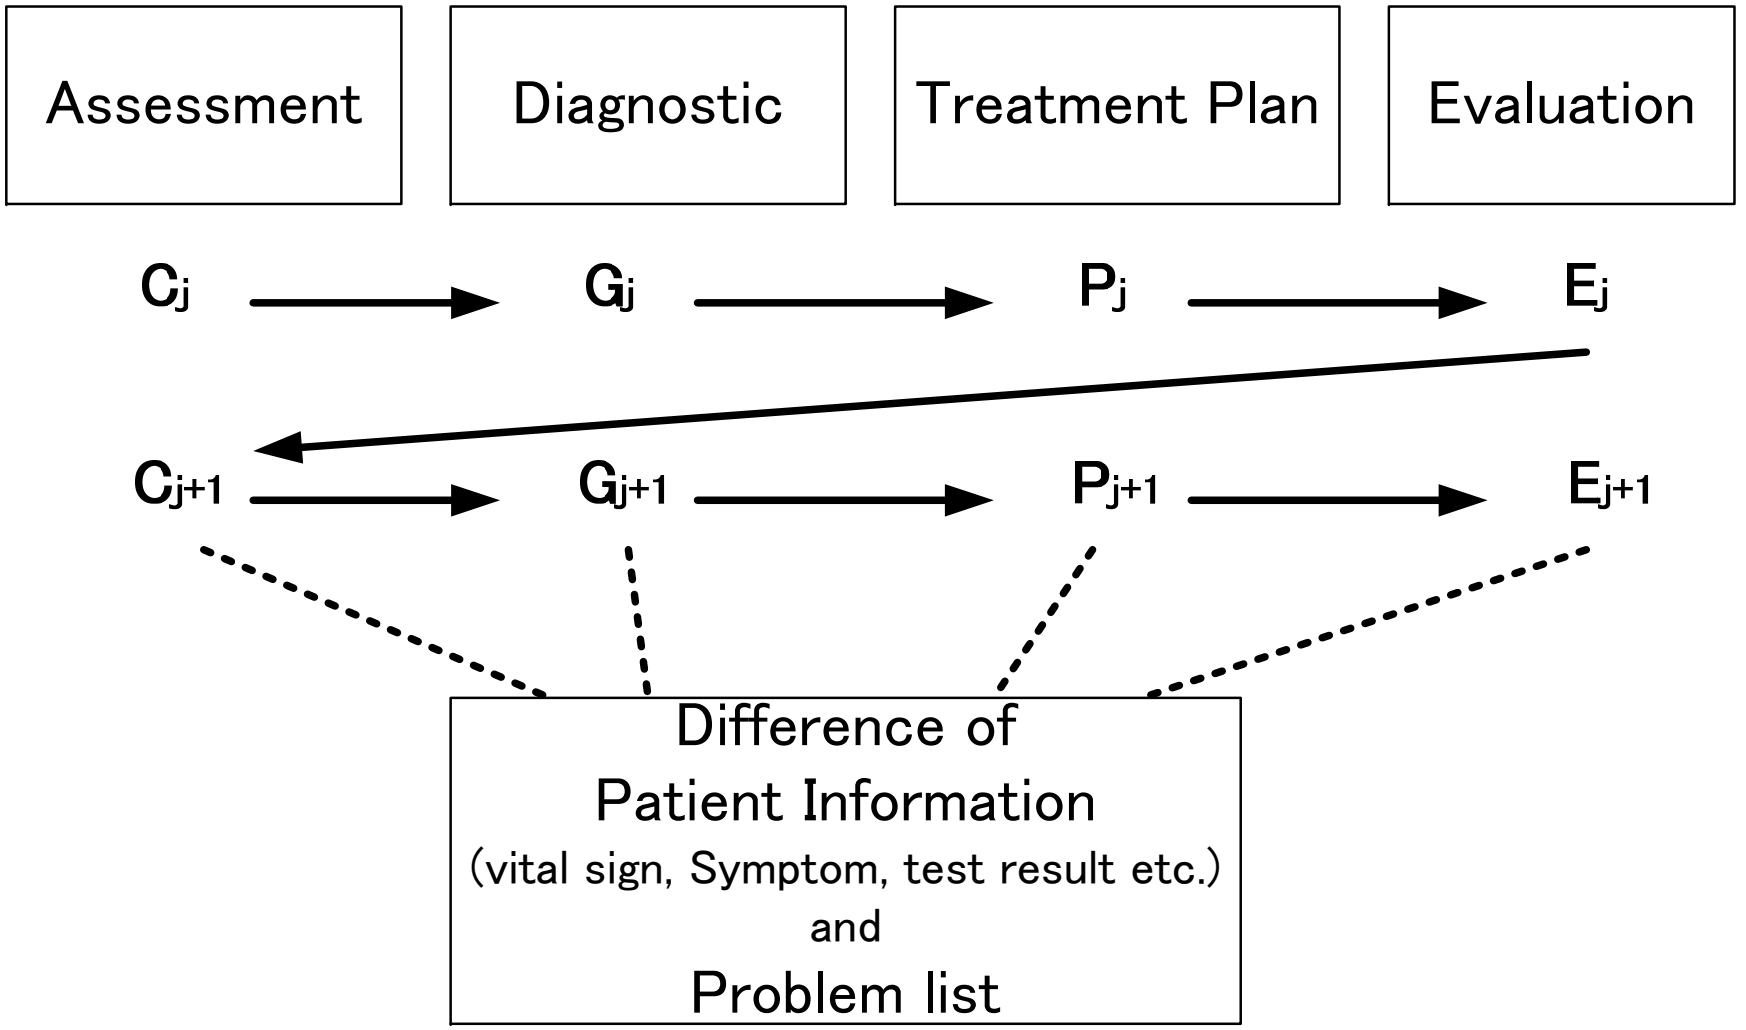

Figure 2 – Data Relationship and decision cycle

What kind of point became clear

- Process of diagnosis
- Information that contributed to diagnosis
- Evaluation of the critical pathway
- Difference of the process in the experience years
- Important point of judgment on process
- Factor of the changes of the process
- Factor of goal setting

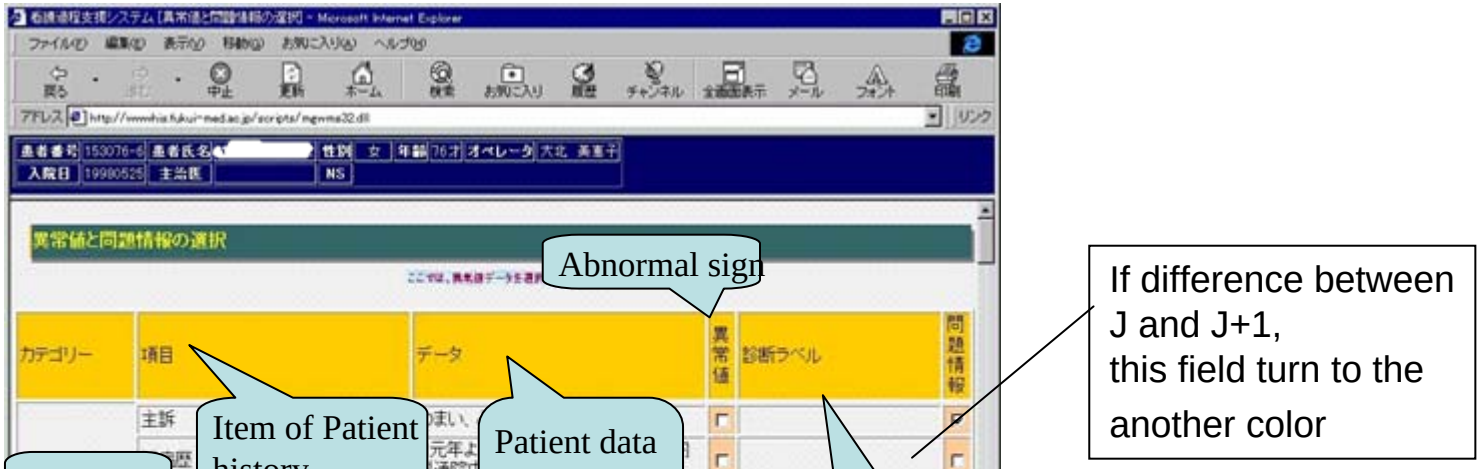

Figure 3 - Example screen of the Problem selection

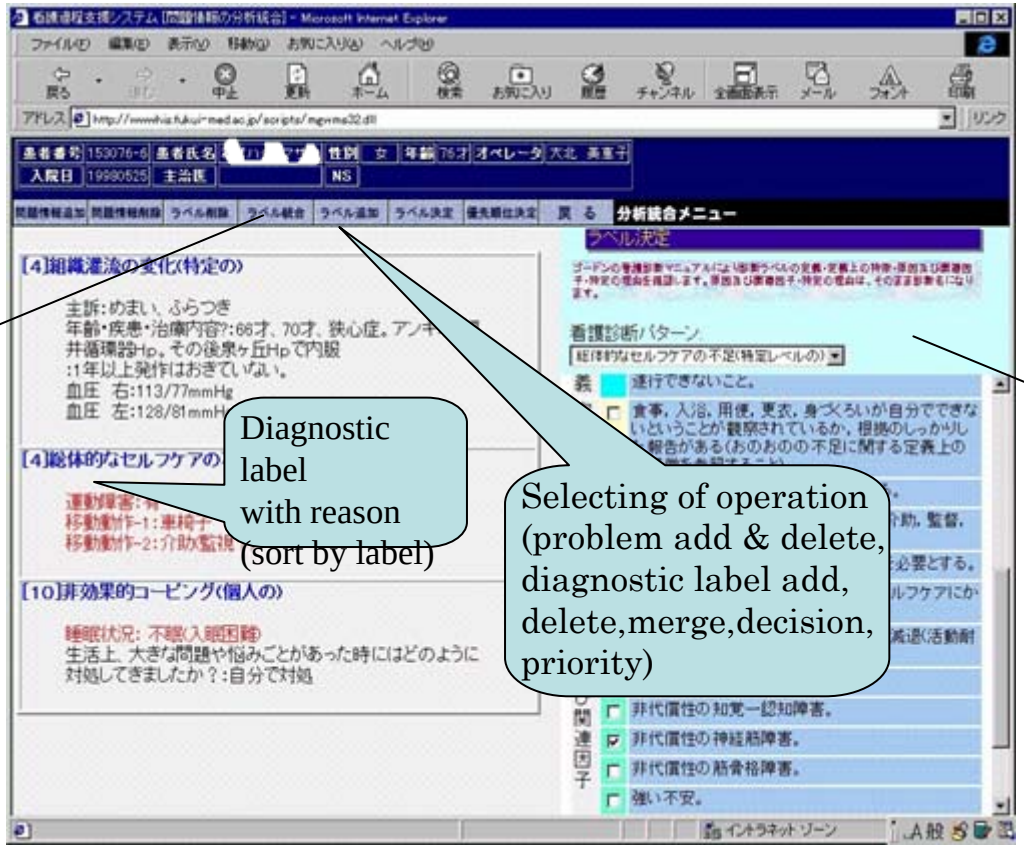

Figure 4 - Example screen of the Diagnosis

Results

- The system of the region of the physician is incomplete, although the system of the nursing region was finished.
- It is possible to supports the process of the nursing diagnosis. The support of diagnosis and plan has obtained many satisfactions.
- we are using to education and discussion such the analysis result.

Internationalization of Medical Logic Modules and Extended Time Operations in Arden Syntax Version 2.6

Sven Tiffe[a], Kristian Struck[a], Michael Dahlweid[b]

[a]*Agfa HealthCare, Healthcare Application Platform, Metatools, Germany*
[b]*Agfa HealthCare, Product Management, Germany*

Abstract and objective

Using Arden Syntax based systems in an international environment poses new requirements in terms of localization of knowledge. To support translatable, multi-lingual rules that can be maintained centrally, extensions to Arden Syntax have been defined and approved by HL7. Further extensions of this version deal with extended time operations. First international projects prove the usability of these extensions.

Keywords:

Clinical Decision Support, Arden Syntax

Introduction

Many factors affect the reusability of Arden Syntax 'Medical Logic Modules' (MLMs). While recent studies mainly focused on the curly braces problem [1], another important but neglected factor is the language of the message text of an MLM. Rules in multilingual countries or rules that are used in more than one country should always create messages in the language of the message recipient. Recent extensions to Arden Syntax defined a structured message format with natural language parts but did not address localized messages [2]. During the rollout of Orbis, a widely used hospital information system in Europe, this kind of localization of an MLM became an important issue in terms of reusability and maintainability. The natural text parts of an Arden Syntax rule that represent the result message have to be translatable, while the rest of the rule usually has to be centrally maintainable. Therefore, separation of an MLM's message part from the logical section should be possible. These requirements finally led to a set of extensions to the Arden Syntax in its latest version 2.6 [3].

This version includes further extensions dealing with temporal conditions to facilitate the readability of MLMs. Since the first version, Arden Syntax has placed emphasis on supporting rule authors to express temporal conditions and other temporal expressions in an easily readable way. For example, the blood glucose values from a list 'bg_values' that have been measured within the past three months can be selected by

```
bg_values where they occurred within past 3
months
```

Each information in an Arden Syntax MLM that has been read from the data base or from similar sources has an implicit attribute 'primary time' which defines the medically relevant timestamp associated with the information. This attribute is automatically used by temporal operators, as shown in the previous example. In a similar way, operations on other time ranges can be defined.

However, as these operators always refer to a timestamp that consists both of a date and a time, some expressions such as "this examination can be ordered only from 10 pm to 8 am" are hard to express. To support temporal expressions that do not refer to a specific date, a new data type "time of day" has been introduced.

Methods

Internationalization of Medical Logic Modules

Arden Syntax MLMs have been designed to serve as knowledge exchange format. One requirement was therefore that MLMs should always include all required information for making a decision. Whenever an MLM is transferred from one system to another, all required information is loaded into a text file in Arden Syntax format. To support MLMs with multiple languages for the result messages "resource bundles" have been added to MLMs that contain the required translations of all text fragments of the MLM that need to be available in more than one language. As an MLM is defined to consist of one file, all language resources of a localized rule have to be part of the individual MLM text file.

Up to Arden Syntax version 2.5, one Medical Logic Module is structured into the three categories "maintenance", "library", and "knowledge". These categories contain various unstructured and structured information ("slots") which describe administrative facts, such as author or version, background information, such as an explanation, and the decision logic. The logic is modeled as an algorithm within the knowledge category that contains the structured slots "data", "logic" and "action". For internationalization, in addition to these existing, mandatory categories of an MLM, a fourth category "resources" has been specified. This category contains all relevant text used in the logic or

action slots of the MLM. Entries in the resources slot are structured by sections that define translations for individual languages. Each language is identified either by a 2-character language code or by a combination of a language code and a 2-character geographical code, such as 'en', 'en_us' or 'de'.

Within such a section, all resources are identified by a unique textual key and the corresponding text, for example[1]

```
language: en
   'msg': "Caution, the patient has the following
           allergy to penicillin documented: ";
   'creat': "The patient's calculated creatinine
             clearance is %f ml/min."
;;
language: de
  'msg': "Vorsicht, zu diesem Patienten wurde die
     folgende Penicillinallergie dokumentiert: ";
 'creat': "Die berechnete Kreatinin-Clearance des
     Patienten beträgt %f ml/min."
;;
```

Like in the previous examples, translatable resources usually are message parts or format patterns. A new operator "localized" has been introduced that returns the translation of a text for the current language setting. It returns the localized resource whose key corresponds to the argument of the operator. For example, in an English setting the expression

```
creat formatted with localized 'creat'
```

returns[2]

```
"The patient's calculated creatinine clearance is
                0.33 ml/min."
```

while in a German setting the same expression returns

```
"Die berechnete Kreatinin-Clearance des Patienten
            beträgt 0,33 ml/min.".
```

This use of the operator implies that the implementing system is able to retrieve an implicit "language setting". In a multi-lingual system where the destination language cannot be implicitly detected, the localized operator can be used with an additional argument that defines the language or combined language-locale code.

Extended temporal operators

As described in the introduction, Arden Syntax provides a timestamp data type termed "Time" and various operators that deal with temporal aspects. In addition to this data type, a new data type "time of day" has been introduced. This data type is used to define temporal conditions such as "lab order was placed after 10 pm and before 6 am" in an easily readable and comprehensive way, for example

```
order_time was within 10:00 to 18:00
```

This expression returns true, if the order was placed within the defined time range without considering the date fraction of the 'order_time' variable. Special attention was paid to cases where the defined time range spans midnight. If a rule has to check whether an order is to be placed during night hours, the condition may be expressed by

```
now is within 22:00 to 03:00
```

Here, the operator checks whether the time of day is after 10 pm or before 3 am. The new data type has been applied for most temporal operators and conditional expressions and can be combined with normal "Time" values, for example

```
  irregualar_measurements := measurements where
measurements.time not occurred within 1 hour sur-
                rounding 14:00;
```

The last example selects those entries of a list of measurements that have not been measured within a time range of 13:00 to 15:00 and that may therefore not conform to a guideline.

Accordingly, another set of new operators and constants can be used to refer to a day of week to express conditions, such as "lab order was not placed on Sunday".

Results

The internationalization of MLMs allows commercial and academic suppliers to address an international range of users with rules that can be centrally maintained. This extension was limited to the textual parts of the structured algorithms that represent message sections. Other parts of the rule which also consist of free text, such as the explanation and description of the rule, have not been extended. The focus of has been set on those parts where localization in terms of communication to the users is crucial. However, as the rationale of other textual slots of an MLM was to increase transparency of the rules and to support user acceptance, also these resources may have to be localizable one day. While former versions of Arden Syntax were based on a 7-bit ASCII file format, for many international users UTF-8 encoded rules may be required.

The time of day data type allows an easy and intuitive definition of temporal conditions and harmonizes with existing elements of the Arden Syntax. The option to express temporal conditions independently from a specific date and the option to directly support week days was found useful by the members of the HL7 Arden Syntax Special Interest Group.

1 All examples have been cited from [3].

2 This example presumes that the variable ‚creat' represents a numeric variable with a value of 0.33.

Both extensions may be another step towards a broader use of Arden Syntax. They have been balloted as Arden Syntax version 2.7 by HL7 and have also been successfully implemented in Orbis.

Internationalization of Medical Logic Modules and Extended Time Operations in Arden Syntax Version 2.6

Isabel Barth[a]; Sven Tiffe[a]; Michael Dahlweid[b]

[a]*Agfa HealthCare, Base Technologies, Metatools, Germany*

[b]*Agfa HealthCare, Product Management, Germany*

AGFA HealthCare

Arden Syntax V 2.6

- Arden Syntax for Medical Logic Modules
  - Knowledge representation & transfer format maintained by HL7
  - Knowledge bases consist of a set of individual rules
    - Medical Logic Modules (MLMs)
    - MLMs consists of Categories structured by slots
    - Each MLM should contain all knowledge for one specific decision
- Additions in version 2.6
  - Internationalization (I18N) of MLMs
  - Extended temporal elements and operators (“time of day” data type)

Rationale: I18N

- Usually, results of MLMs are textual messages
  - Contents are mostly unstructured
  - Arbitrary contents
- International use of MLMs in “Orbis”
  - Individual countries require messages in their own language
  - Some countries may require more than one language (US, Belgium,…)
- Requirement for broad reusability: good maintainability
  - “Orbis” Hospital Information System ~ 1200 installations in Europe
  - Decision logic of a rule may be valid without modifications for many countries
  - Goal: Split logic and translatable resources, but keep them in one MLM

MLM's Resources Category

- As knowledge representation format, MLMs keep information all information for the decision in one file

```
maintenanance:
   […]
;;
library:
   […]
;;
knowledge:
   […]
;;
resources:
   […]
;;
```

Information about author, version, state of the MLM

Explanatory information

Decision and data access logic

New: structured language resources

- MLM text file composed by "categories" structured by "slots"

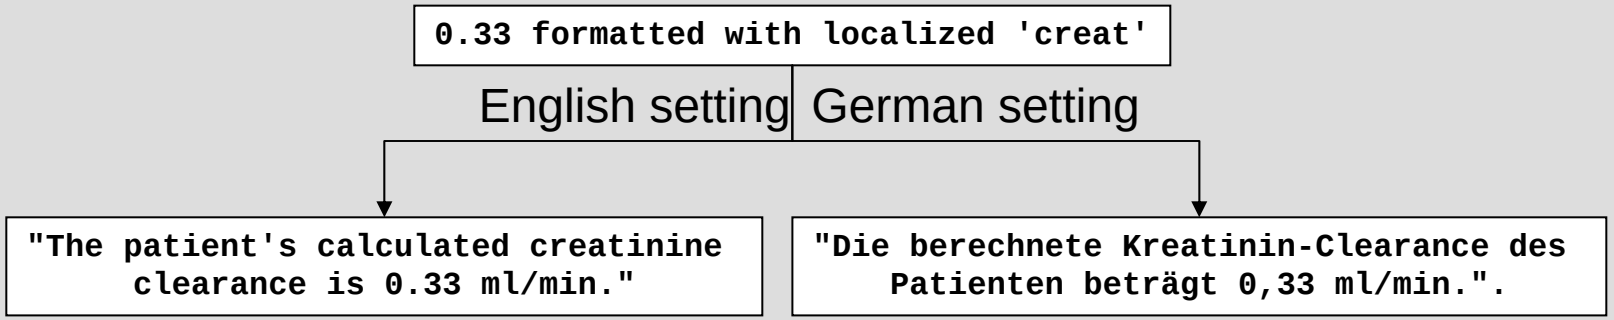
Structure of Resources Category

- All translations for the required languages defined in “language slots”
- Use of 2-character ISO 639-1 language code or combined language code and ISO 3166-1 geographical code

```
language: en
   'msg': "Caution, the patient has the following
           allergy to penicillin documented: ";
   'creat': "The patient's calculated creatinine
             clearance is %f ml/min."
;;
language: de
   'msg': "Vorsicht, zu diesem Patienten wurde die
        folgende Penicillinallergie dokumentiert: ";
   'creat': "Die berechnete Kreatinin-Clearance des
             Patienten beträgt %f ml/min."
;;
```

“localized” operator

- String operator that retrieved the translated resource from the resources category



- The simple use of this operator presumes that the implementing system is able to determine the current language setting
- If the current setting cannot be retrieved, either
  - a default code can be defined in the resources category or
  - the “localized” operator can be used with an explicit language code as additional argument

Arden Syntax I18N: Limitations

- Focus on crucial parts of message creation
  - Messages are usually built in logic or action slot of an MLM
  - Message parts can be translated
- Other free text sections of an MLM have not been extended
  - Explanation slot, description slot, etc.
- The resulting message that is written from the MLM to the implementing system is still “plain”
  - The message itself is not multi-lingual
  - Message handling depends on implementing system
  - Future extensions of Arden Syntax may be harmonized with HL7’s Reference Information Model (RIM) and be structured and standardized

Rationale: Extended Time Operators

- One focus of Arden Syntax lies on temporal conditions

```
bg_values where they occurred within past 3 months
```

  - selects those blood glucose values from a list that occurred in the last 3 months
  - Other operators allow additional kinds of time ranges
- Time constants are defined either by timestamps or by dates
  - Time constants always refer to points in absolute time
  - Temporal conditions that refer to a specific time of day without being affected by the day itself are hard to express
    - “Do not send an order to a specific lab from 20:00 to 06:00”
    - “Have all blood glucose measurements been taken after lunch?”
- A new data type “time of day” has been introduced
  - Existing operators have been extended to work with this data type
  - In addition, constants and operators for “week of day” have been defined

“Time of day” data type

- Time of day constants are defined in a similar way like Arden Syntax timestamps (“time” data type), for example
  - 20:00:00
  - 00:00:00.000 (midnight)
- Time of day values (constants and variables) can be used with most existing operators in Arden Syntax, for example

```
if now is within 20:00:00 to 06:00:00 then
    msg := "Orders to this organizational unit during night hours are
            not possible!";
endif;
```

or

```
irregualar_measurements := measurements where measurements.time not
occurred within 1 hour surrounding 14:00;
```

- As shown in the first example, time ranges may span midnight

Day of Week extensions & Delayed MLM Triggers

- "Day of Week"
  - extensions are based on
    - A set of constants (Monday, Tuesday, …, Sunday)
    - The "day of week" operator
  - Like expressions that refer to a time of day, this extension can be used for easy readable temporal conditions that refer to a day of

```
If Day of week of now is in (SATURDAY, SUNDAY) then
   msg := „Sorry, we‘re closed.";
Endif;
```

- Both extensions can be used in Evoke slot to delay execution, for example to execute an MLM at
  - Today at 18:00:00;
  - Tomorrow at 05:00:00;
  - Monday at 12:00:00 or Wednesday at 12:00:00;

Conclusion

- I18N of Medical Logic Modules
  - Focus on knowledge representation and exchange format
    - All information is stored in one file and one format
    - Implementing systems may organize their language resources in other ways
  - Important step for international reusability
    - Further extensions may be required to translate also explanatory sections
    - First, good experiences during roll out of Orbis in European countries
- Temporal expressions based on “Time of day” data type
  - Easy readable way to express temporal conditions that not refer to points in absolute time
  - Fits into Arden Syntax’ philosophy of dealing with time constraints
    - Usable by most existing operators
    - Low efforts to extend existing Arden Syntax based implementations

Thank you

Integration of Medical Publications into the Clinical Routine Using HL7 "Clinical Decision Support Context-Sensitive Information Retrieval"

Kristian Struck[a], Sven Tiffe[a], Michael Dahlweid[b]

[a]*Agfa HealthCare, Healthcare Application Platform, Metatools, Austria*
[b]*Agfa HealthCare, Product Management, Germany*

Abstract

To support clinical staff in their daily decisions, a context-sensitive information retrieval mechanism has been embedded into a widely used health information system. This mechanism implements the HL7 "Infobutton" approach that has been extended to formalize the search result. These results consist of articles whose characteristics match the patient's information like diagnoses, gender and age.

Keywords:

Clinical Decision Support Systems, HL7 Infobutton, Context-Sensitive Search

Introduction

An important goal of Clinical Decision Support is to provide the right information to the right users at the right time. One approach to achieve this goal is to provide adequate medical articles to both clinical staff and patients. We integrated a context-sensitive information retrieval based on the HL7 "Infobutton"[1] approach into Orbis, a hospital information system (HIS) with over 1200 installations and more than 450,000 users. With "Infobutton", various medical information sources can be embedded into the clinical routine process.

Methods

The "Infobutton" technology

Based on an early specification of the "Infobutton" [1], we developed a component "Infobutton Manager" (IM) that is embedded in the client-platform of the HIS. The IM is able to query various content providers (e-resources) and is responsible for providing additional information from the enquiring user context, current task context (type of task the user is trying to perform) and patient context (gender and age).

The search request is well defined in the "Infobutton" specification and includes a set of main search criteria that can be either free-text or formalized values. The set of supported search criteria depends on the e-resource and is not restricted by the specification.

As a first e-resource, the ICD-based retrieval of medical documents has been connected. This provider uses an intelligent fingerprint mechanism to map ICD-codes to medical articles [2] from Medline. We were able to use ICD-10 codes as search criteria as in German hospitals diagnoses are already documented during the patient's admission and also during the whole clinical process.

Another e-resource enables semantic full-text retrieval in publication databases of publishers like Springer Medizin Verlag [3].

Both e-resources are web-services that use the Simple Object Access Protocol (SOAP) as the communication layer and as payload the XML "Infobutton" resource request.

In contrast to the outlined request, the "Infobutton" specification does not define a structured result format.

Searching for information

The general information search- and retrieval-workflow can be described as follows: The user starts a search by selecting diagnoses or full-text for which he needs more information. Then, the request is extended with contextual information and forwarded to the e-resource by the IM.

As a result, the e-resource sends a list of documents and related concepts back to the enquiring system. The user may either select documents for ordering or he can refine the search by adding or removing related concepts based on MeSH-terms or ICD-codes as search criteria.

The "Infobutton" specification does not define the result of the e-resource request, thus we have implemented two different approaches to model the search and retrieval workflow:

Structured result format

As a first approach, an XML structure has been introduced as request result. This structure contains meta-information on the documents such as title, authors, journal, related concepts and ordering information. The result-XML can be stored, processed by other applications or shown to the enquiring user in the search dialog. From here, the user is

1 HL7 "Clinical Decision Support Context-Sensitive Information Retrieval" (Infobutton)

able either to start another search-workflow if he modifies the search criteria, or to order a document.

Web-based result handling

As second approach, the e-resource result is a URL that serves as an entry point to the web-based search- and retrieval-workflow of the individual e-resource provider. The e-resource request is initiated only once. Then the resulting URL is forwarded to the web-browser in the enquiring system. Further refinement of search criteria and document orders are realized within the website via hyperlinks.

Results

The HL7 "Infobutton" approach can be used to integrate knowledge sources into the diagnostic and therapeutic process. Its open concept allows connecting to different knowledge providers but lacks a structured result format. Both introduced approaches have advantages and disadvantages.

Structured result format

The approach of using structured result formats has the major advantage that the receiving system can directly react on the result and integrate the information in its application framework.

- All parts of the result can be processed electronically.
- The result can be integrated into the HIS platform and processes with respect to the HIS vendor's design guideline and look & feel.
- It is possible to modify, add or remove both context-data and search criteria during the whole search process.

However, we also have to take the disadvantages of this method into account.

- This proprietary XML strongly reflects the structure of the special e-resource that was used. Without a standardized result, we have new implementation efforts to integrate the result handling for a new e-resource.
- Other types of information (e.g. picture or audio databases) are difficult to integrate with this special literature search.

Web-based result handling

Currently, from our point of view, the web-based approach is the preferred way.

- Processing the URL is easy to implement. The result is simply passed to the system's web-browser.
- The HIS vendor is not responsible for developing the user interface. The e-resource vendor can influence presentation of the result.

The web-based method implies disadvantages, too.

- For optimal user guidance, the e-resource web-result has to be developed with respect to the HIS vendor's design guidelines. This means that the e-resource has to provide different web-services for their customers.
- Once, the search is started, it is not possible to modify, add or remove context-data and search criteria by the HIS system. The context information and search criteria are collected only once, with the initial resource request. The modification of search criteria during the search process is a function, that has to be provided by the respective e-resource.

Conclusion

The integration of HL7 "Infobutton" approach is a good way to serve the clinical staff with up-to-date information.

Like the e-resource request, the result data should also be covered by the HL7 "Infobutton" specification.

In terms of semantic interoperability the use of formal codes instead of free text search criteria may also be an issue when used in an international context where code systems of e-resources and customers differ. In such cases, additional efforts to convert "Infobutton" queries are required.

Integration of Medical Publications into the Clinical Routine Using HL7 “Clinical Decision Support Context-Sensitive Information Retrieval”

Kristian Struck[a]; Sven Tiffe[a]; Michael Dahlweid[b]
[a]Agfa HealthCare, Healthcare Application Platform, Metatools, Austria
[b]Agfa HealthCare, Product Management, Germany

AGFA HealthCare

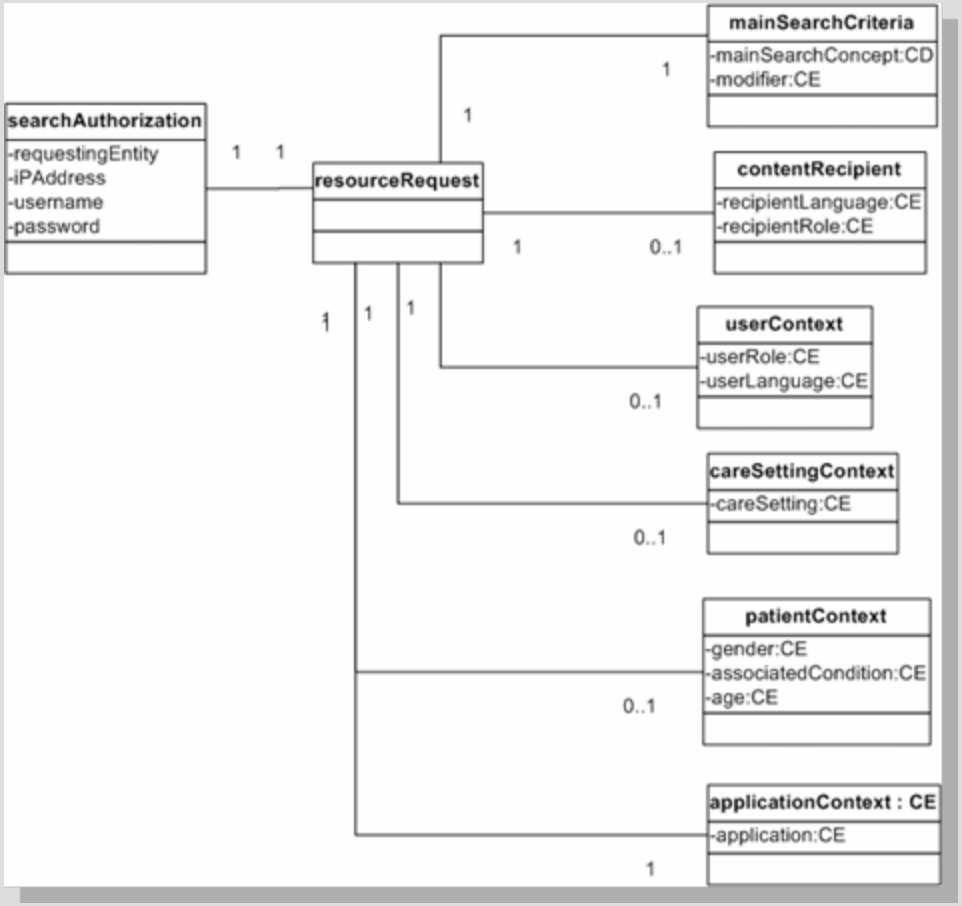
Rationale

Context-sensitive information retrieval to …

- serve the clinicians with latest medical publications directly in the application
- inform the patients about their treatment
- embed knowledge directly into the HIS
- detect lacks of knowledge in the hospital
- collect frequently asked questions or special fields of interest of the clinical staff

HL7 „Infobutton“ Approach

Parts of the „Infobutton“-request



User defined search criteria (ICD, full-text)

The Infobutton-Manager (IM) collects information about the current context.
That allows the e-resource to return the adequate information.

AGFA HealthCare

„Infobutton“ – ICD-10 based information retrieval

- ICD-10 codes given as search criteria

```
<mainSearchCriteria>
   <mainSearchConcept code="A00.0" codeSystem="ICD-10">
     <qualifier>
       <name code="main" />
     </qualifier>
   </mainSearchConcept>
   <mainSearchConcept code="A00.1" codeSystem="ICD-10" />
</mainSearchCriteria>
```

- Multiple main search concepts allowed
- Qualifier labels the „main“ diagnosis

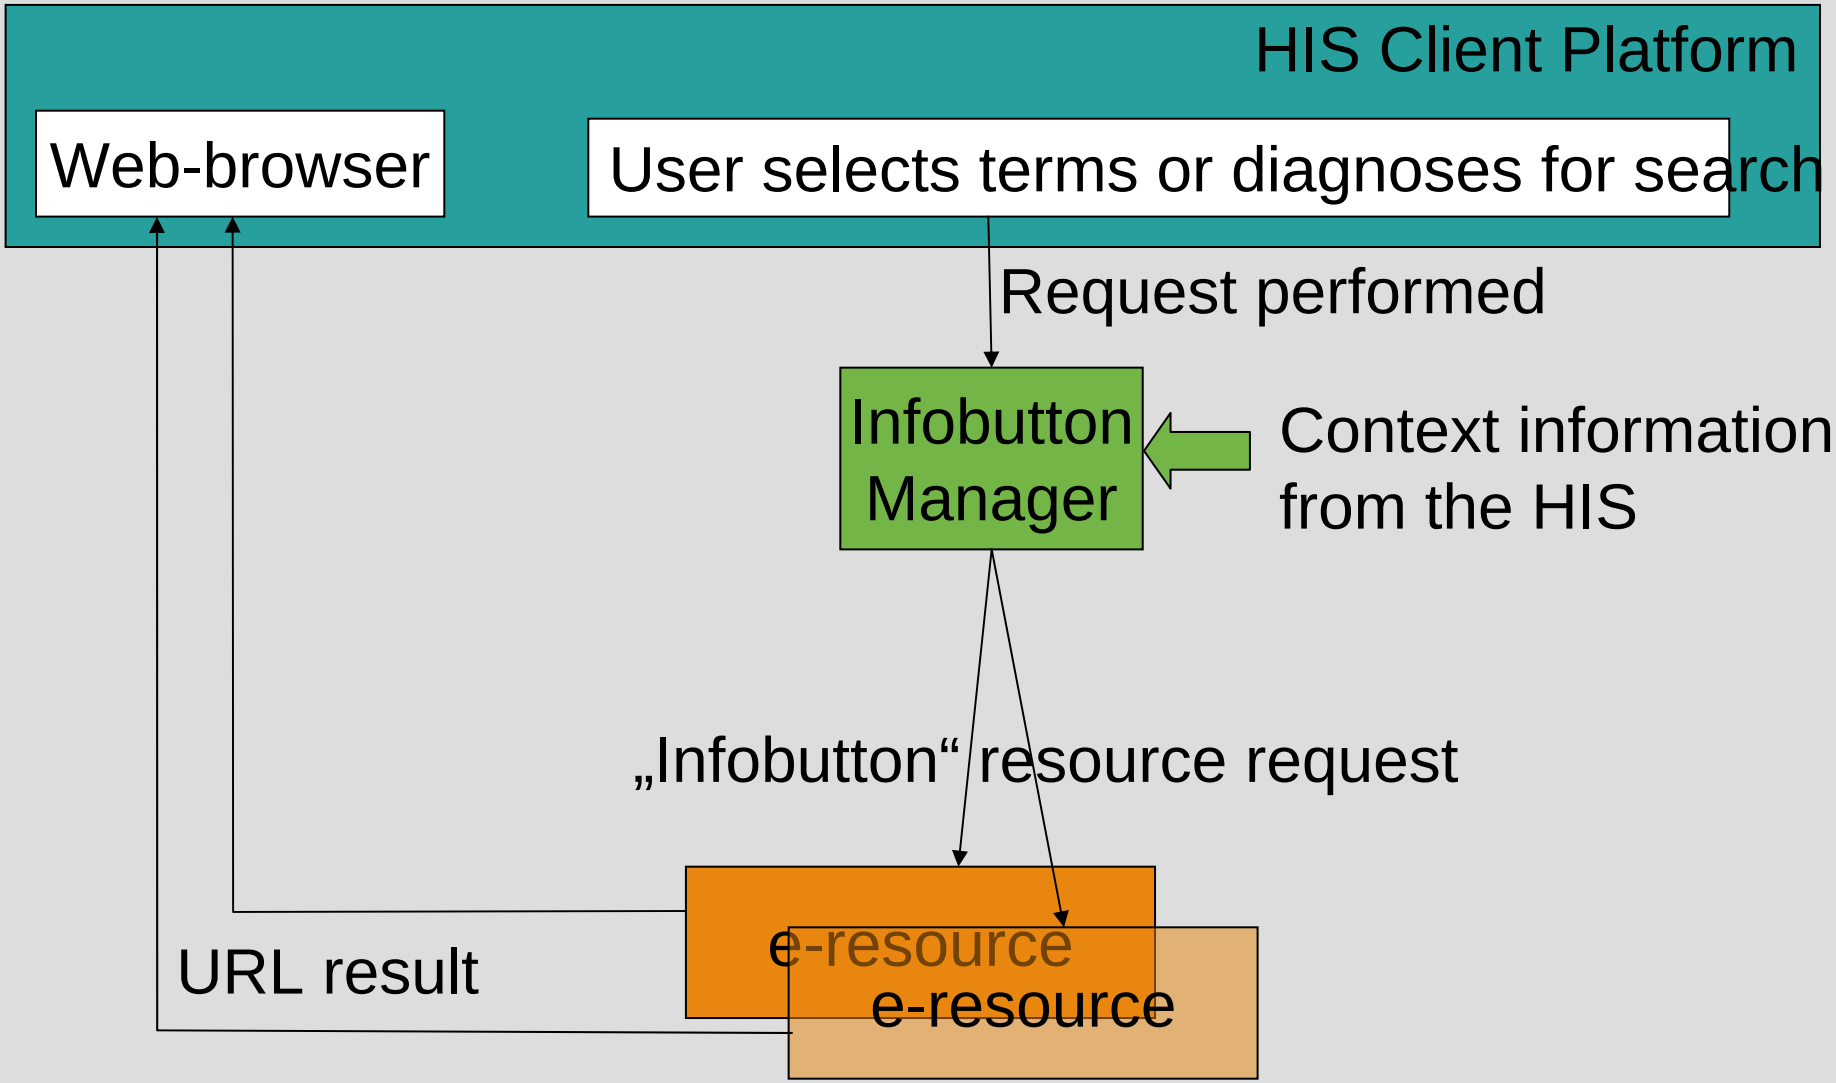
„Infobutton“ – Full-text information retrieval

- Full-text used as search criteria

```
<mainSearchCriteria>
     <mainSearchConcept displayName="colon cancer">
       <originalText>colon cancer adenocarcinoma</originalText>
     </mainSearchConcept>
     <mainSearchConcept displayName="adenocarcinoma">
       <originalText>adenocarcinoma</originalText>
     </mainSearchConcept>
   </mainSearchCriteria>
```

- Concatenation of the search string
  - AND
  - OR
  - NOT

Searching for Information



Web-based Result Handling

- The e-resource returns an URL that is passed to the web-browser in the enquiring system
- We consider the web-browser as a black box
- Refining the search by adding or removing of search criteria is only possible within the browser session and is implemented by the webservice
- The e-resource is responsible for presentation
- Presentation and data is mixed

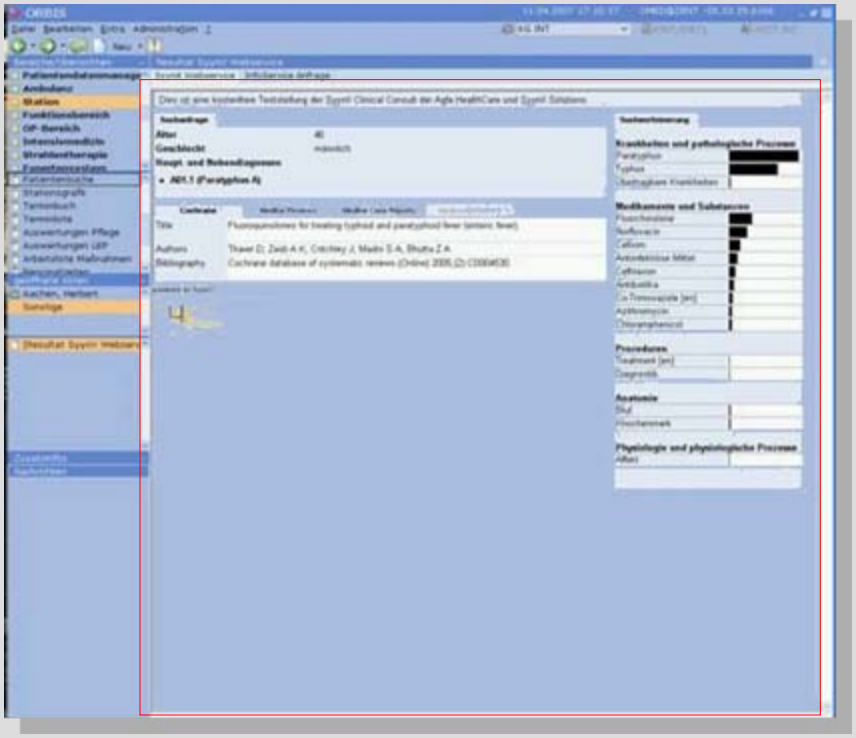
Structured Result Format

The proprietary result-XML contains meta-information of the document

- Title, authors and publication information
- The document‘s source (e.g. Cochrane, Medline Reviews, Medline Guidelines)
- Related concepts and categories, e.g.
  - Chemicals & Drugs: Cholera Vaccines, Vaccines, Toxines, …
  - Molecular Biology: Cholera Toxin, Evolution, …
  - Organisms: Vibrio cholerae, Bacteriophages, …

An Example – The Integrated Webbrowser

Agfa‘s HIS Orbis uses the embedded web-browser component to show the „Infobutton“-result in a convenient way.



Results and Conclusion

- The preferred way is the web-based retrieval
  - No development effort if the e-resource changes
  - All e-resources are treated in the same manner
  - Little time to connect new e-resources
- However, it is not possible to
  - Analyze the search- and refinement-process
  - Optimize the knowledge- / information management within the hospital

Discussion

- A standardized „Infobutton“ result would be the solution for
  - A better integration into the clinical routine process
  - An easier use of new e-resources
  - Better knowledge management and knowledge sharing in the hospital
- But, how can different types of information (like literature, pictures, audio or video) be standardized in the same manner?

Thank you

MEDINFO 2007
HISA Ltd Australia

Semantic Annotation of Patient Data in a Commercial Health Information System

Isabel Barth[a]; Sven Tiffe[a]; Michael Dahlweid[b]

[a] Agfa HealthCare, Health Care Application Platform, Metatools, Germany,
[b] Agfa HealthCare, Product Management, Germany

Abstract and objective

To facilitate reusability of information in a complex Health Information System, a semantic component has been created that allows for formal descriptions of clinical data at a very granular level. Through an extension to the clinical database, semantic concepts selected from controlled vocabularies residing on a terminology server can be directly linked to the patient data. The use of specifications such as LexGrid and CTS allows for cross-terminological information retrieval and interinstitutional exchange of clinical data.

Keywords:

terminology, semantics,
clinical decision support systems

Introduction

Understanding the semantics of a healthcare provider's data is crucial for use cases where this information has to be interpreted, such as for applying clinical decision support systems (CDSS). Such systems need to operate on formal information from controlled vocabularies whenever reusability of the knowledge base is required [1].

We added a semantic extension that operates on controlled vocabularies to Orbis, a hospital information system with more than 1200 installations in Europe. In contrast to other systems that are based on a central data model, Orbis allows its users to define an arbitrary amount of data structures during runtime by providing a visual tool for the definition of forms. Such forms have a graphical representation and are stored in a generic, entity-attribute-value (EAV) based data model. Through this mechanism, users can add implicit data structures that meet their needs in terms of documentation. The classification of such customized data structures necessary for use by CDSS is a major challenge that can be addressed by applying formal codes to the EAV model.

Methods

Large parts of Orbis' electronic patient record (EPR) consist of EAV structures in a generic data model [2]. These structures are termed 'forms' and are designed by administrative users. Later on, these form definitions can be instantiated by clinical users of the system during runtime ("form instances"). The flexibility of this approach empowers clinicians to define arbitrary forms which meet their specific documentation needs, instead of being limited to a central data model. The set of input fields that constitute a form represent a data structure which can be accessed within Orbis like a database table. Thus, in this context, a form is more than a user interface representation, since it also corresponds to a virtual data structure.

This openness implies that there are multiple ways to document the same clinical fact. For example, the administrative user who is required to offer the documentation of a patient's childhood illnesses in the scope of an anamnesis form is free to define a text field expecting free text or a select box offering a set of predefined values. Alternatively, the information request might be modeled with checkboxes or radio buttons. At runtime, the clinical user may document a childhood illness by selecting a checkbox (figure 1) or by filling a free text field (figure 2).

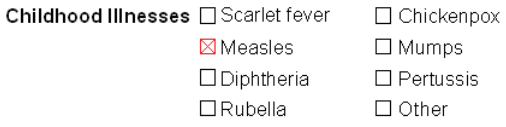

Figure 1 - Representation of infantile diseases as a set of checkboxes

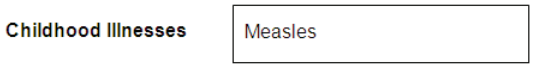

Figure 2 - Representation of infantile diseases as a free text field

To describe the semantics of such a form structure, each of its elements can be annotated by one or more formal semantic concepts. During design time, this annotation is performed manually by the form author or a coding expert and describes the attribute of the element, such as *'systolic blood pressure'*, *'allergy'* or *'infantile disease'*.

In the previous example, there are several possibilities to annotate the "measles" input fields of the form definition with a SNOMED code. One possibility is:

[14189004 Measles – disorder – Clinical findings].

Since the larger context is the patient's medical history, this code is incorrect, because the SNOMED code denotes an acute illness. Considering this, the following SNOMED code could be more appropriate:

[161419000 History of Measles – situation – Context dependent categories]

One important factor to reinforce valid coding is to consider the context clinical information is embedded in. To the clinical user, much of this context is obvious and presents itself in form of the document's graphical structuring. If 'context clues', such as the semantics of a field's label or of the embedding form, are not available during the annotation process, it can become impossible to deduce the correct code.

All formal concepts that describe these semantics are stored in the same relational database as Orbis' EPR and are linked to the attribute and value entries through foreign keys. Based on these links, queries have been added to Orbis that retrieve all patient information for a specific medical case whose semantic annotation equals the search criterion that is also a formal semantic concept. For example, querying 'allergy' for a specific patient, retrieves all form instance data whose semantic annotation corresponds to allergies. In the last example, the result would be a Boolean and a free text from a technical point of view.

Thus, during runtime, *values* entered by the clinical user should also be formalized if possible. Both user support through semi-automatic machine-aided selection of appropriate terminology items and fully automatic semantic tagging of medical terms in free text by natural language processing algorithms are possible. By this, the result of the query not only consists of the technical data types, such as "Boolean" or "text" but also of their semantic meaning as a formal code. Another special kind of information are numeric values, such as *'blood pressure'*. Queries on these elements retrieve both the stored values and their semantic type, such as *80* and *'systolic blood pressure (mmHg)'*. To specify units of numeric values, post-coordinated concepts are used.

The underlying data model for semantic annotation is open for all kinds of vocabularies and terminologies. For maintaining them and searching adequate concepts during the annotation process, we used an external terminology server. For this purpose, LexGrid [3], a data model and software developed by Mayo Clinics which provides a common data format has been has been connected using the HL7 Common Terminology Services interface. LexGrid offers tools to convert terminologies of different formats to the LexGrid database structure. For example, an attribute of an EPR annotated by a LOINC code could be retrieved, although the query searches for a synonymous SNOMED code.

Such queries have been applied to one of Orbis' rule based decision support systems that is founded on Arden Syntax for Medical Logic Modules (MLMs). Here, extensions in the data retrieval part of the rules allow to access clinical information identified by formal codes. The current implementation is limited to using formal codes in the rules that exactly match those used in the annotation of the EAV structures, but is open to future cross-terminological queries. In this way, information stored in arbitrary customized data structures can be retrieved by a single rule.

Results

By linking formal concepts to atomic data elements of Orbis' EPR we have been able to describe patient data semantics at a very granular level.

The combination of LexGrid and the NCI Meta Thesaurus empowered us to carry out cross-terminological and cross-lingual searches.

Instead of defining queries directly on the EPR, data retrieval works on an abstract, semantic level that focuses on individual concepts and follows their links to the EAV entries.

Discussion

However, the application of this method does have certain limitations when applied to compound concepts such as *'blood pressure'*, which consist of a set of individual EAV entries. Whether this aggregation can best be achieved by post-coordination or through an additional abstract layer that defines compounds or clinical archetypes [4], requires further evaluation.

Conclusion

Our bottom-up approach to semantic annotation ensures maximum reuse of the database's inherent knowledge by avoiding premature reduction of primary data as a side-effect of summarization. Thus, through the separation of annotation process from abstraction, the knowledge base is open for interpretation from various perspectives arising form different requirements. Further layers of semantic abstraction may allow the interpretation of the same knowledge from different views.

Semantic annotation has to be carried out in a way that ensures the retrievability of the documented data. The success of unambiguous annotation is dependent on the form element's data type and the form items' larger context.

Using the generic LexGrid data model for the administration of clinical vocabularies and a standardized terminology server interface, the gap caused by a proliferation of terminologies in different data formats can not

only be bridged, but the terminologies can also be shared among different institutions.

Semantic Annotation of Patient Data in a Commercial Health Information System

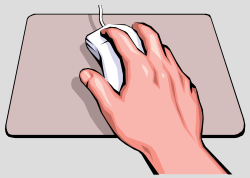
Isabel Barth[a]; Sven Tiffe[a]; Michael Dahlweid[b]
[a]Agfa HealthCare, Health Care Application Platform, Metatools, Germany
[b]Agfa HealthCare, Product Management, Germany

AGFA HealthCare

The ORBIS Hospital Information System

- ORBIS technologies allow both Agfa and the customer to
  - Define forms for medical documentation and to build applications
  - Implicitly define arbitrary data structures (as part of applications or customer specific)

Define forms



IT staff of the hospital

clinical users

Use of forms for documentation

ORBIS EPR
Form definition and instances

- Common applications: medical history (anamnesis), letter of discharge, nursing, etc.

Rationale

Orbis forms are stored

- as Enitity-Attribute-Value structures
  - Attributes are defined at design time, values are added by the clinical user during runtime
- in a generic data model

- The approach is extremely flexible (no restrictions through a rigid central data model) and renders the system extensible
- There are multiple ways to model the same clincial fact
- Utilizing the knowledge inherent in these forms requires semantic annotation

Semantic Annotation

- Semantic annotation of form elements is achieved through codes from controlled vocabularies
- These semantic annotations are stored in a set of tables located in the same database as the forms

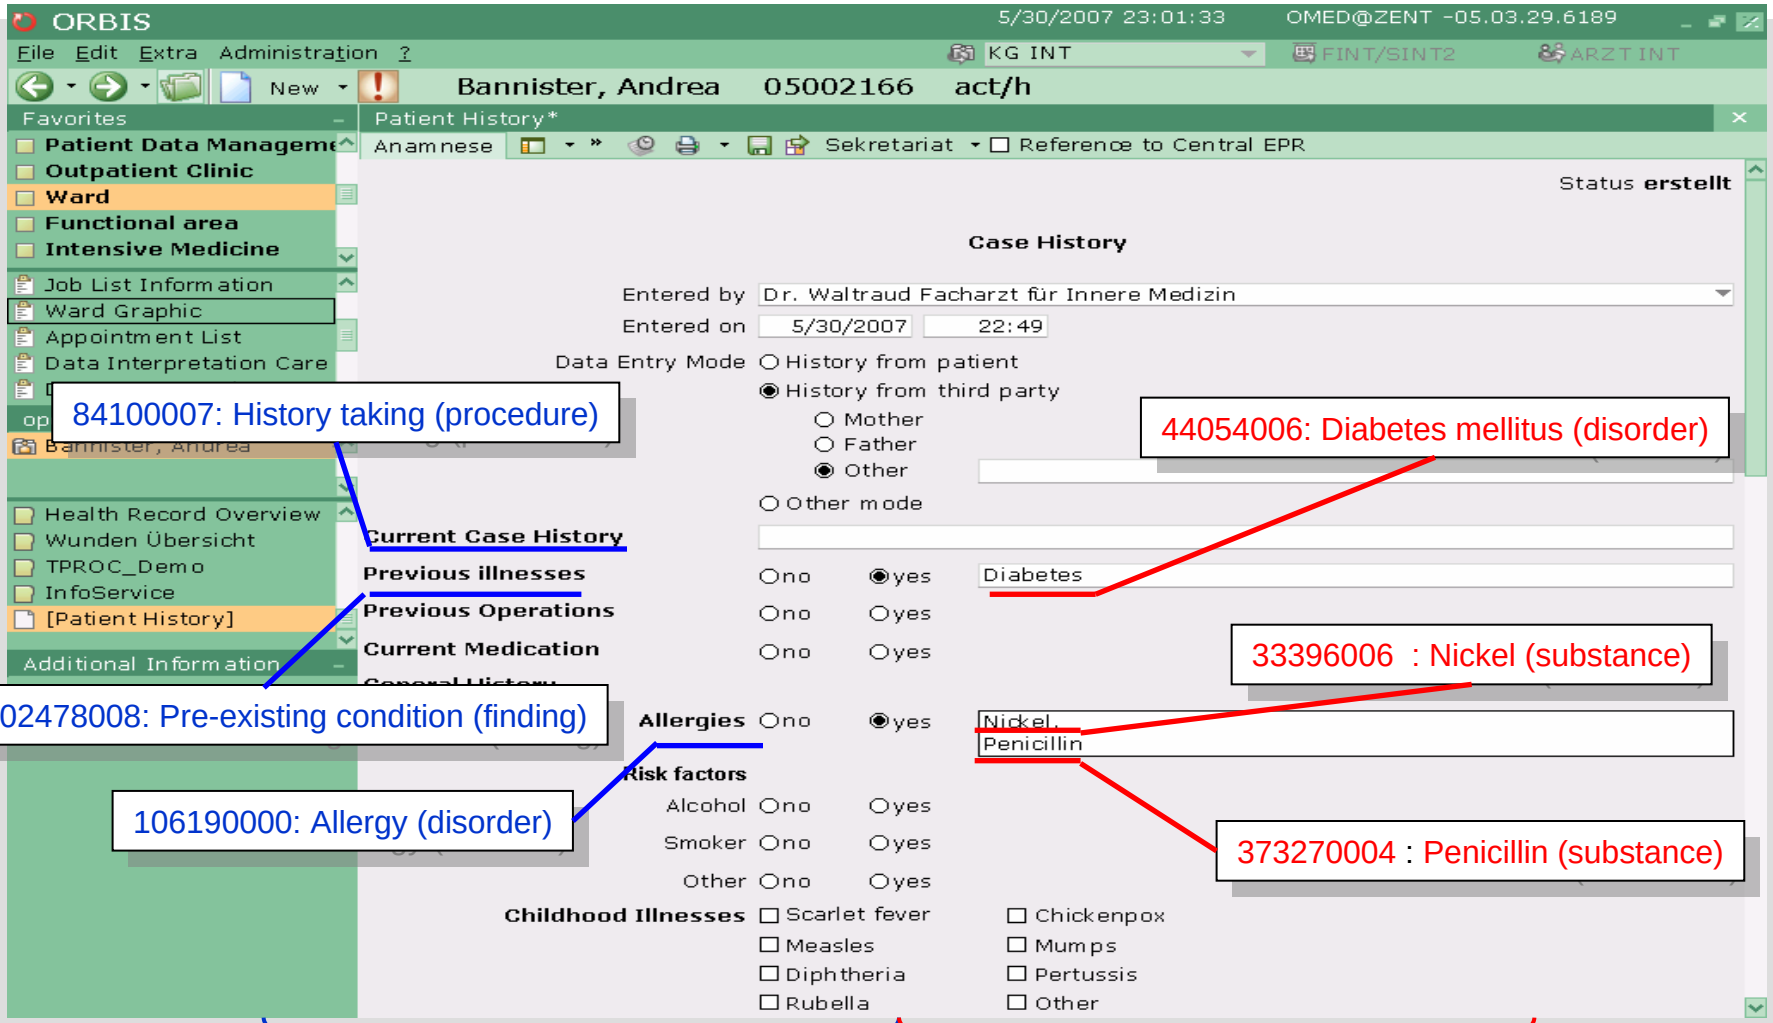
- ➢ Turns raw data into accessible knowledge
- ➢ Enables CDSS and other applications to exploit and structure this knowledge according to their own needs

The Annotation Process

- What is annotated?
  - Semantic annotation of form elements during design time (attributes)
  - Semantic annotation of form instances during runtime (values)

  How is the data annotated?
  - Manually (at design time)
  - Semi-automatically (at runtime)
  - User support through specific tools is essential for (Terminology Browser, NLP algorithms for semi-automatic text analysis)
  - Assignment of multiple semantic concepts is possible

Semantic annotation applied to a form

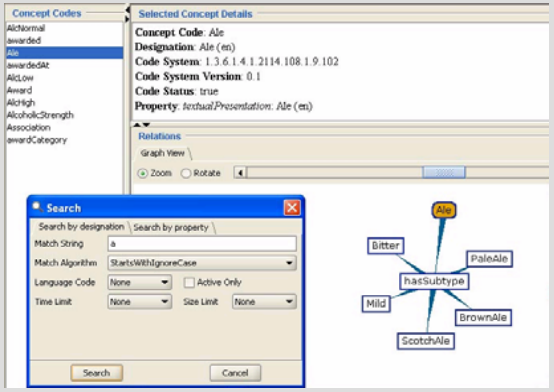


AGFA HealthCare

The Coding Interface
During form definition and during runtime

Form Composer

- Manually used by form author
- Result: Code, Terminology-System, Version



CTS Terminology Explorer [1]

Form

- Automatic evocation during runtime
- Information sent to coder: pre-classified information (Code, System, Version) plus raw data
- Result: Code, State

- LexGrid as a terminology server
- HL7 CTS to access terminological contents

Architecture of the Semantic Components

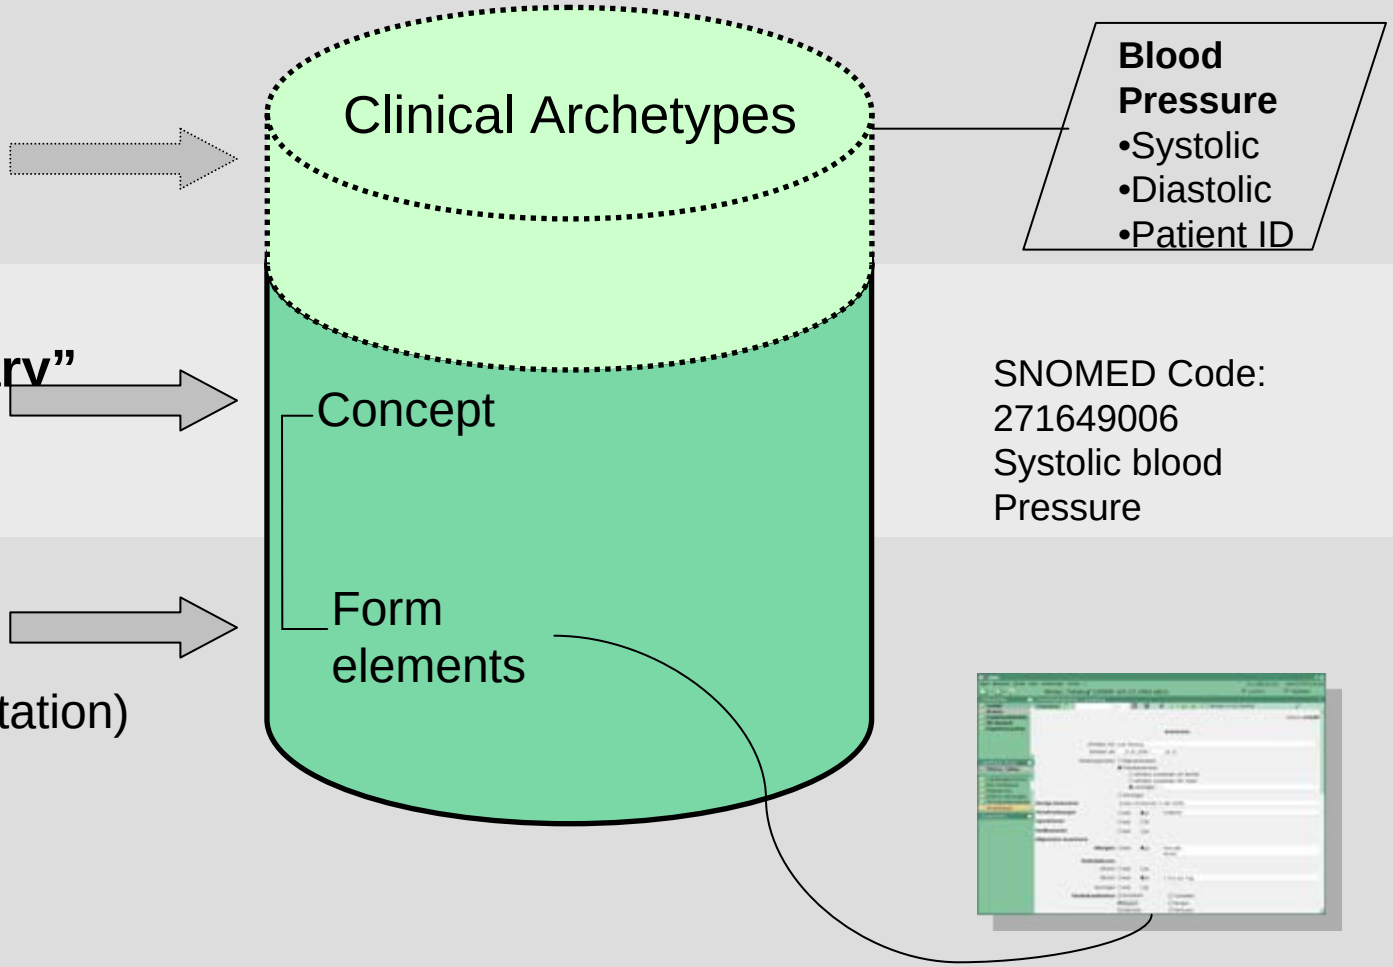
- The terminologies reside in a central terminology server
- HL7 CTS is used as a communication protocol to exchange data between the data repository and the terminology server
- ➢ Maintainability and interchangeability through usage of evolving standards and OpenSource Software
- ➢ Openness for all kinds of ontologies, terminologies and nomenclatures

Semantic Layers in the Generic Data Model

Possible further semantic layer

“Medical Dictionary” Layer

Form Data (Database Representation)



Information Retrieval

- Queries are SQL reports that are stored or user-defined
- The query terms search the database for matching form annotations
- Queries retrieve
  - the semantic code and label of the associated input fields (attributes)
  - the raw form data stored in the form instances (values) and their semantic codes
- Sample query

  “Get all information related to patient x which refers to allergies, except for allergies having occurred in his family history”

Results and Conclusion

- Through semantic annotation at a very granular level, the annotation process is separated from the abstraction
- A flexible architecture preserves openness for all kinds of terminologies
- Open for knowledge interpretation from different views (realized by additional semantic layers)

Thank you

Probabilistic Asthma Case Finding – A Pilot Study using the CHICA System

Vibha Anand[1], Stephen M. Downs[1,2]

[1]*Children's Health Services Research, Indiana University School of Medicine*
[2] *Regenstrief Institute for Health Care, Indianapolis, IN*

Abstract

Identifying and prioritizing decision support messages can be a challenge. We use Bayesian Belief Networks as a strategy for modeling patients' clinical status with the goal of case finding in childhood asthma. ***Methods:*** *We compared two Belief networks, one developed by a domain expert and one mined using data from a retrospective cohort consisting of 16,187 children having wheezing. Data were used to derive a directed acyclic graph (DAG) for a Bayesian Belief network. We evaluated this mined network with a domain expert's belief network using two test datasets- (a) 1/3 of the data (5000 cases) from the 16,187 case training cohort (b) data from 2000 children collected prospectively from the clinic. We used Area under the receiver operating curves (AUC) to compare the ability of the networks to predict asthma.* ***Results:*** *For the retrospective test data (a) the expert's network had AUC=0.697, mined network = 0.708. For the prospective test data (b) the expert's network AUC = 0.637, mined network = 0.603.* ***Conclusion:*** *The mined Bayesian Belief network was able to detect asthma cases comparably to the expert's network in both test scenarios suggesting that this technique can be used for asthma case finding and dynamically prioritizing alerts in a decision support system.*

Keywords:

computer decision support, rule based systems, alerts and reminders, guidelines, pediatric, asthma, prevention, Arden Syntax, belief network, Bayesian Network

Introduction

Computer alert and reminder systems improve rates of preventive services [1-3]. However the number of services recommended by authoritative bodies exceeds what can be addressed in a typical clinic visit [4-6]. Providers are often overwhelmed with competing demands, [7] leaving little or no time to address patient specific services. Reminder systems should prioritize alerts to maximize the benefit to patients. Expected value decision making provides an attractive model for prioritization of these services [8]. In Nov. 2004 we developed and deployed a decision support system -Child Health Improvement through Computer Automation (CHICA) for pediatric preventive services and disease management in a busy Primary Care Clinic. [9-13]. CHICA has a static, global prioritization scheme that limits the flexibility of the system - The Arden Syntax Medical Logic Modules (MLMs) [14] that encode the CHICA knowledge are prioritized using a global priority scheme to address the most relevant questions and reminders. [8, 11, 15].

We are experimenting with Bayesian Belief networks (BN) as a strategy for modeling a patient's clinical status with the idea of calculating the expected value of making alternative recommendations to physicians, tailoring prioritization to the patient.[8] BNs are appealing because they can be derived from clinical experts or empirically from data. In this paper we compare BNs derived in two ways: 1) using a clinical expert to define the nodes and arcs in the BN and training the resulting BN using data or 2) using data mining techniques to derive the BN from data. We compare these approaches in the domain of childhood asthma.

Methods

CHICA Overview – CHICA provides decision support by collecting data from families before a clinic visit, using a prescreener form (PSF) and reminders to physicians on a Provider Worksheet (PWS). CHICA now has records of over 11,000 patients, with an average of 3 visits per patient. The question in Figure 1 is asked on the PSF to find children who may have asthma. If answered "yes," the physician is asked to consider the diagnosis of asthma. Such a question appears on the PSF because it is assigned a high global priority among the questions that could be asked. Potentially, for a given patient when other questions are relevant that have higher global priority the asthma question may not appear on the questionnaire. It has the same global priority regardless of data in the medical record that may indicate higher or lower risk of asthma. Therefore, a patient specific prioritization would be very desirable which takes into account the evidence and the expected value of decision making.

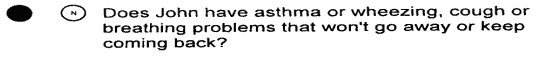

Figure 1 – Asthma question on Prescreen Form (PSF)

Model – Belief Networks (BN) and Influence Diagrams (ID) have been shown to represent domain knowledge with natural perception of causal influences [16]. They have been used widely in medical diagnoses because of their concise representation and ability for belief propagation [17]. We used Netica software [18] to construct a BN designed by our expert and the WinMine toolkit [19] software from Microsoft Corporation for mining a directed acyclic graph (DAG) directly from data. Netica was used for parameter learning from data in both BN models.

Table 1 – Data Variables for Model

Variable	Values
Race	White, Black, Hispanic, Other, Unknown
Sex	Male, Female
Eczema	True, False
Wheeze	ICD9 or clinic billing diagnosis before age 2 (True, False)
Asthma	ICD9 (493.*) or any clinic billing diagnosis after age 5 or at least 3 drugs from a specified list within 12 months after age 5 (True, False)
X-ray	Chest x-ray before age 2 (True, False)
Drug	Drugs from a specified list before (True, False)
Wz_hosp	Inpatient admission with hospital ICD9 as wheezing (True, False)
Wz_er	Any ER visit with billing ICD9 as wheezing (True, False)
Ins_cat	Insurance category - first available insurance in the same year of the first wheezing diagnosis (True, False)

Data – We compared the performance of the BNs on two datasets – (1) data from 16,187 cases from Regenstrief Medical Record Systems (RMRS) previously identified for a large retrospective cohort study of asthma predictors and split randomly into 2/3 of cases for a training set and 1/3 for a test set. (2) Clinical observations collected prospectively from children aged 5 and above collected by CHICA from the RMRS database for every patient visit. Data were filtered and preprocessed to extract the data variables listed in Table 1. At the time of the writing, the CHICA system had prospective data for about 2000 cases.

Expert's Design of BN with training using Netica: Using the predictor data variables in Table 1 as nodes and the domain knowledge for joining them with arcs, the domain expert (SMD) created a BN. This BN was trained with the training set and compiled using Netica. The BN showed prior probabilities of each node and an asthma prior probability of 18.6%.

BN Derived using Data Mining Techniques: The training set from RMRS data was used to derive the directed acyclic graph (DAG) for this approach. The software from WinMine toolkit was used to preprocess the data and to instruct the learning algorithm to derive the DAG. Using the structure from the data-mined DAG, we created the BN in Netica software. This BN was also trained and compiled using the same training set as the expert BN to get the prior probabilities. The asthma prior probability in this model was 13.9%.

Testing the Two Models - The two BN models were evaluated, first, using 1/3 of the retrospective data from our test set removed before data mining or network training; and, second, using the data set derived from CHICA database. Asthma, our outcome of interest was treated as an "unobserved node" in Netica. We derived the sensitivity, specificity, positive predictive value and negative predictive value. We compared BNs using Receiver Operating Characteristics (ROC) curves [20]. The area under the curve was used as a measure of overall test performance. The ROC curve was obtained by plotting pairs of true positive rate (sensitivity) and false positive rate (1-specificity).

Results

We had 5188 cases in our RMRS test set and 2000 cases in the CHICA test set. Both the Expert and the Mined BN were tested using these sets, the results of which are shown below.

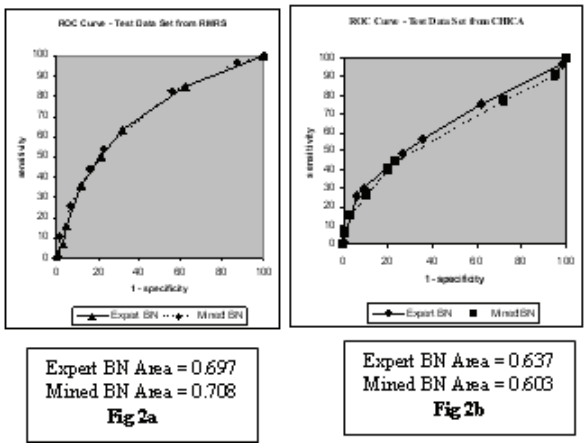

Figure 2a – ROC curves using test data from RMRS
Figure 2b – ROC curves using test data from CHICA

Discussion

The results of area under the ROC curve for both networks using the same test set are comparable. Both the expert BN and the mined BN performed better with the test data set from RMRS (for large retrospective study) when compared with the CHICA test data set. We attribute degraded performance when testing with CHICA test data set to less stringent inclusion criteria in the CHICA test set. For example, any chest x-ray observation will satisfy the inclusion criteria for CHICA data, where as X-ray finding before age 2 will satisfy the inclusion criteria for the RMRS test set.

Conclusion

Similar performance of each BN in each test scenario goes to suggest that the mined BN has a predictive value similar to an expert and hence can be used for case finding. We acknowledge that the performance of a BN would vary on the quality of data and the predictor variables used to model it however, we believe there is a value in the data mined approach. We can attach utility nodes for each of the desired outcomes in our model to drive the prioritization scores of prompts in the CHICA system using the expected values of case finding decision.

Our future work will involve developing a framework to mine the DAGs from data with in our system for many more preventive services such as lead screening and evaluating TB risk and utilizing the mined BNs with CHICA programmatically.

Probabilistic Asthma Case Finding A pilot study using the CHICA System

Vibha Anand, MS[1]
Stephen M Downs MD, MS[1,2]

[1] Children's Health Services Research, IU School of Medicine
[2] Regenstrief Institute Inc.
Indiana, USA

Introduction

- In pediatric primary care, eligible preventive services may exceed time available in a visit
- Decision support systems must prioritize what reminders are most important
- Bayesian belief networks provide a strategy for assessing patient risk and selecting reminders

Challenge

- Bayesian belief networks are acyclic directed graphs
- Nodes are random variables and arcs represent probabilistic dependencies
- “Learning” the probabilistic relationships can be challenging
- Expert judgment may be necessary where data are not available

Study Objective

- Compare the performance of two Bayesian belief networks for identifying children who will develop asthma
  - Network A developed by a clinical expert
  - Network B mined from data by a learning algorithm
- Probabilities for both networks were derived from data

Methods – Model Development

- Domain expert model:
  - Developed by a pediatrician trained in informatics and decision sciences
  - Using Netica Software (http://www.norsys.com)
- Mined model:
  - Directed Acyclic Graph (DAG) derived from clinical dataset
  - Using WinMine Toolkit software (http://research.microsoft.com/~dmax/WinMine)
- Both models trained on clinical data using the Netica software

Data Source

- 16,000 cases were extracted from the Regenstrief medical record system (RMRS)
- Cases randomly split
  - 11,000 training cases
  - 5000 test cases
- An additional 2000 cases collected prospectively to evaluate the model
  - These data were incomplete (missing values)

Variables in the Dataset

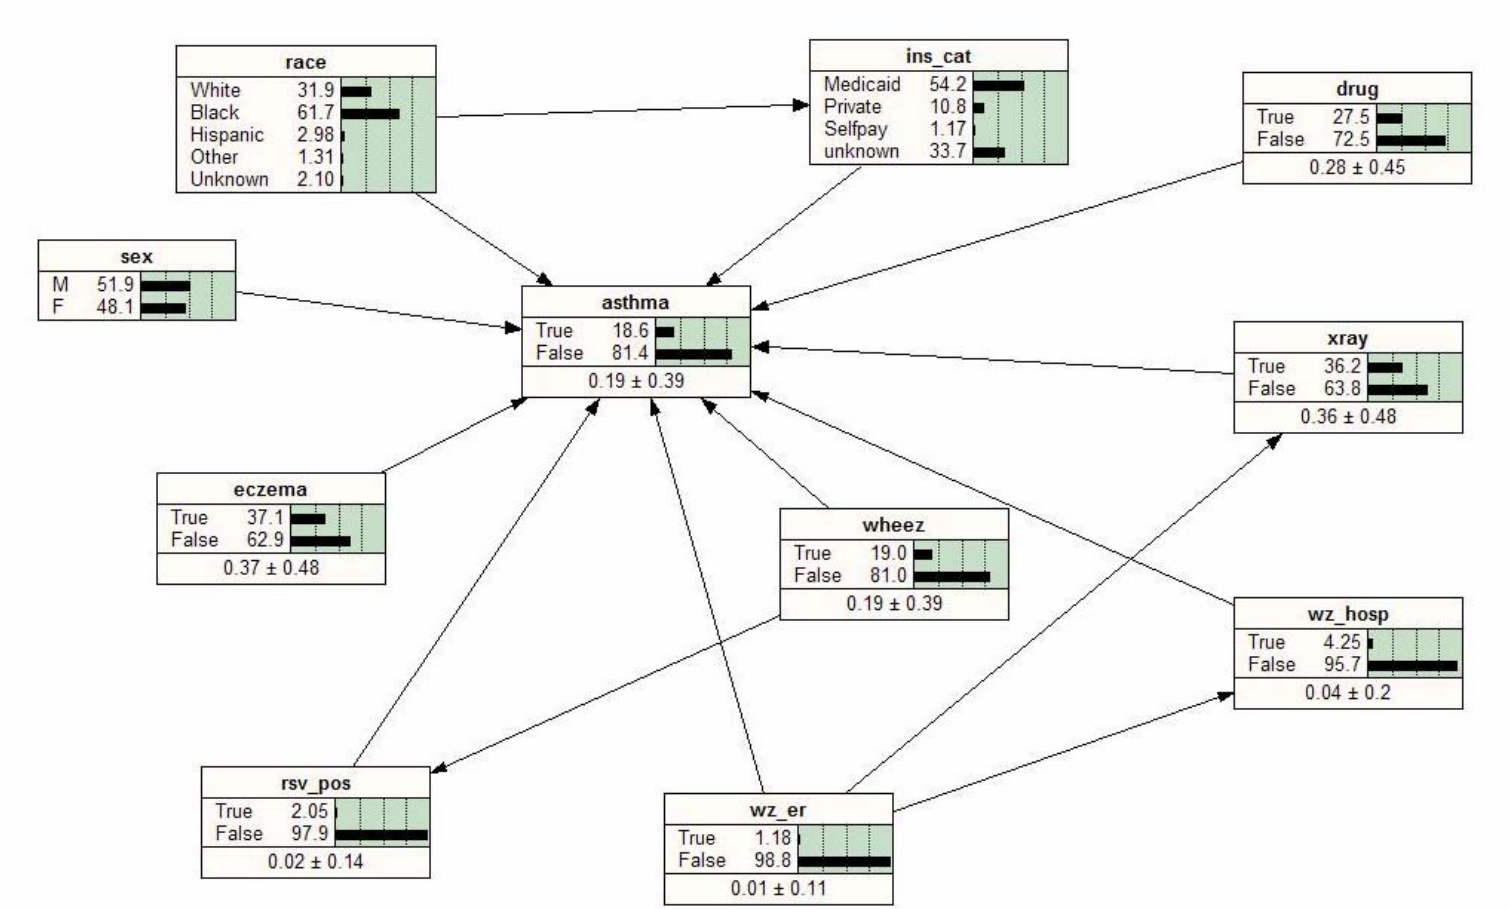
- Predictors measured before age 2 years
- Outcome asthma after 5 years

Variable	Values
Race	White, Black, Hispanic, Other, Unknown
Sex	Male, Female
Eczema	True, False
Wheeze	ICD9 or clinic billing diagnosis before age 2 (True, False)
Asthma	ICD9 (493.*) or any clinic billing diagnosis after age 5 or at least 3 drugs from a specified list within 12 months after age 5 (True, False)
X-ray	Chest x-ray before age 2 (True, False)
Drug	Drugs from a specified list before (True, False)
Wz_hosp	Inpatient admission with hospital ICD9 as wheezing (True, False)
Wz_er	Any ER visit with billing ICD9 as wheezing (True, False)
Ins_cat	Insurance category - first available insurance in the same year of the first wheezing diagnosis (True, False)

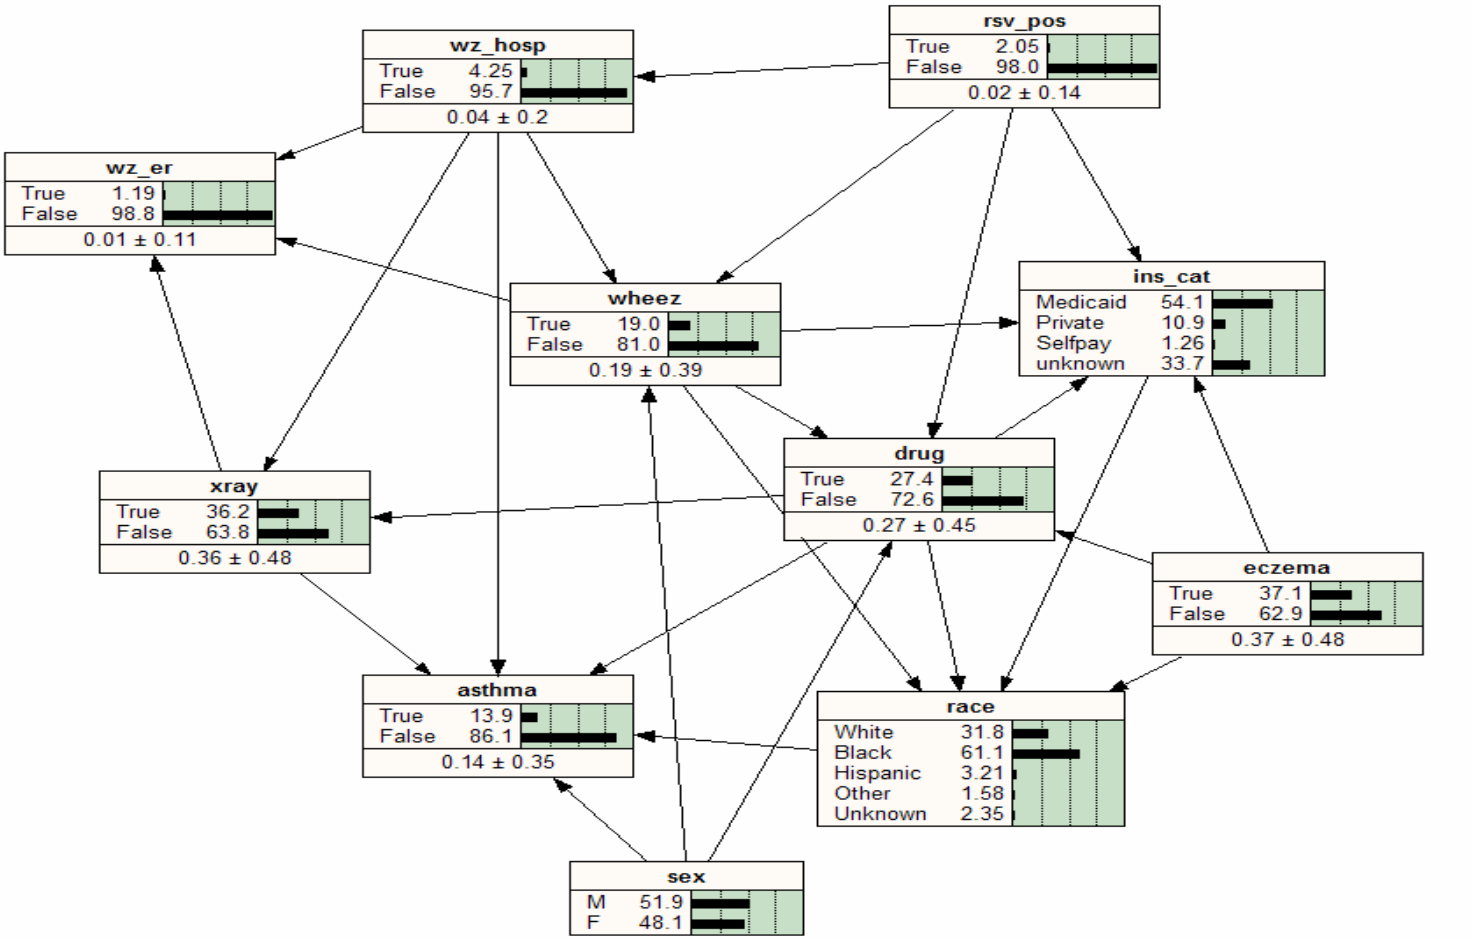
Evaluation

- Bayesian belief networks were trained on 11,000 training cases
- Ability of each network to discriminate children who develop asthma evaluated
  - 5000 test cases
  - 2000 prospective cases
- Power to discriminate was compared using receiver operator characteristic (ROC) curves

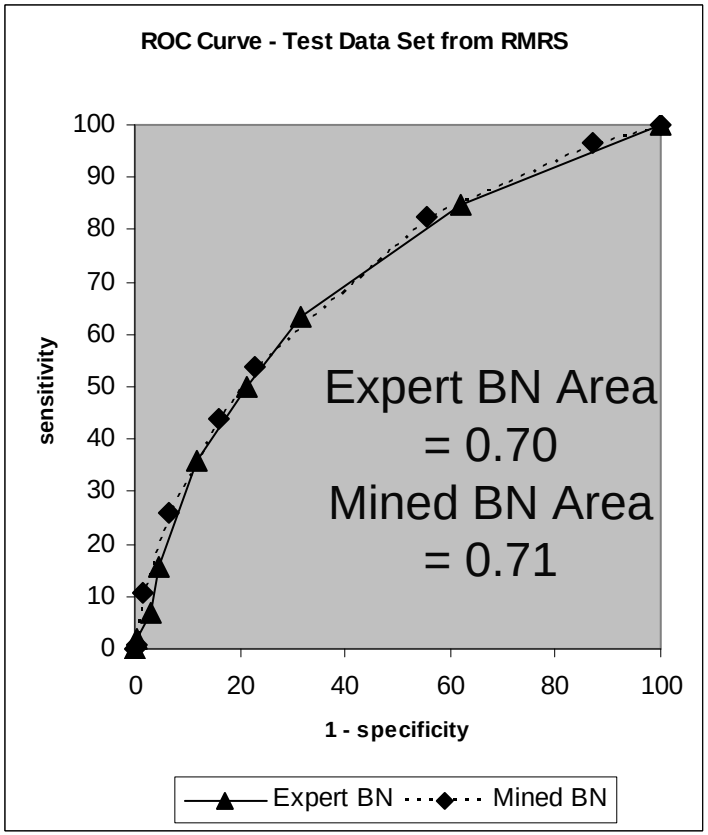
Belief Network Model (Domain Expert)



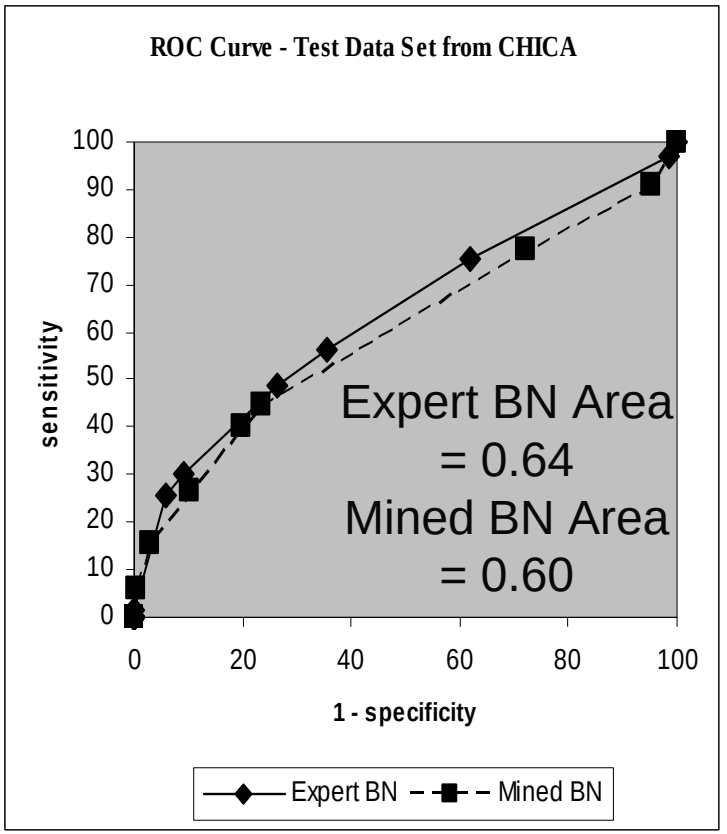
Belief Network Model (Mined from Data)



Results



ROC curve derived from 5000 test cases



ROC curve derived from 2000 cases collected prospectively

- Data Mined model had similar discriminative power to Domain Expert model.
- Slightly degraded performance when tested with prospectively collected data - data were incomplete.

Automated Surveillance for Catheter-Associated Bloodstream Infections

Keith F. Woeltje[a,b], Ashleigh J. Goris[a], Anne M. Butler[a], Nhial T. Tutlam[a], Joshua A. Doherty[c], M. Brandon Westover[a], Vicky Ferris[b], Thomas C. Bailey[a,c]

[c]*Medical Informatics, Center for Healthcare Quality and Effectiveness, BJC HealthCare, St. Louis, MO, USA*

Abstract

Traditional manual surveillance for catheter-associated bloodstream infections (CA-BSI) by an infection control specialist is costly and labor intensive. An automated computer-based surveillance system that utilizes existing laboratory, pharmacy, and clinical electronic information offers a more efficient and timely method of surveillance. We applied combinations of simple rules to patients with positive blood cultures in the intensive care unit (ICU) to determine whether automated surveillance is feasible. Compared to traditional manual surveillance, sensitivity and specificity of the best rule combination was 87.1% and 73.8%, respectively. This ruleset consisted of four rules: (1) culture collected > 48 hours after admission; (2) patient had central-venous catheter; (3) organism not a common skin contaminant OR either confirmed by repeat culture within 5 days or treated with vancomycin; and (4) organism not a coagulase-negative Staphylococcus. Monthly trends of infection rates rose and fell appropriately. This is comparable to previously reported results [1]. Additional rules may improve prediction performance.

Keywords:

algorithms, catheterization, Central Venous,
cross infection, Septicemia

Introduction

CA-BSI are a significant cause of patient morbidity and mortality in hospitalized patients. Surveillance of nosocomial bloodstream infections (BSI) is traditionally performed in the ICU by infection control specialists using medical charts, physician summaries, microbiology and pharmacy data. Standardized case definitions, usually those from the United States Centers for Disease Control and Prevention (CDC) National Healthcare Safety Network (NHSN), are used to identify CA-BSI. Yet, traditional manual surveillance is labor intensive and costly. Application of case definitions by infection control specialists requires considerable clinical judgment, and definitions are sometimes inconsistently applied. Electronic surveillance offers the potential for more efficient and timely detection of CA-BSI than traditional manual surveillance. An automated surveillance approach that utilizes existing laboratory, pharmacy, and clinical electronic information could shift infection control specialists' time towards prevention, rather than surveillance. Furthermore, development of an automated surveillance system could potentially extend surveillance outside of the ICU, where there is currently an absence of surveillance efforts at most hospitals. The aims of this study were: (1) to develop an automated computer-based surveillance system with the use of existing laboratory, pharmacy, and clinical electronic information; and (2) to compare traditional manual surveillance to electronic surveillance among ICU patients.

Methods

The study was conducted with patients in the ICU at Barnes-Jewish Hospital, a 1250 bed tertiary-care teaching hospital located in Saint Louis, Missouri. Positive blood cultures collected between July 1, 2005 and June 30, 2006 were evaluated; cultures were excluded if the same organism had been recovered from the blood in the previous 7 days. Infection control specialists reviewed each patient to determine presence or absence of CA-BSI using CDC NHSN definitions [2]. Simple "yes-no" rules and combinations of these rules, similar to those used by Trick et al. [1], were applied to electronic data to determine if a positive blood culture represented a CA-BSI. The rules were:

1. Culture collected > 48 hours after admission
2. Patient had central-venous catheter (CVC)
3. Organism not a common skin contaminant OR either confirmed by repeat culture within 5 days or treated with vancomycin
4. Organism not a coagulase-negative Staphylococcus
5. Organism not grown from wound or urine cultures after positive blood culture
6. Organism not grown from wound or respiratory cultures after positive blood culture
7. Organism not grown from wound, urine, respiratory, sterile other, or non-sterile other cultures after positive blood culture

Secondary culture sites such as wound, urine, respiratory, sterile other, and non-sterile other were considered, as well

as their collection time relative to the positive blood culture (i.e., before, after, or ever). Using infection control as the gold standard, we evaluated the ability of various combinations of rules to determine CA-BSI; sensitivity, specificity, predictive values were calculated. The agreement between infection control surveillance and the rulesets was assessed with the kappa statistic. Monthly rates of CA-BSI per 1,000 patient line-days were calculated for manual and electronic surveillance. Discrepancies of case determination were compared between manual surveillance and the best performing rulesets.

Results

During the study period 771 positive blood cultures from 540 patients were evaluated. Infection control specialists identified 70 (9%) CA-BSIs. The most common organisms were coagulase-negative Staphylococci (45%), Corynebacterium species (6%), *Candida albicans* (5%), *Staphylococcus aureus* (5%), *Enterococcus faecalis* (5%), *Enterococcus faecium* (5%), and *Klebsiella pneumoniae* (3%). Rules did not perform well individually. Performance of the best performing combination of rules is shown in Table 1.

Table 1 - Performance of combined rules

Rules	# BSIs predicted	Sens %	Spec %	PVP %	PVN %	Kappa
1,2	459	97.1	44.2	14.8	99.4	.118
1,2,3	362	95.7	57.9	18.5	99.3	.186
1,2,3,4	245	87.1	73.8	24.9	98.3	.287
1,2,3,4,5	230	80.0	75.2	24.3	97.4	.272
1,2,3,4,6	208	72.9	77.6	24.5	96.6	.267
1,2,3,4,7	184	62.9	80.0	23.9	95.6	.247

The combination of rules with highest agreement with infection control surveillance (kappa = .287) identified 245 (32%) CA-BSIs. This ruleset, which included rules 1, 2, 3, and 4, had a sensitivity and specificity of 87.1% and 73.8%, respectively. Although the rulesets with rules 1 and 2 as well as rules 1, 2, and 3 had higher sensitivity, this ruleset had higher specificity and better agreement with infection control surveillance. Augmentation of the best ruleset with cultures from secondary sites marginally increased specificity but decreased sensitivity and the kappa statistic. Secondary site cultures collected before positive blood cultures improved rulesets better than those collected after or ever. Manual surveillance detected 2.64 CA-BSI per 1,000 line-days while the best performing ruleset predicted 9.24 CA-BSI per 1,000 line-days. CA-BSI rates are displayed in Figure 1.

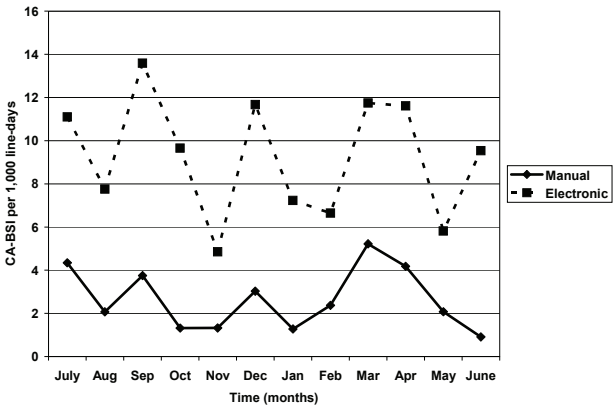

Figure 1 - Performance of rules in determining rates

Of 771 positive blood cultures, 193 (25%) were classified differently by manual versus electronic surveillance methods. Among 70 gold standard CA-BSI, the ruleset failed to classify 9 of these positive blood cultures as CA-BSI; 7 patients had a common skin contaminant, 1 had a community-acquired infection and a common skin contaminant, and 1 had misclassified CVC usage data. Among 701 positive blood cultures not classified as CA-BSI by infection control specialists, the ruleset classified 184 positive blood cultures as CA-BSI; 73 had a secondary organism grown from wound, urine, respiratory, sterile-other, or non-sterile-other sites. Other reasons for misclassification remain to be studied.

Discussion

An automated surveillance system that utilized existing patient data was able to identify CA-BSI with reasonable sensitivity and specificity. Our results are comparable to those reported by Trick et al. [1]. Although sensitivity and specificity need to be improved, trends of infection rates rose and fell appropriately. The high negative predictive value of our rulesets is promising. In the absence of perfect sensitivity, infection control specialists may benefit most from a list of patients without CA-BSI. As with any analyses dependent on electronic data, errors exist. For instance, 1 gold standard CA-BSI was not classified as a CA-BSI by the ruleset due to not having a CVC; yet the patient medical chart recorded CVC usage. In addition, July and August line-day information did not include PICC lines; a sensitivity analysis shows that this did not change CA-BSI rates substantially. Automated surveillance of CA-BSI has several advantages including consistent application of case definitions, reallocation of infection control specialists' time from surveillance to prevention efforts, and extension of surveillance outside of the ICU.

Conclusion

Automated CA-BSI surveillance may be useful for identifying trends for manual investigation. Future work will be to improve on the rulesets and to evaluate alternative methods of analysis, such as logistic or Bayesian prediction models.

Physicians

Introduction

- Catheter-associated bloodstream infections (CA-BSI) are a significant cause of patient morbidity and mortality
  - Adds approximately 20 days to hospital length-of-stay[1]
  - Increases costs by $35,000 to $56,000[2,3]
  - Attributable mortality of up to 35%[1]

- Traditional surveillance for CA-BSI
  - Performed by Infection Control Specialists
  - Apply United States Centers for Disease Control & Prevention (CDC) National Healthcare Safety Network (NHSN) case definitions
  - Use medical charts, physician summaries, lab & pharmacy data
  - Limitations
    - Time consuming & costly
    - Often limited to Intensive Care Units (ICUs)
    - Inconsistent application of case definitions

1 Pittet D, et al. *JAMA* 1994;271:1598–601.

2 Rello J, et al. *Am J Respir Crit Care Med* 2000;162:1027–1030

3 Dimick JB, et al. *Arch Surg* 2001;136:229–234.

Methods I

- Specific Aims
  - To develop automated surveillance system for CA-BSI by integration of existing electronically available data
    - Microbiology positive cultures
    - Pharmacy information
    - Laboratory data
    - Vital signs
    - Central venous catheter (CVC) usage
  - Compare automated surveillance to manual chart review (gold standard) with sensitivity, specificity, predictive values, kappa
- Study Population
  - Barnes-Jewish Hospital, a 1250 bed, tertiary-care teaching hospital affiliated with Washington University School of Medicine in St. Louis, Missouri
  - ICU patients with a positive blood culture between July 1, 2005 and June 30, 2006 (1 year)
  - Cultures were excluded if same organism recovered from blood in previous 7 days

Methods II

- Manual Surveillance
  - Infection Control Specialists identify patients with positive blood cultures from hospital informatics database
  - Review of medical charts, physician summaries, microbiology & pharmacy data
  - Application of CDC NHSN case definitions to determine CA-BSI

- Automated (Electronic) Surveillance
  - Patients with positive blood cultures identified from hospital informatics database
  - Additional electronically available data on these patients pulled by standardized query into an analysis dataset
  - Simple yes/no rules and combinations of rules applied to electronic data to determine presence or absence of CA-BSI

Simple Rules (Yes/No)

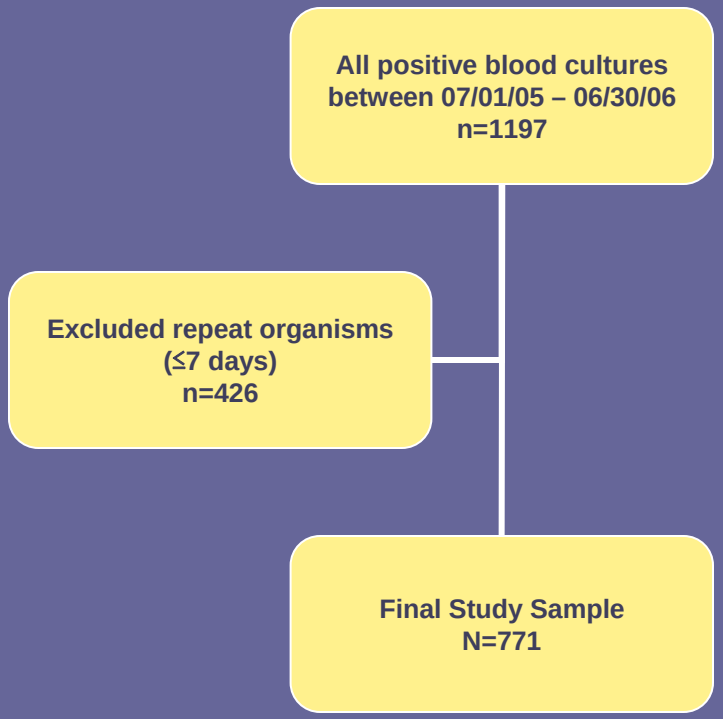
1. Blood culture >48 hrs after hospital admission*
2. Patient had CVC ≤48 hrs before blood culture*
3. At least one of the following:*
    a. Blood culture positive for non-common skin contaminant pathogen
    b. Blood culture positive for common skin contaminant
        - Confirmed within 5 days

          OR
        - Patient received vancomycin
4. Blood culture positive for organism other than coagulase-negative staphylococci*
5. No wound cultures before**
    – i.e., no wound culture positive for same organism before positive blood culture collection
6. No urine cultures before**
7. No respiratory cultures before**
8. No sterile other cultures before**
9. No non-sterile other cultures before**

*Similar to rules reported by Trick et al. *Emerg Infect Dis*. 2004;10:1612-1620.

**Cultures from secondary sites were also evaluated if collection was (1) after or (2) before or after blood culture collection

Results I



- Study Population
  - 771 positive blood cultures
  - 540 patients
  - 70 (9%) CA-BSI by manual review
  - 701 (91%) without CA-BSI
- Positive Blood Cultures
  - Coagulase-neg Staphylococci (45%)
  - Corynebacterium species (6%)
  - *Candida albicans* (5%)
  - *Staphylococcus aureus* (5%)
  - *Enterococcus faecalis* (5%)
  - *Enterococcus faecium* (5%)
  - *Klebsiella pneumoniae* (3%)
  - Other (26%)

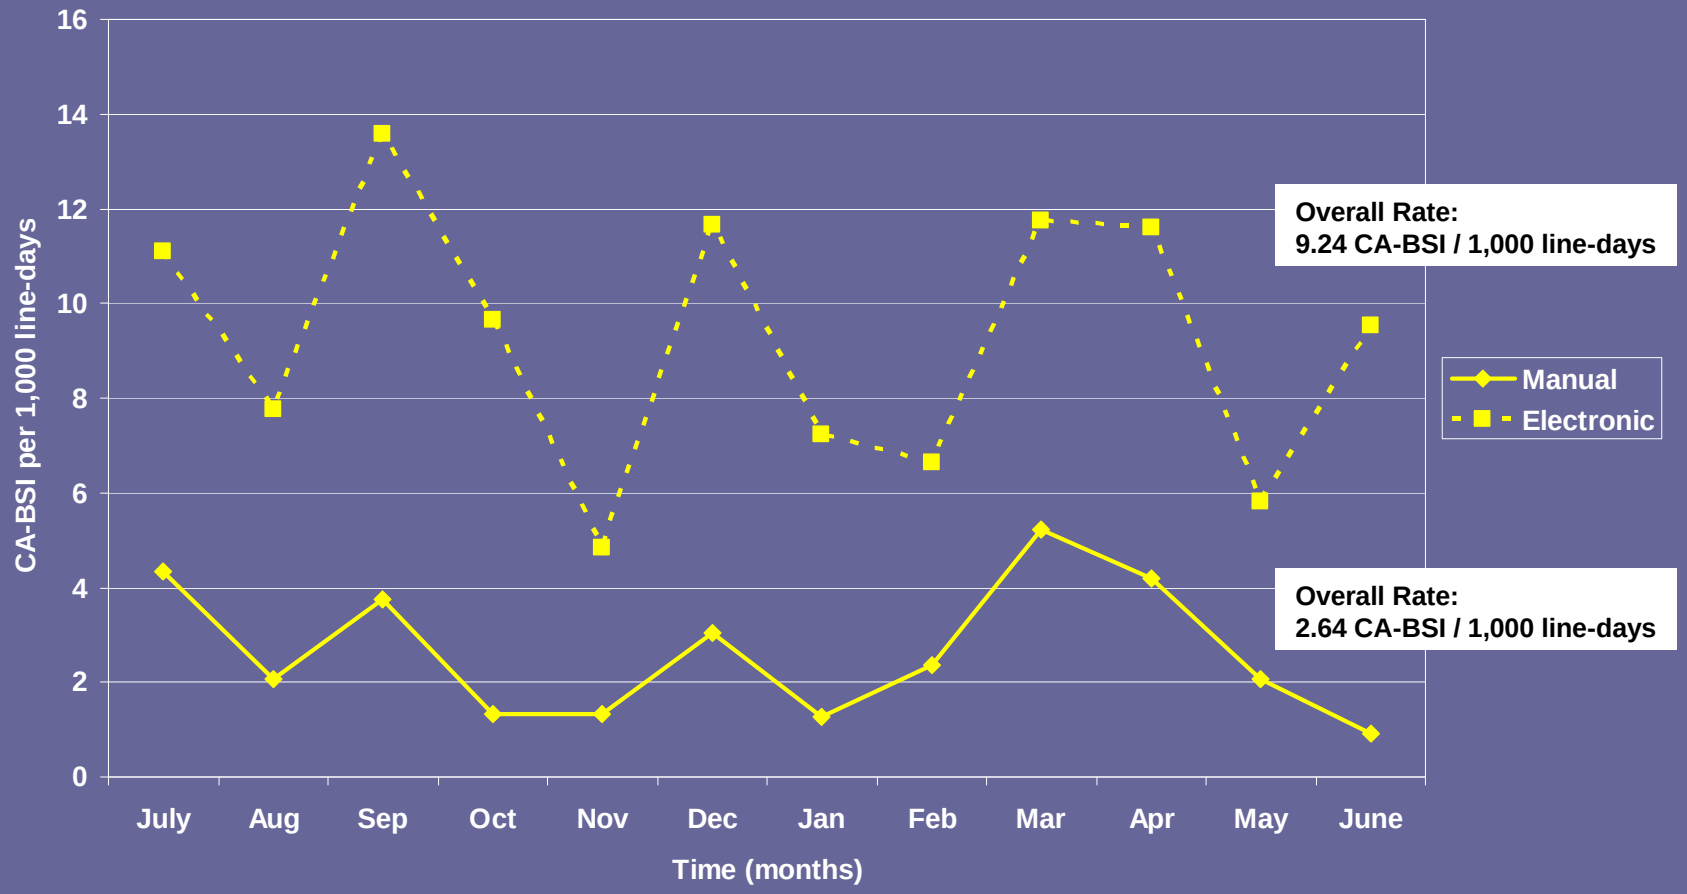
Table 1. Performance of Rulesets

Ruleset	# CA-BSI Confirmed by Rules N (%)	Sensitivity %	Specificity %	PPV %	NPV %	Kappa *
1,2	459 (59.5)	97.1	44.2	14.8	99.4	.118
1,2,3	362 (47.0)	95.7	57.9	18.5	99.3	.186
1,2,3,4	245 (31.8)	87.1	73.8	24.9	98.3	.287
1,2,3,4,5,6	230 (29.8)	80.0	75.2	24.3	97.4	.272
1,2,3,4,5,7	208 (27.0)	72.9	77.6	24.5	96.6	.267
1,2,3,4,5,6,7,8,9	184 (23.9)	62.9	80.0	23.9	95.6	.247

* 0 ≤ Kappa ≤ 0.4 denotes *marginal* reproducibility

* Secondary site cultures collected before blood cultures improved rulesets better than those collected after or ever

Figure 1. CA-BSI Surveillance Rates



Results II

- Of 771 positive blood cultures, 193 (25%) were classified differently by manual versus electronic surveillance methods
  - Among 70 gold standard CA-BSI, the ruleset with rules 1,2,3 and 4 failed to classify 9 of these positive blood cultures as CA-BSI
    - 7 patients had a common skin contaminant
    - 1 had a community-acquired infection and a common skin contaminant
    - 1 had misclassified CVC usage data
  - Among 701 positive blood cultures not classified as CA-BSI by infection control specialists, the ruleset with rules 1,2,3 and 4 classified 184 positive blood cultures as CA-BSI
    - 73 had a secondary organism grown from wound, urine, respiratory, sterile-other, or non-sterile-other sites
    - Other reasons for misclassification remain to be studied

Discussion

- Advantages
  - Consistent application of case definitions
  - Reallocation of infection control specialists' time from surveillance to prevention efforts
  - Potential extension of surveillance to non-ICU wards
  - High negative predictive value of rulesets provides infection control specialists with a list of patients that do not have CA-BSI
- Limitations
  - Errors in electronic data
    - Not all CVC usage captured by electronic data (e.g., 1 gold-standard CA-BSI with CVC usage recorded in medical chart was not classified as having a CVC in electronic data)
  - Line-day data lacks PICC line information for 2 out of 12 months
    - Sensitivity analysis: Adding PICC line information to CVC line data increased line-usage by 3.9%, on average. This did not substantially change CA-BSI rates.

Conclusions

- An automated surveillance system that utilized existing patient data was able to identify CA-BSI with reasonable sensitivity and specificity.
- Although sensitivity and specificity need to be improved, trends of infection rates rose and fell appropriately.
- Automated CA-BSI surveillance may be useful for identifying trends for manual investigation.

Abstract

Medical decision making and health care managements are more and more a multidisciplinary approach especially in the field of oncology. Multidisciplinary meetings have to be supported in order to improve decisions taken and patients care. To meet this objective, supporting the various decision making processes and facilitating the use of the best medical knowledge is essential. We have identified and explained six decision making processes to assist MCO (multidisciplinary committees in oncology). We are offering a conceptual framework aiming at pointing the means to be used for decision making in order to improve this process. Support for structuring and carefully presenting each patient's case, support for the selection of the most appropriate treatment using both computable guidelines and computable clinical trials is at the heart of our proposition.

Keywords:

professional staff committees,
decision support techniques, clinical practice guidelines,
clinical protocols, clinical trial, medical oncology

Introduction

Medical decision making and health care management are more and more a multidisciplinary approach especially in the case of complex or malignant diseases. Oncology is a typical example of such care organization. In many countries, multidisciplinary committees in oncology (MCO) have been set up in order to discuss patients' cases with the objective of optimizing each patient's healthcare management, taking into account the knowledge of the different domain specialists (including surgeons, radio-oncologist, pathologist, chemotherapist). Recently in France, a national plan has been launched to impose a mandatory consultation of such committees before any treatment strategy in oncology. These committees have to use multidisciplinary meetings, existing guidelines and standard protocols in order to provide patients with specific care recommendations according to the best accepted practices. Usage and compliance with guidelines and standards on care is one quality criteria explicitly mentioned in the French Cancer National Plan and have to be regularly reported by MCO.

As mentioned by Hammond et al. ten years ago [1]: "The number and wide variety of guidelines and protocols used in treatment trials, and the amount of clinical data generated suggest the need for computer-based support". Nowadays, because of the ever more important mass of information, we argue that using computers is mandatory if continuous quality improvement for patients care is required. Indeed, computable guidelines and decision support systems may be useful [2] at several levels for establishing and practically organizing a MCO. In this article, we present a conceptual framework which is efficient both in terms of improvement of the patients management, and in terms of producing and enriching the medical knowledge required for this improvement.

Our aim in presenting this conceptual framework is to offer an analysis that suggests decision support system solutions and organization principles that applies broadly to almost any situation in which multidisciplinary committees must be efficiently set-up and consulted in order to improve patient cares.

MCO Organization

There are several MCO in a care structure (one for each neoplasm domain: neurology, hematology, genecology …). These multidisciplinary committees follow similar work processes and often follow the same organization and planning in order to perform their tasks. The typical organization of a multidisciplinary committee in oncology has been analyzed by Castel et al. [3]. The MCO operational principle and the patient's case workflow on which a therapeutic opinion must be given can be summarized as follows:

- all cancer patients for whom the establishment or modification of an oncology treatment is required must be gathered and registered by the MCO secretariat;
- MCO regularly schedules Multidisciplinary Committee Meetings (MCMs) in order to provide therapeutic advice on the patients' cases submitted.
- each case submitted and registered is integrated in a summary clinical document used as basic information during each MCM to decide on the patient specific care management to recommend. It should be noted that those cases corresponding to a standard management procedure which has a multidisciplinary agreement translated into a clinical practice validated and up to date, are not systematically presented and discussed during an MCM. In some MCOs, an expert coordinator working in contact with the multidisciplinary committee members may decide for the most appropriate approach in compliance with the reference guidelines approved by this multidisciplinary committee. The expert's mandate aims at relieving the work load during MCMs who will then dedicate more time to complex and / or atypical cases);
- whether discussed during a MCMs or resolved by the expert, a written recommended therapy supported by reference practices and / or items of discussion stating any reason for non compliance to the existing reference guidelines, is given for each case;
- finally, the MCM's therapeutic recommendations are recorded and the referring practitioner is informed of the future management decision for the patient concerned.

MCO must organize and control the quality of the whole decision making process and the effective application of the opinion/recommendation given. Usage and compliance with clinical practice guidelines is a key point in this respect. Establishing procedures for controlling, monitoring and improving is paramount to check that the opinion given complies with the clinical practice guidelines approved by the MCO. The adequacy rate between the opinion given and the practice standards is one of the quality oriented indicators of the compulsory report activity required from any MCO.

The MCO typical workflow description must be supplemented with additional data for all MCO involved in therapeutic trials. In some care centers indeed, MCO have the responsibility to offer patients alternative treatments to the standard ones, informing them of the availability of one or several potentially promising therapeutic treatments they might benefit from. Improving patients' enrolment in on going therapeutic trials is a constant concern viewed as a supplement to a treatment or to standard alternatives possibly submitted to patients.

System design: objectives and features

The MCO workflow review highlights various processes in which several decision support systems might efficiently help optimizing the organization and improve the patient's management situation (figure 1):

1. **support for structuring the document presenting the case of each patient.** This document content is essential to the decision making process, given that therapeutic options are going to be founded on this information basically. It must contain all the relevant, rigorously informed decision making criteria. The decision focuses on the use of explicit criteria to which a value is attached [4]. The nature of these criteria is obviously dependent on the type of tumor (volume, lymph nodes, hormone receptors, chromosome deletion etc.). Within the collaborative medical decision making process framework, Christensen et al. [5] evidenced the relevance and importance of formatting and presenting problem-relevant information by means of such a document. This is conventionally a paper or an e-form filled-in before or during the MCM. The main objective of a system for structuring the case record of a patient would be to ensure that the relevant information for the patient's case and for the final decision is brought to light and shared by all members of the committee. All relevant information describing the patient's case must be drawn from decisional criteria available in the guidelines and protocols, from those cases already resolved and from on going therapeutic trials.
2. **support for selection of cases which have to be discussed within a MCM.** To that effect, a decision support system based on MCO approved guidelines is required. The system's main objective is to provide with recommendations relevant to the patient's case. When for instance such a system offers a standard therapy with no alternative solution, the expert may then support the system's decision and decide not to present the case to the MCM.
3. **decision and argument support for the MCM.** Such a system must make use of all the knowledge available to put forward alternative therapies issued from: 1) standard guidelines and protocols; 2) clinical trials in which the patient can possibly be enrolled; 3) the case database to identify similar cases for which a positive (or negative) therapeutic response was recorded. Using a case database presupposes the patient's follow-up and an adequate feedback on the effective observance of the therapy recommended by the MCO, with its effect on the patient. Rossille et al. [6] have proposed a system aiming at supporting the MCM in their decisions for non-standard cases (cases

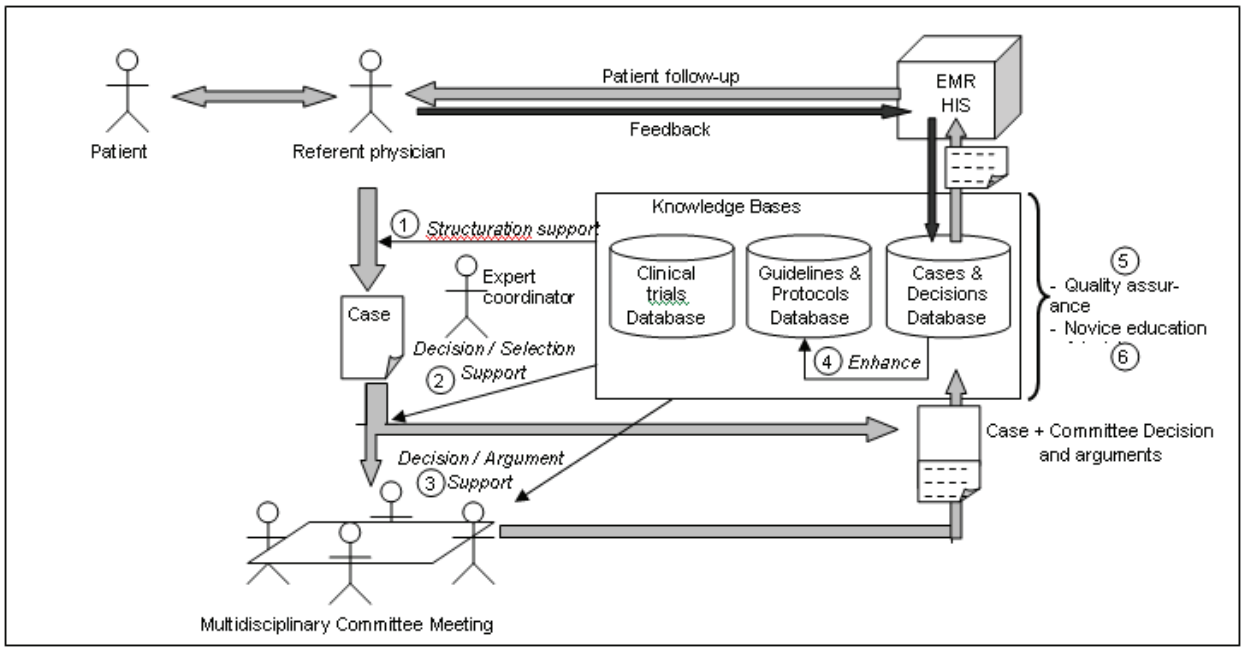

Figure 1 - MCO organization and workflow

that do not/cannot comply with guidelines' recommendations). This system technically used both rules basedand case based reasoning. In our opinion, such system could be improved taking into account clinical trials database in order to provide selection of relevant trials for a given patient. Using a comprehensive decision support system to decision making process would also be interesting used as a support to the discussion during MCMs and to support and evidence the committee's decision based on the system's proposition.

4. **guidelines improvement and local adjustment**. Sauvagnac et al [4]. argue that a multidisciplinary committee is the right place for advancement and particularization of protocols and guidelines. To that end, we must bear in mind that these care standards must be explicitly expressed in order to be clearly understandable and unambiguous for all the specialists. Computerization of guidelines is a good mean to achieve this in depth explanation. Guidelines become fully operational and can be checked and strengthened. In the same line, the decision criteria can be specified during to the computerization process and during their use within the MCMs. Thus, it can become a virtuous circle: guidelines operate for multidisciplinary committees; multidisciplinary committees operate for the advancement of the guidelines themselves. Improving the guidelines and their possible local adjustment or adaptation means using the knowledge derived from the MCMs decisions and using the information on the patient's follow-up (efficiency of the treatment, therapies available, side and noxious effects, quality of life, life expectancy,…). A review of cases for which a recommendation was put forward by the system and the MCM prescription who followed this recommendation on the one hand, and actions actually implemented for these patients on the other hand, is extremely useful in improving the Departments operational procedures (in those Departments treating these patients) and in assessing the guides and recommendations adaptation to the real clinical conditions.
5. **facilitating the quality control**. We need tools which provide help in order to analyze the cases for which the Committee has given an opinion beyond the usual guidelines. Setting up a cases and decisions database and computable guidelines database can facilitate the quality assurance process and results. A computable guidelines system can be used both 1) prospectively, to help the expert or the committee in their search of the best standard solution satisfying adequately the case of the patient; 2) retrospectively to identify and review those cases for which a non standard solution was recommended by the MCO.
6. **education and training**. Setting up and making available knowledge bases can also be used as tools for the physicians' formation and training. Such bases can be used to enrich a training environment and enable trained practitioners to look into the decision making rules, check their scope of implementation and identify their limitations.

Pilot implementations

Within our healthcare establishment's MCO, we have implemented the functionalities described above. This pilot implementation is based on a re-use of our guidelines development and dissemination platform described elsewhere [7].

Computable guidelines (neuro-oncology domain)

In a collaborative effort with the neuro-oncology MCO, we have established an I.T. based system using computable guidelines to facilitate the identification of standard and validated therapies applicable to each patient's case. Within this MCO, cases that will be reviewed during the next MCM are collected in a computer file and recorded in a proprietary database into the hospital information system (HIS).

We have developed a prototype focused on the treatment of gliomas. Textual guidelines provided by authoritative organization [8] have been successfully computerized using our platform. A software component has been built in order to couple this HIS database and the computable guidelines. This component is based on XSLT facilities in order to process the data extract from the HIS database into an XML document which can be processed by our computable guidelines system. The system output for each patient case is a synthetic and structured document on which the patient's data are summarized on the left hand side and the recommendations adapted to the patient's profile are displayed on the right hand side (figure 2). This document is designed for printing and use both by the MCO expert and by the multidisciplinary group during the MCM.

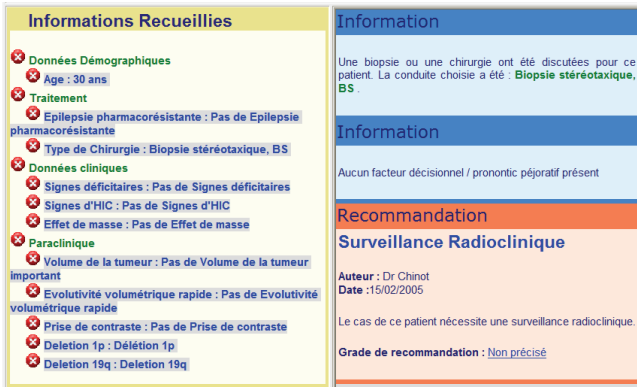

Figure 2 - Output of the computable guidelines system

So far we have computerized 4 guidelines focused on the different glioblastoma grades. We are working on computerizing other guidelines.

Clinical trials (thoraco-oncology domain)

In joint collaboration with the thoraco oncology MCO, we have developed a system aiming at improving the patient's enrolment rate in on going therapeutic trials.

To meet this objective, we have come up with additional developments to enrich and modify the functionalities of our decision support system and turn it into a management and reminder tool for those therapeutic trials in which patients are susceptible to be enrolled. The result is a definition of all inclusion criteria for the various therapeutic trials concerned and translation into the formal format used in our decision support system. The inclusion criteria correspond to the « rule-in » and the exclusion criteria are the « rule-out » elements of a conventional computerized guideline system. Here again we make use of a software component to link computerized therapeutic trials to the patients database used by the MCO (in this MCO they use a MS Access database). The software application is hosted in a laptop computer with real time use during the MCM. The screen displays the patient's data and possible inclusion protocols, and this is in turn displayed to the MCM participants (figure 3). For each individual patient, the system mentions inclusion or not within the therapeutic trials(top of the screen), the number and reason(s) for non inclusion in each trial (bottom right of the screen), and the relevant patient's data (bottom left of the screen).

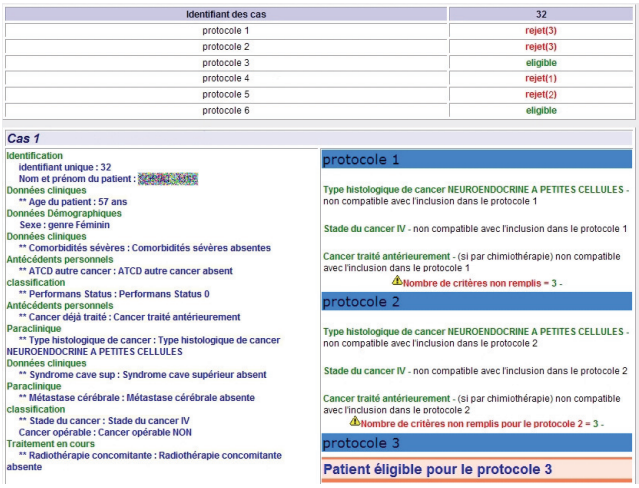

Figure 3 - Screen copy of the clinical trials selection system

Future work will be the enhancement of the graphical users interface and assessment of the efficiency of the system using a before- after study.

Discussion

The multidisciplinary decisions and management are a prerequisite to any medical act, especially when dealing with complex, intricate pathologies whose management

involves a delicate approach. As to oncology, MCO offer an organizational frame enabling to partly formalize the decision making process. The MCO ultimate objectives are to improve therapy management and to cut down any non justifiable deviation and disparity when managing patients. These objectives are best met when the various decisions making processes are supported to the best extent and when the best medical knowledge is used within the processes. We propose a conceptual framework to help identifying those decision support systems which should be used to improve the decision making process applied within the MCO. Support for structuring and carefully presenting case of the patient, support for selecting the most appropriate therapy using both computable guidelines and computable clinical trials is the core of our propositions.

Implementing computable guidelines is the way to make operational that knowledge directly in-bedded into the decision making process. The use of decision support systems which are based either on guidelines or/ and on case-bases validated within the MCO frames the approach while avoiding any drift when selecting therapeutic options. During the MCM, guidelines play a safeguard role in removing part of the unnecessary subjective opinions in order to opt for a treatment compliant with objective scientific data and meeting the patient's needs. Using guidelines for instance may contribute to put into perspective experts opinions and judgments which sometimes impact more than required on the final decision. The weight of the expert's knowledge during a MCM can indeed be deleterious if justified only by the authority representing the rule specific to that expert [4]. It should also be seen to it that the inevitable social component presiding during the MCMs becomes over important, and that the discussion should be turned into a « battle of experts » far from the standard, validated and shared knowledge [9]. To that effect, computerized operational guidelines may contribute to avoiding this type of deviation while refocusing the discussion on tangible, accepted and explicit facts and knowledge. Finally, a more rigorous use of data from the literature and from the guidelines should be encouraged given that it contributes to the strengthening and support of evidence based decisions taken during the MCM.

Another justification for implementing computable guidelines within the MCO comes from the need to optimize the case workflow for those patients for whom an opinion is required. Optimizing the time to processing a patient case is vital especially in the field of oncology where any delay in the therapeutic management can have a fatal impact. There are cases when the MCM discussion is fully justified when facing a special, non typical case, for which no guideline can rigorously be applied or when the wish of a patient may induce a reviewed protocol decision, assessing the risks generated by deviating from the approach recommended. But many are the cases subject to discussion during a MCM which actually pertain to the standard protocol decision making process [4] and could therefore be identified, as is our suggestions, by means of an I.T. decision support system based on computable protocols and guidelines. What is important is to identify those standard cases and improve their processing time to dedicate more time to complex patient cases.

Using guidelines within MCO is also beneficial to better adapt and upgrade guidelines themselves. National or international guidelines are seldom used "out of the box". They must be customized and require a preparatory work with the physicians so that they can be used more easily – computerization is part of this work- with update based on the latest publications or for strategic refinement. They must therefore be locally adapted before becoming fully operational. MCMs are the right forum for improving the guidelines given that this is where such guidelines can be upgraded not in the light of new data or knowledge but based on their actual use [4]. Such improvement is made possible if what is recorded following a MCM is not the decision only, but the features of the cases treated which must also be registered; above all the elements in the decision helping to better understand the reason behind the decision must be recorded. Thus, the 'discussion trace' must be rich: discussions should be recorded in full and not limited to the final decision taken; it should be justified, with other hypothesis presented, the reasons for discarding them, the knowledge not shared by all (i.e. over specialized) reported to all the meeting participants during the discussion. These elements must enrich the case database from which it will be possible to update or find new knowledge used in setting the healthcare management standards. What is essential is preparing a virtuous circle. This presupposes formalizing the MCO practices and having adequate tools which will be beneficially used for decision taking in these committees and for building up on medical knowledge. What we are proposing as a conceptual framework within the MCOs using these computer-based supports follow this line.

A Model Proposal for the Rational Prescription of Antimicrobials in Intensive Care Medicine

Pedro Costa[a], Ricardo Cruz-Correia[a], Telmo Fonseca [a,], Ernesto Oliveira-Palhares[a], Altamiro Costa-Pereira[a], António Sarmento[b]

[a] *Centre for Research in Health Technologies and Information Systems – CINTESIS, Faculty of Medicine, Univ. of Porto, Portugal*

Abstract and objective

Inadequate prescription of antimicrobials has been associated with increased toxicity and selection of resistant strains that adversely affect patient's health, especially for the infections treated in the Intensive Care Units. The AB+K clinical decision support system gathers information from electronic patient records, laboratorial reports, radiological findings, bed-side monitoring devices, antimicrobials and pathogenic agents resistances databases aiming at the choice of a rational antibiotherapy, based on the current condition of the patient and available drugs.

Keywords:

pneumonia, anti-infective agents,
computer-assisted drug therapy, intensive care units

Introduction

Inadequate prescription of antimicrobials has been associated with increased toxicity and selection of resistant strains that adversely affect patient's health and increases the costs of care. This problem is especially relevant for the community and nosocomial infections treated in the Intensive Care Units (ICU) due to the severity and complexity of their patients.

The AntiBiotherapy+Knowledge (AB+K) project aims at the design, development and validation of a solicited decision support system for friendly clinical guidance on the use of antimicrobials in Intensive Care Medicine. The applied decision rules are expected to reflect the expert knowledge on the area but also to validate and, if possible, infer novel knowledge.

Through the combination of several information technologies, clinical expertise and pharmacological concepts, the AB+K system is expected to improve the prescription of antimicrobials in Intensive Care Medicine. The clinical decision support system combines information collected from an Electronic Patient Record (EPR), laboratorial reports, radiological findings, bed-side monitoring devices, an antimicrobials database and a regularly updated model of pathogenic agents resistances in order to help the intensivist in the choice of a rational antibiotherapy, based on the current condition of the patient, the available drugs, and of the resistance profile of the pathogenic agent(s).

This research project may contribute to improve clinical performance concerning the prescription of antimicrobials and to the study of the community and hospital epidemiology of infectious diseases. All this is likely to improve the clinical management of ICU and patient's outcome.

Methods

General architecture

The AB+K decision support module feeds from three main sources: the Intensive.CARE electronic patient record, the Antibio-therapy Knowledge Base and the Medical Guidelines Module.

AB+K is intended to be fully integrated with the EPR. Specific screens are added to the EPR's graphical user interface, allowing the health professional to introduce the patient related values for the decision related variables. Nevertheless, in order to minimize data input by AB+K users, interfaces for other Information Systems (IS) are implemented to enable automatic collection of relevant data. The main sources are administrative applications (such as the Hospital Admition System (HAS)), other EPRs, bed-side monitoring, and laboratory departmental systems, supplying respectively demographic data, clinical data, vital signs reports and laboratory results. All patient related data is stored in a proper database schema.

A different database schema holds the antibiotherapy related data. This database schema is regularly updated with the list of available drugs, their pharmaceutical characteristics, recommendation, possible alternatives, side effects and interactions. Likewise, a regular update is performed on the documented resistances to antibiotics developed by the known pathogenic agents.

Decision rules, expressing the clinical guidelines, are used to infer relations among the variables and suggest a therapy the health professional. The ability to explain thoroughly every expressed suggestion is required to the decision module; hence decision trees are to be shown in

user interfaces. The health professional is asked to validate or refute the suggestions, thus contributing to the evolution of the expert knowledge.

Auxiliary departmental systems

Most Portuguese hospitals use a common Hospital Admission System (HAD). A set of Web Services have been developed to integrate the AB+K system with the HAD, through the EPR. The Clinical Pathology data is also incorporated, via a database level interface that enables the transfer of data between AB+K and the Clinical Pathology Departmental System.

Automatic acquisition of vital signs

The automatic acquisition of vital signs improves the quality and speed of data collection, while enabling the assembly of large electronic archives. Most Vital Signs Monitoring Centrals feature network interfaces that broadcast data in the Health Level 7 (HL7) standard. To take advantage of such a powerful tool, the AB+K framework is provided with a HL7 communication handler. For the time being, received data conveys the patient identification, a timestamp and five physiological parameters: arterial tension (PNIs and PNId), temperature (T), arterial oxygen saturation (SPO_2), cardiac frequency (FC) and respiratory frequency (R).

The AB+K decision module

Arguably, the implementation of internationally accepted medical guidelines is the best way to emulate medical reasoning. The patient current status is usually described in a number of variables (age, sex, symptoms, diagnosis, etc.) that may derive medical guidelines, medical papers on related topics or from the expert own experience. For the time being, AB+K implements the American Thoracic Society guidelines for the management of adults with community-acquired pneumonia, regarding the diagnosis, assessment of severity, therapy and prevention.

Due to the actual scarceness of data, no advanced decision models, like Bayesian networks, Decision Trees or Neural Networks can be yet applied. For any given patient, the decision variables instances are handled as Datalog facts and guidelines are expressed as Datalog rules, evaluated by a Prolog meta-interpreter. The reaches conclusions and respective explinations are sent to the Intensive.CARE interface through a specialized Java-Prolog interface.

The decision process is divided in two phases. Decision variables associated with patient's symptoms, epidemiologic conditions, physical examination, laboratory and radiology findings are handled first, trying to fit the case at hand into one of four distinct etiologies. The health professional is then asked to sanction the reached conclusion, if necessary by navigating the returned decision tree. In case of disapproval, the health professional may override the system suggestion and manually select the correct etiology.

Phase two proceeds from this point on. Specific rules are applied to discover the best possible prescription taking under consideration the list of available drugs, the documented resistances and the patient medical history. Again, the final suggestion, as well as the decision trees, is sent to the interface and the health professional is asked to sanction them.

Expected results

Speed

AB+K is expected to spend no more than 60 seconds in answer computing and delivery, because that is the amount time we consider the health professionals are willing to wait in the intensive care context.

Presentation

Therapeutic suggestions will be presented in an intuitive manner, illustrating the AB+K rationale. This is expected to improve the acceptability of the system, as well as the detection of inappropriate suggestions. Arguably, it will also improve the knowledge of the implemented guidelines by the health professionals using the system.

Integration in daily activities

Whenever possible, the EPR's data forms will be automatically populated with already known values for decision variables, in order to improve usability. These values may originate from the EPR, lab results or other patient data sources. Special attention will be given to the transformation of existing data on current information systems into the input variables used by the clinical decision support system.

Conclusion

Despite the importance of decision support systems for rational antimicrobials prescription in Intensive Care Medicine, many difficulties arise in their practical implementation.

First of all, information is highly scattered through-out many different data sources, possibly with many different data support structures and data access policies. The isolation of some information systems, the non-adoption of communication standards between the already existing data exchanging systems and several other issues of bureaucratic nature constitute great obstacles for the implementation of specialized interfaces to help integrate data.

Another major faced difficulty is the absence of a standard medical ontology that relates several different concepts and denominations hardens the task of expressing medical knowledge. Moreover, medical guidelines are most often subjective, providing great degree of freedom for the interpretation of the rules.

Conceptual Model as a Tool for Assessing Knowledge in Decision-Support Development

Helena Lindgren

Department of Computing Science, Umeå University, Sweden

Abstract

In the development of a decision-support system the domain knowledge as well as the target work environment need to be assessed in order to capture the knowledge to be integrated in and provided by the system. This work describes the model used for the assessment, which is based on Activity theory and case studies of patients investigated concerning suspected dementia. The purpose is to investigate to what extent the theory is useful for the assessment and for transforming the informal knowledge into formal descriptions for knowledge representation and design of interaction. The resulting structure provides the data and their sorts and qualities, the tools that are used in assessing the data, the actions of transforming the data and contextual factors such as who is responsible for a certain action. The semi-formal structure can be transformed into a formal structure for representation by using the structure to identify requirements for formalisation languages.

Keywords:

decision making, computer-assisted;
artificial intelligence; models, theoretical, logic

Introduction

The decision-support system COGITAMUS is being developed for assisting medical personnel in the investigation of suspected cases of dementia [1]. When focus is put on the clinical activity, issues such as the distinction between facts, judgements, qualities of evidence, what is normal vs. abnormal, levels of dysfunctions, distinction between acts of decision and acts of data collection, sources of evidence, etc, become essential to clarify in order to formalise the knowledge correctly. An analysis of the qualities of the medical domain knowledge expressed in clinical guidelines is needed [1] as well as a thorough activity analysis of how the actual clinical work is performed. This work presents the investigation of the informal structures in the use context such as decision making processes, clinical guidelines, patient's health, domain knowledge, actors involved, vocabulary and language, etc, and the process of transforming the informal knowledge into a formal structure useful in decision-support development. The main purpose is to investigate the use context of the system through a work analysis with the prototype system integrated, which can serve as a coarse system specification for further development and be used for future evaluations of the system in daily practice.

Tools are needed in the process to accomplish this transformation, which have the ability to capture both low level details about qualities of evidence and high level purposes and other ingredients of clinical activity. Important aspects are the dynamics of a changing and evolving work situation and individual patients' need when facing a degenerative disease such as dementia. While there are methods that can be used for assessing structures of tasks and data-flow, Activity theory provides in addition the dynamic perspective, means to define levels of skill and knowledge of actors and motives for activity [2]. These are important aspects when evaluating decision-support systems. We use the cultural-historical Activity theory as described by Engeström [3] as theoretical framework in the analysis of the clinical work situation, since the theory embraces the multi-purposes of a decision-support system. The theory evolved within Russian psychology in the 1930's [2] and has been extended since then, mainly within social sciences, CSCW and developmental work research [4, 3]. The theory however, is often considered too broad and general to be of use in concrete design or formalisation tasks when developing systems [3, 5]. Therefore, a second purpose of this work is to evaluate the theoretical framework in this perspective, and form a model based on the theory useful for assessing formal knowledge and for informing the design of the interaction with the system.

Materials and methods

The activity analysis is conducted as qualitative case studies of five patients in the setting of an out-patient ward at a geriatric clinic which investigates patient's cases with suspected cognitive diseases including dementia. The patient's encounters with a physician were observed during a period of investigation. The physician's use of the decision-support system was video-taped and interviews were conducted with the patient, relatives and medical personnel.

The data was analysed by categorising events by their purposes and what object was in focus, in terms of Activity theory. Themes were identified, and further categorisation evolved in the process. When a semi-formal structure was obtained, the patient's cases were re-analysed using this

structure in order to test the validity and usability of the structure. The structure was adjusted accordingly.

Results

We take as starting point, the view that the clinical activity of investigation essentially consists of two parts; the *clinical activity* with its actions and sub-processes, and an *activity system* in terms of Activity theory, which includes the object for activity, resources involved and their relations, and which imposes constraints on the execution of the investigation activity. A necessary property of the anticipated model is an ability to capture dynamic and changing situations and objects. We use the notion of *object* for data and phenomenon such as symptoms or diseases, when referring to what is in focus for each action.

The presented results include definitions of views on the investigation process, sorting of purposes of activity, definition of activity, and the relation between clinical actions, evidence and mediating tools.

Levels of activity

In the initial analysis of actions with different purposes as part of the main activity, three types of processes were identified. Two of these constitute *reasoning procedures* including medical decisions; the investigation of specific domains and the main reasoning process. Further, a distinction is made of the *logistic* or *administrative* process, which is imposed by the rules governing the whole process. The three types represent different views of the clinical investigation activity. The processes are executed in parallel, they are cross-fertilizing and dependent on each other, and are partly overlapping depending on circumstances in the environment. This dynamic view of the activity of investigating cognitive diseases will be used as a basis for the analyses in subsequent sections and they correspond roughly to the levels of activity defined by Activity theory.

Some of the sub-processes involved in the activity are viewed in Fig 1. The levels distinguished by lines in the figure indicate the different levels of complexity in the actions. As can be seen in the figure, the activities of analytic and decisive character are organised in the upper levels. The actions defined at this level are typically defined as necessary for the main activity to be executed, according to the clinical guidelines and the domain knowledge. However, the level of necessity can differ depending on which guideline is used as tool for reasoning.

The object-creating actions, which are typically automated processes (i.e. operations in terms of Activity theory) for the experienced actor, are organised at the bottom of the structure in Fig 1. They are automated in the sense that the actor does not have to put mental load or conscious thought on the execution, instead the actor can focus on the larger perspective and motive for the activity, of which the action constitutes a part. These actions are typically administration of tools, such as executing tests and examinations involving the patient. The actions defined at the lower levels in our analysis can be exchanged by other actions which produce equivalent information necessary for accomplishing the decisive actions. Typically, this is the case when the routines and priorities at different workplaces direct the usage of different tools in the process, for instance, which x-ray methods to use. Differences in which tools that are used can also be consequences of different habits and values hold by individual actors.

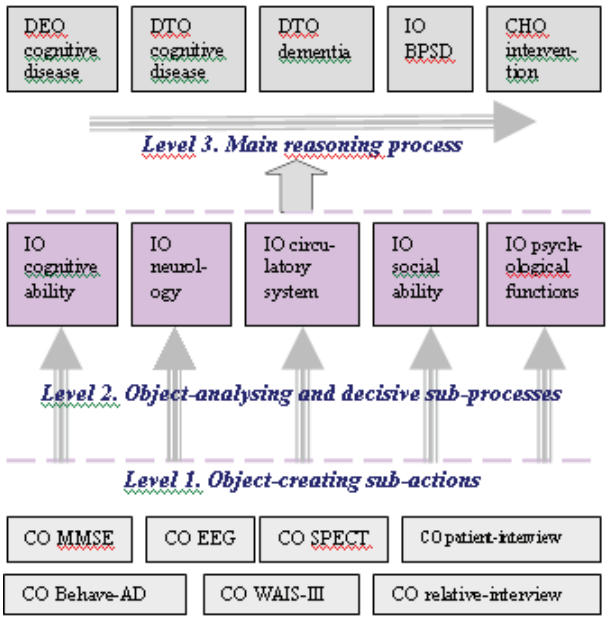

Figure 1 - Different levels of complexity in activities in the process of investigating cognitive diseases

The participation of patient and/or patient's family is necessary in the object-creating actions at the lowest level, however, not at the other levels. This gives suggestions on how a decision-support system should be designed and for what kind of clinical situations, depending on which kind of actions are to be supported. There may be less need of a support system in the clinical patient encounter situation for the experienced actor when the examinations for obtaining evidence are executed. However, at this level there are different clinically validated methods as well as ad-hoc methods that can be used. The less experienced actor can be supported in the choice of methods and in the execution of these sub-actions, as well as in the higher level actions of diagnostic reasoning.

A decision-support system should reflect the two-dimensionality of the reasoning process where one dimension can be seen as the gathering of data and interpreting the data into information, which is a process done with the general perspective of (healthy) function vs. dysfunction

(Level 2 in Fig 1). This process is orthogonal to the process of diagnostic reasoning and intervention, to which the information is fed as evidence in the reasoning towards diagnosis and appropriate choice of intervention. These two different purposes of actions are important to distinguish in the formalisation of the domain knowledge that is used in the transformation of information at the different levels. Basically, the first purpose is to value functionality per se and the second purpose is to value the function or dysfunction in the perspective of dementia diagnosis and intervention.

Sorts and typing of activity

When the investigation process as performed in the case studies was analysed, different sorts of actions were distinguished by the purpose, or the *goal* of a particular action (Table 2). Typically, the actions were aimed at either collecting raw data (CO); refining or interpreting raw data or knowledge (RO); using the interpreted data for higher level of reasoning for the purpose of determining the existence of a phenomenon (DEO); determining the type of a phenomenon, i.e., increasing the level of granularity in the knowledge (DTO); imposing changes to the phenomenon in focus, and valuing the effects thereof (CHO; ECHO). The actions of higher complexity which aim at a holistic assessment and change of a phenomenon we denote *investigation* actions (IO), which typically integrate all the other purposes. In addition, actions were identified which aim at controlling and directing the process (DA). Examples of such actions are referrals for examinations, involving colleagues for consultations, assignment of tasks to team-members and team-meetings. In Table 2 the sorts of actions are defined.

Table 1 – Sorts of action

Sort	Purpose	Examples of clinical procedures
CO	Create object	Laboratory tasks, executing clinical tests, interviews, etc
RO	Re-representation / refinement of object	Interpret test results, documentation
DEO	Determine the (amount of) existence of object	Value evidence, diagnosis
DTO	Determine the classification of object, increase granularity	Differential-diagnosis
CHO	Change of object	Interventions
ECHO	Evaluating results of change action	Follow-up
IO	Investigation of object	Include diagnosis, intervention, follow-up
DA	Direction of activity	Referral, delegation, consultation, teamwork

IO corresponds to the level of *activity* in terms of Activity theory. The definition implies both assessment of information about the object and change of the object, thus, including the other types of actions. In the larger perspective of investigation of dementia, activities of sort IO can also constitute actions. The basic difference between the different levels of activity in terms of Activity theory is the definition of the purpose of the task, where activity has a *motive* and is driven by a need, while actions have a *goal*, which constitutes a sub-goal for the activity they are sub-actions to. Operations have no consciously defined goal on their own. We make no firm distinction between the levels other than distinguishing the main activity as an activity. Whether the operations are interesting to distinguish from actions depends on the perspective of analysis. An evaluation of an individuals' use of the system needs to integrate the distinction in order to capture a learning process. However, for the purpose of the general analysis in this work we take the notion of *action* as the basic entity for all tasks independent of level of activity.

Definition of activity

All types of actions are executed by the same kind of structure, the *activity system*, here represented by *Actor, Tool* and the context-related sort *Community* which includes roles, rules and division of work. Further, since the foci of all actions are related to issues concerning the patient, a patient ontology contributes with the *Object* and *Motive* to the definition of activity. Lastly, the components which describe the execution of an action are added, such as the sort, state, outcome and information about the hierarchical structure of actions. We use the same constructor for all sorts of actions, where *Goal* defines the sort of an action and the sets of actions (*Act, A*) can be used to identify the position of an action in the main activity. Further, the actor, set of communities and set of tools (*Actor, T, C*) define the physical and social context of the activity. The following constitutes a general definition of *Action*:

action: [Motive, Goal, Object, Act, A, T, Actor, C, State, Outcome] −> Action

where *action* is the constructor, *Motive* is the anticipated, needed change of the *Object* in focus, *Actor* is one or several subjects representing the social organisation responsible for the execution of the activity, and C is the set of related social organisations or persons (communities) involved, including the rules and division of labour governing the behaviour of its members. *State* can be one

of the following at a certain time point: {*Not initiated, Initiated, Paused, Aborted, Completed*}. *Outcome* is simply the changed object when the state of the action is completed. *Act* is the set of "parent-actions" the action is a part of, which in the case of a main activity is the empty set. Consequently, the only distinction between activity and action in terms of Activity theory becomes a structural issue of in what context a certain action is executed.

Capturing the object of activity

The object in focus for activity can be an abstract mental construct such as medical knowledge or a physical entity such as the human body and its parts. The purpose of focussing the object in an activity is to monitor, or change it, therefore each object has measurable or describable qualities which are used in the clinical activity. These qualities are preferably captured and valued by using validated tools, such as cognitive screening tests. Therefore, the information about which tool or tools that were used in the execution is essential, together with the outcome of the valuation. The constructor for the Object becomes:

Object: [Entity, V] −> Object

where Entity is the object in focus, and V is the set of different valuations based on the usage of different tools: V_i={$Tool_i$, Qualifier}. At this level of analysis tool can be seen as the sort for the measure. In our work analysis we use the sort *Subjective* in the case when no validated tool is available and used.

The object and its qualities is the current state of the object at a certain time point, for instance, when the action is initiated. The outcome of an action, i.e. the Object and its qualities when the action is completed, is defined as the *Evidence*, which is used in subsequent clinical reasoning.

Clinical actions, evidence and tools

The different sorts of activity distinguished in Table 2 put different demands on the formal representation of the evidence and generate different types of outcome.

The first type concerns the actions which create data, or objects, where the outcome consequently constitutes the created object. The status of the object can be seen as the Boolean value *present* to distinguish it from before the action was initiated, when it was *absent*. One example is the executed cognitive screening-test, which exists, in the form of a test protocol in the electronic health record (EHR).

The second case is when an analysing or refining action (RO) is executed which aims at interpreting an object at a primitive state into a more useful state. Examples can be when thresholds are applied to numerical values in order to identify pathologic features or when the numbers in the cognitive screening-test protocol is summarised and documented in the EHR. There is a range of situations in which data and knowledge needs to be re-represented and/or refined in order to be communicated and documented in the process.

The third relates to the DEO type which determine whether a particular critical phenomenon is present or not (Boolean valuation), and if present, provide if possible a valuation of the degree of presence (qualitative or quantitative), preferably based on a clinically validated screening tool. Consequently, the outcome may be a set of valuations of different specificity of the same entity, using different tools. Ideally, these values can be mapped to each other in a valid and reliable way when a certain level of specificity is required.

In the case when the goal of the action is to differentiate between types of an entity (DTO), the level of specificity of the entity increases in the execution of the action. Consequently, the values will correspond to each type at the higher level of specificity, i.e. as a set of sub-entities, however closely related to (constituting sub-sorts of) the original entity.

The fifth case constitutes the completion of an investigation activity (IO), which provides an assessment of the situation in focus. If interventions have been executed, also the outcome of the interventions is included in the assessment. Typically, this information is documented in the EHR using natural language. If the information concerns the outcome of the main investigation activity, an answer to the initial referral is formulated and sent to the referring organisation in addition to the documentation in the EHR. A corresponding assessment is provided by the prototype system COGITAMUS, however, at a more specific level of interpretation.

Mediating tools

Tools are identified by its mediating function in the framework of Activity theory [2, 3, 4]. Three main categories of tools were identified for our purposes: 1) tools used for mediating physical actions, 2) tools mediating reasoning processes and 3) tools mediating the logistic process.

We chose to distinguish complex cognitive processes such as reasoning, decision making and learning from basic cognitive functions such as memory, recognition and language production. These basic functions are supported in the logistic work process, where tools are typically used for the storage and mediation of knowledge. These tools may also serve the reasoning process when a system integrates intelligent inferences, i.e., has mechanisms of transforming / refining data or presents information as if it does. One example is the list of data from laboratory examinations, which highlights measures which are abnormal.

In addition to these tools external to the actor who uses them, there are tools integrated (internalised) in the actor

such as knowledge, rules of thumb, conceptual models of interpretation, models of procedures, etc. A majority of those used for professional work were external tools when a person first used them, which have been internalised by practice and learning. Examples are terminologies and classifications of diseases. However, internal tools are also created as conceptual models of how things work and should be organised, models which are continuously modified in the interaction with the environment. Internal tools can be externalised when focussed as an object of re-interpretation, which is the case when internalised knowledge needs to be communicated to others.

The aim for the development of the decision-support system COGITAMUS is to provide knowledge and support to novice users, which may become internalised in the process of using the system. For both novice and skilled users, the system should support the externalisation of knowledge if needed in difficult cases in order to consult colleagues or the integrated guidelines. Furthermore, the knowledge integrated in the system constitutes a synthesis of external evidence-based domain knowledge and internal expert knowledge, which has been externalised by the participating domain experts in the development process.

The category of tools which are particularly interesting in the formalisation of evidence are those which are used for valuing features, qualitatively or quantitatively. External, validated tools are preferred to the internal subjective assessments, in order to assure equal care and reliable decisions based on objective common grounds. However, since there are several tools that can be used for the same purpose, and which may produce ambiguous evidence, the actor sometimes needs to value which tool to use and on which to base further reasoning. Further, in some situations there are no validated tools available, thus leaving the valuation to the actor. In the actions where the user's experience and internal knowledge is needed for valuation of evidence, these tools need to be assessed as well, in our analysis by referring to them as *Subjective*.

A knowledge tool such as a clinical guideline integrates both knowledge in the form of implicit rules and a set of values which can be used in the valuation of evidence. By identifying these qualities of a clinical tool, the basic elements (sentences and types) necessary for the integration of the knowledge into a formalism can be identified. As an example from the domain of dementia, a tool such as the clinical guideline DSM-IV-TR [6] may come equipped with a formalisation of the content in the form of a set of sentences as part of a logic language where $^{\text{DSM-IV-TR}}$ consists of a set of rules formulated in propositional logic [7]. A sub-set of these rules, $^{\text{DEO-dementia}}$, corresponds to sets of core features necessarily present or absent in a patient in order to establish the presence of a state of dementia, as formulated in the guideline. The result of a valuation using the guideline may become:

Evidence: [State of dementia, $\{^{\text{DEO-dementia}}, \textit{present}\}$].

The user can be provided the evidence interpreted within different contexts of valuation, contexts consisting of the tools used for the valuations, thereby giving the user access to clinical guidelines and an overview of evidence in a patient's case.

Discussion and conclusions

The presented work provides a conceptual model for a clinical investigation activity based on analyses of the domain knowledge and case studies of investigations of actual patients. The model is used to frame the investigation process, as an alternative method to the formal ontology and workflow approaches. The purpose is to identify relevant actions to formalise for decision support in the system and actions to support by the design of interactive reasoning. The model can be viewed as a bridge between the informal view on clinical actions obtained in field studies and the formal implementation of the reasoning using suitable formalisms for representation.

The framework integrates the domain knowledge, procedural knowledge, resources and constraints imposed on the investigation activity by the environment, and in particular, the framework is dynamic and patient-oriented in that it is the need of the individual patient that defines the investigation activity and corresponding activity system.

The conceptual structure is based on Cultural-historical Activity theory and forms a foundation for the formalisation of the knowledge. The adapted theory is well suitable for the purpose in the semi-formal version presented in this work. The structure provides the data and their sorts and qualities, the tools that are used in assessing the data, the actions of transforming the data and contextual factors such as who is responsible for a certain action. A key issue is how the semi-formal structure can be transformed into a formal structure for representation. A critical feature is the formalisation of the content of guidelines, treatment protocols, scales and values provided through the use of different tools in the process. In order to extend the model to include a framework for the formalisation, we use category theory as a meta language for the identification of the fundamental building blocks, independent of the logic language used in the implementation of the knowledge. To what extent the activity structure is useful for the integration of knowledge in the formal framework of category theory and institutions [8] is currently being investigated.

Since the work presented in this paper is based on a limited amount of patients and focussing a specific domain, the structure will be further evaluated and developed using

additional patient's cases and used for developing knowledge systems in different domains.

Acknowledgments

I am grateful to the clinical personnel, patients and their relatives who participated in the study.

Abstract

The implementation of electronic health records in a rural setting generated new challenges. The preparation, implementation, and sustaining the operation of the electronic health record requires extensive attention to standards, content design, support resources, expert knowledge and more. The complexity associated with implementing alerts, reminders, and decision support was not taken lightly. The rural community hospital was able to use urban community designed clinical decision support rules (CDSR) to promote safety, prevent errors, establish current evidence-based practice (EBP), or support communication. The paper provides progress on evaluation of the electronic health record implementation using CDSRs. The descriptive research findings illustrate 13 clinical processes supported by 54 CDSRs used in a rural community hospital. The findings provide the goals (as experienced in urban sites) supported in the clinical processes. Rural community hospitals can rapidly overcome the barriers to preparation and implementation as well as sustain use of CDSRs with systemized approach and support structures. A model for implementation of nursing expert clinical decision support to use in workflow processes is presented. Future research is planned.

clinical expert systems, formative program evaluation

Introduction

The implementation of electronic health records in a rural setting generated new challenges 18 months ago. This paper shares the formative evaluation of developing clinical decision support rules for a rural setting which was implementing an electronic health record (EHR). From this evaluation, the team shares a developing model to integrate the sciences of computers, information, and health to use medical and nursing evidence in clinical workflow processes. It was confusing to hospital clinical staff when the selection and design of CDSR were a separate piece of the EHR preparations. This meant having separate meetings for many of the components tied to implementing an EHR. In the end, it became easier for clinical end-users to integrate the three sciences upfront rather than overcoming the missed opportunity to include clinical decision support rules (CDRS) in the design of clinical workflow processes.

The formative evaluation on steps in the preparation processes highlighted the need for integration of decisions on CDSR with the redesign of clinical workflows. We will primarily focus on the inclusion of clinical decision support rules, but many other decisions for screen displays for data entry and view, computerized order sets and more design details need to be a part of the work effort by clinical teams when deciding on redesign of clinical workflows. There is nothing easy about the preparation, implementation, and sustaining the operation of the electronic health records. Each step requires extensive attention to standards, content design, training, user support resources, expert knowledge resources and more. Health care informaticians will find as we experienced the need to integrated decisions on design with the decisions on clinical processes. This included clinical decision support rules.

Clinical decision support rules

Clinical decision support was defined as any electronic or non-electronic systems designed to aid clinical decision-making in which characteristics of individual patients are used to generate patient-specific assessments or recommendations that are presented to clinicians to consider [1, 2]. More recently, clinical decision support is defined as "providing clinicians or others with knowledge and person-specific or population information intelligently filtered or presented at appropriate times to foster better health processes, better patient care, and population health" [3]. A clinical decision support rule (CDSR) is one

type of clinical decision support that is defined as an automated evaluation of a pattern of patient and/or clinician data elements that prompt a nurse, physician or other clinician to take an action. The automated evaluations of data patterns are initiated by an event called a trigger. A trigger, also called the evoke event, is defined as patient information generated within the EHR or passing form another application into the EHR system and initiates the automated evaluations of data patterns by aggregating and processing data to prompt the a decisive action. CDSR are used to express therapeutic recommendations, to formulate queries about relevant interventions for a patient, and to assess the effectiveness of a treatment. Decision support expert rules provide clinicians with alerts and reminders, data interpretation and patient diagnoses, patient management suggestions, and clinical protocols. There are multiple data components necessary to activate an expert rule within the EHR.

Methods

The formative and summative evaluation were used to study the implementation of a comprehensive integrated, electronic health record (EHR) system using uniform data standards, with computerized provider order entry, and clinical decision support tools in several rural health care settings (hospital inpatient units, ambulatory care, primary care and specialty clinics). This CDSR study is a part of a larger healthcare information technology study partially funded by the Agency for Healthcare Research and Quality (HS015196-01). In this 3-year study in its final year, 54 clinical decision support rules (CDSRs) are described for the rural hospital and 17 for clinics using a title name, the clinical process using the CDSR, the purpose for the CDSR, the explanation of the rules logic, the evidence supporting the clinical rule's use, the start date for the rules existence in the Cerner EHR, and whether the rule is used only by the rural hospital or is it used among the system by other organizations. The study described the number of times the CDSR was triggered and the number of times the action was completed, cancelled, voided, discontinued or remained as an action by the Cerner EHR system, if captured. The formative evaluation and descriptive findings on the types of clinical processes supported by 54 Expert Rules used in a rural community hospital and 17 for the physician clinics and the goal for supporting clinical processes are presented.

Formative evaluation of preparation

In this section, a formative evaluation describes the preparation processes that existed in 2004. The rural community hospital informatics specialist and clinical leaders received initial education on the steps for preparing for the electronic health record (EHR) in the spring of 2004. This education included learning about many key items. For the focus of this paper, we will discuss the education on redesigning clinical workflows, designing order sets, electronic forms, and selecting CDSRs. The training sessions were part of formal online and in-person training sessions. The preparation steps began by discussing the designing of current state and future state workflows with clinical teams. The formative feedback from informatics specialist and clinical teams were that every item was disjointed and done in "silos" and therefore, it was difficult to internally integrate the pieces of the EHR application. For example, evaluation revealed the workflow redesign was separate form the electronic forms, which was separate from the CDSRs. So the disjointed processes resulted in the design of order sets starting in June of 2004, the review of clinical workflows occurring in August 2004, and the electronic forms in October of 2004 and the steps on selecting CDRS did not begin until December of 2004. Hence, the formative evaluation of the preparation was that every step was disjointed and confusing.

In summary, this process lead to extensive resource use, missed opportunity to select the CDSR options and request new CDSRs. Despite the confusion in the 2004 preparation processes, the rural community hospital received remedial education and was supported in submitting 22 requests for CDSRs (previously operating in 3 urban hospitals) in February 2005. Subsequently, the informatics specialist was able to submit another 25 requests in March 2005, which 13 were previously used in one other urban hospital and 4 were new requests for CDSR. The research team's evaluation of the process for selecting and designing CDSRs for EHR application has lead to multiple recommendations to improve the process. The lead author, Discern Expert analyst worked with others to construct an improved process [4]. In 2005, the authors worked with clinical teams and information system analysts to integrate many recommended CDSRs into the patient-centered clinical workflow processes.

Evaluation of implementation

In this section, a description of the implementation and progressive evaluation of the implementation of Cerner PowerChart EHR which included the Cerner's Discern Expert computer application for providing clinical decision support rules (CDSRs). The activation of the redesigned clinical workflow processes with EHR were implemented during a 24 hours time period beginning July 8th 2005 as planned. This activation included the following components: Cerner PowerChart within hospital inpatient and outpatient settings; Cerner FirstNet Tracking system and PowerNote physician documentation in the Emergency Department; Cerner PharmNet verification and profiling for pharmacy services integrated with robotic bar coding dispensing system and Pyxis dispensing system; HealthQuest patient management quick and pre-registration processes; Cerner Profile Health Information

Management processes for coding, physician electronic signature and record management; and PeopleSoft financial billing and auditing processes. When the EHR was operating on July 9th the clinicians used computerized provider order entry within the Emergency Center and in all other areas. Additionally, nurses and ancillary professionals initiated electronic clinical documentation. Forms were 95% prepared from previous urban hospital use. At time of activation, 53 CDSRs were initiated to complement the already 17 adverse drug event rules using Cerner Discern Expert application. Other types of decision support included 43 emergency room PowerNote templates and over 250 service specific order sets for anesthesia, behavioral medicine, cardiology, cardiothoracic, critical care, EENT (ears, eye, nose and throat), medicine, neurology / neurosurgery, newborn /pediatrics, obstetrics /gynecology, oncology, orthopedics, radiology, specialty procedures, surgery, vascular services. All CDRS remain in operation today.

Results

Eighteen months after implementation, the rural hospital continues to use of 53 CDSRs for medication processes, adult inpatient nursing processes, medical care, and ten other clinical processes. The goals for CDSRs for all disciplines were designed to establish evidence-based practices, prevent errors, promote safety and support communication. See Table 1 for where the CRSR met two of the four goals for clinical workflow processes.

Table 1 - CDSR Goals for supporting processes

Clinical Workflow Process	# Rules	# To Prevent Error	# To Promote Safety
Medication	5	2	3
Medical Staff	4	0	1
Maternal-Child	9	0	0
Pediatric	3	0	0
Nursing Care	13	2	1
Behavioral Health	4	0	1
Nutrition Service	6	0	0
Infection Control	2	0	0
Respiratory Care	1	0	0
Diagnostic Radiology	3	1	1
Rehabilitation	1	0	1
Social Worker	1	0	1
Spiritual Care	2	0	0

Many of the CDSRs were supporting communication and evidence-base practices. Very few CDSR were categorized as other. Each of the CDSRs were analyzed for consistency in triggers over a three-month post-implementation period from July 22, 2005 through October 21, 2005. All the CDSR were functional as the end users expected.

Despite the many challenges, the rural community hospitals and affiliated clinics had overcome the barriers to preparation, implementation and sustaining clinical decision support. The results are rural hospitals and clinics can sustain use of expert rules with systemized support structures, change control procedures, and improved integration.

Discussion

The findings form evaluations to-date suggest integrating the CDSR selection within the decisions needed for clinical workflow processes is necessary to eliminate confusion between components of the EHR. The authors, information system analyst and nurse informatics specialist have initiated steps to design CDSR that are used in most settings to be designed into patient-centered clinical workflow processes. Therefore, the inpatient adult clinical workflow process includes eight CDSRs frequently used with the EHR applications because nurses now use those CDSRs in admission and daily care clinical workflow. The new design for patient-centered clinical workflow processes inclusive of CDSRs were used to prepare two subsequent urban hospitals and one rural critical access hospital for their alike EHR implementations. The change in method reduced confusion and improved the process for implementation. The new method required fewer changes to workflow processes after activation. This has led to the development of a model for CDSRs.

Conceptual model for CDSR in workflows

CDSRs were first integrated within EHRs merely 17 years ago for medicine, yet little has been done to provide guidance on designs and tests for clinical workflow processes. CDSR for nursing care were most prevalent, so the conceptual model for expert clinical decision support rules illustrates: the data sources for information patterns; the nursing workflow; and the evoke events, syntax logic, and action responses central to expert rules See Figure 1. Nursing informatics is built on the framework of three sciences (nursing science, information science, and computer science) operating together to produce nursing process results [5, 6] After observing nine hospitals in selecting, designing, implementing and using expert rules with the electronic health records [4], the model includes the steps that integrate the three sciences for the development of nursing expert rules. The model considers fit with factors used by the Patterson, Nguyen, Halloran, and Ash [7] decision support framework.

In the nursing expert decision support rule model, nurses' input and use of data to support decisions in patient care are illustrated. Data within the EHR are used to trigger the

expert rule operation and to evaluate the data to produce a response. The model (Figure 1) displays within the Information Science: Data Use how data are entered, downloaded from devices or transmitted into the EHR from other applications, as well as the required Computer Science: Expert Rule programming steps for "Event Input" and "Event Action," the "Clinical Decision Support Logic," and "Action Response." Patterson's team [7] also identified need for key contextual and design factor components for decision support. Finally, the "Nursing and Health Sciences: Workflow Process" in Figure 1 represents what Patterson's team [7] described as organization, team and individual factors. The "Change Control Procedures" provide an organization's stability and safety to sustain ongoing operation of expert rules. The clinical workflow processes are dependent on the health, medical and nursing evidence used to articulate team and individual roles with clinical workflow processes. Interdisciplinary roles interact with expert rule in initiator roles that triggers the events and receiver roles to decide the action responses. This model explains the nurse's interaction with the data used for the expert rules through the workflow of the nursing process. Another factor that has not been described in previous models but is central to expert rules is the translation of research evidence into practice by integrating knowledge into each of the steps to produce the best results [8].

The model illustrates the decision-making activities that impact the design and use of the expert rule. The evidence from health sciences guides what clinical findings and responses are collected during patient workflow, the patient care orders available for use, and the available patient diagnostic results to use. These three areas supply the clinical data used to evoke/trigger the conditions of the rule as illustrated by "event input." If not driven by the clinical data from the patient, the rule may be driven by the caregiver's actions of opening the record or performing functions in the electronic record as illustrated with "event action." For example, pharmacists use event action method to receive alerts when entering a record to know they are preparing medications for a patient with a latex allergy.

In summary this model is inclusive of the many components with expert rules for nurses to support the nursing process. The data entry process for the ERH impacts the design and accuracy of CDSRs. If the data are valid, the real-time triggers when working directly with the patient and the electronic record can reduce work in a patient encounter. If reliable and valid, expert rules change the nurse's workflow to facilitate the timely use of information.

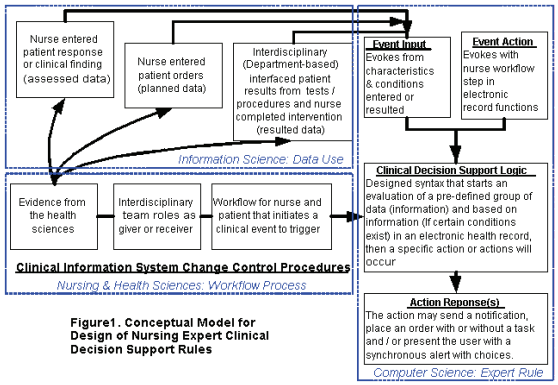

Figure 1 - Conceptual Model for Design of Nursing Expert Clinical Decision Support Rules

Conclusion

Little attention has been given to the clinical workflow processes that involve all the disciplines working directly with the patient. Nurses are the largest group of healthcare professionals that are deciding steps to coordinate and manage multiple patients' care and activities. Nurses rapidly learn and adopt the technology into their nursing workflow processes. Nurses do not hesitate to use the patient data entered or received in electronic health records. Nurses, dieticians, radiology technicians, pharmacists are requesting expert clinical decision support to achieve the four goals to support patient safety, prevent errors, establish evidence in daily practices and improve communication as identified for CDSRs. Nurses coordinate care for many disciplines and the goal to facilitate communication is important. The benefits in efficiencies and cost-effectiveness are unknown and untested with the new technologies that aid nurses' workflow and many other clinicians. This paper begins addressing the workflows for the largest group of healthcare professionals who interact with patients.

Further research is planned to complete the summation evaluation for this implementation in 2006. Other research is planned for testing validity and reliability of evidence-based content design with complex CDRS. This model will be used to test expert rules and guide others in the use of these electronic decision-driving interventions.

About 25% of women give birth by cesarean section

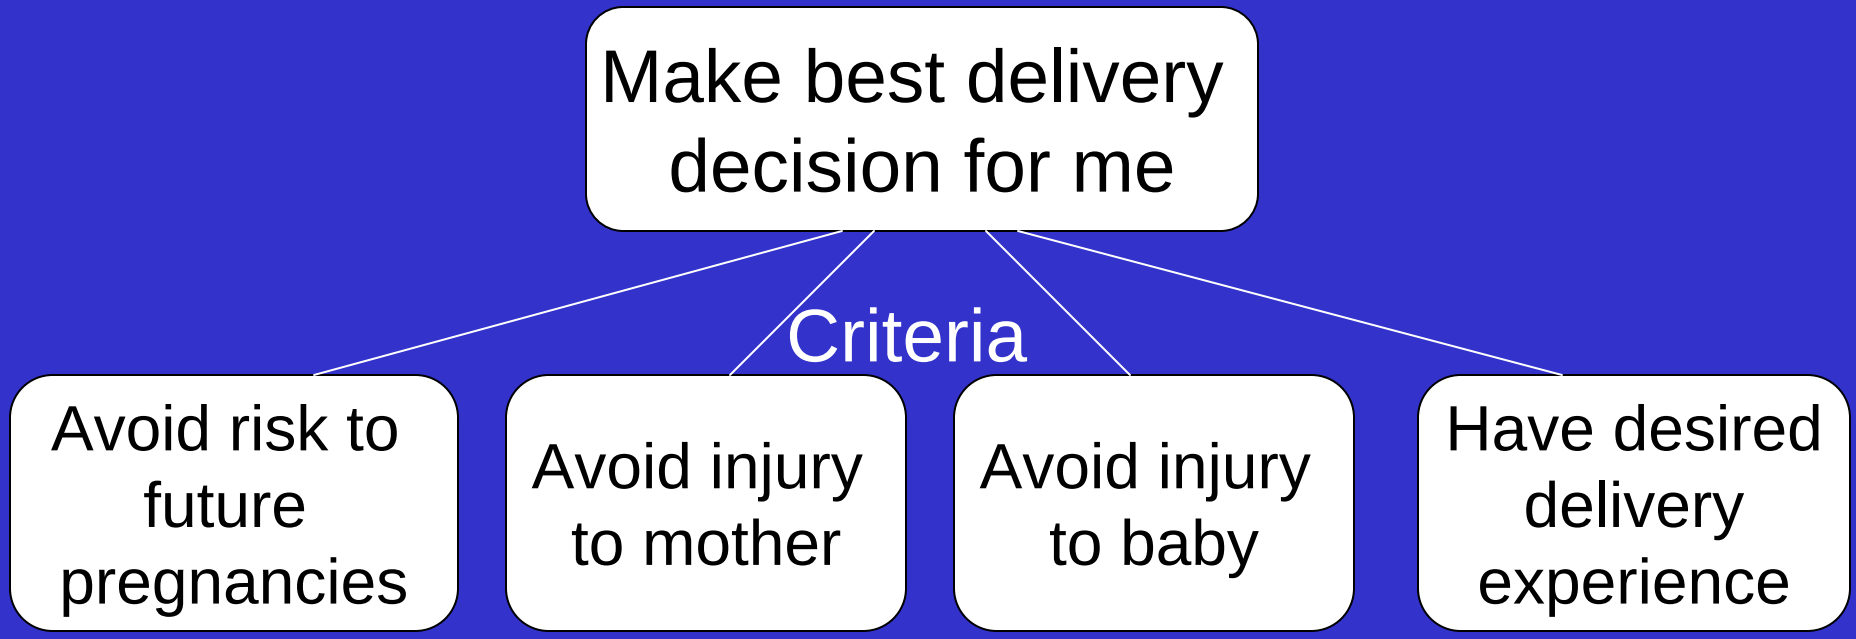
- Australia, 21%
- Canada, 19%
- Denmark, 18%
- Brazil, 35%
- United States, 29%

- Women with a prior cesarean face a difficult decision for their next childbirth as there are risks with either repeat cesarean or a vaginal birth after cesarean.

The study aims were to:

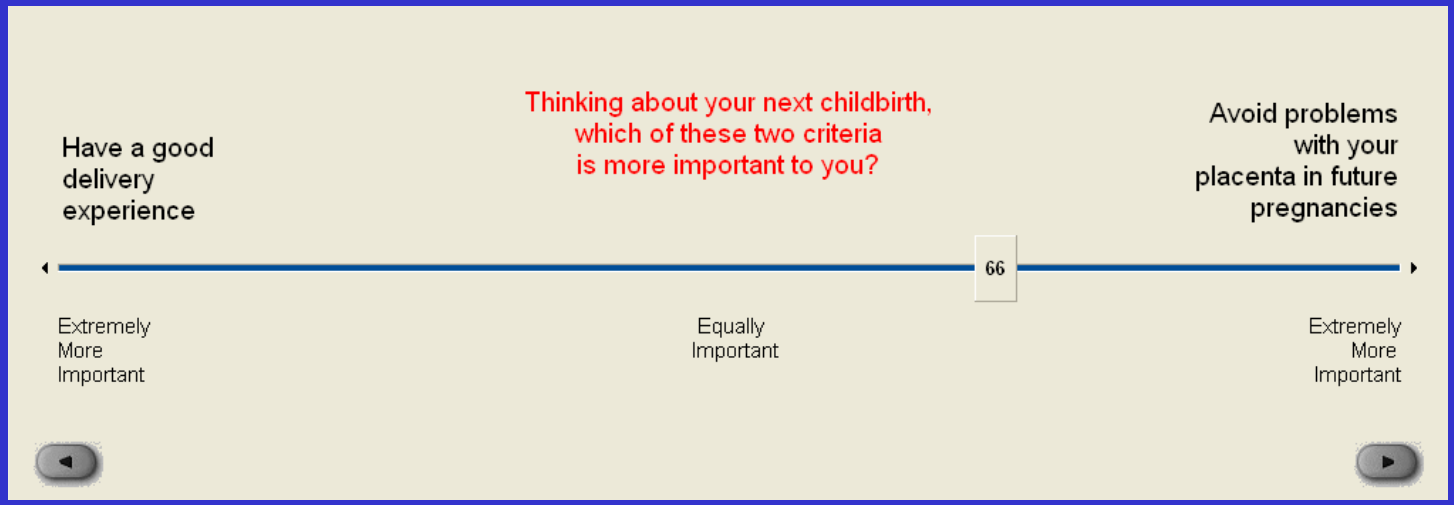
- Create a decision model for childbirth based on medical evidence.
- Create a computerized decision aid based on this model and evaluate its effect on decision making processes in a randomized trial.
- Compare two versions of the decision aid for measuring the patient's inconsistency in assessing preferences: a graphic-numeric scale versus a text-anchored scale.

Decision Model (Top Tier Only)

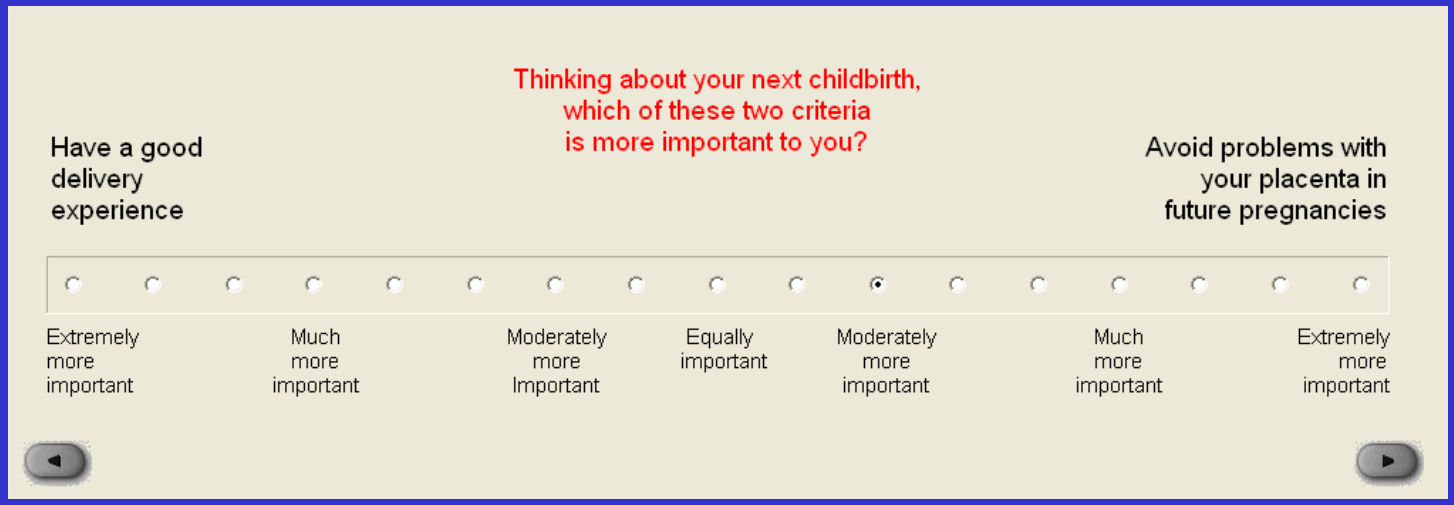


The women made pair-wise comparisons among the criteria to assess their childbirth priorities (or preference weights) in the decision.

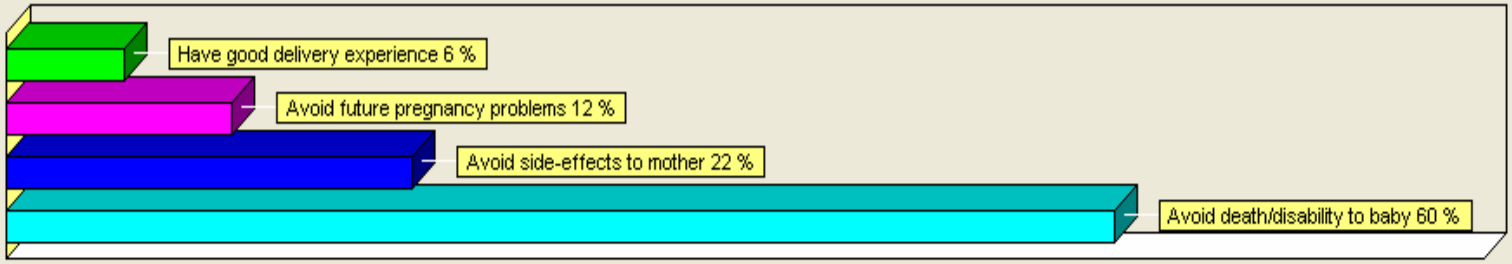
The women were randomized to use one of two formats for assessing childbirth priorities:



OR



Feedback on Childbirth Preferences



Based on your selections so far, it appears that you consider avoiding death or disability to your baby most important.

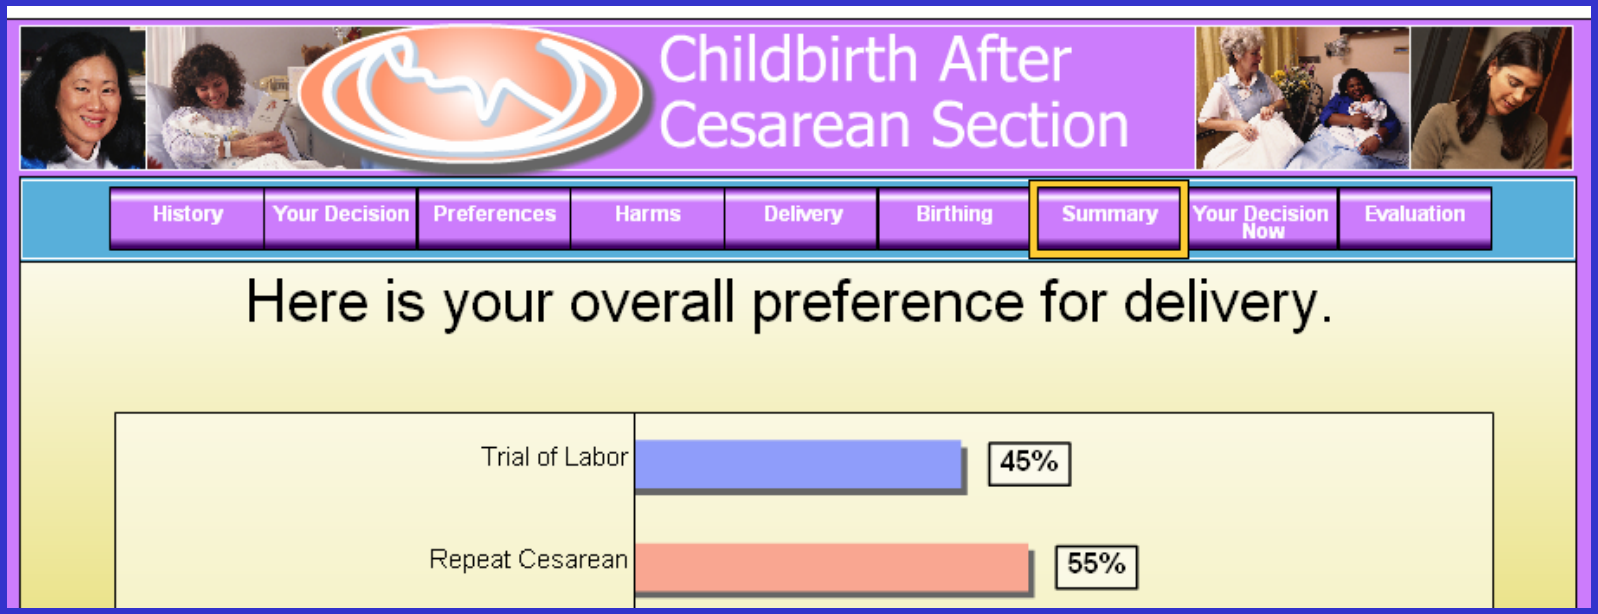
So far you have compared criteria based on your personal feelings. The table below lists the actual chances of some of these criteria. Do you want to adjust your choices now that you have reviewed the actual chances of these events occuring to you or your baby?

Baby	1 to 5 of 1000 babies may die; 2 of 1000 babies may be disabled from delivery.
Future Pregnancies	30 to 60 of 1000 women may have problems with their placentas in future pregnancies.
Side-Effects	70 to 140 of 1000 women may experience numbness by their incision; 2 of 1000 women may need a
	hysterectomy right after delivery; About 500 of 1000 women will leak urine by middle age.

Yes, let me adjust my answers | No, let's proceed

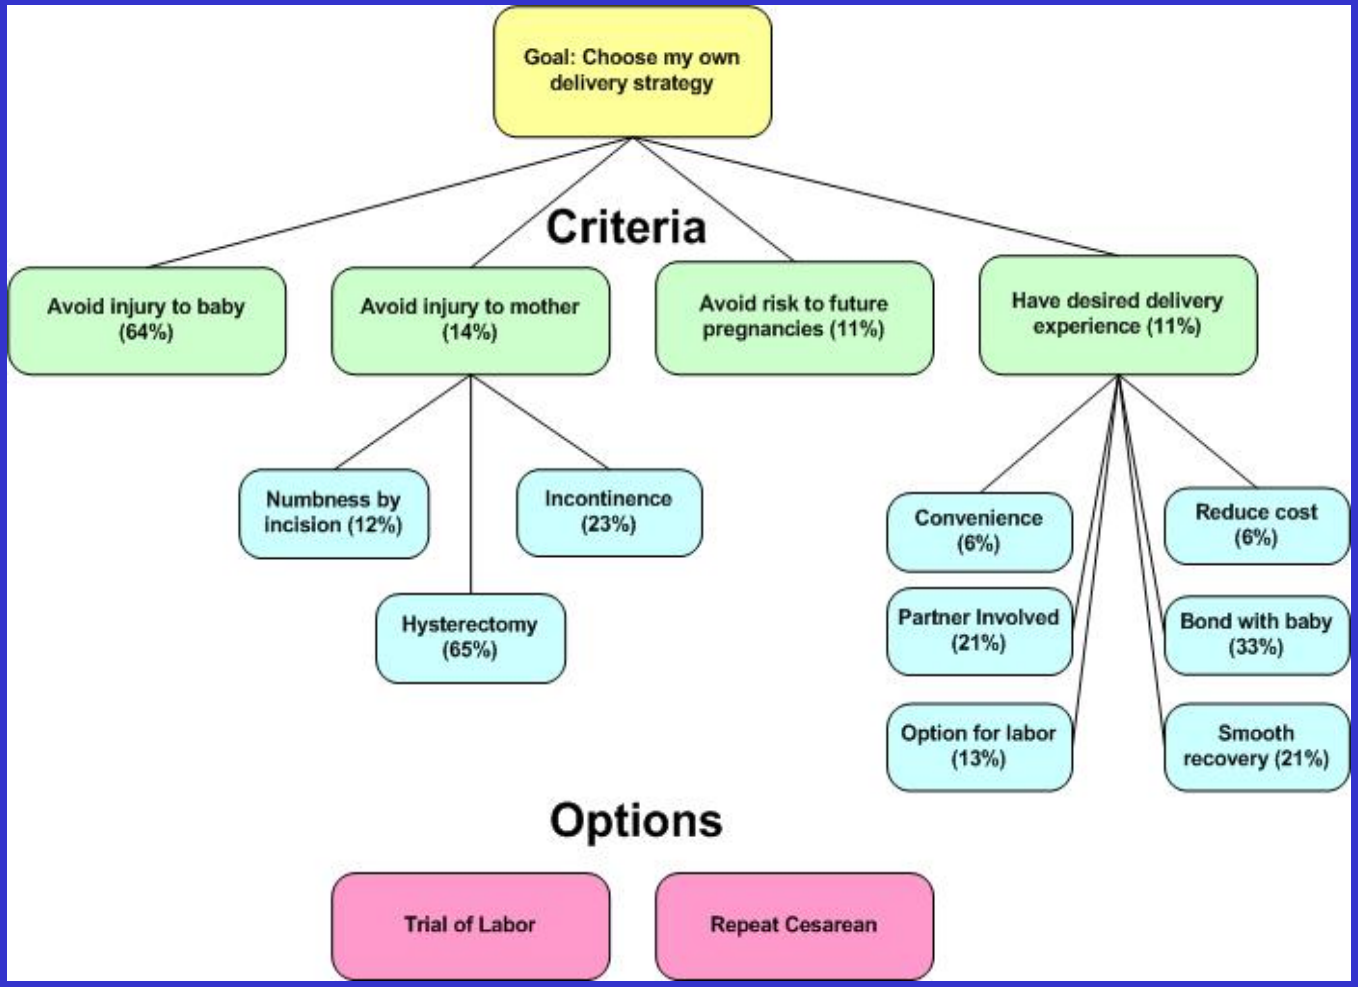
In this case, the woman placed the most importance on avoiding death or disability to her baby (60%) followed by avoiding side-effects to herself (22%).

Summary Feedback



The delivery option with the highest score is most closely matched to your specific childbirth preference weights.

Full Childbirth Decision Model with Average Preference Weights (n=96)



Impact on Decision Making Processes

	Baseline Mean	After Decision Aid Mean	P
Certainty about decision	33.9	33.9	.97
Felt informed about options	33.9	24.2	.00
Had clarity about preferences	31.9	21.6	.00
Felt supported in the decision	33.0	28.3	.00
Overall Decisional Conflict Score	33.1	27.0	.00

*From the Decisional Conflict scale (O'Connor, 1999). Uses five-point Likert scales scored with values ranging from 0.0 (best) to 100.0 (worst). Scores for Overall Decisional Conflict lower than 25 are associated with making decisions; scores exceeding 38 are associated with delaying decisions or feeling unsure.

Patients improved their decision making processes to the same extent regardless of format (graphic-numeric or text-anchored).

Observations of Patients Using Decision aid

- The patients found the decision aid easy to use and to understand.
- The decision aid allowed for “safe” decision making.
- The patients were forced to make trade-offs of factors they may have been “avoiding”.

Conclusions

- Several decision making processes were improved with the decision aid regardless of format.
  - Improved knowledge
  - Improved clarity of preferences
  - Improved support
  - Reduced decisional conflict
- Patients were more consistent in evaluating childbirth preferences when using the graphic-numeric format.
- The decision aid was well received by patients.

Innovative Approach to Childbirth Decision Making

Karen B. Eden PhD,[a] James G. Dolan MD FACP,[b] Deborah Rosenberg BA,[a] Jennifer J. Williams MPA,[a] Megan Palinsky[a] MS, Nancy A. Perrin PhD[a] and Jeanne-Marie Guise MD MPH[a]

Abstract and objective

In the era of limited healthcare resources, patients will increasingly manage their own health including making decisions. We have developed a computerized decision aid to help a woman with a prior cesarean consider decision factors for a future delivery (vaginal vs. repeat cesarean). The objective was to evaluate the impact of the decision aid on the decision making processes in a randomized trial.

Keywords:

decision support techniques, vaginal birth after cesarean, response format, patient preferences, decision aid

Introduction

The childbirth decision aid is built on an underlying, evidence-based,[1] multi-criteria decision model. In using the decision aid the patients determined the importance of decision criteria and considered the two options, trial of labor (vaginal) and repeat cesarean. Because there was uncertainty about which scale format for measuring childbirth preferences was most accurate and user friendly, we compared a graphic-numeric scale to a text-anchored scale in a randomized trial.

Methods

We recruited 96 women who had just had a cesarean delivery from the postnatal unit of a large university hospital. After all patients completed a baseline computerized questionnaire, they were randomized to use either a graphic-numeric scale (n=48) or a text-anchored scale (n=48) for measuring their preferences. The patient made a series of pairwise comparisons to determine the importance of each decision criterion,[2,3] e.g., comparing the importance of "wanting convenience" of a scheduled delivery to "wanting a smooth recovery," using one of two formats (Figures 1, 2).

Figure 1 - Graphic-Numeric Scale

Figure 2 - Text-Anchored Scale

For both interfaces, the women received summary information on their preferences related to having a repeat cesarean or attempting a vaginal delivery. Our analyses focused on changes in the decision making process measures (baseline and after using the decision aid) and the patient's internal inconsistency using the two formats.

Results

The dominant criterion was "Avoiding injury to the baby" (64%) (Figure 3).

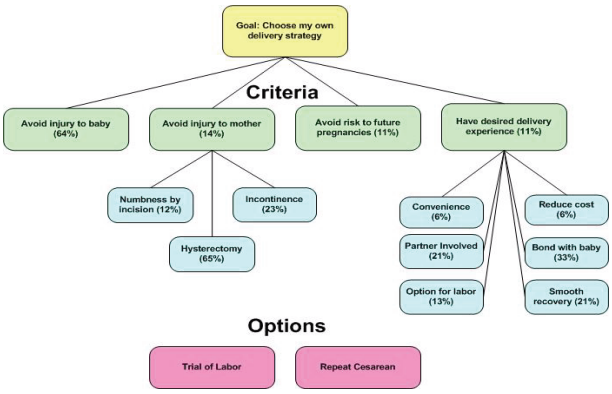

Figure 3 - Decision model and preference weights

Our ANOVA revealed that both groups of patients significantly improved several decision making processes: increased knowledge, $p<0.001$; increased clarity about childbirth values, $p<0.001$; increased sense of support, $p<0.001$; and reduced overall perceived decisional conflict, $p<.001$ to the same extent after using either scale format. The patients were more consistent in evaluating risk using the graphic-numeric format, $p<0.05$.

Conclusion

While both formats improved the decision making processes, patients were more consistent in decision making involving risk when the scale format was graphic-numeric.

Abstract

The use of intentions in computer-based guidelines may help to make them more flexible, easier to adapt to local standards, easier to evaluate and to improve. We see possibilities of using intentions to reduce the number of unnecessary warnings sent to the user. Building guidelines with use of intentions gives the possibility to reduce the complexity of the guideline flowchart and the use of formalized language makes the description of every step of the guideline insightful for all users. In this contribution we present our approach to intention-based guidelines.

Keywords:

guideline, intention, decision support system

Introduction

Currently there is an increasing use of clinical practice guidelines (CPG) in medicine. CPGs improve the quality of healthcare, lower costs of treatments, reduce practice variability or prevent errors [1]. Clinical practice guidelines are mostly paper-based but the trend is to implement them in computer based decision support systems (DSSs).

Even though computer-based CPGs have a lot of advantages, the users face also some problems like for example lack of flexibility that causes unnecessary reminders or warnings. Reduction of practice variability is mentioned as one of the advantages. However, in some cases following the guideline is not the best treatment for specific patients. Sometimes physicians may choose an alternative treatment that is within the spirit of the guideline. Usually guideline systems will warn the physician, although that is not strictly necessary. When the physician gets too many unnecessary warnings he will stop using the system [2].

In the literature also approaches based on intentions hidden behind actions are discussed. Miksch et al. [3] presents intentions as temporal patterns of actions or states, to maintain, achieve, or avoid. Advani et al. [4] describes intentions as formal temporally extended goals and uses them to build a prototype medical critiquing application. In the Trauma AID project, Webber et al. [5] implement intentions as a commitment to use resources to try and achieve a particular goal. We think that the use of intentions may alleviate the problems mentioned above. Because intentions are stated, a guideline system for example can deduce whether alternative treatments are in the spirit of a guideline and if that is the case can postpone warnings.

In our work we made use of the heart failure guideline which in cooperation with the Cardiology department of the Academic Hospital Maastricht was implemented in the GASTON system [6].

We started our work with the formalization of the paper based guideline and local protocol for treating heart failure and implemented it with the help of the GASTON guideline editor. Figure 1 shows a part of the heart failure guideline flowchart. This is the flowchart at the highest level of the guideline where the guideline is entered. The flowchart is built from primitives, components with predefined logic. The top primitives of both charts are eligibility decisions which allow entering the flowchart only if predefined criteria as stated in the primitives are fulfilled. All white rectangular elements are sub-guidelines which represent other flowcharts containing primitives.

While designing the guideline we noticed that flowcharts become very complex and difficult to oversee. In Figure 2 the flowchart of how to administer angiotensin II antagonist is presented. This flowchart is part of a sub-guideline and in some cases can contain sub-guidelines as well. Without detailed knowledge about the implemented guideline it is very difficult for others to follow the logic or to find possible mistakes.

We evaluated our model with a cardiologist and we faced another problem; the model seems to be not flexible enough. Even though it was according to the guideline and the local protocol, in some cases physicians would like to bypass some steps. For example the protocol describes exactly in what dosage steps the drug should be increased while in some cases the physician would like to increase the dose faster. Current systems would send a warning to the user, but a system that uses intentions is accepting the choice of the physician, as it is in the spirit of the guideline.

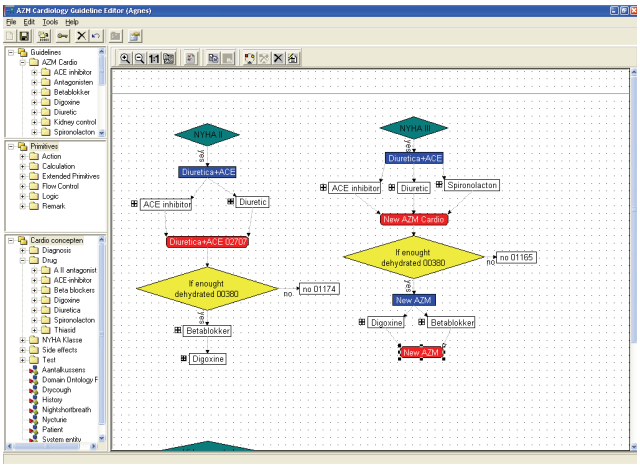

Figure 1 - Flowchart of the heart failure guideline

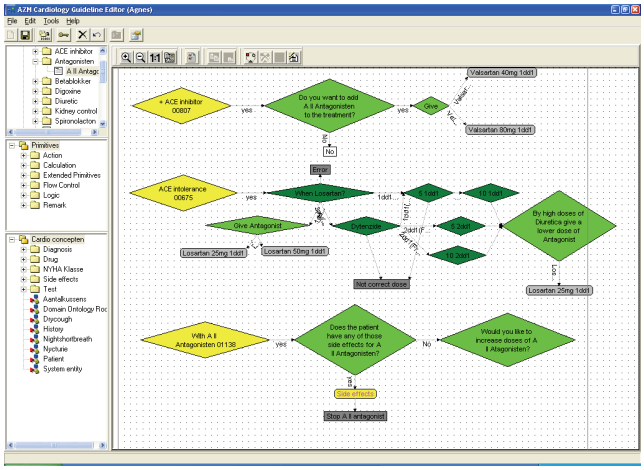

Figure 2 - Complex flowchart of how to administer angiotensin II antagonist

We also used the runtime version of the heart failure protocol for educational purposes. During the course third year medical students were confronted with the guideline and the system. The students had to enter patient data in an EPR that was interfaced with GASTON. After this data entry the students were asked to find out what the paper guideline proposed for treatment. Thereafter they could ask the system for advice. The system provided the patient specific advice very quickly and in this way they could experience the advantage of having system support.

Based on the experience we gained we decided to improve our system. The flowchart should be less complex, so that the maintenance of the flowchart will be relatively easy. Also users should be able to follow the logic of the flowchart and must be able to understand the rationale of the different steps. Also the system should be able to accept, at least initially, alternative actions that fulfill the same purpose. We therefore investigated the adequateness of the use of intentions, as already introduced in the ASBRU project. We want to show that use of intentions in building computer based guidelines can make them more flexible, insightful and reduce the number of unnecessary warnings.

Definitions

Before specifying intentions in more detail, we define some terms we use in association with intentions.

Intention. An intention is a determination to act in a certain way or to do a certain thing; is a high level goal which is abstract and not measurable.

Goal. A goal is an object of one's efforts; something to reach; is situation/state dependent; is concrete and measurable.

Plan. A plan is a proposed or intended method of getting from one set of circumstances to another. They are often used to move from the present situation, towards the achievement of one or more goals. A plan contains a series of actions to be carried out.

Action. An action is a work or an activity in a specific area or field.

Purpose. A purpose is an anticipated outcome that is intended or that guides planned actions.

System

Our system with problem solving methods (psms) related to intentions is being implemented as an addition to the GASTON framework that facilitates the development of clinical guideline application tasks. It consists of three parts: a guideline editor, where intention based guidelines are created; a knowledge base, where ontologies about medical knowledge and intentions are stored; and an execution engine, that during runtime reads data entered into the Electronic Patient Record (EPR) and uses these data to determine, on the basis of guideline information, the action that is the most appropriate for the current patient.

The physician communicates with the system via an EPR. The EPR has bidirectional communication with the execution engine. Further, the execution engine exchanges data with the guideline base and the knowledge base as shown in Figure 3.

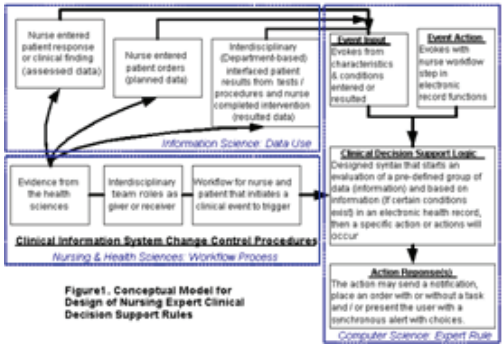

Figure 3 - General architecture of the system

The guideline is built in our system as a flowchart of intention psms. The intention psms can be carried out in parallel or in sequence. When it decomposes into other intention psms it is an intention psm on a higher level. When it does not decompose into other intention psms then it contains a flowchart of actions that fulfill the goal of the intention. The intention on a higher level is fulfilled only when the sequence of the intentions on the lower level is satisfied.

In the intention psm there is a possibility to write an explanation of the step or to make a link to the paper-based guideline where users can obtain more information about the current step of the guideline. Also the structure of the intention psm allows the designer to express if this intention psm decomposes into other intention psms, 'has sub-intentions' is on, or decomposes into a flowchart of actions, 'has sub-intentions' is off. If 'has sub-intentions' is on it means that success of fulfilling the current intention psm depends on the status of intention psms on a lower level. If 'has sub-intentions' is off it means that to fulfill this intention psm some actions have to be carried out. Further, the contents of the intention psm have to be defined, which are pre-conditions, abort conditions, and goal. The inside of the intention psm is shown in Figure 4.

During the design phase all parameters of every intention psm are defined. In the preconditions part all information needed to decide whether this intention psm may be entered or not are described. Abort conditions contain the description of situations when the execution of this intention psm has to be cancelled. The next part, goal, is a measurable part of the psm. The goal might be set in two ways: by the physician, based on the patient condition (e.g. blood pressure) or by the guideline designer, based on general medical knowledge (e.g. calcium level); also it might contain time constraints.

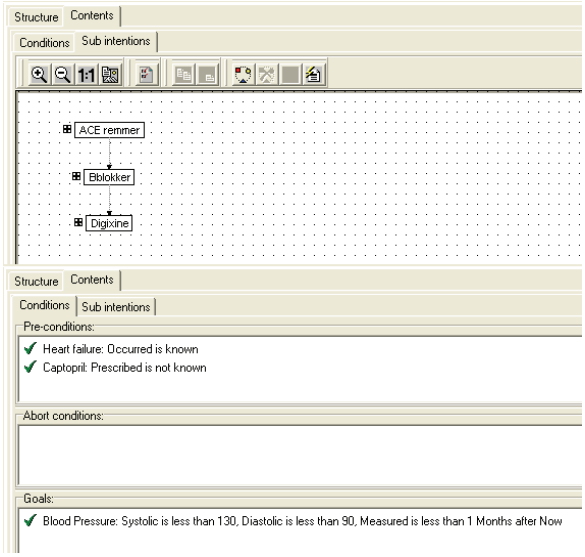

Figure 4 - An example of an intention problem solving method

Mechanism to reason with intentions

Information about the intention and the goal is used during the runtime phase. The execution engine uses that information together with data stored in the EPR and purposes of actions stored in ontology to provide flexible and adequate support to the user.

Before we explain how the mechanism of reasoning with intentions works we would like to introduce more information about the knowledge base (ontology). The ontology is a database where medical knowledge is stored. It is fully compatible with the Gaston system. All entries of the knowledge base have predefined properties. Dependent on the sort of the class of the data, we define mappings, attributes and purpose. For example, between attributes of the drug class we can distinguish prescribed, dose, or frequency; and between attributes of the diagnosis class, occurred or stopdate. Figure 5 shows properties of the drug class.

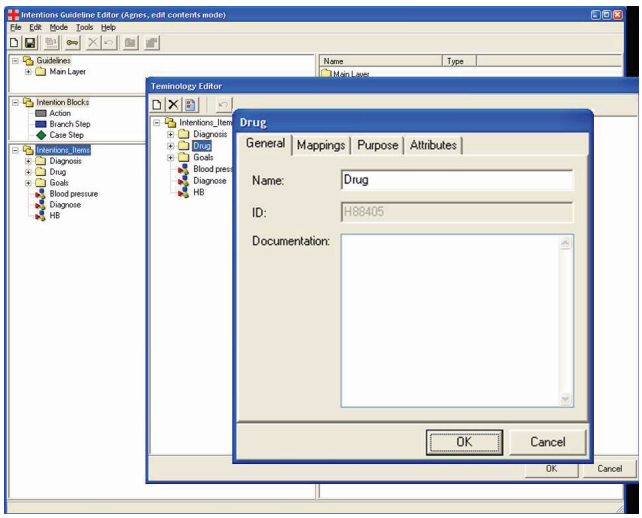

Figure 5 - Properties of the Drug class stored in ontology editor

All data in the knowledge base has a predefined purpose. Both intentions and purposes are standardized so that the system can see whether an alternative action is within the spirit of the guideline (purposes are equal).

The mechanism to reason with intentions and purposes is executed during runtime and compares those two pieces of information. If the action taken by the physician does not match the action stored in the guideline our system compares the purpose of the action stored in the EPR with the intention of the preferred action as mentioned in the guideline. No warning will be sent to the user if his decisions are made in the spirit of the guideline.

Real life data test

At the current stage of the project we concentrate on testing the system with real life patient data. In order to be able to test the guideline system we developed a simple EPR which cooperates with GASTON. Based on the results from this trial we want to see how the advice given by our system compares with decisions made by the physician; how flexible is system in giving advices when decisions are not exactly the ones mentioned in the guideline, but when they are still within its spirit.

The results of those experiments we would like to present during the conference.

Discussion

In this project we concentrate our efforts on extending existing software to obtain computer based guidelines that are easier to implement (reduced complexity), to evaluate, and are more flexible in processing received data. In this discussion we would like to point out the biggest advantages of our software.

Building guidelines with use of intention problem solving methods gives the possibility to reduce the complexity of the guideline flowchart. Figure 6 shows two levels of the heart failure guideline. The background window contains sub-intentions while the front window shows the inside of one of the sub-intentions.

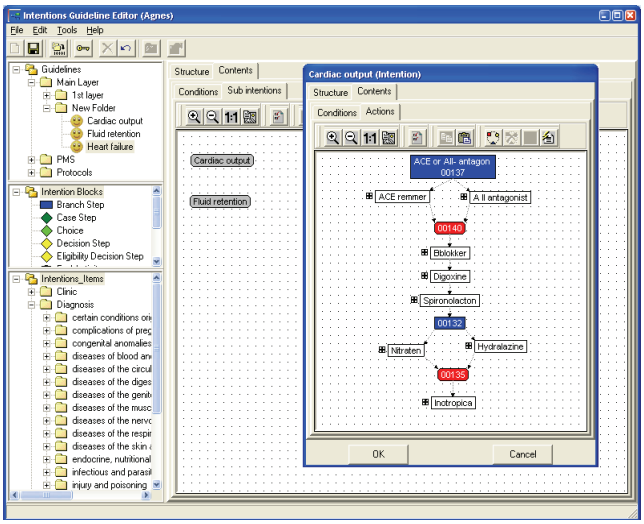

Figure 6 - A part of the heart failure designed with the use of intention psms

The user describes the preconditions, intentions and goals of every step by use of a formalized language. As Patel et al. [7] pointed out in her work, translating paper based guidelines into computer based ones is not easy. Already in the design phase we can make a lot of mistakes. Guidelines are developed by experts (e.g. physician) like also by non experts (e.g. computer scientist) and they may interpret information differently. Developers interpret the guidelines based on their knowledge, so different level of experience influence the way guideline is translated. When a computer scientist analyses the protocol he concentrates on surface information when given a text description of the clinical problem, while a physician includes the underlying clinical model.

The use of an ontology editor where medical knowledge with its attributes is stored has a number of advantages. By use of time-related concepts (e.g. prescribed, stopdate) it is possible for our software, based on date stored in the EPR, to follow the guideline and give relevant advice if needed. Another property, purpose, is used in the runtime and gives possibility to deliver flexible advice within the spirit of the guideline. Namely, the action stored in the EPR is compared with the one mentioned in the guideline. Even if the action taken is not the same as an action stored in the guideline, it is possible that the user will not receive any warnings. The purpose of the action taken by the user is verified then in the ontology and compared with the intention of the guideline. If user prescriptions are within the

spirit of the guideline, the system is accepting the choice the user made.

By use of intentions, we built a new kind of guideline flowcharts where the priority is set on fulfilling the goal than on following the guideline step by step.

The evaluation of our work will give us an answer to our hypothesis; is the use of intentions in building computer based guidelines making them more flexible, insightful and reduces the number of unnecessary warnings? In this study we have shown that the inclusion of intentions into GASTON is possible and intention based guidelines can be constructed.

Development of Standardized Technique using EHR to Describe Clinical Processes

Nakao Konihsi[a], Hidehiko Tsukuma[b], Kiyomu Ishikawa[b]

[a] *Department of Pediatrics, Hiroshima University, Japan*
[b] *Department of Informatics, Hitoshima University Hospital, Japan*

Abstract

This study aimed at the development of a standardized technique, to describe the clinical care process comparison using Electronic Health Record. We divided the clinical process into three parts; input, process, and output. In the care process, the flow chart was automatically made from EHR. There were two methods of record of the process. Event type and continuous type. The event type is a treatment act done single-engined. The continuation type is treatment continuously done. It was thought that this technique was suitable to describe the clinical process.

Keywords:

electrical health record, care process, flow chart

Introduction

It is important to compare content of the diagnosis and treatment process between facilities for the purpose of quality improvement of the medical treatment. For this, the clinical pathway and the clinical indicator have been used. The clinical pathway is prospective approach. Treatment route is first designed, and the one to discuss the result. The other clinical indicator is retrospective approach, and the method of examining the factor that influences in the result.

The method of comparing the diagnosis and treatment processes using EHR (Electronic Health Record) has not been standardized yet. Then, this study aimed at the development of a standardized technique, to describe the clinical care process comparison using EHR.

Methods

We divided the clinical process into input, process, and output. The state of the patient before the treatment was described in input. The state of the patient as the result of the treatment process were described in output. Flow chart, by the prescribed form, was made automatically from clinical information accumulated in EHR. The record of the patient of neonatal care unit was used.

Result

There were two methods of record of the process. Event type and continuous type. The event type is a treatment act done single-engined, such as endotracheal intubation etc. The continuation type is treatment continuously done, such as respirator and fluid infusion management etc.

Discussion

It was thought that this technique was suitable to describe the clinical process. A quantitative evaluation of the event type process was easy. A qualitative evaluation in the event type process became a problem. It was guessed that the continuation type influenced hospital days.

Nakao Konishi (a), Hidehiko Tsukuma (b), Kiyomu Ishikawa (b) , Norikazu Iwata (b), Takeshi Tanaka (b)

Background

- We did the computerization of patient information in our hospital.
- Patient information was recorded in an individual data base.
- The standard method to retrieve by skewering two or more patients has not been established yet.
- We aim at operating analysis of clinical procedure.
- We aim at evaluation of the validity of care process.

Objectives

- To establish the methodology of clinical process analysis.
- To develop prototype application that use the methodology.
- To analyze the patient data by using the prototype application.
- To evaluate the methodology by assessment of analytical result.

Method 1: Definition of various events in clinical process

- INPUT: condition of the patient on admission.
- PROCEDURE: therapeutic intervention
- OUTPUT: condition of the patient at discharge

QuickTimeý Ç²
TIFFÅiLZWÅj êLí£ÉvĚçÉOÉâÉÄ
Ç™Ç±ÇÃÉsÉNÉ`ÉÉÇ¾å©ÇÈÇžÇ½Ç…ÇÕïKóvÇ-Ç⃞ÅB

Method 2: Type of Therapeutic Intervention

- Event type intervention
  - Endotracheal intubation, one shot injection, etc
- Continuation type intervention
  - Use of incubator, oral intake, tube feeding , etc.

Method 3: Treatment intervention analysis algorithm

- Patients are sampled according to the condition on admission.
- Treatment intervention data of the sampled patients are extracted from electrical flow chart.
- Various analyses are tried to each intervention.
- Analytical results are compared with the output.

Result 1: Development of prototype application

QuickTimeý Ç²
TIFFÅiLZWÅj êLíf£ÉvÉçÉOÉâÉÄ
Ç™Ç±ÇÃÉsÉNÉ`ÉÉÇ¾å©ÇÈÇžÇ½Ç…ÇÕïKóvÇ-ÇÍÅB

Result 2: Difference of analysis method according to type of the record.

- Event type intervention.
  - It is possible to evaluate it quantitatively by the frequency.
  - Other table that describe quality of the record is required for a qualitative evaluation.
- Continuation type intervention (string data)
  - When the intervention is described on one record, the beginning day of the procedure, the end day of it, the continuation days are appreciable.
- Continuation type intervention (numerical value)
  - The beginning day of the intervention, the end day of it, the continuation days of it are appreciable.
  - The maximum value, minimum value, average value are appreciable.

Result 3: Analysis sample

QuickTimeý Ç²
TIFFÅiâ¨èkÇ»ÇµÃj êLí£ÉvÉçÉOÉâÉÄ
Ç™Ç±ÇÃÉsÉNÉ`ÉÉÇ¾å©ÇÈÇžÇ½Ç…ÇÖïKóvÇ-Ç¶ÅB

Discussion

- The study was retrospective study that had examined the analysis method based on an electronic record.
- In the event type intervention, a qualitative evaluation was difficult though a quantitative evaluation was easy.
- It is necessary to prepare the relation-table for a qualitative evaluation separately.
- In the continuation type intervention, it is necessary to structurize the accumulated database.
- If a related item is not described in the same record, the table that describes the relation of another record is necessary.

Conclusions

- The methodology of operating analysis of the clinical process was studied using the electronic hospital record.
- There were variety of operating analysis of clinical procedure by way of the various patient's extraction method.
- The importance of the construction of the structurized patient information data base was suggested.

Abstract

In conventional clinical studies, costs of data quality control and the burden of paper case report form collection tends to rise. We developed a data capture system for cancer which directly accumulates clinical study data from electronic health records. Cost reduction and quality improvement of clinical studies are expected from this system.

Keywords:

electronic data capture, electronic health records, cancer, outcomes research, clinical study, data warehouse

Introduction

In conventional clinical studies, costs of data quality control and the burden of paper case report form collection tends to rise, because of making and filling out a paper case report form based on each clinical study protocol.
The secondary use of electronic health records is expected for cost reduction and quality improvement of clinical studies, but current electronic health record systems are structured in which various clinical information is stored in mixture. Such information is not usable for a clinical study.

Purpose

The purpose of this study is to develop a data capture system for clinical studies to accumulate necessary information from electronic health records, and to evaluate the prognosis, prognostic factors, outcomes of treatment and safety of that.

Methods

In Outpatient Oncology Unit, Kyoto University Hospital, we developed a data capture system which includes a cancer clinical database system and a data warehouse for clinical studies.

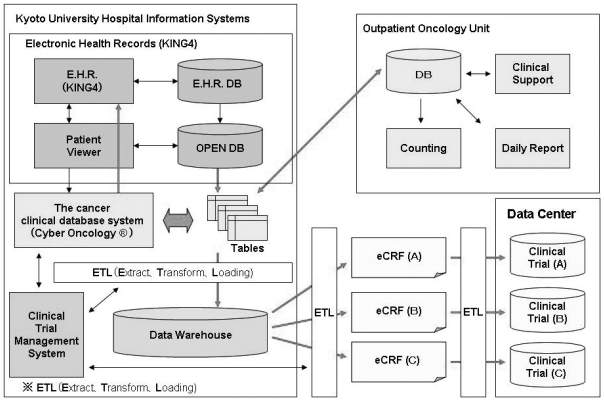

Figure 1 - Architecture of the system

The cancer clinical database system has structure which can file the results in the right data type, as well as high-level support functions to everyday clinical practice for cancer and on-line counting functions of stored data.

Data like laboratory values or patient characteristics are transferred from electronic health records directly and stored in the system. Data input into the system like adverse effects are transferred to electronic health records via copy and paste by the medical staff.

The stored information in this system is regularly transferred to the data warehouse, and become anonymity at the same time. Accumulated data in the data warehouse is used for analysis of adverse effect, interaction of drugs and outcome evaluation.

Data of individual clinical studies are extracted from the data warehouse from each protocol, converted into an electronic case report form, and forwarded to researchers to collect additional data. The researchers add necessary data to the electronic case report forms, transfer to a data-center, and databases for clinical studies are made there.

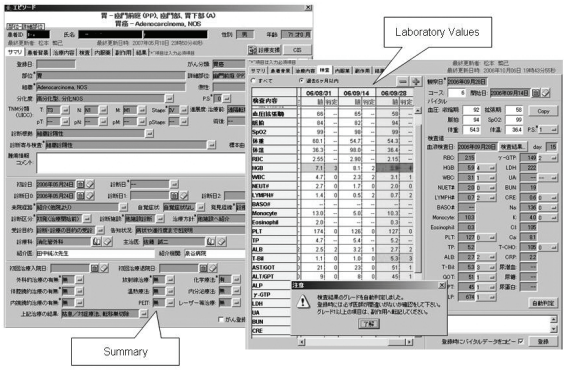

Figure 2 - Screen sample (summary, laboratory values)

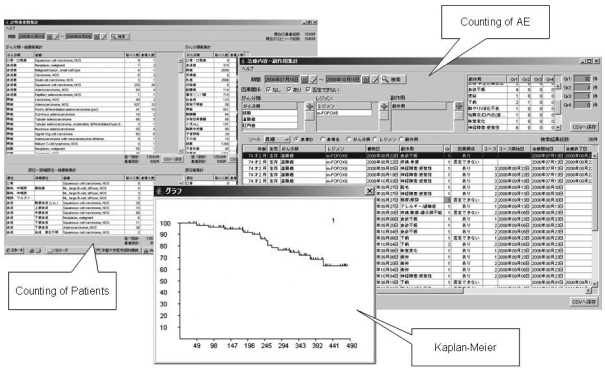

Figure 3 - Screen sample (on-line data analysis)

Results and conclusion

The system which directly accumulates clinical study data from electronic health records has developed. We are now evaluating the system.

We have planned to promote the cancer clinical database system in other institutions and collect data to the data warehouse to establish large-scale database for clinical studies of cancer in Japan.

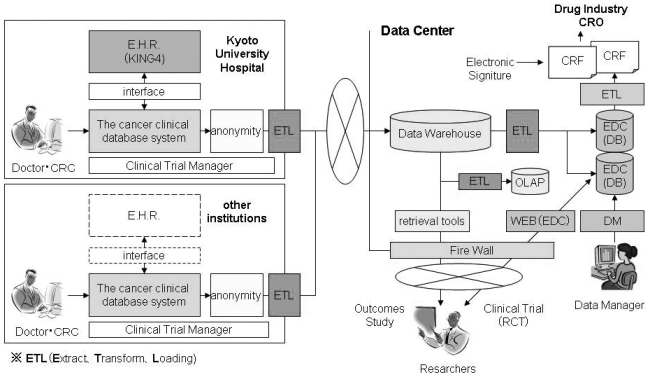

Figure 4 - Prospect

Cost reduction and quality improvement of clinical studies are expected from this system.

The Application of a Clinical Data Warehouse to the Assessment of Drug-Warfarin Interactions

Qiyan Zhang[a*], Yasushi Matusmura[a], Hiroshi Takeda[a]

[a] *Department of Medical Informatics, Graduated School of Medicine, Osaka University*

Abstract and objective

Studies on drug-warfarin interactions in human subjects were typically based on single case reports or extrapolated in healthy volunteers. In this study, we proposed a method to apply an institutional clinical data warehouse (CDW) to address this issue in a real-world setting. A case-control study was conducted by using the CDW in Osaka University Hospital from 2000/01/01/-2005/12/31. We randomly selected the steady-state outpatients who were under warfarin mono-therapy as Group A and those who were on the pre-existing warfarin therapy but with only the added medication X as Group B. The difference between the PT-INR values on one-month interval in Group A and those before and after taking medication X for one month in Group B was compared. The warfarin-Allopurinol interaction was illustrated as one example. We identified 25 cases in Group A and 15 cases in Group B respectively. The difference of the PT-INR values on one-month interval between the two groups was not significant (P=0.394,Mann-Whitney test), indicating that no warfarin-Allopurinol interaction was present. This method can be used as an alternative approach to assess drug-warfarin interactions.

Keywords:

clinical data warehouse, Warfarin, drug interaction, PT-INR

Introduction

Warfarin is an effective and commonly used oral anticoagulant agent for the treatment and prevention of thromboembolism in a variety of conditions. The risk of major complication- hemorrhage may be increased when concomitant drug therapy is required. Previous studies on drug-warfarin interactions in human subjects were based on single case reports or extrapolated in healthy volunteers. Clinicians need to balance the therapeutic benefits with the bleeding risk through monitoring patient's PT-INR values during warfarin therapy. In this study, we proposed a method to apply an institutional clinical data warehouse (CDW) in a real-world setting to reduce certain practical and ethical problems faced by studies drawn from healthy volunteers and aimed to provide an alternative approach to assess drug-warfarin interactions.

Methods

The CDW in Osaka University Hospital was built in 1995 as a subject-oriented database. The outpatient's prescription data and PT-INR results were picked up from 2000/1/1/-2005/12/31 through Business Objects 6.5.1. Data were processed via Microsoft Access 2003 and statistic analyses were performed via SPSS 11.0 Japanese Version for Windows. A case-control study was conducted. The steady-state outpatients who took warfarin consecutively for at least one month were considered as the eligible study subjects. We randomly selected those who were under warfarin mono-therapy as Group A and those who were on the pre-existing warfarin therapy but with only the added medication X as Group B. Then we compared the difference between the PT-INR values with one-month interval in Group A and those before and after taking medication X for one month in Group B. The warfarin-Allopurinol interaction was demonstrated as one example.

Results

For the chosen example, we identified 25 cases in Group A and 15 cases in Group B respectively. The difference of the PT-INR values on one-month interval between the two groups was not statistically significant (P=0.394, Mann-Whitney test), indicating that no warfarin-Allopurinol interaction was present.

A Web-based Service for the Management of Data Quality

Jürgen Stausberg, Reinhard Mauer, Michael Nonnemacher

Institute for Medical Informatics, Biometry and Epidemiology, University Duisburg-Essen, Germany

Abstract

We developed a guideline for the adaptive management of data quality in registers and cohort studies. The guideline is to focus on the adaptation of source data verification (SDV) and feedback to the actual level of data quality observed. 24 indicators for data quality are combined into one ordinal quality score, each with its individual relative weight. Sample sizes for source data verification are calculated so that the sample size will be larger for sites with bad data quality and smaller for those with good quality. The observed data quality is reported back to each site, optionally with open or anonymous benchmark data of the other sites. The recommendations as well as the workflow model for its use were implemented in a three-tier-architecture as web-based service. Through a web-browser or by upload of XML-files the input data are recorded. After execution of the guideline the recommendations are available in XML-format, as PDF-files or through the web-interface. Data quality becomes a crucial issue in the fast growing use of health-related data. The guideline and its implementation as web-based service is a major step towards a systematic and evidence-based approach covering respective challenges in data management.

Keywords:

data quality, feedback, quality indicator, source data verification, web-based service

Introduction

It is time to replace a skeptical position to mass data in health care with a systematical approach for the control of data quality. That should include the measurement of data quality, the interpretation of data quality parameters, and the linkage between data quality and data management procedures. As member of a meta-organization for networked medical research (called in German "Telematikplattform für Medizinische Forschungsnetze e.V.", cf. http://www.tmf-ev.de/) we conducted a project dealing with data management of registers and cohort studies.

Focusing on requirements of research databases we developed a guideline for an adaptive management of data quality and implemented a web-based service for a computer mediated application of its recommendations. The recommendations took also into account studies, concepts, and experiences from routine care, clinical studies, and other industries. To some extend the results are therefore applicable to non-research databases.

Adaptive management of data quality

Based on a detailed literature review and expert interviews the guideline identifies 24 quality indicators in the categories plausibility, organization, and trueness. A threshold differentiating between normal and problematic rates and a relative weight is given for each indicator.

A score of data quality is calculated in the following way. The rate measured by a project is compared with the threshold, either with its raw value or with a confidence interval. The weights of indicators with normal results are summed up. The sum is divided by the optimal sum of weights of the included indicators and multiplied with 100. That gives a score between 0 and 100 which is independent from the number of included (i.e. for the project at hand calculable) indicators. We defined 5 grades of data quality: 0 to less 20 points - very poor, 20 to less 40 points - poor, 40 to less 60 points - moderate, 60 to less 80 points - good, and 80 to 100 points - very good.

Within the scope of the guideline, the data quality grade is used twofold. First it is used to adapt source data verification, i.e. the comparison of registered data with source data as the paper-based patient record, to the data quality in such a manner, that resources are concentrated to sites with worse data quality. Secondly, the information on data quality is included in regular reports. Both actions are regarded as operations for quality control to reach a predefined level of data quality.

Source data verification (SDV)

SDV is an established procedure for the assessment of completeness and correctness of data quality. Its application could also raise data quality through the interaction with the responsible sites. The guideline offers recommendations for the volume (number of observation units e. g. patients), depth (number of data items), and frequency of SDV in a given interval. It takes into account the data quality grade, rates of the two indicators "agreement with source data referring to data items" and "agreement with source data referring to observation units" from the last analysis period, a precision parameter and the estimated total number of data items and observation units in the next period.

Sample size calculation of the volume is based on an estimation of the number of observation units with at least one wrong item. We assume a binomial distribution which is approximated by a normal distribution. The adaptation to data quality is controlled by the absolute value of the confidence interval's half width**,** which is smaller in case of poor data quality and larger in case of good data quality. We propose 0.01 for grade very poor, and an increment of 0.01 until 0.05 for grade very good. Sample size calculation of the depth is done identically. Frequency is calculated by spreading the necessary number of visits for the next analysis period regularly.

Feedback

Feedback improves data quality. In the guideline's recommendations three feedback strategies are offered: for a specific site no further data included, for a specific site with additional anonymous benchmark data for other sites, and for a specific site with additional open benchmark data of other sites.

The feedback consists of reports with information on data quality score, grade, and results of each included quality indicator with thresholds, weight, and rate. The reports are combined for the central data management as well as divided for each participating site.

Application

From the beginning it was planned to offer the guideline paper-based as well as mediated through a computer application. In consequence, the role of the guideline within data management was modeled using the Unified Modeling Language (UML) even in the paper-based form. UML was then chosen as methodology for software design as well. We complemented the activity diagrams with class and sequence diagrams. In addition to the requirements formulated in the guideline, the application should offer multi-subscriber capability, a history of recommendations, an interactive web-interface, input-/output-interfaces for data in eXtensible Markup Language (XML) and an output in Portable Document Format (PDF).

For the WWW-based service a three-tier architecture was chosen making special use of the Model-View-Controller (MVC) design pattern. On the data-layer (Model) the data are stored in XML-files. XML-files exist for the following data-subsets: general information on the project (input), numerators and denominator of each quality indicator (input), constants used for statistical calculations (input), summary covering quality indicators etc. (output), and results of the sample size calculation (output).

According to the web-based approach a standard WWW-Bowser is sufficient as user interface (View). The link between the user interface and the data is realized by Java Server Faces, a special extension of Java Server Pages enabling a simple definition of dynamic HTML-pages (Controller). The use of a secure protocol (HTTPS) insures the confidentiality of the transmitted data.

Further work

Focusing on research data bases as registers and cohort studies, the implemented guideline represents the utmost evidence in the field of management of data quality. Many thoughts will be relevant for data bases in routine health care as electronic health records as well. The delivery of the guideline through a web-based service offers a mean to overcome the obstacle of guideline implementation in daily practice. But some tasks to solve remain for the future.

Workload is still needed to apply the guideline, even by using the web-based service. In particular, the determination of numerator and denominator of each quality indicator by the central data management is labor-intensive. A generic interface to research data bases in medicine would be desirable, but was outside the attainable objectives of our project. Some years will pass until interface standards are available covering the details necessary for the determination of quality indicators.

Still needed is an empirical evaluation of the guideline's impact on data quality. We are in preparation of a randomized, multicentric and open trial with about 120 sites from a couple of projects. In this trial we will have three arms, one performing a full SDV, one following the guidelines recommendations using the web-based service, and one without any SDV. The guidelines itself could not be blinded, because it was published by the TMF.

Acknowledgments

The work presented here is a project for cooperative medical research on behalf of the "Telematikplattform für Medizinische Forschungsnetze e.V." and was funded by the Federal Ministry of Education and Research. We thank our project partners from the Competence Networks on Congenital Heart Defects, Dementia, HIV/AIDS, and Parkinson's disease for cooperation.

[2]Division of Biomedical Informatics, Mayo Clinic, Rochester, Minnesota

Abstract

We describe a high throughput, real-time modularized text analysis system integrated into a production medical information retrieval system at the Mayo Clinic. The system identifies clinically relevant entities and concepts from unstructured medical reports, e.g. drugs, diagnosis and concepts, as defined in RxNorm, SNOMED CT and UMLS. To achieve the desired performance, the text analysis components were either developed for or adapted to the clinical domain. In this paper, we discuss one of several required innovations, disambiguation of mapped concepts with respect to an ontology. The methodology for the identification of a set of problem ambiguities and the creation of a manually sense-tagged data set for each of them is presented. Based on this data set, methods for word sense disambiguation for clinical notes were developed. In this paper, we report one set of F-scores (range is 0.47-0.98) which are substantially above the majority sense baseline.

Keywords:

natural language processing, word sense disambiguation, UMLS, UIMA

Introduction

With recent advances in Natural Language Processing (NLP) technology, the biomedical community has begun processing large amounts of textual unstructured data for a number of tasks. The MedTAS system developed by IBM is a modular text analysis and search system for the Life Sciences domain based on IBM's Unstructured Information Management Architecture (UIMA) ([1], [2]), http://incubator.apache.org/uima]. A source of errors in any NLP-based system is the mapping of a word token to multiple concepts ([3], [4], [5]). For example, "ms" maps to 10 UMLS concepts in the test set we created. Concept-based indexing and retrieval involves the unique mapping to a single representation. This is the problem of word sense disambiguation (WSD). In this paper, we present the design and architecture of a large-scale, highly modularized, real-time-enabled text analysis system and the development of its WSD component..

Methods

Figure 1 shows the architecture for bulk and real-time processing of clinical documents for subsequent information retrieval (IR), in production since 2005.

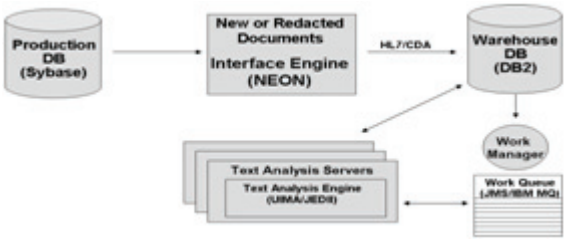

Figure 1 - Text analysis process flow

The UIMA-based text analysis system is a sequence of "annotators", each performing specific tasks. The annotators are native UIMA annotators, GATE-based and Open Source modules, and are either finite state automata or trained on hand-annotated corpora with a variety of machine learning (ML) algorithms. In addition to executing traditional NLP tasks on un-grammatical medical text, the annotators identify and extract named entities such as drugs, diagnosis and sign and symptoms allowing for concept-based indexing and retrieval. To increase retrieval results precision, multi-sense terms are to be uniquely mapped to a concept. Although there is a publicly-available WSD corpus derived from MedLine abstracts and manually sense-tagged with UMLS concepts ([5]), no comparable corpus for clinical ambiguities exists. We pose two specific questions: 1) are the most critical ambiguous terms in MedLine the same as those in the clinical domain, and 2) can the same algorithms be applied to both domains (biomedical literature and clinical text). Our first task was to create such a corpus.

The first step in the process was the identification of 50 frequent and highly relevant ambiguities from a medical retrieval perspective. We processed the entire 2002 collection of clinical notes through MetaMap ([6]), took the terms that mapped to multiple concepts and ranked them by their raw frequency. The top 1000 most frequent ambiguities were presented to four medical retrieval experts

who filtered them by relevancy for medical retrieval. The top 50 most relevant terms were included in our final WSD data set (referred to as Mayo WSD set). The corpus was then manually sense-tagged by four experts against UMLS. A "none of the above" category was added for those instances that did not have any sense representation in the UMLS.

The Mayo WSD set poses a number of challenges for any WSD annotator regardless of the technique employed. Some terms have over ten senses, e.g. "ac", thinly distributed over the 100 instances. Other senses have high representations of one specific sense, e.g. "ms". In addition, the "none of the above" category does not represent one monolithic sense.

Results

We used a ML approach to build the WSD annotator [7]. The experiments were based on 28 different feature sets on three variations of the corpus. The baseline F-score represented by the averaged majority sense is 0.6032. All feature sets performed well above the baseline. Detailed and comprehensive results will be presented in a subsequent paper. Here, we report one a set of F-scores, which was achieved by using a simple feature set of bag of unique stems filtered with a tf*idf formula within a window of 10 nonstop list tokens on both sides. This resulted in an average F-score of 0.776, well above the baseline.

Discussion

There are 9 ambiguous terms that overlap with the NLM WSD set described in [5]. Of note is that the senses themselves do not necessarily overlap. For almost all ambiguities, there are more senses in the clinical notes than in the literature abstracts, exemplifying that, in general, clinical notes are more complex than medical literature. Columns 4, 5 and 6 of Table 1 present the best results from three studies – [3], [4] and the current study. The first two studies worked with the NLM WSD set but excluded some ambiguities mainly because of the sparsity of the training instances. We experimented with the Mayo WSD set and achieved our best results with different feature sets than the one used to compute the F-score reported in the last column of Table 1. Extensive comparisons and error analysis will be presented in a subsequent publication.

Table 1 - Overlapping ambiguities between the Mayo WSD and NLM WSD set: number of senses in each set and best results from three studies

Ambiguity	Number of senses in Mayo WSD set (clinical notes)	Number of senses in NLM WSD set (literature abstracts)	Best F-score on NLM WSD set: Liu, Teller and Friedman	Best F-score on NLM WSD set: Leroy and Rindflesch	Best F-score on Mayo WSD set: current study
adjustment	5	4	not included in study	0.620	0.930
cold	6	6	0.909	not included in study	0.720
condition	6	3	not included in study	not included in study	0.900
discharge	2	3	0.908	not included in study	0.950
fit	5	3	not included in study	not included in study	0.740
lead	5	3	0.910	not included in study	0.900
sensitivity	7	4	not included in study	0.700	0.780
strain	9	3	not included in study	not included in study	0.690
support	6	3	not included in study	not included in study	0.740

Conclusion

We presented the Mayo Clinic IR system and part of our effort to incorporate a WSD component. For that, we created a manually sense-tagged set of 50 frequent and highly relevant ambiguities derived from the Mayo Clinic medical records, which is used to built and test a WSD annotator. In the future, we are planning to evaluate whether the disambiguation component indeed contributes to improved retrievals.

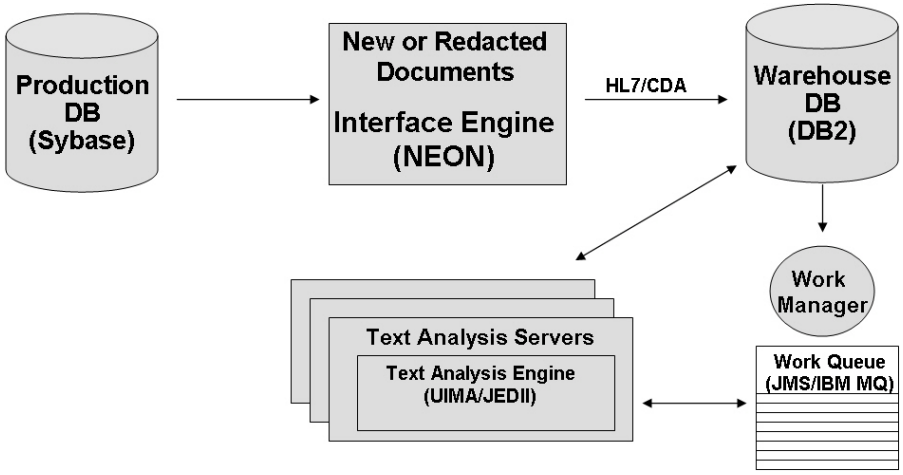
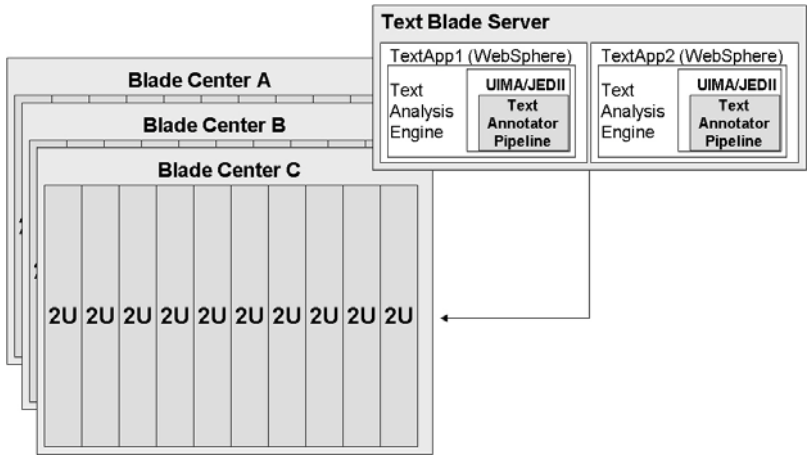
Text analysis production system

- **Large scale, highly modularized, real-time-enabled system**

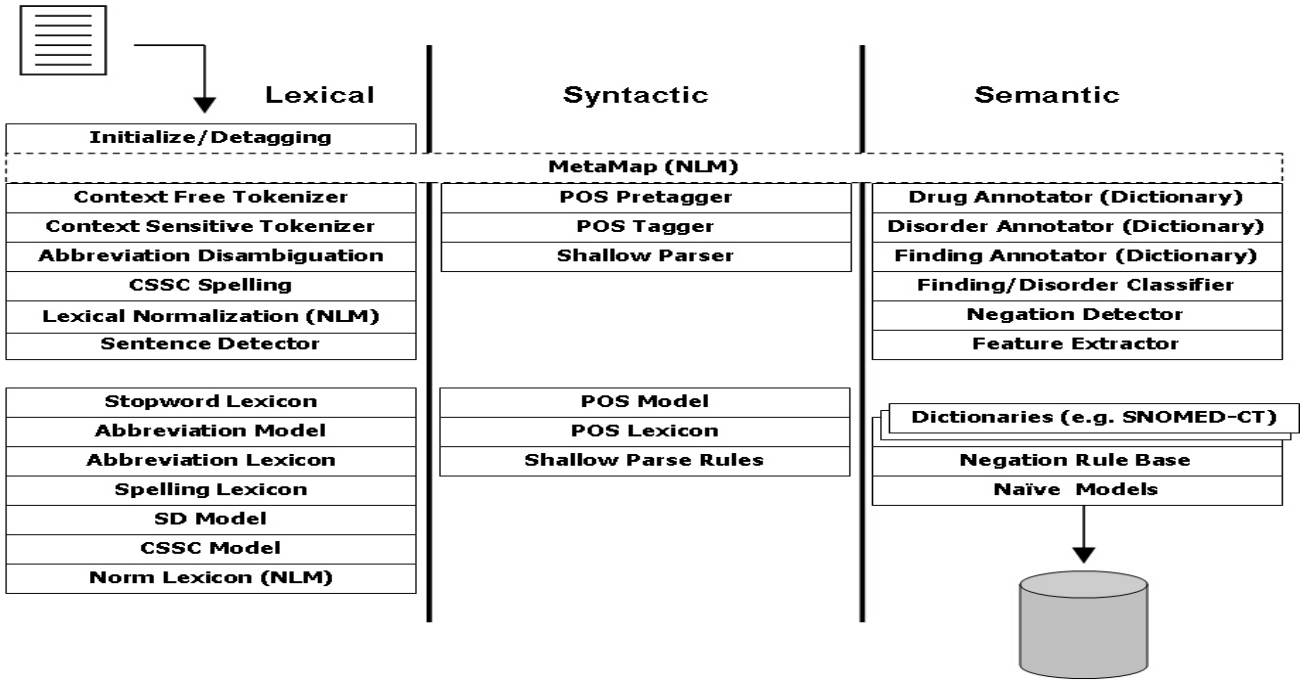


Text Analysis Process Flow



Text Analysis Deployment

Text Analysis System



- Finite state machine – tokenizer, shallow parser, dictionary lookup, negation detector
- Machine learning – abbreviation disambiguator, sentence detector, part-of-speech tagger, finding/disorder/drug classifier

Word Sense Disambiguation Corpora

- Publicly-available corpus based on MedLine abstracts – manually sense-tagged with UMLS concepts
- Built a comparable corpus for clinical ambiguities
  - 50 most relevant clinical terms/phrases
- Comparison
  - 9 terms in common between corpora

Manual Annotation

discharge				
CUIs	Definitions			
C0012621	Discharge, Body Substance			
C0600083	Discharge, Body Substance, Sample			
C0030685	Patient Discharge (Health Care Activity)			
Instance #	**Annotator 1**	**Annotator 2**	**Consensus**	**Text**
1	C0030685	C0030685	C0030685	Patient did not get to school after being **discharged** from the hospital due to there being multiple illnesses going around in the community.
2	C0012621	C0012621	C0012621	She and her family are instructed on signs and symptoms of wound infection including but not limited to pain, erythema, **discharge**, fever or chills.

- Interannotator agreement
  - Number of instances where the annotators agreed over all instances
  - Average: 0.772

WSD algorithm

- Built model for each ambiguity
  - Modification of Huber's robust loss for regression algorithm
- Experimented with 28 different feature sets
- Averaged majority sense: 0.6032
- Average F-score: 0.776
  - Feature set: bag of unique stems, filtered with a tf*idf formula, windows size=10, nonstop list of tokens

Challenges

- Terms have many senses distributed thinly over 100 instances
  - Example: ac
- Terms have high representation of one specific sense
  - Example: ms
- “None of the above category”
  - Does not represent a monolithic sense

Comparison to NLM corpus

Ambiguity	*Number of senses in Mayo WSD set (clinical notes)*	*Number of senses in NLM WSD set (literature abstracts)*	*Best F-score on NLM WSD set: Liu, Teller and Friedman*	*Best F-score on NLM WSD set: Leroy and Rindflesch*	*Best F-score on Mayo WSD set: current study*
adjustment	5	4	not included in study	0.620	0.930
cold	6	6	0.909	not included in study	0.720
condition	6	3	not included in study	not included in study	0.900
discharge	2	3	0.908	not included in study	0.950
fit	5	3	not included in study	not included in study	0.740
lead	5	3	0.910	not included in study	0.900
sensitivity	7	4	not included in study	0.700	0.780
strain	9	3	not included in study	not included in study	0.690
support	6	3	not included in study	not included in study	0.740

Comparison to NLM corpus

- Senses do not necessarily overlap for the 9 terms between the corpora
- In general, more senses per term in clinical notes than in literature abstracts
- For best F-scores on clinical corpus, distinct feature sets for each term

Conclusion

- Built medical information retrieval system
  - Clinical notes accessible via keyword and concept search
  - Near real-time processing
  - Facilitates identification of patient cohorts
  - Nessary building block for other NLP applications
- Ambiguity of terms: source of errors
  - Create a manually sense-tagged set of 50 frequent and highly relevant terms in the clinical domain
  - Integrated a high accuracy sense disambiguator into the medical information retrieval system

A Text Mining Approach to Explain What Being Actively Engaged in Life Means

Richi Nayak[a], Laurie Buys[b]

[a] *Faculty of Information Technology,* [b] *Centre for Social Change Research Queensland University of Technology, Brisbane, Australia*

Abstract

This paper shows the findings and analysis of a national survey data on 'Active Ageing'. We examine the applicants responses on "what being actively engaged in life means to you?" with the text mining approach. The analysis shows that the 'Family', 'Friend' and 'Activity' were the most important concepts appearing across all age groups and both genders.

Keywords:

text mining, data mining, active ageing

Introduction

It is widely accepted that many first world countries are experiencing extended life expectancies and reduced fertility rates, which is resulting in an ageing population. A definition of active ageing is "the process of optimizing opportunities for physical, social, and mental well-being throughout life in order to extend healthy life expectancy [2]. The Australian Active Ageing (Triple A) study at the Queensland University of Technology (QUT) has conducted a national-wide postal survey to collect the responses of older people on a wide range of questions related to 'work', 'learning', 'social', 'spiritual', 'emotional', 'health and home', 'life events' and 'demographics'. The survey also included an open-ended question that the applicants responded to was "Briefly describe what being actively engaged in life means to you?". The purpose of this paper is to present the findings and analysis of the open-ended question in the survey using the text mining techniques [1]. This paper attempts to gain a better understanding of the impact of aging upon older Australians' engagement in society and their sense of well being. The findings and analysis are based on the responses from 2645 (45% response rate) participants over the age of 50 years residing across Australia.

Method: Text mining

Text mining extracts the important concepts and emerging themes from the collection of text sources using computation linguistics, machine learning and information science methods [1,3]. We utilize the Leximancer text mining application [3] to extract relationships from the text data. It is based on the bayesian theory using the words which make up a sentence to predict the concepts being discussed. Each *term* appearing in the text data is analyzed to form a *concept* and then many concepts are put together to form a *theme* based on the co-occurrence of terms and concepts in the text.

Data

The Triple A study data includes responses of 2645 members of a large Australia wide seniors organization on a wide range of questions related to their life. The survey includes 178 questions grouped into 8 sections covering the life aspects of social, health and home, emotional etc and an open-ended question. The sample included a reasonable balance of gender (57% female) and state representation (NSW: 32%, Vic: 24% and Qld: 20%). The respondents were quite comfortable financially, well educated and majority were living with a companion, in their own home in a metropolitan area.

Table 1 - Categorization by Age and Gender

Grouping	Category	Qty
All comments		1964
Grouped by age	55-64	1252
	65-74	474
	75 & over	238
Grouped by gender	Male	870
	Female	1094
Males grouped by age	55-64	523
	65-74	230
	75 & over	117
Females grouped by age	55-64	729
	65-74	244
	75 & over	121

Process

Preprocessing such as (1) removal of surveys (instances) that did not have sufficient information of age, gender etc, (2) application of spelling and grammar checking function in Excel in order to locate and correct the misspell words, incorrect abbreviations and slang, and (3) stop word removal and stemming were performed. The data file was then arranged and split into categories of both Age and Gender that allowed us to thoroughly compare and contrast the different combinations of categories (Table1).

Results and discussion

Comparison by age groups

Age group 55 – 64: The most significant concept and theme is 'Family'. 'Life' and 'Active' are next in the level of frequency. There is an integral relationship between 'family' and 'time' as well as having close ties with the 'enjoy' entity. 'Work' is considered a significant concept ranking highly for both males and females. 'Work' and 'Active' aspects comes to the fore in Males whereas 'Health' and 'Social' aspects are more frequent in the Females. This may indicate that Males place a greater importance in physically active aspects while Females signal social themes as figuring in their perception of active ageing.

Age group 65 – 74: This age group shows that they consider an active life to being engaged in it, living a full life, having a life with purpose and friendship in terms such as visit, involvement and participation. In this age group, males considered 'work' a more important concept than females. Both males and females emphasize on Family. However the terms that form the 'Family' concept in both groups differ. The females were concerned with interaction with emphasis on meeting, touching, visiting, whereas the males, although the terms indicate a need to be interactive, are less personal. Their terms include social, involved, community, and activities. Although it is a subtle difference, it could possibly indicate that for males, family is also a source of activity or social events. Whereas with the females, it could be perceived as a more emotional connection as opposed to as a source of activities or social connectivity.

Age group 75+: Ageing is perceived as having a close association with family and friends and maintaining an engagement in life through activities with these people. The concept of 'health' emerges as a significant concept, more highly ranked by the males than the females. This differs from the prior age groups indicating that this group may be considering health issues more frequently in relation to active ageing.

A very interesting difference that appears between male and female of this age group is the 'enjoy' concept. Female associate enjoy with life concept. However, male segregate the enjoy concept from either of family or active concept. Male population subtly emphasizes more on 'active' concept in comparison to female. Male population being actively means being involved with people. The female population seems to relate being actively with being involved with their loved ones, friends and social groups such as church.

Comparison by gender

All Females: Ageing is perceived as having a close association with family and friends and enjoying the activities with these people. Ageing is also perceived as being active in life through the time based work activities.

All Male: Ageing is perceived as being active in life and spending time with family and friends.

The most significant difference between the results of the males and females, are that where the females population were concentrated around 'Life', 'Family' and 'Friends', the male population seems to include a wider range of concepts including 'Active' and 'Work' as heavily weighted.

Using the whole population

To understand the behavior of the whole population including various age groups and all gender, we grouped the respondents according to the way they reflect active ageing using the clustering method [4]. This method also utilizes the computation linguistics to analyses the terms that mainly form a theme and consequently puts them into the same group. All respondents are grouped into 6 clusters. Following is the detail of each cluster including the few top-most terms due to which the respondents were put together in same group along with number of similar respondents in that cluster according to the written response.

Cluster 1: people, thing, good, new, health (1073)

Cluster 2: friend, social, work, child, grandchild (736)

Cluster 3: physical, mental, good, health, activity (175)

Cluster 4: mental, physical, happy, independent, family (136)

Cluster 5: help, other, helping, helping others (99)

Cluster 6: body, mind, help, good (89)

Cluster 1 is the biggest cluster in the dataset, which gives a general description for the meaning of active aging. The concepts covered are as follows: learning new things and skills, maintain good health, dealing with other people etc. Cluster 2 focuses more on the aspect of personal life, involves the family life, the friendship and the attitude to society. These respondents would like to enjoy with their family, look after their grandchild, stay with their friends, participate in social event and contribute to the society. Respondents in cluster 3 realize good health (mental and physical both) is the basis for happy life and are willing to participate in activities according to their health status. Cluster 4 respondents find the mental and physical health along with the family surroundings as key aspects for active ageing. People in cluster 5 wish to find out their personal values by helping others, in the aspect of daily life or whatever and wherever others need. The responders in cluster 6 wish to be interactive with other people to make their body and mind active as well as help the others.

These clusters show the various characteristic that each group of common respondents have. Further drilling to each group will identify more common concepts and themes.

Conclusion

A strong common themes across all groups, male, female and age groups were that 'Family', 'Friends' and 'Activities'. The younger age group considers 'Work' an important variable in active ageing, and this drops off to be important for only males in the next group, and is not ranked in the 75 and older group. Within the eldest group however, 'Health' emerges as an important concept, and given that this group is in a minority in the population as a whole, could explain that lack of representation overall of health concerns. These trends seem to indicate that the respondents are considering factors that are relevant to them in the immediate timeframe when responding to the question without consideration toward their future. There are various areas where these results may have impact and warrant some consideration such as future planning for government funding of community activities.

Abstract

The healthcare-data-mining presented here extracts personally useful information, such as rules and patterns concerning lifestyles and health conditions, from daily time-series personal health and lifestyle data stored on a personal dynamic healthcare system by using mobile phone and web technologies. This paper focused on time-series data analyses in the healthcare-data-mining process. Interesting results concerning the relation between soybean protein ingestion and body-fat percentage were obtained.

Keywords:

personal healthcare, Internet, data mining,
time-series data

Introduction

We have developed a personal dynamic healthcare system (PDHS) utilizing the Internet. It enables time-series daily-health and lifestyle data to be stored in a database by using mobile phone and web technologies. Users of this system can input their daily data through a mobile phone and can transfer this data to a web-application server via the Internet. The web-application server provides a data mining service and notifies users, through a mobile phone, of important rules relevant to their health and lifestyle data. Here we report details of the time-series data analyses for the healthcare data mining and also present interesting results concerning the relations between lifestyle and health data for a volunteer user.

Methods

Healthcare-data-mining algorithm consists of two processes.

First process

We determined effective input fields by pre-examining the correlation between time-series lifestyle data and health data of interest as shown in Figure 1, where *e* is the given lifestyle data and *h* is the given health data. Here h_n is the value of *h* at date *n* and e_i is the value of *e* at date *i*. Assuming that lifestyle data affect health data with some delay, we defined a retarda-tion parameter *s* (=*n*-*i*).

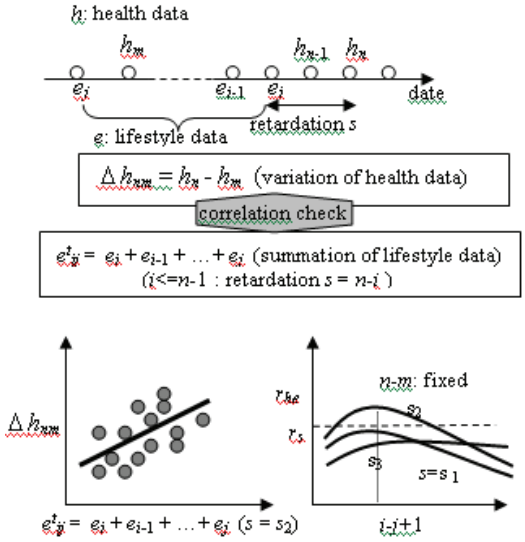

Figure 1 - Time-series data analysis

The correlation between Δh_{nm} and e^t_{ij} in time-series data was checked by changing *n-m, i-j* and *s* as parameters and calculating Pearson's product-moment correlation coefficient r_{he} for each (*n-m, i-j, s*) set. Here,

$$r_{he} = s_{he} / s_h \cdot s_e \quad (1)$$

where s_{he} is the covariance and s_h and s_e are respectively the standard deviation of Δh_{nm} and the standard deviation of e^t_{ij}. If, as shown in Figure 1, for some (*n-m, i-j, s*) set the r_{he} is larger than the threshold value r_s, then e^t_{ij} is selected as an input field. Actually, an input field is defined according to the values of *i-j* and *s* at which r_{he} becomes largest.

Second process

The second process is a rule induction from a number of time-

series data sets consisting of defined input fields and an output (target) field. An example of data set and a rule induction algorithm are shown in Figure 2.

Example of data set — input fields Y — output field X

date	Energy expenditure 5 (kcal)	Ingestion at meal 5 (kcal)	Alcohol intake	Body-fat index
10/06	1000	12000	much	higher
10/07	1200	11000	little	lower
10/08	800	13500	much	higher
……	……	……	……	……

Rule: If $Y = y$, then $X = x$ with probability p.
Y: input field, y: condition X: output field, x: value

Rules having higher-J-measure survive in the rule table

J-measure:

$$J(x|y) = p(y)\left(p(x|y)\log\frac{p(x|y)}{p(x)} + (1-p(x|y))\log\frac{(1-p(x|y))}{(1-p(x))} \right)$$

$p(y)$:probability of the rule's antecedent matching an example from the data set
$p(x)$:probability of the rule's consequent matching an example from the data set
$p(x|y)$:conditional probability of the rule's consequent conditioned on the antecedent

Figure 2 - Algorithm for rule induction

Input fields in the example of data set are defined by the first process. Energy expenditure 5, for example, is the summation of energy expenditure for 5 days. Output field (in this case, body-fat index) values are categorized into three classes, each having a symbolic value such as "higher", "moderate", or "lower". Border values used for this classification are determined so that the data frequency is similar in each class. In this rule induction algorithm, J-measures are estimated for all possible rules, and rules having higher-J-measure survive.

Results

In the automated healthcare-data-mining, the two processes described above are executed successively. The first process itself (time-series data analysis), however, produces interesting results. Here, we will report effects of soybean protein ingestion for an example.

Soybean protein is well known to lower blood cholesterol. Soybean β -conglycinin is thought to lower triglyceride levels and decrease body fat. One volunteer user (female, 22 years old) ingested different amount of soybean milk each day for about 6 months and measured her body-fat percentage almost every day under the same conditions.

The correlation coefficient r_{he} between body-fat percentage and the summation of soybean milk ingestion is, for various values of the retardation parameter s, shown in Figure 3 as a function of summation-day number (i-j+1). Negative correlation coefficients mean that ingestion of soybean milk was associated with a lower body-fat percentage (Figure 4). It should be noted that the r_{he} between body-fat percentage and the sum- mation of soybean milk ingestion strongly depends on (i-j+1) and s and that its absolute value is greatest when i-j+1 =12 and s = 4.

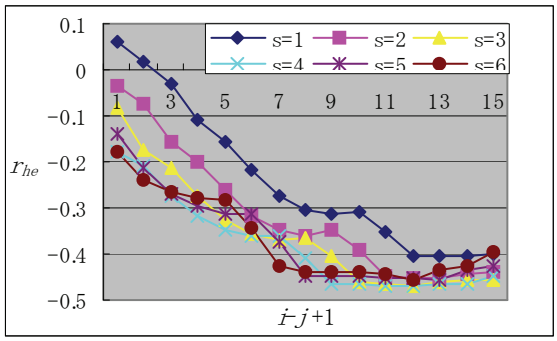

Figure 3 - Correlation coefficient r_{he} between body-fat percentage and summation of soybean milk ingestion as a function of summation-day number (i-j +1) for various values of retardation parameter s

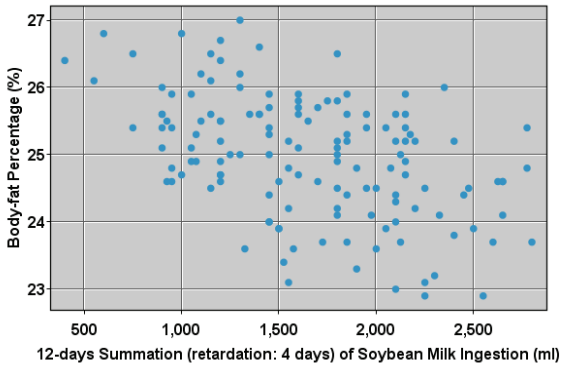

Figure 4 - Typical scatterplot of body-fat percentage (n:139, max:27.0 min:22.9, med:25.0, SD:0.906) versus soybean milk ingestion (correlation coefficient: -0.470)

Discussion

Body-fat percentage lowering may be due to an action of soybean β -conglysinin, which is reported to act on genes related to fat metabolism and thereby decrease triglyceride level. If so, Figure 3 suggests that in the human body the effect of β -conglysinin is gradual: for this volunteer user, the absolute value of the correlation coefficient r_{he} was maximum at i-j +1 = 12 (twelve days successive ingestion) and s = 4 (four days delay). These values of i-j and s at which correlation coefficient becomes largest may differ from person to person.

In the automated healthcare-data-miming process, the correlation between Δh_{nm} and e^t_{ij} in time-series data is checked by changing n-m, i-j, and s as parameters (n-m = 1-10, i-j = 0-9, s = 1-3). Time-series data analyses described here, however, suggest that ranges of i-j and s values should be extended more.

Conclusion

Time-series data analyses for healthcare-data-mining process in the personal dynamic healthcare system produced interesting results concerning the relations between soybean protein ingestion and body-fat percentage for a volunteer user of our PDHS.

Extracting personal rules relating lifestyle and health data

ingestion

energy expenditure

sleep

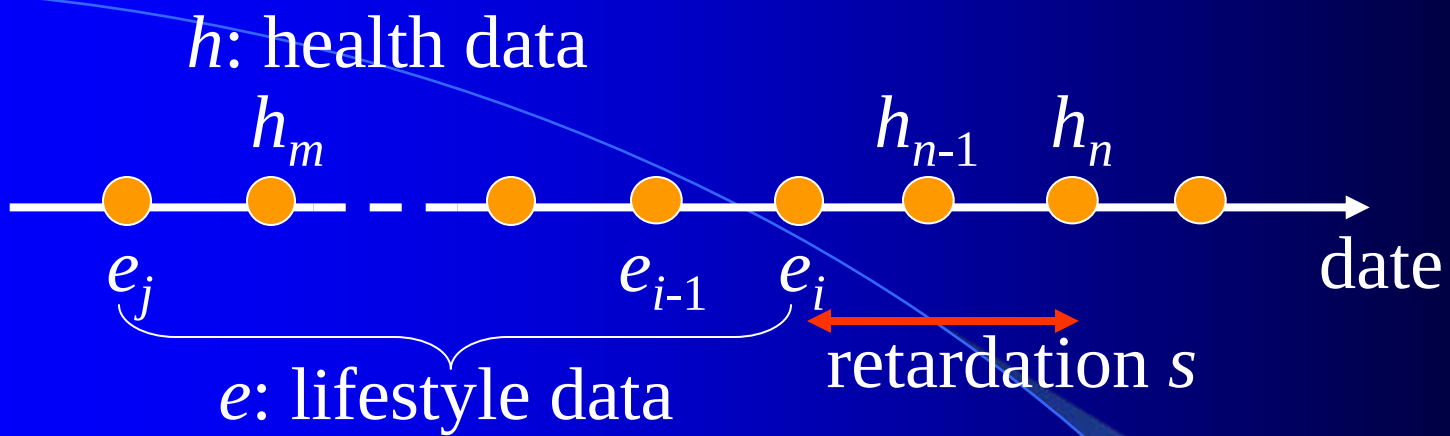
alcohol intake

smoking

daily vital signs

(blood pressure, body-fat index, body-temperature etc.)

Concept of healthcare-data-mining



$\Delta h_{nm} = h_n - h_m$ (variation of health data)

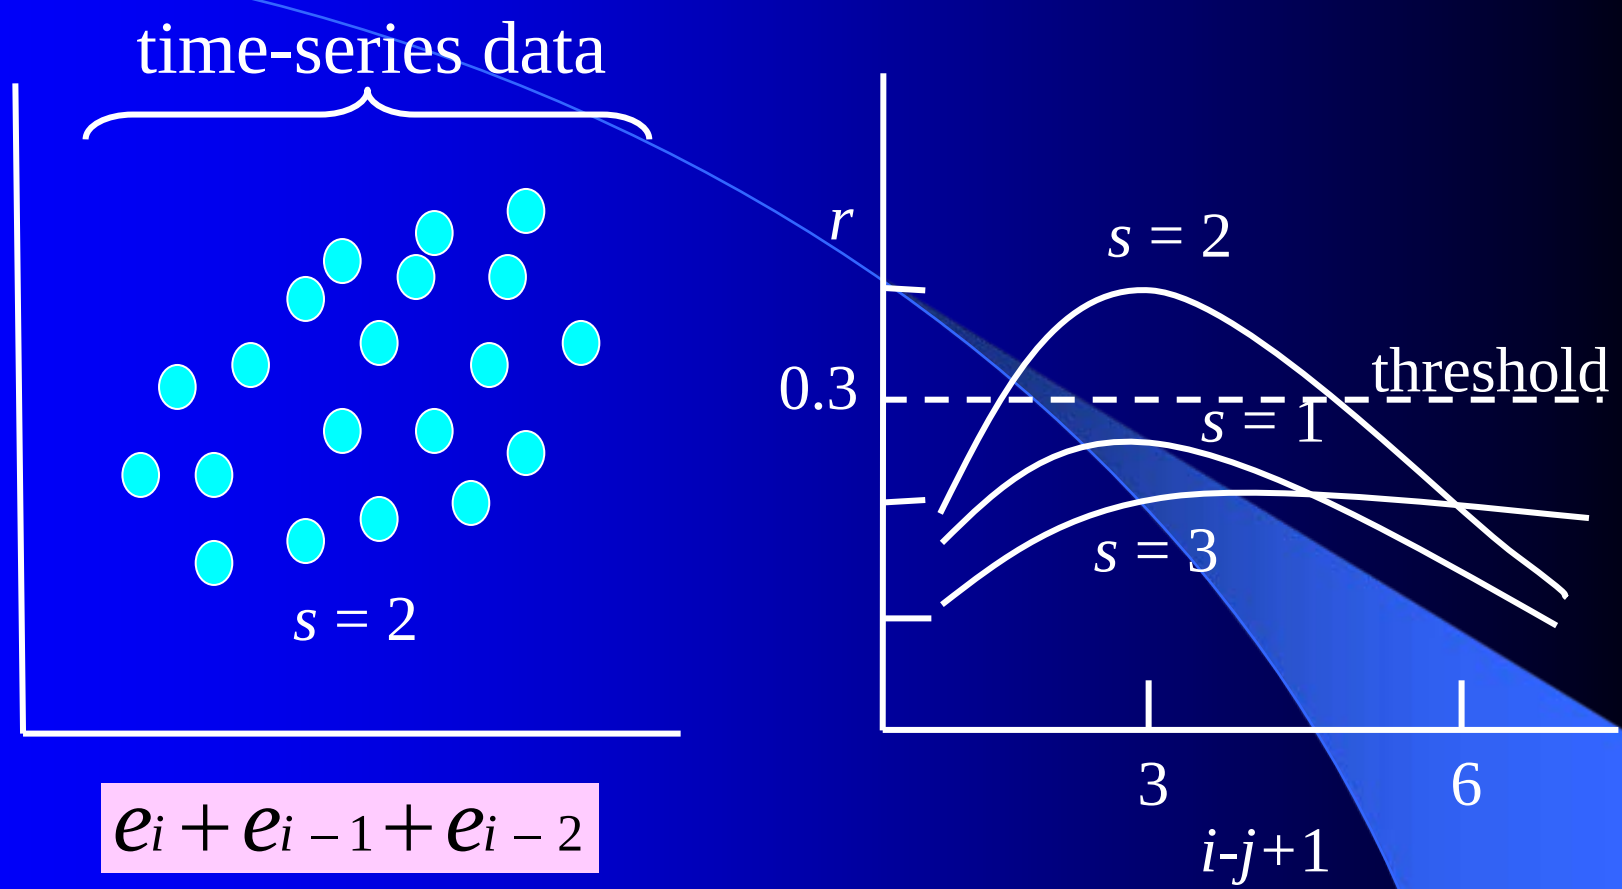
Correlation check

$e_{ij} = e_i + e_{i-1} + \ldots + e_j$ (summation of lifestyle data)

$(i <= n-1 : s = n - i)$

Calculate correlation between Δh_{nm} and e_{ij} in time-series data while changing *n-m*, *i-j*, and *s* as parameters

Algorithm for defining the input field (1)



$$e_i + e_{i-1} + e_{i-2}$$

(i = n-2)

r : correlation coefficient

input field is $e_i + e_{i-1} + e_{i-2}$ (i=n-2) in this case

Algorithm for defining the input field (2)

Data set Y_i X

Date	Energy expenditure 5 (kcal)	Ingestion 5 (kcal)	Alcohol intake	Body-fat Index
06/06	1000	12000	much	higher
06/07	1200	11000	little	lower
06/08	800	13500	moderate	moderate
....	....	....	....	....

Rule

If Y_1 is y_1 and Y_2 is y_2, then X=x with probability p.

Y_i : lifestyle data item, y_i : condition X : health data item, x : value

Rules having higher-J-measure survive in the rule table

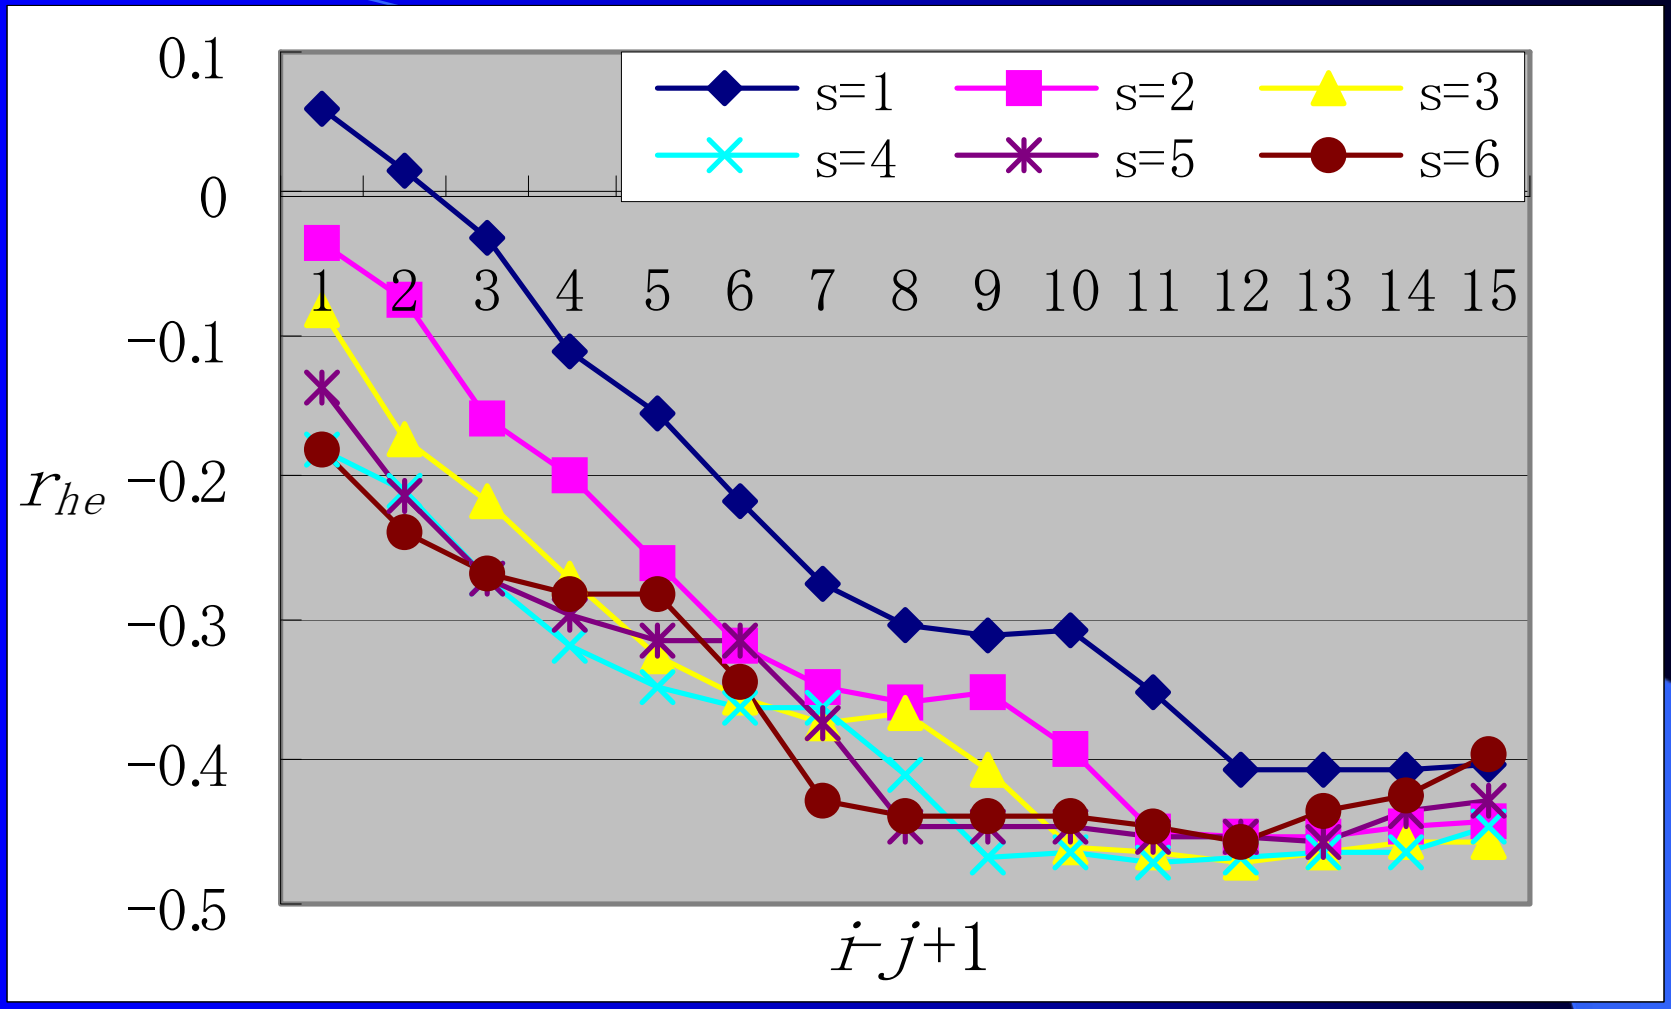
J-measure

$$J(x|y) = p(y)\left(p(x|y)\log\frac{p(x|y)}{p(x)} + (1-p(x|y))\log\frac{(1-p(x|y))}{(1-p(x))} \right)$$

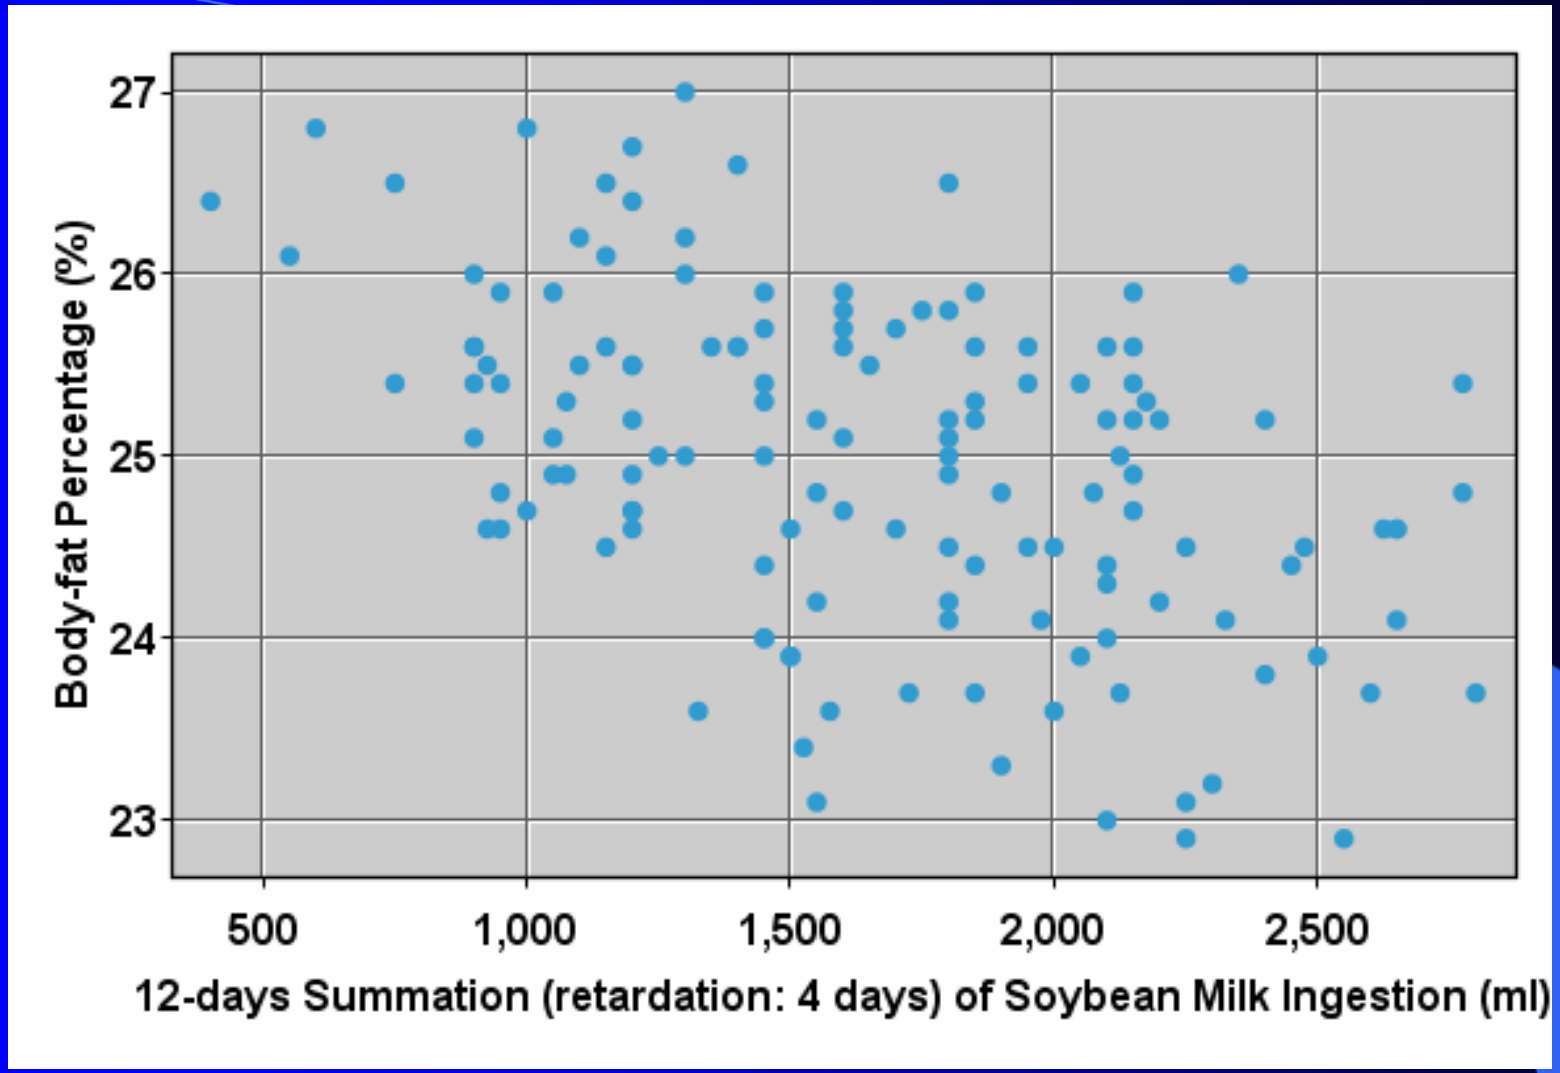
$p(y)$, $p(x)$ } probability of the rule's { antecedent, consequent } matching an example from the data set

$p(x|y)$: conditional probability of the rule's consequent conditioned on the antecedent

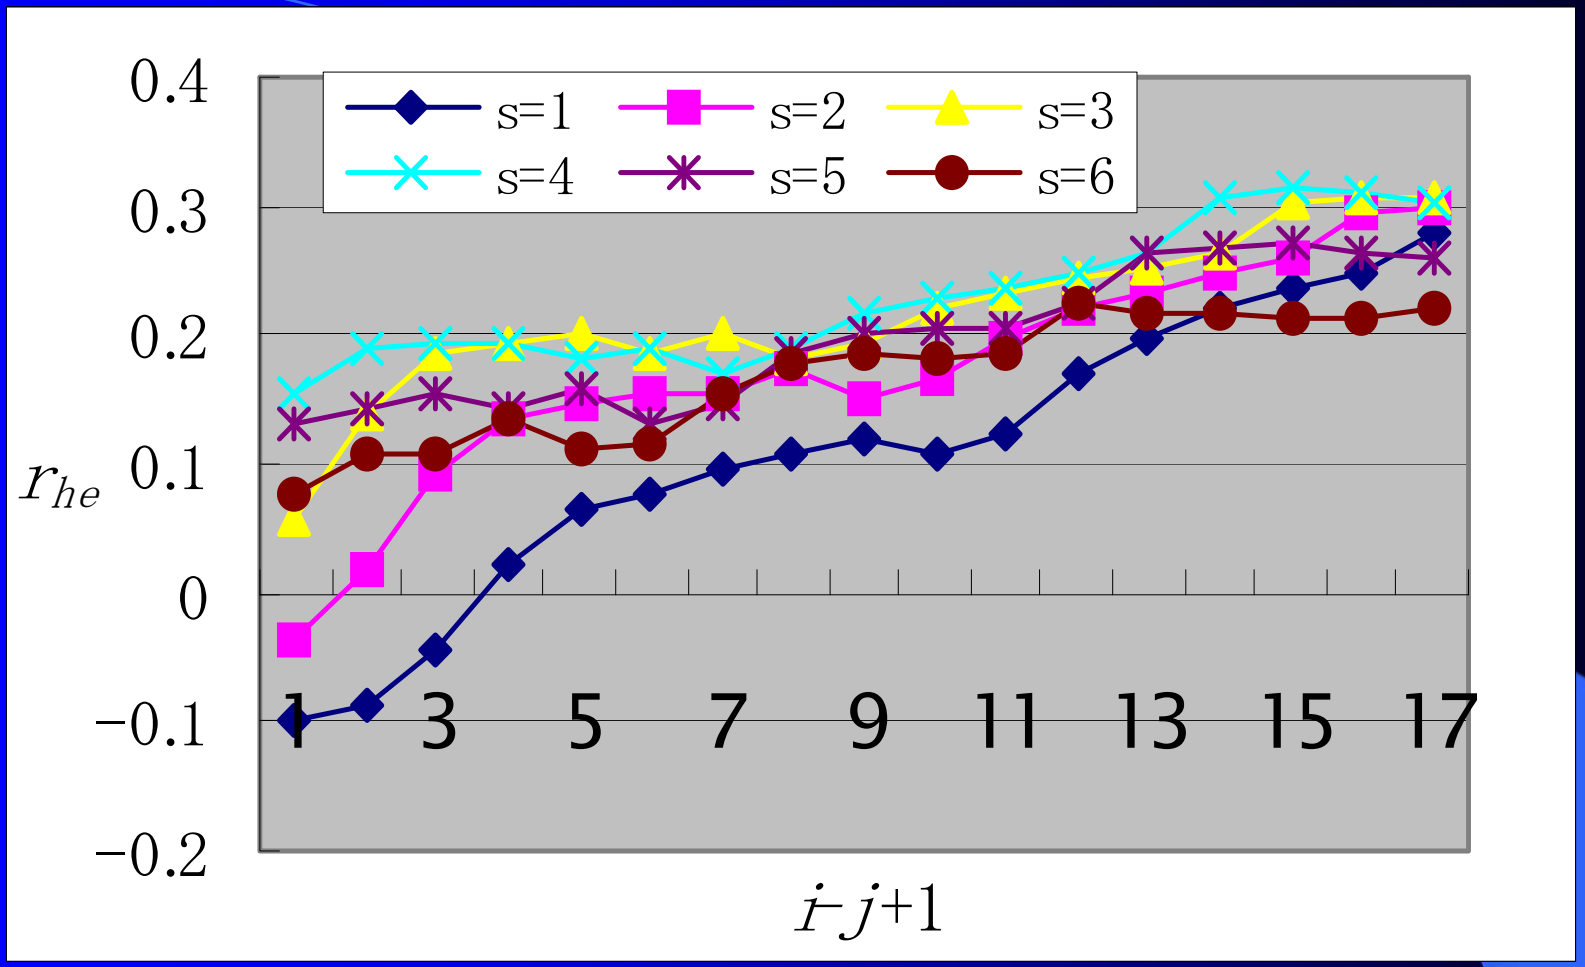
Algorithm for automated rule mining



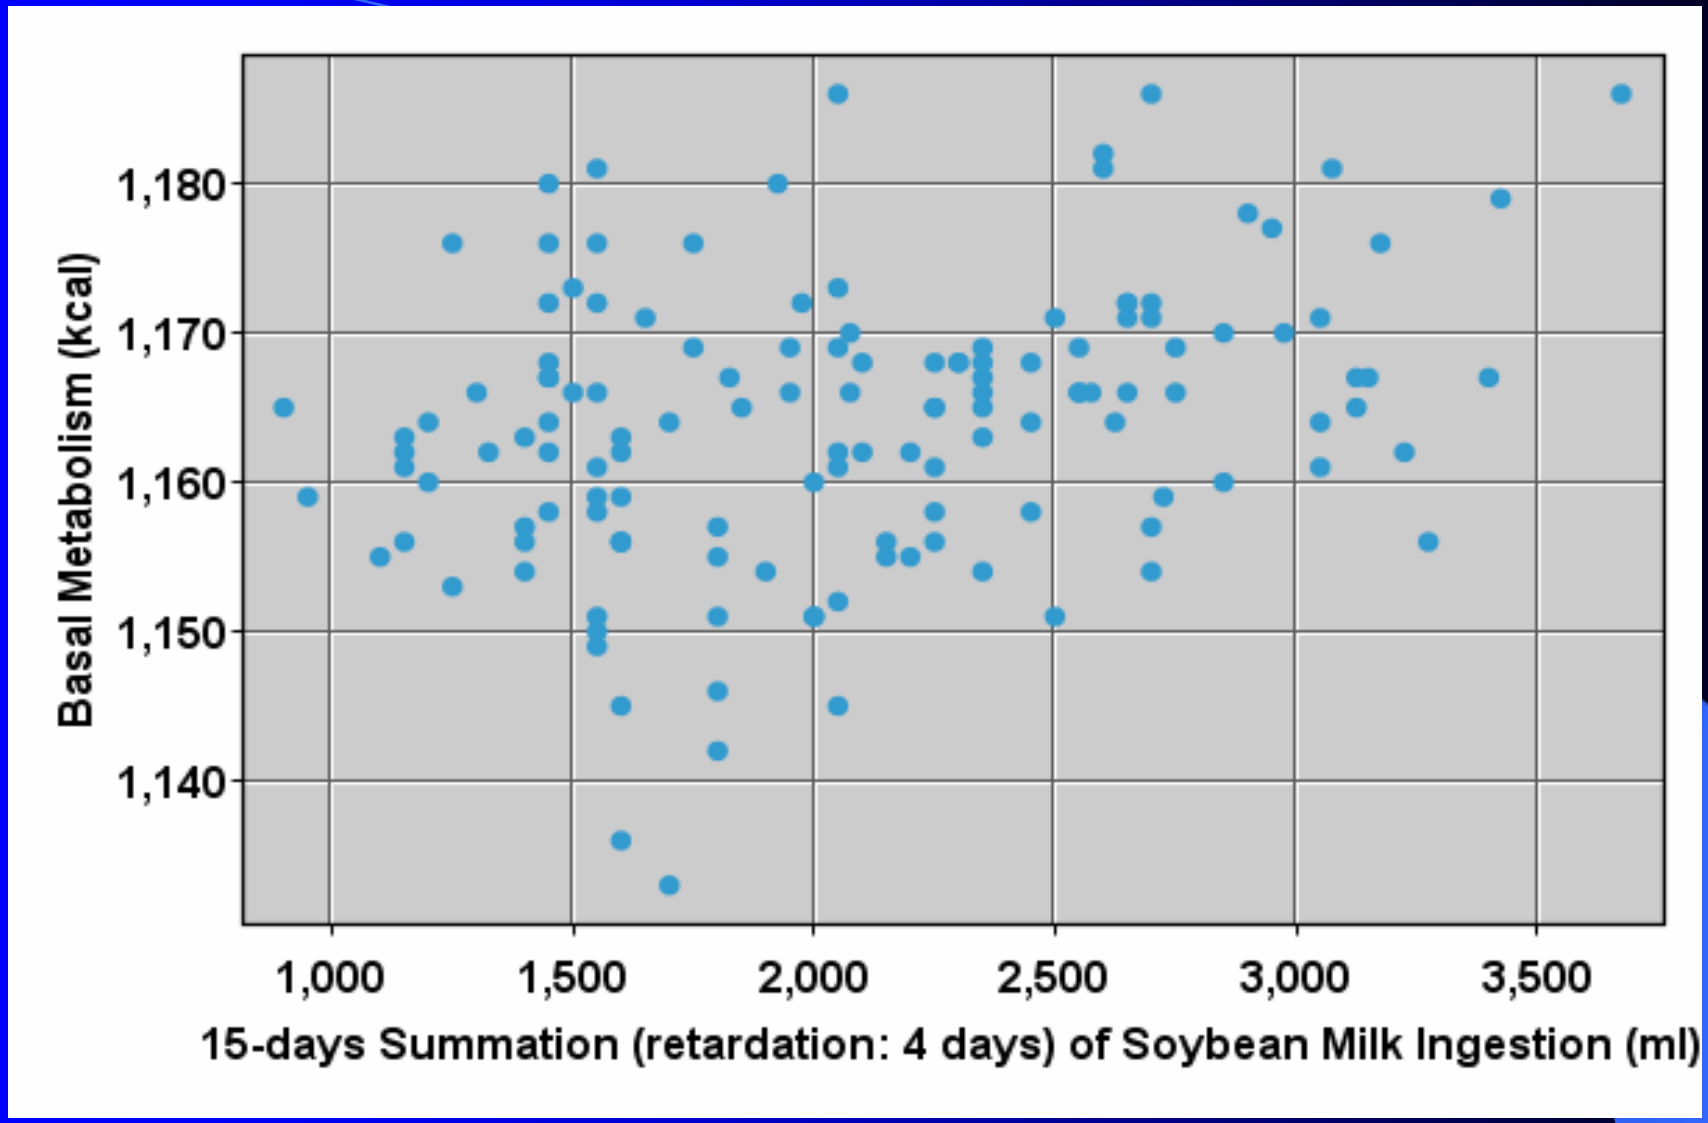
Correlation coefficient r_{he} between body-fat percentage and summation of soybean milk ingestion as a function of summation-day number ($i-j+1$) for various values of retardation parameter s



Typical scatterplot of body-fat percentage (*n*:139, *max*:27.0, *min*:22.9, *med*:25.0, *SD*:0.906) versus soybean milk ingestion (correlation coefficient: -0.470)



Correlation coefficient r_{he} between basal metabolism and summation of soybean milk ingestion as a function of summation-day number (i-j+1) for various values of retardation parameter s



Typical scatterplot of basal metabolism (*n*:138, *max*:1186, *min*:1133, *med*:1160, *SD*:9.48) versus soybean milk ingestion (correlation coefficient: 0.313)

Conclusion

Time-series data analyses for healthcare-data-mining process in the personal dynamic healthcare system (PDHS) presented here produced interesting results concerning the relations between lifestyle data and health data for volunteer users of PDHS.

Example: Daily soybean protein ingestion gradually decreased body-fat percentage (12 days successive ingestion was most effective with 4 days delay), and gradually increased basal metabolism (14 days successive ingestion was most effective with 4 days delay).

Index and Query of Clinical Documents Complied with HL7 CDA Documents Using Weighted Navigational Expression

Zhijing Liu PhD[a], Sam Brandt MD[a], Floyd Eisenberg MD[a]

[a] *Department of Clinical Informatics, Siemens Medical Solution, United States*

Abstract

The Health Level 7 (HL7) Clinic Document Architecture (CDA) is an American National Standards Institute (ANSI)–approved, document markup standard that specifies the hierarchical structure and semantics of clinical document (such as a discharge summary, progress note, procedure report) for the purpose of information exchange. In this paper, a method is developed for index and query of CDA documents using weighted navigational expression. The method is based on templates that define the weighted navigational expression to guide the processes of index and query of clinical documents, so it is configurable. With the method, the index and query of clinical documents is fast and reliable. The method can be easily implemented in a distributed, heterogeneous environment such as a web application and adopted to different clinical settings.

Keywords:

clinical documents, CDA, retrieval, index, query

Introduction

HL7 CDA documents are encoded in Extensible Markup Language (XML). CDA documents derive their machine processable meaning from the HL7 Reference Information Model (RIM) and use the HL7 V3 Data Types. The CDA specification is richly expressive and flexible. Document-level, section-level and entry-level templates can be used to constrain the generic CDA specification. A CDA document can be transferred within a message, and can exist independently, outside the transferring message, with the characteristics of persistence, context, and wholeness. To be able to fully exploit the potential the CDA documents, one has to be able to effectively index, archive, and retrieve such clinical documents and more, query in a manner that takes advantage of the structured nature of such documents.

In the presentation, a weighted navigational expression method is developed to index and retrieve the clinical document, which precisely addresses this concern. The method is based on templates that define the weighted navigational expression to guide the processes of index and query clinical documents.

Methods

The first step of the weighted navigational expression method is document analysis, which analyzes the document *structures,* metadata, XML fragment and value, the filter terms of index and query, and stop context. A XML fragment is structure data represented and a part of a clinical document. The paths of the data fragments are specified in the index template. The filter terms are the content or attribute of atomic elements of XML data fragments. The textual contents of metadata, data fragments, and filter terms are analyzed based on linguists, thesauri or ontology. There are some dependencies between analysis steps because some results of the one analysis are helpfully or even necessary for the other analysis. Term position must be determined before stop word elimination because some terms are not counted and some phrase query may fail. Stop-word elimination should be processed before stemming because stemming is expensive depending on the number of words. Stop words such as ('the', 'a' 'if' etc) that increase the overhead but add no value during query are removed here.

After CDA documents are analyzed, an index process extracts metadata, XML data fragments, ranking terms, filter terms, and their relations to the content. The weighted data to be ranked according to the importance of data and the structure relationship among different levels of data fragments in the clinical documents are profiled in an index template. Figure 1 illustrates some data fragments and its tree structure. The structure relationships are used with the method as paths to locate and extract data from the clinical documents. The context of an individual CDA document, a set of the documents, or multiple sets of the documents are navigated and extracted to generate an index dictionary with different granularities to facilitate the flexibility of the query of the clinical documents. The indexes of clinical documents, their collection, their context, and the clinical setting are stored dictionary which is stored as a set of files. The indexes can be in-memory or map to a RMDS database specified by the index template.

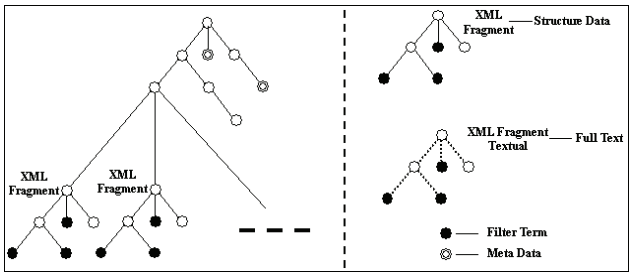

Figure 1 - Filter Term Nodes and XML Data Fragment Nodes

After the index dictionary is generated, users can query and retrieve the documents and can select the query context. If a single collection is selected, users can either specify an individual, multiple, or all the clinical document(s) in the collection. A query agent can perform query parse, query evaluation, pattern matching, and then present the query results. The query agent can perform both information retrieval (text query) and structure query (XML data fragments). The text query expressions can be constructed with simple keyword search, combining keywords within Boolean expressions, or querying for phrases, sentences etc. It can query the metadata, the textual content of XML data fragments, the element values or attribute values of filter terms. The XML Path Language is used to query structure data. The path expressions are embedded in the query template. Path expressions are also used to specify the return document fragments since often not the whole XML document should be referenced in the query result but only a certain fragment. By default, references to the root nodes of the matching documents or matching XML data fragments are returned depending on which how results are presented.

Results

The method has been successfully implemented as web application as shown in Figure 2. The implementation includes two major modules – index module and query module. The index module has an index user interface (UI) and an index agent. The query module has a query UI and a query agent.

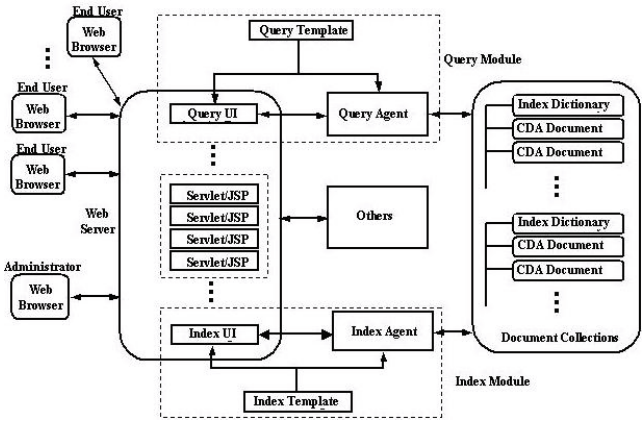

Figure 2 - Implementation of the weighted navigational expression method

Indexer agent performs document analysis, extracts data from the clinical documents, and stores index information to the index files in the server. Both index UI and index agent is configurable with the index template.

The query UI allows users to specify the query range. Users can query information from keywords and can be scoped down with filter terms. The query agent queries data from indexes and performs query parse, query evaluation, pattern matching, and present the query results. The query results are presented to users with two ways. All resulting data fragments are organized together and send back from query agent to query UI, where the results can be displayed either in a HTML page or PDF document depending upon the preferred style.

All matched clinical document names are listed in query UI. Users can select and look their interested document in detail. The matched contents are highlighted in the clinical document. The view of the document can also be displayed either as a HTML page or PDF document depending upon the preferred style

Discussion

There are two kinds of information retrieval IR approaches that deal with the retrieval of structured documents:

The structural approaches enrich text query by conditions relating to the document structure, e.g. that words should occur in certain parts of a document, or that a condition should be fulfilled in a document part preceding the part satisfying another condition, but generally do not support weighting or ranking [3].

Content-based approaches aim at the retrieval of the most relevant part of a document with respect to a given query, but do not allow for structural conditions [4].

Only a few researchers have dealt with the combination of explicit structural information and content-based retrieval. Mayan and colleague [5] use belief networks for determining the most relevant part of structural documents, but allows only for plain text queries, without structural conditions. The FERMI multimedia model [6] presents a general framework for relevance- based retrieval of documents.

In the paper, a weighted navigational expression method is developed to index and retrieve the clinical document, which precisely addresses this concern. The method is based on templates that define the weighted navigational expression to guide the processes of index and query clinical documents. The method can be easily implemented in a distributed, heterogeneous environment such as a web application and adopted to different clinical settings.

Conclusion

The weighted navigational expression method is an easy, effective, and configurable method of index and query of CDA documents. The method is implemented as a web application. The method can also be implemented as a stand-alone application or can be integrated with other web application.

A Transition Model for Patient Conditions Based on Hospital Information System Data

Nobuo Shinohara[a], Shiro Matsuya[a], Hiroshi Oyama[b], Kazuhiko Ohe[c]

[c]*Department of Medical Informatics and Economics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*

Abstract

For efficient use of hospital beds, it is important to know each patient's stage of hospitalization and be able to estimate when the patient may be discharged. In this study, we constructed a time-related transition model based on hospital information system (HIS) data in order to recognize the stage of hospitalization by classifying patient's daily conditions into clusters, and calculating the transition between these clusters for all patients. To classify all patient's daily conditions into clusters, we applied Ward's method, a hierarchical aggregative clustering method. We then constructed a transition model of patients with brain infarction using HIS data of the University of Tokyo Hospital from April 1 2004 to March 31 2005. Validation of the model and generalization of this method to other data sets and diseases are future goals for this project.

Keywords:

Transition Model, Cluster Analysis, Hospital Information Systems, Brain Infarction

Introduction

In large hospitals where many patients are treated, the proper management of inpatients and efficient use of beds is vital. In order to achieve this, it is important to know each patient's stage of hospitalization. The overall goal of this study is to devise a general method for constructing a reference model, based on hospital information system (HIS) data. Prior to generalization of the model, the objective of this preliminary study is to construct a time-related transition model, from admission to discharge, for patients with brain infarction. By comparing the condition of a new inpatient to the transition model, we can elucidate the patient's current stage of hospitalization, predict possible changes in the patient's condition, and estimate when the patient may be discharged.

Methods

Construct of the transition model was carried out in three steps.

Defining patient's daily condition

The accounting data, part of the recorded HIS data, of inpatients diagnosed with brain infarction on the day of admission or on the following day was used for analysis. Three kinds of items were excluded from the data.

- Items unrelated to the medical intervention; e.g., additional fee for special room.
- Items showing the names of drugs or laboratory tests; e.g., AST (aspartate aminotransferase).
- Items that appeared only five times or less.

As a result, 57 items of medical intervention (intravenous drip, physiotherapy, chest X-ray roentgenogram, etc.) were selected, and a patient's daily condition was defined based on the status of these 57 items (being carried out (= 1); or not being carried out (= 0)). Each condition was then plotted on a 57-dimensional binary space.

Classifying patient's daily conditions

The daily conditions of every patient were classified by applying Ward's method ([1], pp.142-145), a hierarchical aggregative clustering method, in the 57-dimensional binary space, to form five clusters.

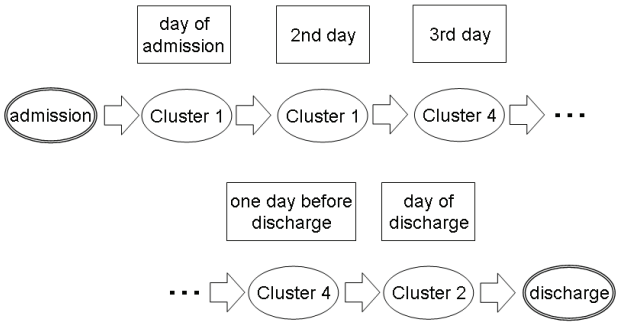

Figure 1 - Transition of one patient's conditions.

Constructing time-related transition model

The transition of each patient's conditions was represented by listing the clusters that the patient was classified into, from admission, the first transition condition, to discharge, the final transition. An example of the transition of one

patient's conditions is shown in Figure 1. A time-related transition model was then constructed by measuring the transition rate between clusters for all patients.

Results

The transition model was conducted using the accounting data stored in the HIS of the University of Tokyo Hospital from April 1 2004 to March 31 2005. The data for 60 inpatients (mean age, 68.2 years (SD = 15.2); male, n = 43; female, n = 17) were selected for analysis, and the total number of inpatient days was 2,561. The characteristics of the five clusters, referred to as Cluster 1 - Cluster 5, are shown in Table 1. Almost all patients were classified into Cluster 1 on the day of admission, and more than three quarters of all discharges followed a Cluster 2 classification (Figure 2).

Discussion

If accurate accounting data can be obtained for a patient on any given day, the cluster in which the patient's daily condition exists can be calculated using Ward's method in the 57-dimensional binary space. This indicates the patient's stage of hospitalization, and calculation of the discharge date and discharge rate of the patient can then be performed by comparing this to the transition model constructed in this study. In order to use this model for this purpose, it is necessary to examine the validity and reproducibility of the model, particularly when created from other data sets. It is also necessary to generalize this method, in order to apply it to other diseases. These challenges will be undertaken in the next stage of this project.

Conclusion

A new method was proposed for constructing a time-related transition model of patient conditions for patients diagnosed with brain infarction, using HIS data. Validation of the model and generalization of this method are future goals of this project.

Transition Model of Patient Conditions

Methods - Defining patient's daily condition

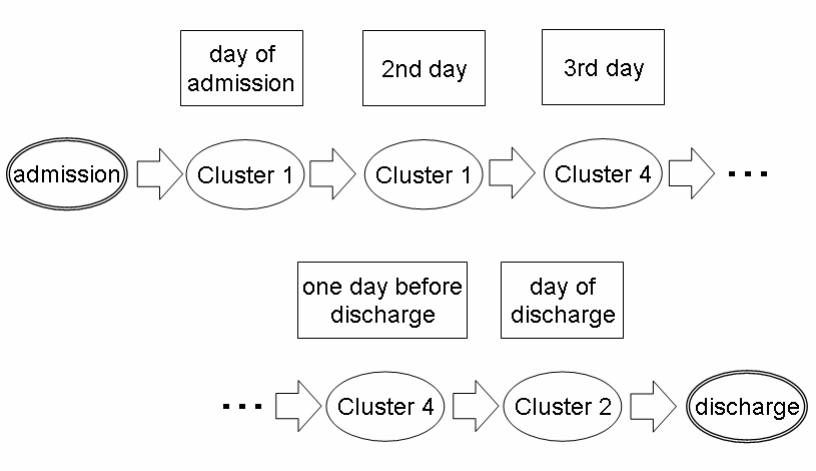
- Data for analysis
  - The accounting data (part of the recorded HIS data)
  - The data of Inpatients diagnosed with brain infarction on the day of admission or on the following day
  - 57 items of medical intervention were selected.
    - intravenous drip, physiotherapy, chest X-ray roentgenogram, etc.
    - Three kinds of items were excluded from the data.
      - ✓ Items unrelated to the medical intervention
        - additional fee for special room, etc.
      - ✓ Items showing the names of drugs or laboratory tests
        - AST (aspartate aminotransferase), etc.
      - ✓ Items that appeared only five times or less.
- Defining patient's daily condition
  - Defined based on the status of these 57 items
  - Each condition was plotted on a 57-dimensional binary space.
    - "item name" = 1 (being carried out)
    - "item name" = 0 (not being carried out)

Methods - Classifying patient's daily conditions

- Ward’s method ([1], pp.142-145)
  - a hierarchical aggregative clustering method
- The daily conditions of every patient were classified by applying Ward's method.

Methods - Constructing time-related transition model

- The transition of each patient's conditions was represented by listing the clusters that the patient was classified into from admission to discharge.



An example of the transition of one patient's conditions

- A time-related transition model was constructed by measuring the transition rate between clusters for all patients.

Result

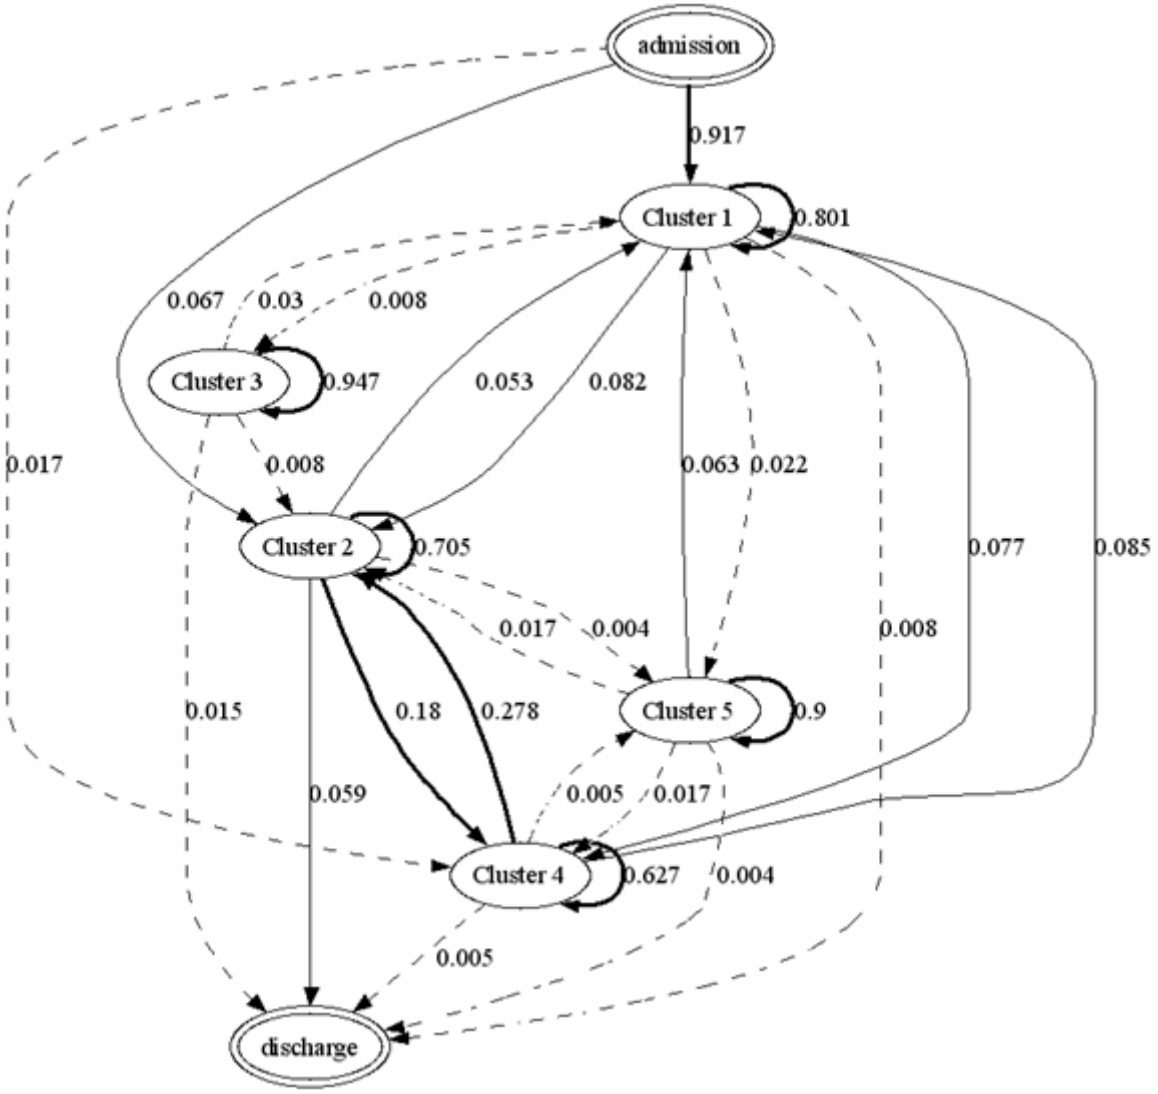
- Data for analysis
  - The accounting data stored in the HIS of the University of Tokyo Hospital from April 1 2004 to March 31 2005.
  - 60 inpatients
    - mean age, 68.2 years (SD = 15.2)
    - male, n = 43
    - female, n = 17
  - The total number of inpatient days was 2,561.
- Almost all patients were classified into Cluster 1 on the day of admission, and more than three quarters of all discharges followed a Cluster 2 classification.

Result - Cluster Characteristics

Cluster No.	intravenous drip	subcutaneous injection or intramuscular injection	gastrogavage	physiotherapy	central infusion
Cluster 1	0.873	0.172	0.007	0.318	0.005
Cluster 2	0.054	0.347	0	0.235	0.015
Cluster 3	0.318	0.811	0.992	0.273	0
Cluster 4	0.125	0.040	0	0.863	0
Cluster 5	0	0.017	0	0.473	0.757

This table shows the appearance rate of five items in each cluster. The item with the highest appearance rate in each cluster is shaded.

Result - Transition Model of Patient Conditions



Bold lines indicate a transition rate over 0.1; while dashed lines indicate a transition rate under 0.05. Numbers indicate transition rates.

Discussion

- If accurate accounting data can be obtained for a patient on any given day, the cluster in which the patient's daily condition exists can be calculated.
- This indicates the patient's stage of hospitalization, and calculation of the discharge date and discharge rate of the patient can then be performed by comparing this to the transition model constructed in this study.
- It is necessary to examine the validity and reproducibility of the model, and generalize to apply it to other diseases.

Conclusion

- A new method was proposed for constructing a time-related transition model of patient conditions for patients diagnosed with brain infarction, using HIS data.
- Validation of the model and generalization of this method are future goals of this project.

Abstract

Obstructive sleep apnea (OSA) is a sleep disorder with a wide range of comorbid conditions. Despite its known aetiology and manifestations, the strength of its association with comorbid conditions has not been fully explored. This research explored a large dataset (1999-2004) derived from the New South Wales Inpatient Data Collection, using a data mining approach, to provide a comprehensive disease pattern of OSA. All diagnoses were coded with the International Classification of Diseases (ICD)-Australian Modification codes. A total of 60,197 OSA cases (4% of total records) were identified. Their onset of occurrence was age-related with a peak occurrence at age 50-59y for both genders with a higher incidence in males. Comorbid conditions, in order of strength of association with OSA, were essential hypertension, obesity, hyper cholesterolemia, type 2 diabetes, and ischemic heart disease. When categorised according to disease systems, all cormorbid conditions clustered mainly into endocrine/ metabolic, cardiovascular and respiratory systems. The data mining approach unveiled the full OSA disease pattern and illustrated the progression of comorbid conditions.

Keywords:

obstructive sleep apnea, data repository, data mining, ICD-10I

Introduction

Obstructive sleep apnea (OSA) is characterised by repetitive, complete or partial occlusion of the posterior pharyngeal airways during sleep [1]. It affects approximately 2–15% of the general population [2]. The symptoms of OSA are snoring, transient cessation of breathing, and excessive daytime sleepiness. OSA patients suffer a poor quality of life due to fragmented sleep and a wide range of comorbid conditions of obesity, diabetes and cardiovascular diseases (CVD) [3]. Although much is now known about its prevalence, demographic characteristics, risk factors and comorbid conditions, a comprehensive disease pattern of OSA remains to be explored.

Data mining is the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data [4]. It assumes no prior knowledge but has the potential to uncover previously unknown relationships. The study aimed to apply a data mining technique to a clinical data repository to identify any unknown disease patterns and relationships with OSA.

Materials and methods

Data sources and definition of OSA

The data repository for this study is the New South Wales (NSW) Inpatient Data Collection. All public and some private hospitals report monthly all inpatient data to the Department of Health. A random dataset (1999-2004) was extracted. All diagnoses and procedures were coded with the International Classification of Diseases (ICD-10) Australian Modification (AM) codes [5]. G47.32 is the code for OSA. When comorbity conditions were subsequently explored, 4th and 5th digits for sub-classification were ignored. The number of codes generated for a patient can range from 5-20.

Data mining technique

The technique used was the association rule analysis that aims to discover the conjunctions of attribute-value pairs that are statistically related in huge data repository [6]. Association rule is an implication of the form X $\rightarrow$ Y, where X and Y are itemsets and X Y= Φ to predict that 'if X occurs in a transaction, then Y will likely also occur in the same transaction'. Each rule has two measures of its strength called support (the frequency of causality) and confidence (the strength of the causality):

$$\text{Support} \quad (X \rightarrow Y) = \frac{|\{t \in T \mid (X \cup Y) \subseteq t\}|}{|T|}$$

$$\text{Confidence} \quad (X \rightarrow Y) = \frac{|\{t \in T \mid (X \cup Y) \subseteq t\}|}{|\{t \in T \mid X \subseteq t\}|}$$

Identified dataset containing a diagnosis of OSA was a *focused dataset*. Frequency patterns discovered by association mining were noted as *focused patterns.*

Results

The dataset contained a total of 1,511,078 patient records (47.5% males and 52.5% females) from 1999-2004. A total of 60,197 (4%) had a diagnosis of OSA, listed as either principal or secondary diagnosis. Of these OSA cases, 72.2% were male and 27.8% were female (Figure 1). Comorbid conditions in order of the strength of association with OSA were essential hypertension, obesity, and type 2 diabetes mellitus (IDDM2), ischaemic heart diseases (IHD), hypercholesterolemia, congestive heart failure (CHF), cardiac arrhythmias, chronic obstructive lung disease, hypertrophy of tonsils/adenoids and disorders of nose and nasal sinuses, and joints problems such as gout, arthrosis, gonarthrosis and osteoporosis. Figure 2a,b show the age distribution for obesity, IDDM2, hypertension and IHD.

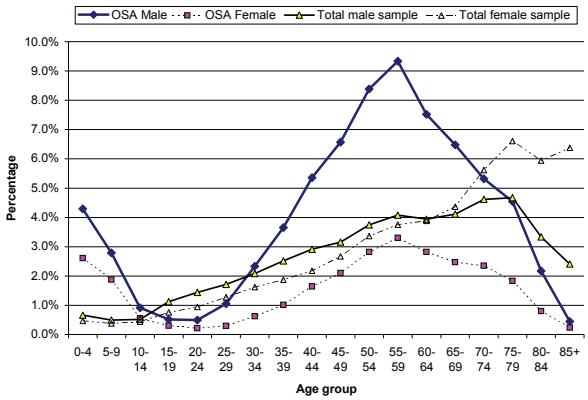

Figure 1 - Age and gender distributions of the sample and OSA cases

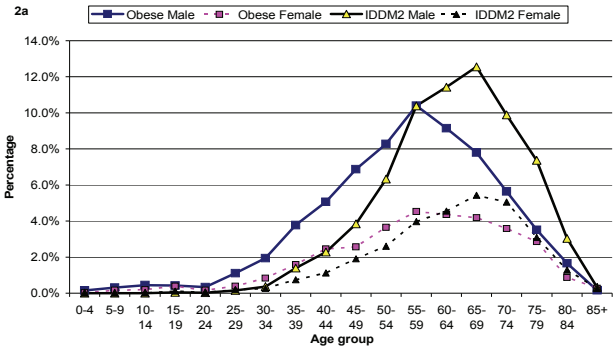

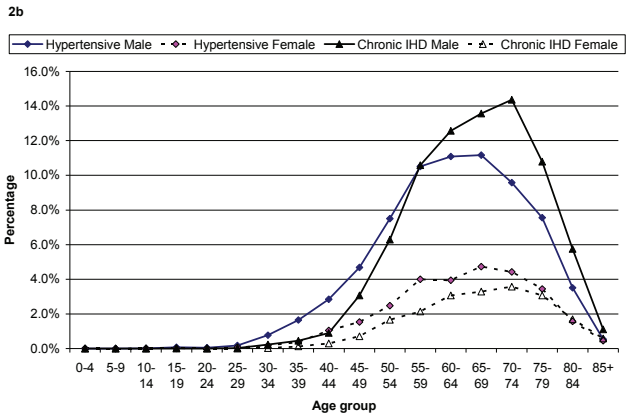

Figure 2 - Age and gender distributions of obestity and IDDM2 (2a), and hypertension and chronic IHD (2b)

Past or current use of tobacco was frequently listed in OSA patients. The comorbid conditions were clustered into the endocrine/ metabolic, cardiovascular and respiratory systems. There was high usage of health services amongst these patients (data not shown).

Discussion

This study has for the first time generated a comprehensive disease pattern of OSA. It confirms previous findings of a higher male prevalence, obesity as a risk factor, and associated comorbid conditions, namely IDDM2, and CVD (hypertension, IHD, CHF) [3].

The strong association of obesity, CVD, hypercholesterolemia and the metabolic syndrome with OSA suggests that a complex relationship of cause and effect exists between these conditions. Increase in obesity cases preceded that of hypertension, diabetes, and IHD. Such observation is in keeping with the knowledge of development and progression of disease patterns. Smoking may be a contributory factor to IHD and pulmonary diseases [7]. Joint diseases (arthrosis and gonarthrosis) are comorbid with OSA, although they are much less common compared to CVD. This observation has not been previously reported. Heavy use of health services related to treatments of OSA and comorbid conditions directly bear on the cost of health services and health burden on society.

In conclusion, data mining uncovers complex relationships between OSA and its associated comorbid conditions, and age and gender distribution of OSA. It offers an insight into the health cost of OSA and management of the disease.

3. Discipline of Exercise and Sport Science, The University of Sydney

INTRODUCTION

- Obstructive sleep aponea (OSA) is a disorder characterized by repetitive, complete or partial occlusion of the posterior pharyngeal airways that results in frequent wake-up during sleep
- Sleep fragmentation often leads to lack of concentration and poor performance.
- OSA has been reported to be associated with a wide range of disorders such as obesity, diabetes, and cardiovascular diseases.
- However, a full clinical pattern of cormorbid conditions associated with OSA is not known.

AIMS

- To explore the common conditions associated with OSA
- To generate a full pattern of the comorbid conditions

METHODS

Data source

- A random dataset (1999-2004) was extracted from the Inpatients Data Collection, a clinical repository for New South Wales (NSW) Hospitals
- The data set consisted of patients' demographics and clinical diagnoses
- All clinical data have been coded with the International Classification of Diseases (ICD)-Australian Modification (AM) codes

METHODS (cont'd)

Data mining

- **A commonly used data mining tool, namely** association rule mining**, was used to identify strongly associated conditions to a given target condition.**
- **This mining method is able to find**
  - **frequent patterns (condition, sequence, etc.) of occurrence in a database and**
  - **regularities in data such as co-existing conditions**
- **The method also performs causality analysis based on the association rule:**

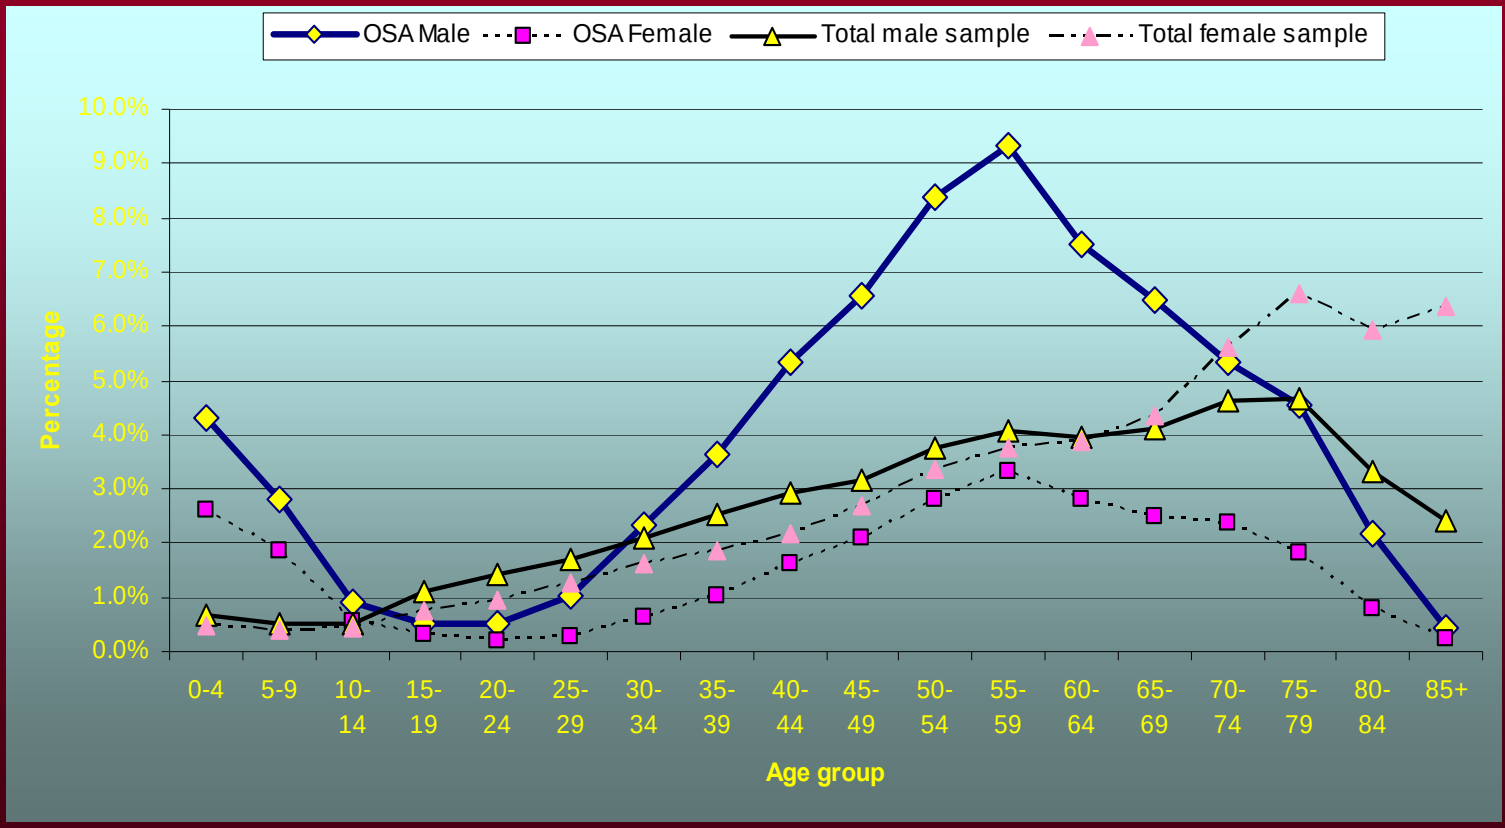
  x→y $X \subset I, Y \subset I$ $x \cap y = \phi$

  (support, confidence)
- **All association rules were searched and ranked without having to specify any minimum threshold values for support and confidence of the association rules.**

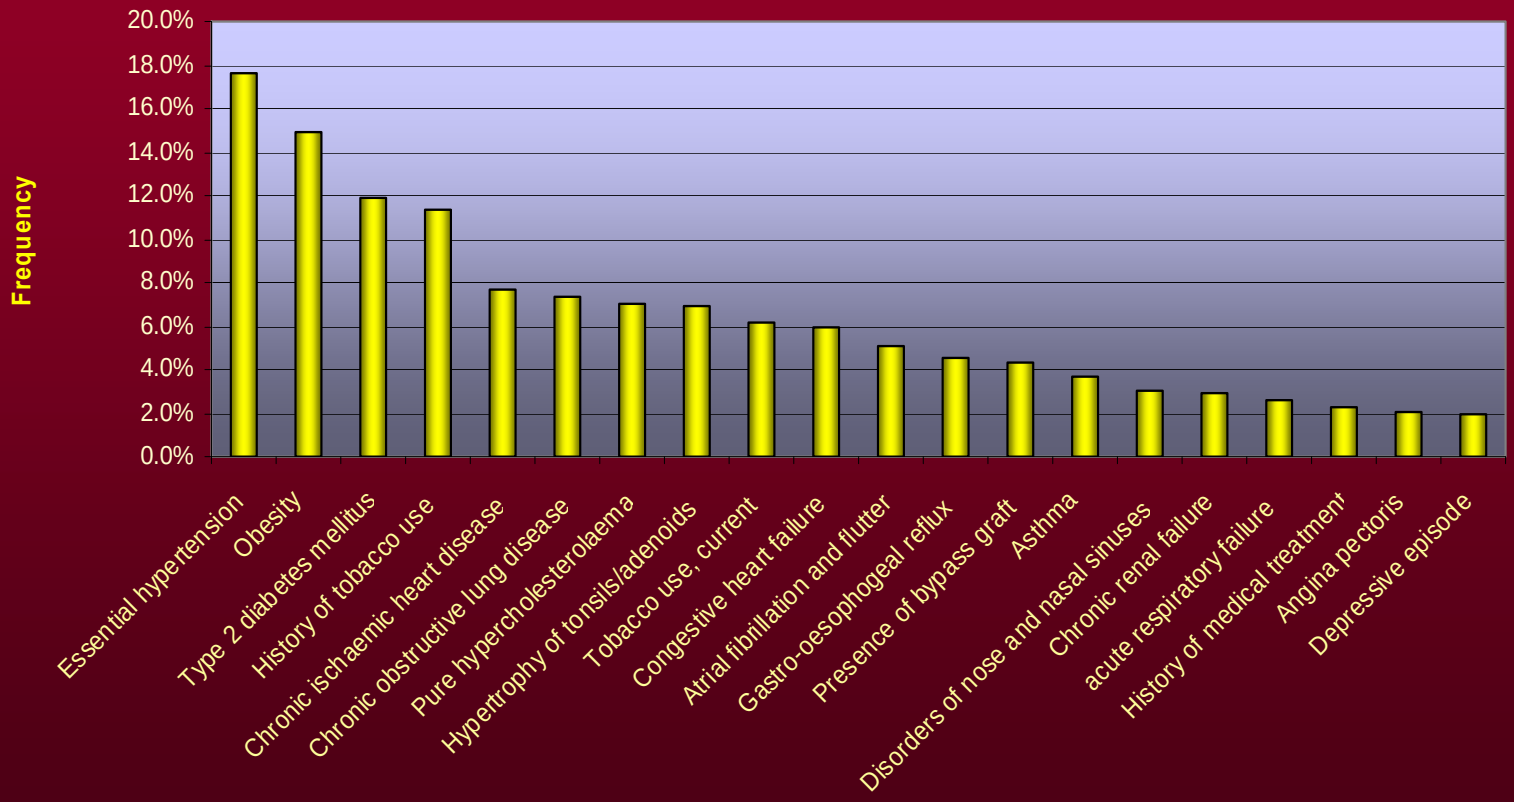
RESULTS

- There were a total of 1,511,078 patient records (47.5% males and 52.5% females) in the dataset
- A total of 60,197 (4% of the total records) had a diagnosis of OSA (72.3% males and 27.8% females)
- A complete comorbid conditions associated with OSA and their patterns were generated.

Age and gender distributions of the total sample and OSA cases

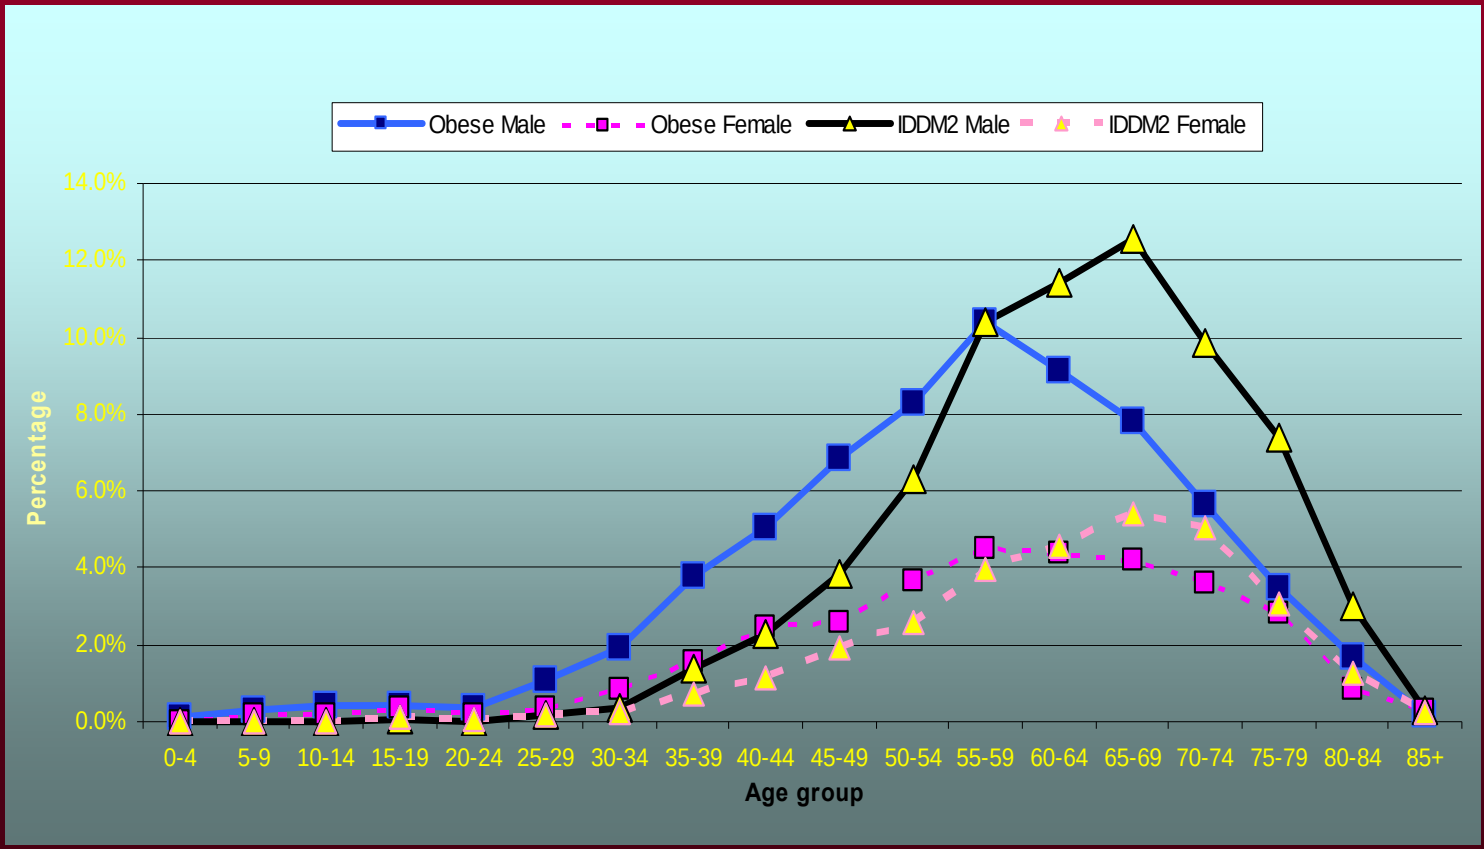


Common comorbid conditions with OSA

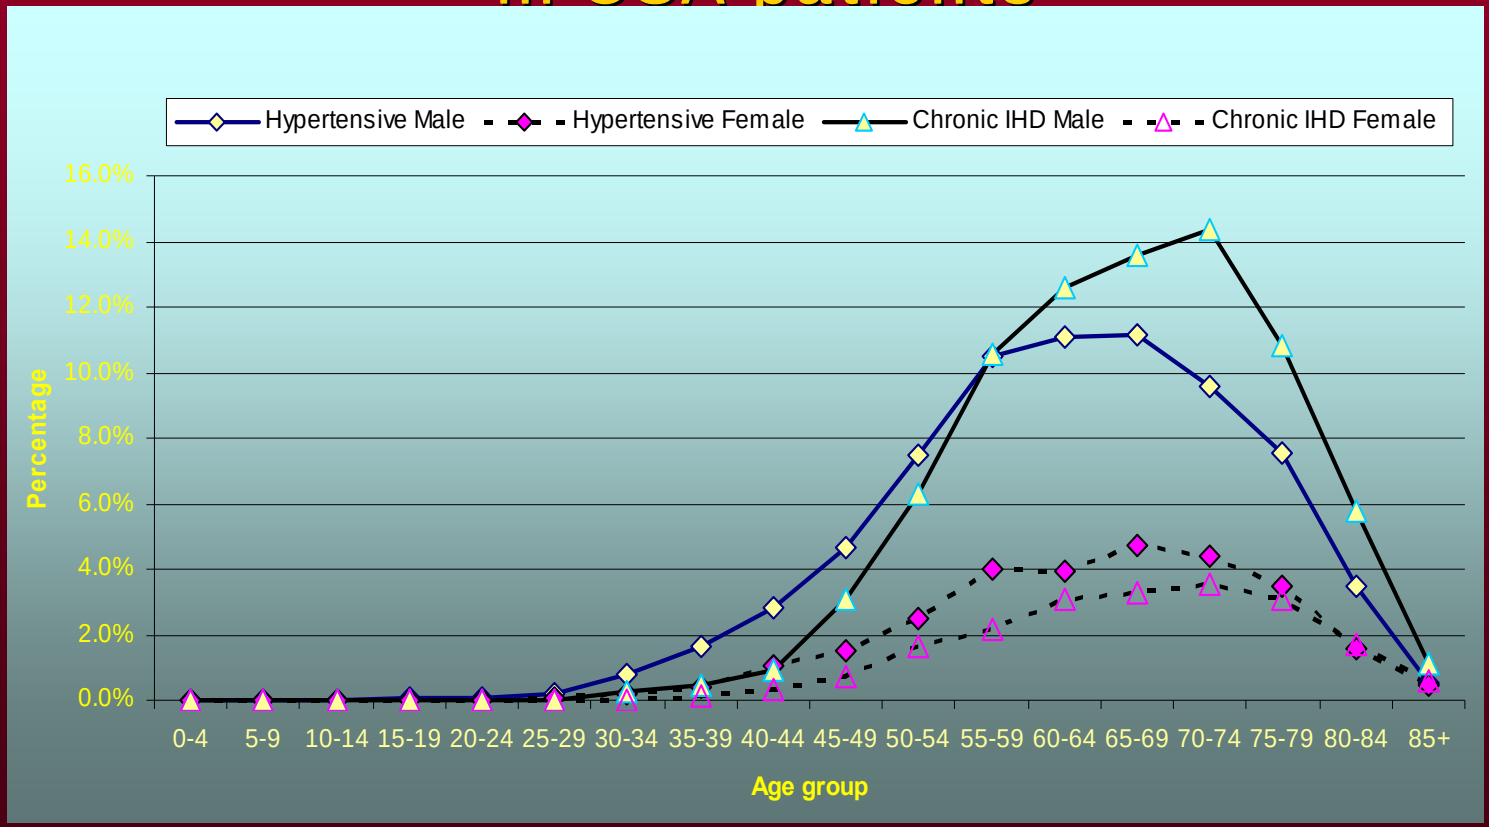


(Note: frequency is the occurrence of a condition of interest against total conditions)

Age and gender distributions of obesity and IDDM2 in OSA patients



Age and gender distributions of hypertension and ischemic heart diseases in OSA patients



DISCUSSION

- This study has for the first time generated a full clinical pattern of comorbid diseases in OSA using a data mining approach.
- It confirms early findings of a higher prevalence in males than in females, obesity as a risk factor, and associated conditions such as diabetes/ metabolic syndrome, and cardiovascular diseases (hypertension, IHD, congestive heart failure, stroke).
- It unveils other conditions that have not been previously reported including atrial fibrillation, asthma, esophageal reflux, chronic renal failure, depression, arthrosis and smoking
- It suggests that data mining, in large data repositories, is a powerful tool in uncovering clinical patterns of a disease with complex comorbidities.

Abstract and objective

There are large amounts of data about patients and their medical condition and evolution, which are stored in electronic databases or simply in archives. These deposits of information contain important nugets which have not been explored. We present our approach in using data mining techniques to investigate the factors associated with care quality and obstetrical risk factors. We also aim at developing suitable models and prediction systems for the two related aspects in obstetrical care.

Keywords:

medical data mining, quality models, obstetrics

Introduction

Following the international trend in health care, the long term strategy of the two Romanian official authorities in the field (the Ministry of Health and the National House for Health Insurance) states that by 2008 there should exist a reliable system for quality assessment in health care and it should serve as a basis for competition on the market. Taking this into consideration, we started a project focused on obstetrical care aiming at identifying the characteristics of our population, so being able to develop a model and a prediction system for this concrete population and environmental context.

Methods

Defining quality measures is not a trivial task and the usual approach is to use a set of measures focused on medical care processes and outcomes [1]. In Romania, we use mainly those available from the DRG system, focused on the outcomes, very limited and difficult to link to the process as they are based on a limited number of 'rate-based' indicators (i.e. occurrence rates of desired or undesired events) [1, 2]. Our approach is to combine pieces of data known as being directly related to quality of obstetrical services (based on criteria like importance as indicators, scientific soundness, and feasibility) [2], and use data mining tools to relate them to other assessments and plans of intervention [3].

Preliminary results and discussion

The work presented in this poster is part of a project aiming at identifying the factors associated with obstetrical outcomes and pre-term risk factors. We began by statistically analyzing reported outcome data from two university hospitals in distant geographic locations of each other, trying to identify patterns of diagnoses (based on the ICD-10 system compulsory in our country). Table 1 presents some raw statistics we obtained, which represented the starting point for further investigations.

Table 1 - Comparison between university Hospital B and university Hospital T (including the limited EHR data set for which we analyzed the pre-term birth risk factors). The ICD-10 codes specified represent the primary DRG reported codes

Year 2006	Hospital B DRG report	Hospital T DRG report	Hospital T EHR data set
No of new born babies	413	2864	211
No of pre-term babies	47 (11.4%)		14 (6.6%)
No of pregnant women (not necessarily distinct cases)	587	4560	211
ICD-10 O80 and O83 vaginal delivery	250 (42.5% of total ob-gyn cases)	2232 (49% of total ob-gyn cases)	157 (74% of deliveries)
ICD-10 - O82.0 elective caesarian delivery	4 (0.7%)	6 (0.1%)	54 (26%)
ICD-10 - O82.1 emergency caesarian section	74 (12.6%)	903 (19.8%)	0
ICD-10 - P03.4 newborn affected by caesarian delivery	40 (10.9% of full-term babies)	263 (9.3%)	22 (11.2% of full-term babies)

The discrepancies between the two hospitals in percent of caesarian section deliveries, as well as between the DRG reported data and the actual data existing in the small internal EHR data set could be related to both the insurance considerations (medical doctors' financial incentives to assign codes for reimbursement purposes combined with little experience in appropriately using the coding) and the patients' preferences or demands (convenience reasons or care for the well-being of the baby). We also tried to calculate some of the proposed performance indices for measuring performance [4, 5].

In parallel, trying to identify the targets for our further efforts in developing models for the obstetrical care outcomes, we focused on the factors associated with spontaneous preterm labour [6, 7, 8]. We have tried a selection of the significant attributes from the EHR database at our university hospital, processing them with Weka 3.4.8, some regressional models with DataFit 7.1.44, and applying a comparative analysis based on the following methods:

M1: a filter type ranking of attributes based on the informational gain (IG) [9];

M2: a filter type ranking of attributes based on the symmetrical uncertainty (SU) [9];

M3: a ranking based on the coefficients obtained by logistic regression (LR); in this case, the higher was the absolute value of a regression coefficient, the higher was the corresponding attribute's relevance;

M4: a ranking method based on the evolutionary multiobjective approach (EMOA) proposed in [10].

Although we have succeeded in identifying only 14 perinatal attributes as contributing to the pre-term delivery risk and the findings mainly confirmed what we already knew from literature or clinical experience [10], the classification results were encouraging (Table 2).

Table 2 - Classification results for attributes subsets selected based on different rankings

Ranks of selected attributes	Correct classification ratio (%)		
	M1(IG), M2(US)	M3 (LR)	M4 (EMOA)
1-14	77.96	77.96	77.96
1-13	78.53	78.53	79.09
1-12	76.27	76.83	77.40
1-11	76.27	77.4	78.53
1-10	78.53	79.09	80.79
1-9	78.53	78.53	80.79
1-8	79.09	80.79	80.22
1-7	79.66	80.22	80.79
1-6	77.96	79.66	81.92
1-5	76.83	81.35	81.92
1-4	78.53	82.48	83.05
1-3	76.83	81.35	82.48
1-2	80.79	81.92	81.92
1	79.09	79.09	79.09

Conclusions

A major problem consisted of the data themselves, which were sparse and incomplete (out of more than 2000 records we started with, we could effectively use only 211 for the pre-term risk model) and in the reported DRG data there were confounding factors in estimating the quality of the perinatal care.

At this stage, we concluded we should reconsider the data collecting methodology as better models require more discriminative clinical information. Despite the difficulties, data mining offers useful tools in this research endeavour.

Specific research questions at this stage

- Are there any patterns apparent in obstetrical DRG code utilisation?
- Could we identify the main factors which determine the obstetrical care outcomes?
- Could we identify the factors associated with the pre-term spontaneous delivery?

Statistical analysis of reported outcome data

- two university hospitals in distant geographic locations of each other
- DRG reported data for each hospital
- EHR data set for Hospital T – more data (demographic, blood chemistry, personal obstetrical history, pregnancy evolution)
- ICD-10 codes reported as primary and secondary diagnostic codes

Comparison between university hospitals B and T

Year 2006	Hospital B DRG report	Hospital T DRG report	Hospital T EHR data set
No of new born babies	413	2864	211
No of pre-term babies	47 (11.4%)		14 (6.6%)
No of pregnant women (not necessarily distinct cases)	587	4560	211
ICD-10 O80 and O83 vaginal delivery	250 (42.5% of total ob-gyn cases)	2232 (49% of total ob-gyn cases)	157 (74% of deliveries)
ICD-10 - O82.0 elective caesarian delivery	4 (0.7%)	6 (0.1%)	54 (26%)
ICD-10 - O82.1 emergency caesarian section	74 (12.6%)	903 (19.8%)	0
ICD-10 - P03.4 newborn affected by caesarian delivery	40 (10.9% of full-term babies)	263 (9.3%)	22 (11.2% of full-term babies)

Newborn babies can be seriously affected by a caesarian delivery

Discrepancy between the DRG reported data and the internal EHR data set

Overall use of ICD-10 obstetrical codes

(mothers & newborns, primary and secondary codes)

- Hospital T – EHR data set

  (211 records after pre-processing)

An Evaluation Study of Three Different Classification Methods on Mammogram Images

Levent E. Akman, Assoc. Prof. Dr. Nazife Baykal

Informatics Institute, Middle East Technical University, Turkey

Abstract

This study focuses on comparing three different types of classification methods –discriminant analysis, back propagation neural network and support vector machines (SVM) - on a special type of information -numerical data extracted from digitized mammography images-. Data extracted from mammography images show high variations among each other and, have an inhomogeneous nature. Therefore classification of this type of data becomes a challenging task. Neural networks have been known to be successful in analyzing data extracted from mammography images. Various examples of SVM analysis are also applied on mammogram classification in the literature. On the other hand, there are not many studies on discriminant analysis. Furthermore these three methods are not evaluated on the same data set. This study aims to compare and evaluate these methods by using the same data. The output of this work would provide valuable information about the comparative effectiveness of the three different classification methods on mammography image analysis for the researchers.

Keywords:

mammogram, microcalcification, classification,
neural networks, discriminant analysis,
support vector machines, evaluation.

Introduction

It is well known that screening mammography is the best tool available for detecting breast cancer before clinical symptoms appear because it can show changes in the breast up to two years before a patient or physician can feel them [1].

The main abnormality that the radiologists go through to detect breast cancer are the presence of microcalcifications [2]. The detected abnormalities are evaluated by the radiologists. This evaluation includes the decision task of whether the detected masses are malignant or benign by visually inspecting the detected microcalcifications [3].

Since mammograms have a high inhomogeneous nature, the data acquired from them have several drawbacks. First the data may be incomplete, inconsistent and very sensitive. These facts make the classification of this specific type of data a very complex problem.

As a first step of this study a detection application is implemented. The application uses Lee et. al.'s algorithm as the detection algorithm [4]. Using the detection application, selected features of the abnormalities are extracted for the classification.

In this study three different methods will be compared. A statistical method –discriminant analysis- and artificial intelligence methods –back propagation neural network and SVM- are selected for the analysis. The main idea behind this selection is to make a meaningful comparison and evaluation since the methods are based on different theories and mathematical backgrounds. Discriminant analysis is not a widely used method in the literature. On the other hand there are man examples on back propagation neural network classifier. SVM is also another analyzed method for the classification of microcalcification clusters by researchers. Our aim is to determine whether discriminant analysis produce worse results then the other two methods and furthermore determine the best classifier for microcalcification classification.

Finally a research study is accomplished for selecting the most discriminative features for the classification.

Materials and methods

Data

A total number of 117 mammograms were used in this study. Mammograms were acquired from two different sources: 68 mammograms from Cardiology service of Medical School of Hacettepe University and 49 mammograms from the mammographic image analysis society (MIAS) mini-mammographic database [5]. All of these mammograms are visually inspected by a faculty member at the Mammography service of Medical School of Hacettepe University. 117 of the mammograms contain microcalcification clusters where 60 of them are malignant and 57 of them are benign clusters.

The mammograms acquired from Hacettepe University were film mammograms. These mammograms are digitized with 300 dots per inch (DPI) using a Fuji's film scanner. The mammograms taken from the MIAS [5] mini-mammographic database were also digitized with 300 DPI.

All of the digitized mammograms are converted to an 8 bit image (i.e. the mammogram pixel intensities are mapped in to a 0-255 grey level range) before starting the applications since it is easier to work with an 8 bit image.

Detection of the abnormalities

The first step for a proper classification analysis on mammography images, is implementing an effective detection algorithm. In this study, two detection algorithms are developed and evaluated. Lee et. al.'s algorithm is selected as for the detection process since it produced better results. It should be mentioned that this detection algorithm is proven to give good results in many different environments.

The detection system is implemented by using Java-2 platform standard edition, software development kit version 1.4.2 (J2SE v 1.4.2 SDK) taken from Sun Microsystems Inc. [6]. The hardware used is a 1.0 GHz Pentium 3 processor with 256 Mb Read Access Memory (RAM).

The algorithm has 4 main steps: *Gradient Enhancement, Contrast Enhancement, Noise Elimination and Segmentation.*

The output of the segmentation sub-module is the final output of the entire detection system. The microcalcifications are detected satisfactorily by this system. Moreover the shapes of the microcalcifications are preserved which is a must for a microcalcification detection system since the classification is based on the shape and intensity features of the detected calcifications. The result of the detection system is depicted in Figure 1.

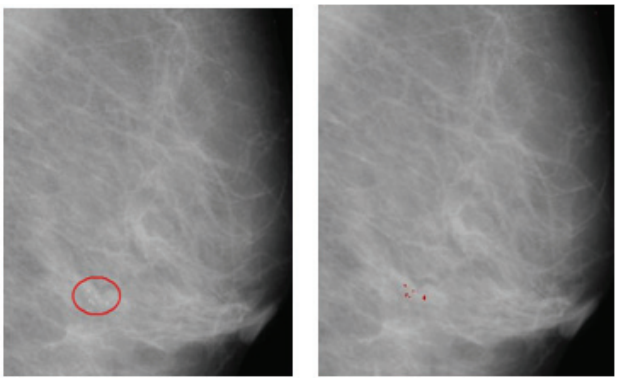

Figure 1 - Original mammogram (left) and segmented mammogram (right) with the detection system

The microcalcifications are marked in a circle in the original view mammogram. The system paints the detected calcifications as depicted in Figure.

The detection system is operated for 153 different mammograms and the detected abnormalities are cropped for the classification analysis. It should be mentioned that the detection results are evaluated by a professional and experienced radiologist and only the successful results (117 samples) are taken for classification.

Classification of the detected abnormalities

After detecting the abnormalities, the radiologists evaluate these results. This evaluation includes the decision task of whether the detected masses are malignant or benign and moreover whether to biopsy the suspicious findings [3].

A false positive diagnosis (i.e. diagnosing a benign tumor as malign) may cause an unnecessary biopsy while a false negative diagnosis (i.e. diagnosing a malign tumor as benign) may lead to cost a human life. .It has been reported that only 15 to 34% of calcifications requiring biopsy are cancerous which indicates a very high False Positive (FP) rate [7].Therefore it is important to correctly identify problematic fields as malignant or benign.

Feature extraction

Feature extraction is a preliminary step for starting classification. It is very important since the selected features will dominate the classification results. In order to define the correct features, the properties of the calcifications that point to breast cancer should be defined. Malignant calcifications are typically very numerous, clustered, small, dot-like or elongated, variable in size, shape and density. Benign calcifications are generally larger, more rounded, smaller in number, more diffusely distributed, and more homogeneous in size and shape [3].

The calcifications are analyzed in two different categories: individual calcifications and clustered calcifications [8]. In a computer aided diagnosis (CAD) system, these two are implemented separately. In other words, it is meaningless to examine only individual calcifications or examine only the groups. Size, shape and radiographic density of the calcifications are the main issues that define the level of malignancy when analyzing individual microcalcifications while their number, orientation, size, position are taken into account when examining microcalcification clusters.

Considering the above definitions about the malignancy indicators the features that point to the breast cancer can be generalized as shown in Table 1 [9].

Table 1

Features relating to descriptions of individual calcification:	**Features relating to the description and the distribution of clustered calcifications:**
Area of calcification	Average distance between calcifications
Average grey level	Orientation of calcifications with respect to its neighbors
Density	Variation of parameters of individual calcifications

Perimeter	Number of calcifications in the cluster
Contrast	Shape of the cluster
Smoothness	Size of the cluster
Approximate horizontal and vertical lengths	Compactness of the cluster
Shape descriptors- compactness, higher moments, Fourier descriptors	Cluster location in the breast
Effective thickness	

Furthermore, additional information can be included in the diagnostic procedure; such as patient history, clinical or demographic data. This study does not include such demographic data but concentrates on microcalcification features only.

Considering the indicators of malignancy described in Table 1,eight different attributes (representing the indicators) are extracted from the regions of interests as follows:

- **Attribute1** is the total number of detected abnormalities in the processed mammogram.
- **Attribute2** is the total area of the detected abnormalities in terms of pixels divided by the total area of the current mammogram.
- **Attribute3** is the mean intensity value of the detected abnormalities divided by the mean intensity value of the mammogram.
- **Attribute4** is the standard deviation of intensity values of the detected abnormalities.
- **Attribute5** is a measure of irregularity of detected abnormalities in shape.
- **Attribute6** is the standard deviation of Attribute 5.
- **Attribute7** is the mean distance between the abnormalities
- **Attribute8** is the standard deviation of the distances between the abnormalities.

Classification

The classification is implemented by extracting the selected features from the detection results. This data set then analyzed in Matlab 6.5 software package for three different classification techniques.

Discriminant analysis

Discriminant analysis is a technique for classifying a set of observations into predefined groups [10]. The classification model is built based on observations, using a set of variables (known as predictors or input variables), for which the groups are known. Discriminant analysis may be used for either measuring the success of classification, given the groups of objects, or assigning objects to one of the groups of objects.

60 of the data will be used for constructing the discriminant formula and the training of the back propagation neural network. And 57 of the data will be used for testing. We have utilized discriminant analysis to classify the mammographic image data.

In this analysis *linear* discriminant analysis and *quadratic* discriminant analysis are used.

For discriminant analysis, we have implemented the test in two different schemes. First we have developed the discriminant function with the training data and then tested it using the test data. “0” value is assigned for benign calcifications and “1” is assigned for malignant calcifications.

When the test data gives a value higher then “0,85” it is accepted in the malignant calcification class. Test values lower then “0,15” is included in the benign calcifications class. This scheme applies for all the three methods implemented in this study.

Before starting the analysis we should define the statistical measures for evaluating the classification methods. “Overall Success Ratio” defines the ratio of the “Total Number of Correct Classifications” to the “Total Number of Observations”. The other descriptive statistics are “Sensitivity” and “Specificity” measures.

Here it should also be mentioned that the same training and testing data which is utilized in discriminant analysis is also used for other classification techniques. The results of the linear discriminant analysis are given in Table 2:

Table 2

Overall Success Rate	Sensitivity	Specificity
84%	0,88	0,80

For quadratic discriminant analysis the results are as follows:

Table 3

Overall Success Rate	Sensitivity	Specificity
82%	0,88	0,76

Linear discriminant analysis gave slightly better results than quadratic analysis for the selected features. However it was expected to gain more benefit from quadratic discriminant analysis since the problem domain is ambiguous and fuzzy in nature.

Neural networks

Neural networks try to solve problems with a structure roughly similar to the neurons in the human brain. McCulloch and Pitts [11] introduced the first neural model. Back Propagation Neural Networks (BPNN) are one of the most common neural network structures, as they are simple and effective, and have a wide variety of application areas.

Neural networks are suitable for applications where only a few decisions are required from a massive amount of data, and also for the applications where a complex nonlinear relation needs to be learned. This property fits with the mammographic data where there is a huge amount of non-linear and fuzzy data which has to be classified into two classes namely benign and malignant.

We started the analysis by utilizing back-propagation neural network. Various back-propagation nets are implemented to get the best results. However due to space constraints we will give the results of the best network structure. The best net structure is determined as a three layered – one input, one hidden and one output- network. Since the data has 8 dimensions there are 8 neurons in the input layer. For this first design 3 neurons for the hidden layer gave the best results. And there is one output neuron. The best results are achieved with 500 epochs of training. The activation function is the tangent function and a standard back-propagation learning algorithm (gradient descent) is utilized. The net is depicted in Figure 2.

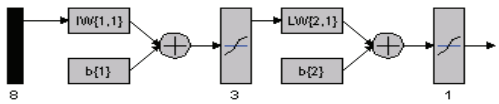

Figure 2 - Back propagation net constructed for mammogram data

The same data set selection with the discriminant analysis is used in the back propagation neural network technique as mentioned earlier. According to this schema the network is trained using 60 pre-selected data. And then the structured scheme is tested with the remaining 57 (27 malign,30benign) data. Below in Figure 3 the results are depicted for 500 epochs which yields the best results among many different trials.

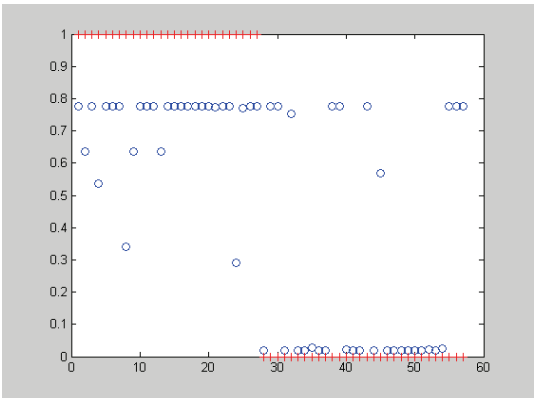

Figure 3 - Test results

The net could not classify 5 samples. The results are shown in Table 4.

Table 4

Overall Success Rate	Sensitivity	Specificity
72%	0,91	0,69

The results of the back propagation neural network can not said to be satisfactory from a clinical point of view. However our main aim is to evaluate this result with the other classification techniques. We can conclude that BPP network is less satisfactory then discriminant analysis.

The less number of epochs resulted in a lower success rate. On the other, when we tried higher number of epochs (i.e. 1000 epochs) the network tends to summarize the data and therefore gives ambiguous results.

Support Vector Machines (SVM)

The attention on this subject is increasing in the last few years. SVMs provide a new approach to the problem of data classification. This approach has relationships with statistical learning theory. SVM is characterized according to its Kernel functin. There are four basic and frequently used kernels. These are:

- linear
- polynomial
- radial basis function (RBF)
- sigmoid

SVM has major differences with comparable approaches such as neural networks: SVM training always finds a global minimum, and their simple geometric interpretation makes further investigation easy. An SVM is largely characterized by the choice of its kernel.

After implementing back-propagation neural networks and discriminant analysis we have analyzed this specific classification problem with SVM. For this analysis, linear SVM and non-linear SVM methods are utilized. Linear SVM uses linear kernel and we utilized polynomial kernel for non-linear SVM in our study. The results of these two methods are discussed below respectively.

Linear SVM results are depicted in Figure 4 and Table 5. In Figure 4, the red pluses represent the original output values, blue circles represent the output values of the test data after toe SVM application and green stars represent the decision values utilized to get the test data output values.

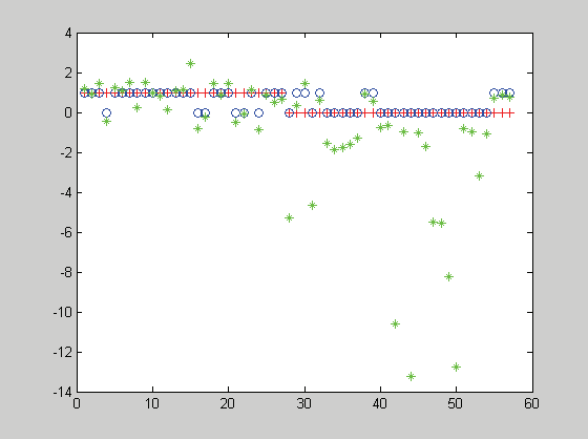

Figure 4 - The linear SVM results

Table 5

Overall Success Rate	Sensitivity	Specificity
75%	0,77	0,73

Linear SVM result in a higher success rate then neural net however the sensitivity and specificity results are not satisfactory. The linear SVM considered being unsuccessful from a clinical point of view.

The non-linear SVM method is implemented finally. We were expecting the most satisfactory results from this method because SVM has a high performance on non-linear and ambiguous data. The results are summarized in Figure 5 and Table 6.

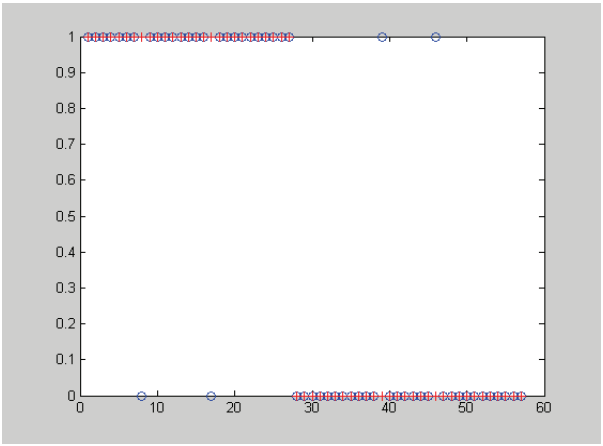

Figure 5 - The results of non-linear SVM

Table 6

Overall Success Rate	Sensitivity	Specificity
93%	0,93	0,93

It is obvious that non-linear SVM is very successful for the classification of mammographic data both from the clinical point of view and respectively to other methods. Only 4 entries are misclassified which is a high satisfactory result.

Discussions and conclusion

Three different classification methods, namely discriminant analysis, back propagation neural networks and support vector machines, are evaluated on a data set that is extracted from mammogram films. Discriminant analysis is not a widely used technique for classifying microcalcifications on mammograms. Using this fact, we comparatively assessed the performance of discriminant analysis method with respect to BPN and SVM techniques on the same training and testing data sets. This study also measures the results of the classifications from a clinical success perspective. In other words, we evaluated the overall success of a method for real life scenarios. Moreover two different detection algorithms are evaluated and the superior one is selected for the detection of microcalcifications. Finally a research study is made to determine the best features for microcalcification classification.

Discriminant analysis produced an overall success rate of 84% which is higher than the BPN success result of 72%. BPN result is also unsatisfactory from a clinical point of view. The most effective method is non-linear SVM for our analysis. Non-linear SVM produced 93% success rate. The sensitivity and specificity measures of SVM are also very satisfactory. SVM is also satisfactory from a clinical usage perspective.

As a result discriminant analysis should be considered during microcalcification classification on mammograms since it produced competent results. The high success of SVM on ambiguous data is again proved after this study.

Acknowledgments

We would like to thank to Prof. Dr. Figen Baaran Demirkazk for her support for her valuable support on providing and evaluating the mammogram images.

[c] *Department of Information and Knowledge Engineering, Danube University Krems, Austria*

Abstract

The study of isolated, inbred populations is a promising approach for the identification of disease susceptibility genes. One of the main challenges for geneticists and epidemiologist is to deal with the very complex genealogies of such populations. We present ongoing research on using a visual analytics based approach for the identification of family clustered diseases, risk factors and heritability patterns.

Keywords:

genetic epidemiology, visualization, disease clustering, pedigree

Introduction

The study of familial disease history is the necessary starting point when assessing the extent of genetic components in the etiology of common diseases. The homogeneity of the shared environmental factors and the limited number of recombination events in the DNA make isolated population studies potentially more powerful than general population studies for dissecting complex traits. The limited population dimension often enables to reconstruct very precise genealogies going back to several generations in the past, including hundreds or thousands of individuals. Available genealogical software is mostly focused on a static representation or is able to visualize only sub-pedigrees [1]. Moreover, it does not provide tools for simplifying the visualization of genealogical trees. On the statistical side, existing methods either focus on small family units or require exact calculations that are not computationally feasible.

The principle of "Visual Analytics" (VA) [2] is to combine the outstanding visual capabilities of humans with the power of analytical methods to support the knowledge discovery process. We propose a new approach for the analysis of family histories at a population level based on the concept of VA. Therefore, we (i) developed an effective pedigree drawing, (ii) integrated results in the visualization and (iii) added various tools for supporting the exploratory process.

Methods

Pedigree drawing

For the proper interpretation of pedigree based data, a clear layout is needed for reducing line crossings. Our speed optimized drawing algorithm is based on the 3 phase Sugiyama-heuristic [3]. Furthermore, to reduce line crossings and to facilitate the identification of heritability patterns, we developed a 2.5D visualization, whereby nodes are distributed on two distinct layers according to different criteria (Figure 1).

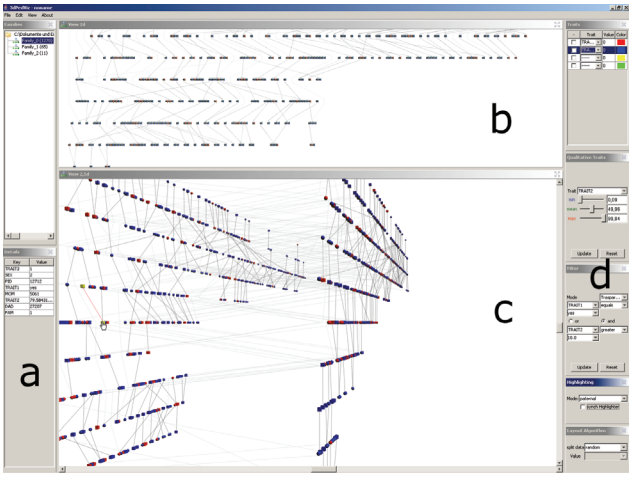

Figure 1 - Prototype PedVizApi: a.) Details on Demand, b.) 2d View c.) 2.5 View, d.) Dynamic Query Interface

Analyzing and visualizing process

The information visualization mantra by Daniel Keim [4] "*Analyse First - Show the Important - Zoom, Filter and Analyse Further - Details on Demand*" was followed.

Analyse first. Initially, various pre-processing steps, such as quantification and normalization, were applied. For the identification of familial disease clusters, different statistical and computational methods are available. Since for this type of analysis the hierarchical structure must be preserved, we integrated the results of the clustering algorithms into the pedigree drawing algorithm.

Show the Important. Depending on the research question, different qualitative and quantitative information is needed and has to be included in the pedigree drawing. Since for family history analysis close relatives are more disease relevant then distant ones, we assigned a transparency value to the connection lines based on the kinship coefficient.

Zoom, filter and re-analyse. The identification of family clustered diseases, risk factors and heritability patterns is an exploratory process. Therefore, we integrated a set of interactive tools, such as dynamic queries.

Details on demand. During the exploratory process additional information is required. On the one hand, static data can be retrieved from a data repository and displayed on demand. On the other hand, on the fly calculated information, such as the connection path between two individuals, is important to identify common risk factors or heritability patterns.

Results

We introduced this novel approach at our institute. Our data consists of the reconstructed genealogy of three isolated valleys, reaching back to the 1600s (50,037 individuals). Health information on 1175 subjects was obtained by means of a screening questionnaire consisting of 960 questions [5].

At this stage of our study, we are especially interested in assessing *which diseases or disease combinations are common and tend to group in families.* Analyses were carried out by three statisticians and four geneticists. Usually, these experts assess the presence of diseases clustering in families using statistical tests and then connecting affected individuals in the pedigree, for each disease of interest. The VA based method was new for them. It starts with an explorative process based on the whole genealogy, whereby the node positions are optimized regarding disease status/cluster, kinship, and line crossings. Based on the following tasks, the differences between the two approaches are highlighted.

Identification of disease clusters

For the subsequent analysis, the probability of familial clustering was estimated [6]. Due the large number of individuals, the exact calculation was not feasible. Moreover, the discovered disease clusters were always limited to small family units. Nonetheless, the VA approach identified clusters at the population level, whereby for the identification of nuclear family disease clusters (parents with less than 3 children) the pedigree must be explored more deeply.

Path between different disease clusters

Using the standard approach was limited to finding common ancestors between different clusters. The process was time-consuming because for every different disease setting paths and sub-pedigrees were reconstructed. With the VA approach, paths between the different clusters could be highlighted during the exploratory process. Moreover, missing and incomplete data were not a problem, because of working with the whole genealogy these parts were inferred by human perception.

Genetics or environment

Analytical methods are able to quantify the contribution of genetic and environmental factors. At the family level this approach is doable; however, at the population level, it becomes time consuming and only a subset of hypotheses can be tested. The VA approach does not quantify exactly the influence of the various factors but, in consideration that this was a screening phase, this is acceptable. All analyses can be performed at a population level, allowing for the exploration of different hypotheses. Missing and uncertain data are balanced partially by the capabilities of the human perception.

Discussion and conclusion

Due the complex structures of isolated population genealogies, classical, analytical methods used in a subsequent visualization setting are only able to identify local and/or single global population clustered diseases. Therefore, the distinction between genetic and environmental factors becomes difficult. Moreover, heritability patterns of rare diseases can only be identified by looking at the whole population in an “error tolerant way”, by exploring different diseases settings.

The VA based approach is capable to perform family history analyses at a population level. Sometimes, the identification of small, single, local disease clusters can be difficult, due to the global optimized representation. However, using the interactive capabilities, the identification of disease clusters and the generation of new hypothesis on the disease etiology are supported in an explorative way.

Integrating the power of the human perception with the VA method provides an appropriated framework for the knowledge discovery process. Nonetheless, experts have to explore findings from different points of view to confirm their robustness and to prevent false positive results.

Data Mining MEDLINEplus Queries, Circa "9-11"

Alicia O. Scott-Wright[a b], Qing T. Zeng[a]

[a] *Decision Systems Group, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*
[b] *Department of Health Policy and Management, Harvard School of Public Health, Boston, MA*

Abstract

We examined query logs circa "9-11" from use of MEDLINEplus, a consumer health information website. Our objectives were to determine to what extent consumers' health information interests were stable over time, and to identify and describe anthrax-related health information categories of presumed interest to users during critical time periods following the attack on the World Trade Center. Analyzing health information query logs may identify patterns of consumer usage that can assist health information website developers and sponsors to link consumers to the knowledge they seek and thus, in an epidemic crisis situation, facilitate adoption of self-protective behaviors.

Keywords:

consumer health information, MEDLINEplus, anthrax

Introduction

Surveys of Internet usage show that health information is one of the most cited reasons for searching the internet. That consumers may have problems forming effective queries which can often result in failure to find information sought has been established by the work of Zeng and associates.[1 2 3]

Twenty-two cases of anthrax were confirmed during the anthrax outbreak in the United States which followed the tragedy of September 11, 2001 (see Table 1). Unfortunately, the initial case of anthrax, confirmed on October 4, 2001, was erroneously identified as sporadic and due to a waterborne bacterial source. This false information from high ranking government officials may have undermined the credibility of subsequent reports coming from public health agencies. A consumer survey by Blendon et al[4] noted that during the anthrax outbreak most respondents trusted their own physician *most* for health information. However, information on health information websites was trusted *second-most highly* more so than information from public health agencies, and government officials or television.

How did consumers use health information found on the internet? In a survey by Kittler, Hobbs, Volk, Kreps, and Bates,[5] 58% of those searching online for anthrax-related information reported behavior changes. After searching for health information on the web, consumers physically handled mail differently, and 65% reported adopting self-protective behaviors, such as, washing hands more often.

We examined query logs, over the 4 month period 8/1/2001 – 11/30/2001, from use of MEDLINEplus, a consumer health information website. Our objectives were to determine to what extent consumers' health information interests are stable over time, and to identify and describe anthrax-related health information categories of presumed interest to users during critical time periods following the attack on the World Trade Center. Analyzing health information query logs may identify patterns of consumer usage that can assist health information website developers and sponsors to link consumers to the knowledge they seek and thus facilitate adoption of self-protective behaviors.

Materials and methods

MEDLINEplus query log analyses

In October 1998, the National Library of Medicine (NLM) announced a new resource, MedlinePlus, intended for consumers of health information.[6] When a user submits a query to MEDLINEplus, a program writes data about the query into the log file on the server. The original files we received from NLM consisted of log data for all queries submitted by consumers to the website (www.MedlinePlus.org) on the dates August 1, 2001 through 11/30/2001. Personal identifiers were not included in the log data we received.

We developed a JAVA program to parse the complex query log structure into fields which included: the actual query search terms, and a month, day, year, hour, minute, and seconds timestamp of that submitted query. Parsed files were imported into and analyzed using SAS v. 9.1 for all results reported in this paper.

To identify patterns in usage of consumer search terms over time, we aggregated web access log data into daily intervals to present it in time order. When plotted, time series formats can be visually assessed for patterns of periodicity, seasonality, and outliers.

Unique search queries

By definition, *One* unique or distinct query represents all queries with exactly matching search terms. For example, the exact search terms "diabetes mellitus" might have been

submitted by consumers numerous times and in differing frequencies per day over a selected time period, but would represent only one unique query.

Unique or distinct search terms were identified over the study period. To determine if consumer queries were stable over time, and to estimate to what extent consumer search queries changed over time, we calculated an *Overlap Rate,* which has been previously described and used in the analyses of query log files,[7 8 9] to measure the similarity between query logs on a month to month basis.

Given a series of query log files $L_1, L_2, ..., Ln,$ the *Overlap Rate* is defined as:

$$OR = (L_1 \cap L_2 \cap L_3 \ldots L_n) / (L_1 \cup L_2 \cup L_3 \ldots L_n) \quad (1)$$

Another example, the Overlap Rate for the top 10 unique queries for the month of January when compared with the top 10 unique queries for the month of February would be the number of *common* unique queries in the top 10 from January and February divided by the total number of *all* unique queries in the top 10 from January or February.

Anthrax-related time series plots

Our web access log study period spans the time of the events occurring just before and just after terrorist attacks on the World Trade Center in New York City on September 11, 2001 and the anthrax epidemic that followed. We divided our time series data of all queries containing the word (or search term) anthrax into periods based on possible dates of significance. Please note, our time series graphs represent the actual number of times English search terms containing the word anthrax (anthracis) were used on each day of our study period. Thus, every anthrax-related query is counted as a hit in our time series plot as many times as submitted.

Period 1 begins 8/1/2001 and ends 9/10/2001. Period 2 begins 9/11 and extends through and includes 9/17/2001. Period 3 begins 9/18, the day the first two of four letters containing anthrax spores were postmarked and extends through 10/3/2001. Period 4 begins 10/4/2001. The day the first case of anthrax was confirmed and hit the media and extends through 11/30/2003. Other important dates: October 9, 2001, the date two additional letters with anthrax spores were postmarked, and November 16, 2001, the date the final case of anthrax was confirmed, fall within Period 4. Below is a Centers for Disease Control and Prevention CDC chronology of the outbreak.

Table 1 - Chronology of Anthrax Outbreak (Source Centers for Disease Control and Prevention CDC, Atlanta GA.)

Date(s)	Event(s)
Sept 11	Terrorist attack on World Trade Center, New York, New York
Sept 18	Postmark date of 2 envelopes mailed to news media companies
Sept 22-Oct 2	Symptom onset dates for nine cases of anthrax (2 inhalational)
Oct 4	Anthrax first confirmed and made public
Oct 9	Postmark date of 2 envelopes mailed to government leaders
Oct 14-Oct 26	Symptom onset dates for 13 cases of anthrax (7 inhalational)
Nov 15	Symptom onset date for one *final* case of anthrax (inhalational)

Anthrax multi-word query classifications

Anthrax-related multi-word queries contained the word anthrax or anthracis and at least one other word. These multi-word queries were qualitatively examined and classified into the topics: epidemiology, microbiology, symptoms (lung, skin, other), therapy, vaccine, veterinary, warfare, and other complex queries aided by the use of a keyword search program written to place queries into categories according to matches of words in a query with keywords we used to define a category (see Table 2). The goal of these categorizations was to identify themes or topics that might help us better describe areas of presumed consumer interest. These categorizations were mutually exclusive and exhaustive.

Table 2 - Anthrax-related multi-word query categories and keyword list of some of the words or word fragments (*) used to categorize queries

Category	Keywords
Veterinary	cattle, woolsort*, dog, cat
Vaccine	vaccin*, immun*
Sympt:skin	rash, lesion, cutaneo*
Warfare	bioter*, weapon, postal
Sympt:lung	inhal*, lung, chest
Therapy	cipro, floxacin, penicillin
Microbiology	enzyme, mice, bacteria
Epidemiology	pregnan*, water, outbreak
Sympt:other	intestinal, gastr*, mening*

Table 3 - Anthrax-related queries by search strategy (one-word vs. multi-word) and by period with category breakdowns of multiword queries

Query Type	8/1 - 11/30		P1 8/1 - 9/10		P2 9/11 - 9/17		P3 9/18 - 10/3		P4 10/4 - 11/30	
	Count	%	Count	%	Count	%	Count	%	Count	%
Anthx Queries	15,481	100.0	63	100.0	64	100.0	594	100.0	14,760	100.0
One-Word	11,138	71.9	48	76.2	56	87.5	485	81.6	10,549	71.4
Multi-Word	4,343	28.1	15	23.8	8	12.5	109	18.4	4,211	28.5
Sympt-lung	203	1.3	5	7.9	0	0	5	0.8	193	1.8
Sympt-skin	752	4.9	1	1.6	1	1.6	2	0.3	748	7.1
Sympt-other	390	2.5	0	0	0	0	5	0.8	385	3.6
Vaccine	203	1.3	2	3.2	4	6.3	24	4.0	173	1.6
Therapy	418	2.7	0	0	2	3.1	32	5.3	384	3.6
Warfare	220	1.4	0	0	1	1.6	10	1.9	209	2.0
Microbiology	334	2.2	1	1.6	0	0	10	1.9	323	3.1
Epidemiology	737	4.8	1	1.6	0	0	10	1.9	748	7.1
Veterinary	30	0.2	0	0	0	0	1	0.2	29	0.3
Other	1056	6.8	5	7.9	0	0	10	1.7	1019	9.6

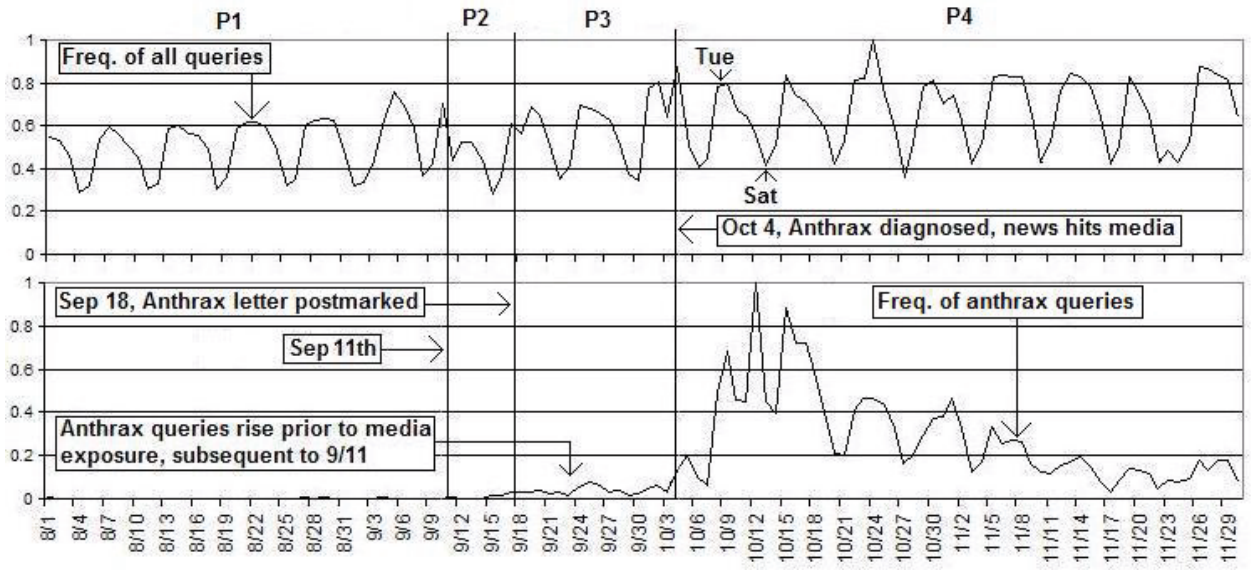

Figure 1 - Top - Normalized graph of all queries showing approximate weekly variation. Bottom - Normalized graph of anthrax-related queries over same time. P1: 8/1-9/10, P2: 9/11-9/17, P3: 9/18-10/3 P4: 10/4-11/30, 2001. Important dates: 9/18 and 10/9 - 2 letters containing anthrax mailed on each date. Nine people become symptomatic between 9/18 and 10/3; thirteen people become symptomatic after 10/4. First case diagnosed 10/4 and hits news the same day. Last anthrax case has symptom onset date 11/16 (CDC)

Results

Over the 121 day study period a *total query volume* of 2,179,571 English queries was submitted to MEDLINEplus; 1,012,542 (46.5%) of these query submissions were of only one word. [Range min: 8,853 queries submitted on 8/4/2001 max: 30,349 on 10/25/2001.] Figure 1 Top presents the normalized aggregated web access log data in daily intervals in time order. As visually depicted and confirmed by counts, queries were submitted approximately according to a *weekly* cycle.

Unique search queries

All submitted queries (regardless of the number of times submitted) or the *total query volume* was 2,179,571; only 634,669 or 29.1% were unique or distinct queries. Mean number of words used in these distinct search terms was 2.23 S.D. 0.14.

Table 4 gives the list of unique queries used 2000 times or more over the 121 day study period and the actual number of times the query was used.

Table 4 - Most commonly used search terms and number of times used

Unique Search Term(s)	Number of Times Used
anthrax	10,958
diabetes	6,093
fibromyalgia	3,549
lupus	3,515
asthma	3,049
multiple sclerosis	2,879
breast cancer	2,516
depression	2,486
cancer	2,392
osteoporosis	2,376
shingles	2,335
hypertension	2,260
alzheimer	2,203
cholesterol	2,138
anemia	2,062
stroke	2,047
arthritis	2,039

Table 5 shows the month-to-month overlap rates for the top 10 and top 100 unique queries of the two adjacent months compared.

Top 10 queries were on average 54% the same month-to-month with a statistically significant 95% Confidence Interval (CI) [34% - 74%].

The top 100 queries were on average 69% the same month-to-month also with a statistically significant 95% Confidence Interval (CI) [53% - 85%].

Table 5 - Month to month overlap rates for top 10 and top 100 unique queries in a month

Months compared	Overlap Rate (OR) Top 10	Overlap Rate (OR) Top 100
Aug. 01 vs. Sep. 01	0.43	0.64
Sep. 01 vs. Oct. 01	0.67	0.70
Oct. 01 vs. Nov. 01	0.54	0.74
Mean OR (S.D.)	0.54 (0.10)	0.69 (0.04)

Anthrax-related time series plots

Over the 121 day study period, 15,481 queries were submitted containing the word anthrax or anthracis; 11,138 of these were just the one-word anthrax or anthracis. Multi-word anthrax queries totaled 4,343 separate (non-unique) query submissions. [Range min: 0 queries submitted on various, but not all, dates between 8/1 and 9/10/2001 max: 885 on 10/13/2001.] Figure 1 Bottom shows a normalized graph of anthrax queries coincident with all queries (including all anthrax queries) on the same timeline.

Anthrax-related unique query classification

Table shows the multi-word anthrax-related query classifications overall and over previously defined periods (see Table 3). Note again, categories are mutually exclusive and that 1056 or 24% of anthrax-related multi-word queries were complex queries on wide-ranging topics and not assignable to the categories selected. Virtually all unassigned queries were submitted during period 4.

Discussion

We analyzed query logs from use of a consumer health information website, MEDLINEplus, over the period August 1, 2001 through November 30, 2001. We found that (for all queries submitted over this time) only about 1 in 3 were unique or distinct. Also, consumers used simple, unsophisticated search strategies; that is, about one-half (46.5%) of consumer queries were of only one-word.

Over our short study period, we determined that consumer health information needs were generally stable and predictable from month to month. With 95% confidence we can say that the top 10 queries would be between 34% - 74% the same month to month and the top 100 queries would be the same between 53% - 85% month to month.

Consumers responded to the events of 9-11 with a presumed interest in information about anthrax using the simple one-word search term for about three quarters of their anthrax-related searches. However, only 127 anthrax-related queries were submitted between 8/1 and 9/18. Once the first case was diagnosed and made public on October 4, 2001, consumers responded with a deluge of "anthrax" queries.

However, between 9/19 and 10/4 before an epidemic was announced, anthrax queries increased to 594. Mounting interest in anthrax, a possible biological warfare agent, following 9-11 might explain this increase, but information on other biological agents such as smallpox was not sought frequently (see Table 4). The predominant interest in anthrax in period 3 seemed to be about therapeutic agents and vaccines or immunization. While in period 4 (after media announcement of first case), the predominant interest was (other) not easily assignable to our selected topics and about cutaneous anthrax or the epidemiology of anthrax.

This study has several limitations. We analyzed queries which are only surrogate measures of actual questions. We could not examine the actual questions users had that led them to submit a query. Also, because of the relatively unsophisticated one word search strategy used for most searches a wide range of information might have been sought which could not be discerned from just that one term.

In conclusion, this study is a descriptive analysis of MEDLINEplus query log data over a 121-day period circa 9-11. In general, consumers used unsophisticated search strategies to access information on a relatively stable body of topics. Sponsors of consumer health information websites may need to provide a broad range of information about a relatively stable number of themes to meet consumer needs.

Also, we conclude that the events of 9-11 sparked an interest in one potential biological warfare agent and this interest was significantly increased once an actual case of anthrax was identified. What else would account for the increase in interest in anthrax between 9/18 and 10/4?

Abstract

The aim of this study is to examine whether or not heuristic modeling of physicians' expert knowledge can improve standardized data mining methods in prognostic assessments of patients with rheumatoid arthritis (RA). Five consultants in rheumatology were interviewed and their experiences of clinical test values for RA patients, as distinguished from corresponding values for healthy reference populations, were modeled in a knowledge engineering step. The results were used in K-mean-clustering to determine prognostic subgroups. Modeling experts' knowledge was found promising for semi-automatic data mining in the chronic disease setting. Further studies using categorical baseline data and prospective outcome variables are warranted.

Keywords:

knowledge engineering, medical decision making,
knowledge discovery in databases,
clinical decision support systems,
semi-automated data mining, rheumatoid arthritis

Introduction

Chronic diseases constitute a large part of the disease burden in western countries. Early identification of patients with chronic disease at risk of progression is essential, especially when early intervention can induce remission or retard the disease process. Identifying subgroups of patients with a less favorable prognosis at an early stage is therefore both a key clinical and public health priority. A specific type of decision support is assistance with knowledge discovery in databases (KDD) [1]. The aim of this study is to examine whether or not heuristic modeling of physicians' expert knowledge can improve standardized data mining methods in prognostic assessments of patients with RA. The starting point for the heuristic modeling is that the clinical test values for patients with a specific chronic disease differ from those of healthy reference populations.

Materials and methods

The research was performed in three steps. In a knowledge engineering step, physicians' experiences from the clinical use of four variables included in the evaluation of RA patients were elicited. In the second step, these data were analyzed and represented in a model that was implemented in an algorithm for the determination of prognostic groups. For comparison, the same algorithm was also used to develop groups based on the crude data set. In the final step, prognostic group validation, the model was validated by comparing physicians' global assessment of disease activity scores (PGA (scores 0–4, where 0 corresponds to no activity and 4 represents high activity)) for the patient groups identified with and without the model.

The knowledge engineering was based on data from a prospective multi-center study (TIRA) where 320 patients diagnosed with RA were diagnosed early and included during 1996 – 1998 [].The interval-/ratio variables in the database were especially interesting for this study, because they could be used in the standard method of K-mean clustering. The set of variables used here included the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), the 'number of swollen joints' and the 'number of tender joints'.

To find different subgroups of patients, the method of K-mean clustering was used on crude data, and then with two kinds of transformed data:

- Model A – Using the transformed data.
- Model B – Using the transformed data but with a predefined group of patients with values below the lower limit values (x_0) for both ESR and CRP.

To keep the results on a clinically comprehensive and not too complex level, the number of prognostic subgroups was limited to a maximum of four groups. The case with two subgroups was found trivial. Further cluster analyses were therefore restricted to three and four subgroups.

Results

Determination of prognostic groups

Running K-mean-clustering using three clusters resulted in a 'low value group' (low values for both ESR and CRP), a 'medium value group' (medium values for both ESR and CRP), and a 'high value group' (high values for both ESR and CRP).

Running K-mean-clustering using four clusters made the situation more complex. As in the case of three clusters, a 'low value group' and a 'high value group' appeared. There were also two 'medium value groups'. Despite minor differences in sizes and medium values for the clusters in the different model(s), the results were quite similar in this respect.

Prognostic group validation

The three patient subgroups identified using model B on the basis of ESR and CRP differed significantly with regard to PGA scores (Table 1). In comparison, the analyses based on the crude data identified only significant differences between the two extreme groups. In the case of four clusters, no significant differences were found in the crude data model with regard to PGA. Model A and Model B, however, both allowed the identification of significantly different groups based on ESR and CRP (Model A: 1 significant difference, Model B: 3 significant differences).

Table 1 – Validation of derived models A and B against crude data using physicians' global assessment scores (PGA) as proxy for patient outcome. Mean values (95% confidence interval) are displayed for each cluster (three and four clusters, respectively)

	Crude data		Model A		Model B	
3 Clusters	N	PGA	N	PGA	N	PGA
1	188	1.89 (1.78-2.01)	154	1.84 (1.71-1.96)	59	1.56 (1.37-1.76)
2	70	2.10 (1.93-2.27)	72	2.04 (1.87-2.21)	149	1.99 (1.87-2.11)
3	21	2.33 (1.89-2.77)	53	2.30 (2.08-2.53)	71	2.30 (2.12-2.48)
4 Clusters						
1	171	1.88 (1.76-2.00)	146	1.82 (1.69-1.95)	59	1.56 (1.37-1.76)
2	36	2.19 (1.98-2.41)	31	2.16 (1.95-2.38)	110	2.00 (1.86-2.14)
3	51	2.00 (1.77-2.23)	62	2.05 (1.86-2.23)	58	2.07 (1.87-2.27)
4	21	2.33 (1.89-2.77)	40	2.30 (2.02-2.58)	52	2.31 (2.08-2.54)

Discussion

A knowledge engineering approach where heuristic expert knowledge was used to transform data showed to be more efficient for identifying prognostic subgroups than K-mean clustering of crude data. The resulting subgroups passed the first 'objective gateway,' which means that they differed significantly when using basic statistical criteria for cross-sectional evaluation, compared to the analysis of crude data. The PGA used for evaluation is the variable available in the TIRA database that was the closest proxy to patient outcomes from a clinical point of view. Within this limitation, we found that the model representing physicians' expert knowledge in chronic disease was more efficient in identifying prognostic subgroups than standard procedures based on crude data. Further studies using categorical baseline data and prospective outcome variables are warranted. This effort will be implemented in the Swedish TIRA project using more comprehensive clinical data sets.

Data Entry Errors in Clinical Research Databases

Saveli Goldberg, Marek Ancukiewicz, Andrzej Niemierko

Massachusetts General Hospital, Boston, MA, USA

Abstract and objective

Human-caused errors occur at all stages of research process. We consider here data entry errors in clinical databases, understood as unintentional mistakes in interpretation or transcription of medical records at the time of data entry, and mistakes resulting from interaction with a computer program. Our experience shows that errors of this type occur commonly The existence, and even the consideration of a possibility of errors of data entry is seldom acknowledged in research practice, despite that they add substantially to the uncertainty about study results and, sometimes, may affect the conclusion of the study. We consider some systematic strategies of database errors reduction.

Keywords:

databases, factual

Methods

To investigate the prevalence of database errors and their characteristics we 1) tested 20 volunteers entering the same data sample, representative of Radiation Oncology databases and 2) used data from a review and consistency checks in a real database of 5500 patients. The volunteer test was performed using proprietary computer software for data entry, which enabled us to capture mistakes, self-corrections, and temporal characteristics of keystrokes. The computer program did not provide the user with a feedback about inconsistent entries, or exceeding allowed ranges for numeric data. However, text data were not allowed in numeric fields and conversely. Test data included 139 records and eight fields: three fields with character data in English text and five fields with numeric data. Between 34 and 100 records were entered per volunteer. A database containing information about 5500 patients was used for estimation of data entry errors. For real database, we considered as an evidence of data entry mistakes the treatment initiation dates and the follow-up date falling on Sunday. To illustrate the significance of database errors we derived two Kaplan-Meier estimates of local control obtained from data interpreted and entered by two physicians from the same medical records of 120 patients.

Results

In data entry experiments, an uncorrected mistake in was made in 0.2%-6.5% of fields entered, depending on the person tested. The average error rate was 2.7%, with S.D. of 2.0%. Type and percent of errors are relatively stable parameters for each person. The actual average distance between errors was significantly less then if we had a uniform distribution of errors. The probability of error in a field was found to depend on nature of the field and relationship of that field with other data. For example in database from 5500 patients Sunday as the day of radiation therapy start was in 0.9% cases, but Sunday as the day of last follow-up visit was in 2.6% cases. For two versions of the data prepared by two physicians, the actuarial local control gave the 69% +/- 6% vs. 61% +/- 6% in 5-year rates. Missing data about local failure is the main source of the survival curves distinction**.**

Conclusions

Database mistakes are a ubiquitous part of the normal research process. As we have demonstrated on Kaplan-Meier estimates of local control, data entry errors may have a substantial impact on study findings and the significance of the results. Different approaches for reduction of data entry errors include proper management of data entry process (including double data entry) and algorithms for detecting inconsistent and out of range entries during time of data entry. Further research is needed to develop algorithms for detecting data entry errors based on temporal characteristics of typing, self-correction of the record, history of the user previous errors, and the style of user typing. A caution should be always exercised during statistical analysis of data and in interpreting study findings. It is possible to propose some methods of database errors reduction, which take into account the statistical properties of the mistakes.

Automatic Categorization of Google Search Results for Medical Queries using JDI

Anantha K. Bangalore, Guy Divita, Susanne Humphrey, Allen Browne, Karen E. Thorn

National Library of Medicine (NLM), United States

Abstract

The web has become the primary source of medical information for consumers and health professionals. It is quite common for people to "Google" for information related to a medical topic. But the problem remains that as the number of documents increases on the web, the difficulty in quickly locating the best documents increases. Classifying results into meaningful categories helps guide users to the most relevant set of results. Journal Descriptor Indexing (JDI) is a novel approach to fully automatic indexing. In this paper we explore the feasibility of using JDI to organize Google search results for medical queries into meaningful categories.

Keywords:

medical subject headings, information storage and retrieval, internet, classification, MEDLINE, indexing and abstracting

Introduction

It is very common for consumers and health professionals these days to use search engines like Google to look up information related to various medical topics. The number of documents for any given topic on the web is increasing exponentially. Even though search engines such as Google are worthwhile for searching the web, the results typically tend to be of low precision and high recall. Users quickly lose interest, if the relevant results are not in the top 2 or 3 pages. To focus the search, users have to develop a good set of search terms, an often time consuming and challenging process. One approach to help users would be to quickly classify the results into meaningful categories that would allow users to drill down into a category of interest.

In this paper we explore the feasibility of using the Journal Descriptor Indexing (JDI) methodology developed at NLM for automatic categorization of Google search results for medical queries. JDI has been proven effective in characterizing MEDLINE documents. Our experiments explore the feasibility of using JDI on Google documents for categorization.

For this paper we extracted 20 documents for 5 terms from Google using Google's SOAP-based application programmer interface (API) [6]. Of the 5 terms, 3 were medical, one was ambiguous with both medical and non-medical meaning, and the last was inherently non-medical. Three reviewers independently evaluated the quality of the categorization for 3 of the same documents for each of the 5 query terms. Based on the results, this is a promising method for categorizing medical search results from Google.

Materials and methods

Journal Descriptor Indexing (JDI)

The JDI methodology associates JDs with words in titles/ abstracts in a training set of about 435,000 MEDLINE records. Each record "inherits" JDs from the serial record matching the journal title. For example, a MEDLINE record with journal title Journal of Pediatric Surgery inherits the JDs Pediatrics and Surgery from the matching serial record. Each word in the training set can then be described by a JD profile, which is a list of JDs ranked according to the number of co-occurrences between the word and the JDs in the training set.

For example, the first three JDs, with scores in decreasing order, for the word "appendectomy" would be:

1	0.8631	Surgery
2	0.6787	Gastroenterology
3	0.5415	Diagnostic Imaging

Once JD profiles have been computed for each word in the training set, they can be used as the basis for indexing documents. We index a document by averaging the scores for each JD across the words in the document; these averages become the JD scores for the document. We then rank the JDs in decreasing order of these score. That is, we treat the JD profile of a word as a JD vector, and the JD indexing of a document is computed as the centroid of these JD vectors.

For example, the first three JDs, with scores, returned by a MEDLINE title "Appendectomy in children" would be:

1	0.4623	Surgery
2	0.4230	Pediatrics
3	0.3675	Gastroenterology

The Surgery score is the average of the Surgery score for the word "appendectomy" (0.8631) and "children" (0.0614) in the training set. The score for Pediatrics is the average of the Pediatrics score for "appendectomy" (0.1645) and for "children" (0.6815); the score for Gastroenterology is the average of the Gastroenterology

score for "appendectomy" (0.6787) and for "children" (0.0563).

Methodology

We selected 5 terms for this experiment. These are:

Chronic bloody nose, Carotid artery surgery, Dark circles, Ventilator, Cold war

We used Google's SOAP API to make queries to Google's Search Web service. We retrieved the top 20 URLs for each of the 5 documents for a total of 100 documents. These files were then used as input to the JDI tool. The JDI tool created a JD profile consisting of the top 15 JDs for each of the documents.

In order to choose the list of the JDs which best categorizes a given document we developed a set of heuristics. We also assigned confidence levels to each of the categorizations within that set. The following describes the heuristics used in determining the category and the confidence level:

1. If the first JD for a document has a score of less than 0.2, categorize that document as "Undefined". The low score indicates that it is difficult to determine whether the corresponding document contains enough information to allow it to be meaningfully categorized.
2. Pick the top *n* JDs where the difference between the score of the first JD and the rest of JDs is < 0.1.
3. Assign a confidence level to the categorization based on the JD score.

0.1 – 0.2:	Undefined	(U)
0.2 – 0.3:	Weak	(W)
0.3 – 0.4:	Barely	(B)
0.4 – 0.5:	Strong	(S)
> 0.5:	Very Strong	(VS)

Results

Table 1 below summarizes the results of the experiments for each of the documents for each of the 5 query terms.

Table 1 - Summary of categorization results by confidence levels

Query term	VS	S	B	W	U
Chronic Bloody Nose	5%	10%	30%	40%	15%
Carotid Artery Surgery	0	5%	30%	35%	15%
Dark Circles	35%	15%	20%	20%	10%
Ventilator	5%	30%	35%	25%	5%
Cold war	0	0	15%	25%	60%

The results of the experiment show that for those documents that contained high quality medical content, the system categorized them with a very strong (VS) or a strong (S) confidence level as expected. On review, the majority of the documents categorized with a VS or S confidence level appear to have been correctly categorized.

In the case of the term "Cold war", though most documents were high quality, they were non-medical in nature. Our system categorized these documents as Undefined as expected.

Evaluation

For evaluation purposes we randomly selected 3 specific documents for each of the 5 terms. Three reviewers independently reviewed these documents

Table 2 - Summary of reviews by Reviewer

Query Term	Reviewer 1	Reviewer 2	Reviewer 3
Chronic Bloody Nose	100%	100%	100%
Carotid Artery Surgery	67%	33%	100%
Dark Circles	33%	100%	100%
Ventilator	67%	100%	67%
Cold war	100%	100%	100%
Average	**73%**	**87%**	**93%**

Conclusion

In conclusion we found:

1. Based on the results and the evaluations, the use of the JDI methodology may prove a valuable technique for categorizing medical search results from Google.
2. The quality of the categorization may be vastly improved if there were a consistent approach to removing noise from Google documents. (Ads etc.)
3. High quality medical documents (MedlinePlus, Wikipedia) were categorized with a very strong or strong confidence level with high scores. Non-medical documents tended to be categorized as undefined with very low scores.

Future work

We plan to perform the following as part of our future work:

1. We plan to perform additional experiments expanding the number of input terms.
2. We plan to explore the feasibility of using the JDI-based Semantic Type indexing for categorization.

Automatic Categorization of Google Search Results for Medical Queries using JDI

Anantha K. Bangalore, Guy Divita, Susanne Humphrey, Allen Browne, Karen E. Thorn

Introduction

- Consumers and Health care professionals routinely use Google to lookup medical information.
- No. of documents for any given topic is increasing exponentially on the web.
- Users quickly lose interest, if the relevant results are not in the top 2 or 3 pages.
- Quickly classifying the results into meaningful categories would allow users to drill down into a category of interest.
- Explore the feasibility of using Journal Descriptor Indexing (JDI) methodology developed at NLM for automatic categorization of Google search results for medical queries

Journal Descriptor Indexing (JDI)

- Based on NLM's practice of maintaining, in its serials file, a subject index to journal titles using a set of MeSH terms, known as JDs (journal descriptors) corresponding to biomedical specialties
- JDI has proven effective in characterizing MEDLINE documents
- JDI associates JDs with words in titles/abstracts in a training set of about 435,000 MEDLINE records.
- Each record "inherits" JDs from the serial record matching the journal title

Journal Descriptor Indexing (JDI)

- Each word in the training set can then be described by a JD profile, which is a list of JDs ranked according to the number of co-occurrences between the word and the JDs in the training set
- A document is indexed by averaging the scores for each JD across the words in the document; these averages become the JD scores for the document
- The JDs are ranked in decreasing order of these scores. That is, the JD profile of a word is treated as a JD vector, and the JD indexing of a document is computed as the centroid of these JD vectors.

Journal Descriptor Indexing (JDI) (example)

- The first 3 JDs for MEDLINE title “Appendectomy in children”
- Surgery score is the average of the Surgery score for the word "appendectomy" (0.8631) and "children" (0.0614) in the training set. The score for Pediatrics is the average of the Pediatrics score for "appendectomy" (0.1645) and for "children" (0.6815); the score for Gastroenterology is the average of the Gastroenterology score for "appendectomy" (0.6787) and for "children" (0.0563).

1	0.4623	Surgery
2	0.4230	Pediatrics
3	0.3675	Gastroenterology

Methodology

- Extracted 20 documents for 5 terms from Google using Google's SOAP-based application programmer interface (API).
- Of the 5 terms, 3 were medical, one was ambiguous with both medical and non-medical meaning, and the last was inherently non-medical
- The JDI tool created a JD profile consisting of the top 15 JDs for each of the 100 documents
- Developed heuristics to choose the list of JD's which best categorizes a given document
- Multiple JDs required to classify documents containing information about multiple topics.
- Assigned confidence levels to each of the categorizations within that set

Methodology

- If the first JD for a document has a score of less than 0.2, categorize that document as “Undefined”. The low score indicates that it is difficult to determine whether the corresponding document contains enough information to allow it to be meaningfully categorized.
- Pick the top *n* JDs where the difference between the score of the first JD and the rest of JDs is < 0.1.
- Assign a confidence level to the categorization based on the JD score.
- 0.1 – 0.2:Undefined(U) 0.2 – 0.3:Weak(W) 0.3 – 0.4:Barely(B) 0.4 – 0.5:Strong(S) > 0.5:Very strong(VS)
- Three reviewers independently evaluated the quality of the categorization for 3 of the same documents for each of the 5 query terms.

Results

Query term	VS	S	B	W	U
Chronic Bloody Nose	5%	10%	30%	40%	15%
Carotid Artery Surgery	0	5%	30%	35%	15%
Dark Circles	35%	15%	20%	20%	10%
Ventilator	5%	30%	35%	25%	5%
Cold war	0	0	15%	25%	60%

Summary of categorization results by confidence levels

Evaluation

Query term	Reviewer 1	Reviewer 2	Reviewer 3
Chronic Bloody Nose	100%	100%	100%
Carotid Artery Surgery	67%	33%	100%
Dark Circles	33%	100%	100%
Ventilator	67%	100%	67%
Cold war	100%	100%	100%
Average	73%	87%	93%

Summary of reviews by Reviewer

Conclusion

- The results show that for those documents that contained high quality medical content, the system categorized them with a very strong (VS) or a strong (S) confidence level as expected.
- Majority of google documents tend to generic in nature, containing information about multiple topics.
- On review, the majority of the documents categorized with a VS or S confidence level appear to have been correctly categorized.
- The quality of the categorization may be vastly improved if there were a consistent approach to removing noise from Google documents. (Ads etc.)
- Non-medical documents tended to be categorized as undefined with very low scores.

Future Work

- Plan to perform additional experiments expanding the number of input terms.
- Plan to explore the feasibility of using the JDI-based Semantic Type indexing for categorization.
- Plan to evaluate whether it is possible to extend our technique for determining the medical or non-medical focus of a document.
- In our experiments we extracted only the first level documents (depth 0) for a given URL. In the future we want to experiment with extracting the second and third level documents for a given site.
- We plan to use the origin of the document (NLM, Wikipedia) in determining the confidence level.

Representation of Smoking-related Concepts in an Electronic Health Record

Mollie R. Poynton[1 2], Lewis Frey[2], Hongying Tang[2]

[1]University of Utah College of Nursing, Informatics Program, United States of America
[2]University of Utah School of Medicine, Department of Biomedical Informatics, United States of America

Abstract

Data-driven models, created using the process of knowledge discovery in databases (KDD), can be used to predict characteristics or outcomes of patients, and thus aid decision-making. These models possess the capacity to augment evidence-based decision making related to smoking cessation on the basis of individual patient characteristics. This study (1) assessed the feasibility of a KDD project related to smoking cessation, and (2) mapped strengths and weaknesses in representation of smoking cessation related concepts in a commonly used electronic health record (EHR), EpicCare EMR. A sample of patient records was assayed and mapped to smoking cessation guidelines. Data quality issues related to coded representation of tobacco use were evident. Both strengths and weaknesses in representation of smoking-related concepts were identified. Analysis of free text patient notes may be helpful to adequately describe smoking and smoking cessation in patient records for the purpose of KDD.

Keywords:

Tobacco Use Cessation, decision support systems, clinical, medical records systems, computerized, data analysis, statistical, knowledge discovery in databases

Introduction

Previous work by the principal investigator demonstrated the capability to build predictive models of smoking cessation status from health survey data using the KDD process [1]. However, this capability has not been demonstrated using data from an ambulatory clinical information system. In order to create or augment clinical knowledge models related to smoking cessation using the KDD process, concepts relevant to smoking cessation must be represented by the data. Data quality must be assessed and considered. Moreover, the labor required to pre-process the large amount of data will be great. So, before engaging in a full-scale study, involving large amounts of data, it is prudent to determine the feasibility of using KDD/ data mining to create predictive and descriptive models of smoking cessation using the intended data. The purpose of this study was to determine the feasibility of using data mining methods to create predictive and descriptive models of smoking cessation using data from a primary care clinical information system.

Methods

This study examined data generated by EpicCare EMR (Epic) in a group of community outpatient clinics [2]. A random sample of 3000 electronic records, each corresponding to a single patient coded as a current or former smoker, and seen at a clinic within the past year, was extracted from the enterprise data warehouse. The Epic data dictionary was used to identify tables and attributes within those tables possibly relevant [3]. Each Epic attribute/ variable was assessed for representation of key concepts related to primary care management of smoking cessation, including the assessment of tobacco use/ dependence, tobacco dependence intervention, and relapse prevention. Attributes were manually mapped to concepts extracted from the VA/DoD clinical practice guideline for the management of tobacco use, and the United States Public Health Service (U.S.P.H.S.) Guidelines on Tobacco Use and Dependence. [4, 5]

Results

A series of forty-one individual reports was created, each containing descriptive statistics for each attribute identified as potentially relevant to a KDD study, and/or decode guides. The random sample of 3000 patients coded as current or former smokers, with at least one visit within the past year, was composed of 56% current smokers and 44% former smokers. Table 1 describes the presence and values of attributes used to describe intensity and duration of tobacco use in this sample of Epic records. The number of packs per day for current smokers ranged from 1-31. The most frequently used words in a free text "Tobacco Comment' attribute within the social history table were as follows: age, ago, day, quit, since, smoke, year, yr.

A concept map was generated – a single table mapping individual Epic attributes with smoking-relevant concepts extracted from the clinical practice guidelines and literature review. Table 2 summarizes strengths and weaknesses in representation of smoking cessation related concepts. Prescribed treatments and follow up visits within the system were clearly described in a coded format. However, other information was not

represented: over-the-counter treatments, social support, referrals for external treatment programs, and advice/ counseling offered in the course of a patient encounter.

Table 1 - Attributes describing intensity and duration of tobacco use

	Current User Records (n=1693)	*Former User Records (n=1307)*
"Packs Per Day" data entered	1220	521
"Packs Per Day": Mean (S.D.)	2.54 (3.48)	3.15 (3.69)
"Years": data entered	1012	542
"Years": Mean (S.D.)	15.71 (13.28)	15.18 (12.86)

Table 2 - Strengths and weaknesses in representation of smoking cessation related concepts

Strengths	*Weaknesses*
Prescribed medications	Advice/counseling to quit
ICD9 code "tobacco use disorder" [6]	Educational intervention
Willingness to quit	Self-help materials
Quit date	Referral to external counseling/ treatment programs
Presence and type of tobacco use	Type/ characteristics of program
Arrangement of follow up	OTC nicotine replacement
Demographic information	Social support
Family history	

Discussion

A fundamental description of a smoking habit is its intensity and duration. In the study sample, the records of most current smokers contained data describing intensity and duration of smoking. However, less than half the records of former smokers contained data describing intensity and duration of smoking. Clinicians entering the data appear to be mixing units of measurement, perhaps documenting number of cigarettes vs. number of packs. This interpretation is supported by the words most frequently entered into a "Tobacco Comment" attribute, words commonly used to describe duration. Many clinicians opted to use the free text field to describe intensity and duration of a smoking habit. Similar findings were encountered in other social history table attributes. Interviews with system users reveal that in many clinics, the social history attribute data are entered by medical assistants, not by nurse practitioners and physicians as they interview a patient.

Strengths and weaknesses in concept representation were noted, and may limit the ability of a KDD project to model smoking cessation. However, there are clear strengths in concept representation that could be leveraged to learn more about primary management of smoking cessation/ tobacco dependence (see table 2). Both data quality issues and weaknesses in coded concept representation may be informed by analysis of free text patient note data, not currently stored in the EDW. It is feasible to code smoking–related concepts in EpicCare free text patient notes with natural language processing (NLP). [7]

Conclusion

This feasibility study revealed significant data quality issues in coded social history attributes. These issues included missing data, particularly in the case of former smokers, and misrepresentation of patient characteristics with default attribute values. Unusual values may be related to clinicians using inappropriate units of measurement. The study also revealed key strengths and weaknesses in an ambulatory electronic health record's coded representation of concepts with known relevance to tobacco/ smoking cessation. The weaknesses in data quality and coded concept representation are anticipated to affect a KDD project using only coded data from this repository of ambulatory patient records, but may be ameliorated with analysis of additional data contained in free text patient notes.

Representation of Smoking-related Concepts in an Electronic Health Record

Mollie R. Poynton, PhD, APRN[1,2],
Lewis Frey, PhD[2], Hongying Tang[2]

[1]University of Utah College of Nursing, Salt Lake City, UT
[2]University of Utah School of Medicine, Department of Biomedical Informatics, Salt Lake City, UT

The University of Utah
Biomedical Informatics

Purpose/ Aims

(1) Assess the feasibility of a knowledge discovery project related to smoking cessation using warehoused data from a group of outpatient clinics, AND

(2) Map strengths and gaps in the representation of smoking cessation related concepts in a common electronic health record system (EHR), EpicCare EMR.

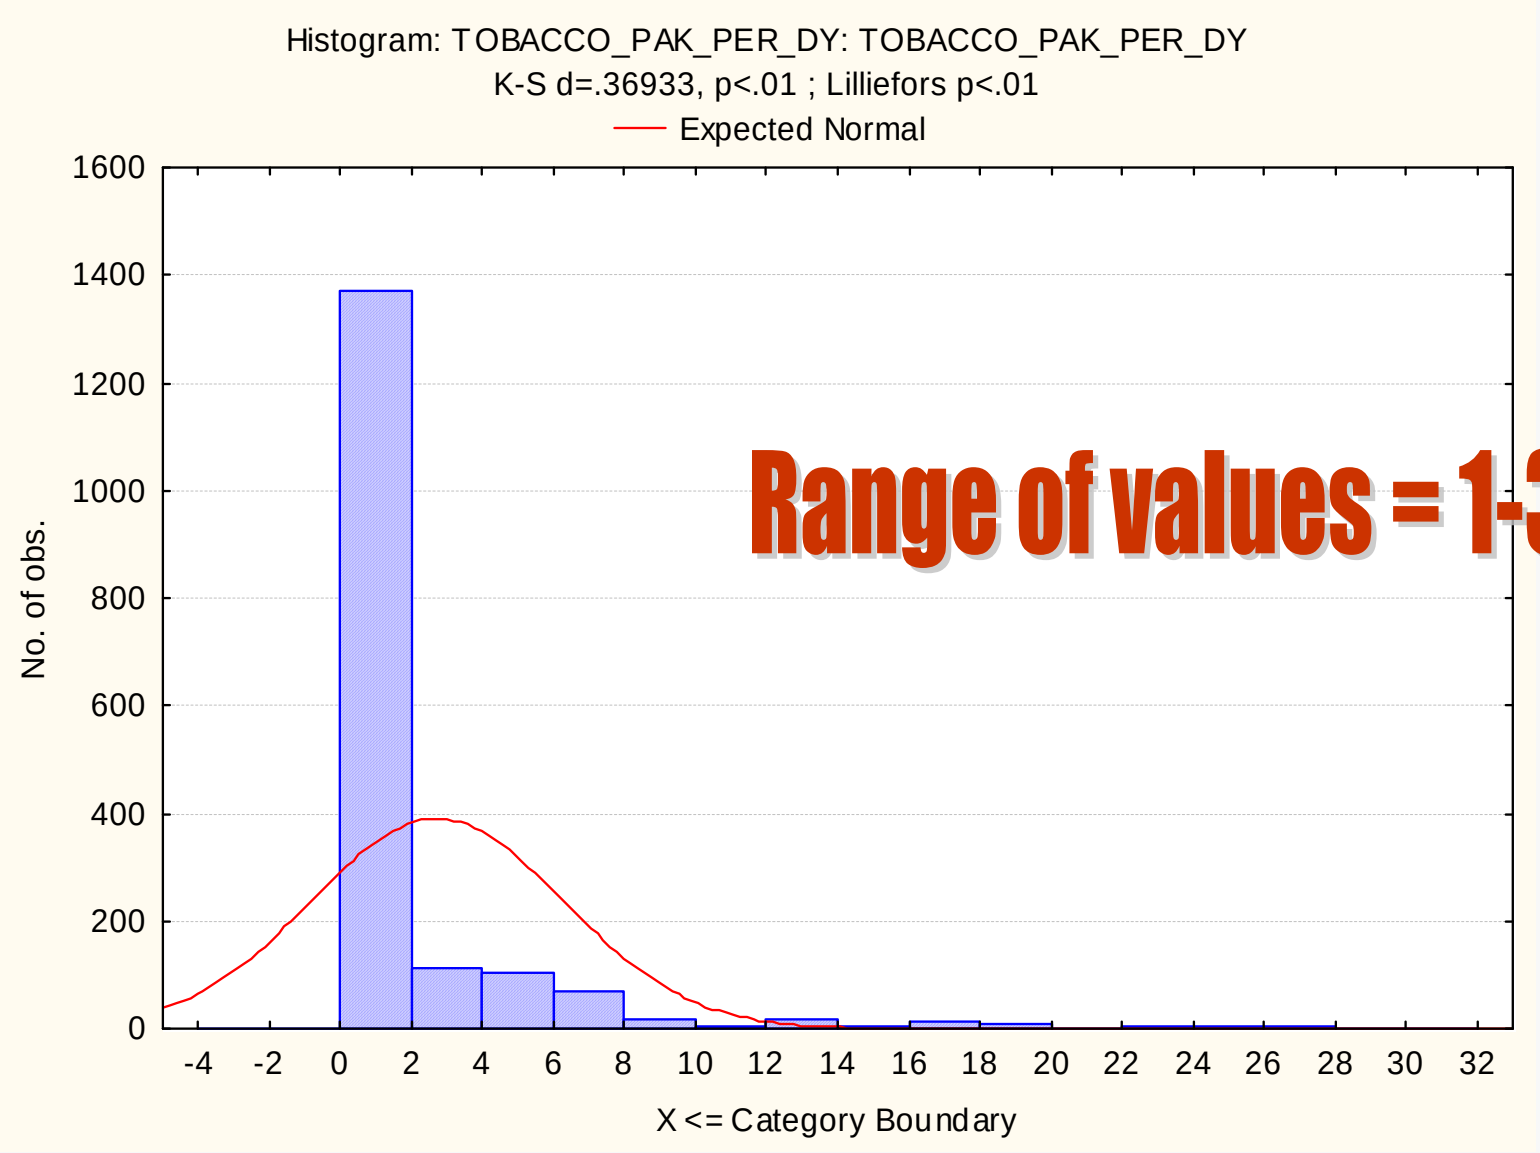
Data

- Source system: EpicCare EMR[4]
- Group of community outpatient clinics in the U.S. intermountain west.
- Data since 2000 (over six years of data).
- Random sample of 3000 electronic records:
  - Patients with a completed social history record
  - Either current or former smoker

Intensity and Duration of Smoking

Tobacco Status	***Current User (n=1693)***	***Former User (n=1307)***
Tobacco Packs Per Day	n=1220	n=521 **39.9%**
Mean (S.D.)	2.54 (3.48)	3.15 (3.69)
Tobacco Years	n=1012	n=542 **41.5%**
Mean (S.D.)	15.71 (13.28)	15.18 (12.86)

Packs Per Day: Distribution



Word frequencies: Tobacco Comment

	Frequency	Number of documents	Stemmed word
age	185	171	age
ago	[illegible]	[illegible]	ago
day	199	196	day
quit	561	[illegible]	quit
since	124	123	sinc
smoke	204	196	smoke
year	157	145	year
yr	178	167	yr

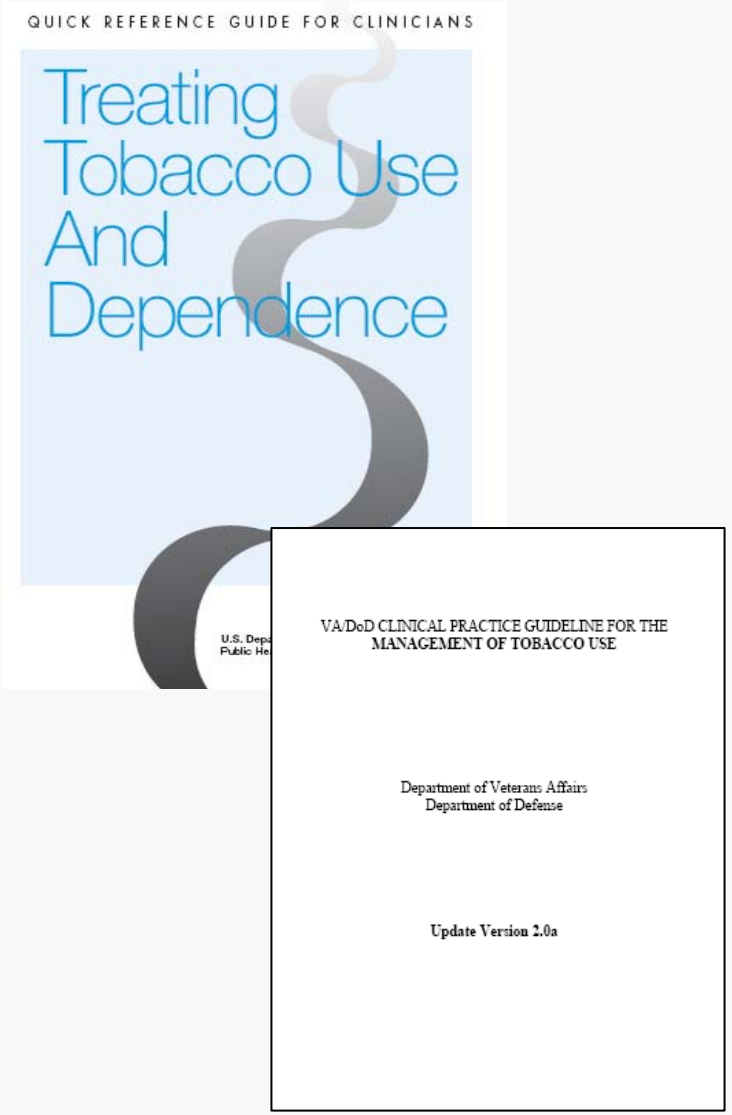
Words used to describe length of time…

Concept Mapping

U.S.P.H.S. Treating Tobacco Use and Dependence[5]

Va/DOD Clinical Practice Guideline for the Management of Tobacco Use[6]

Additional concepts identified in review of the literature[1]



Concept Representation: Strengths

- Prescribed medications
- ICD9 code “tobacco use disorder”[8]
- Willingness to quit
- Quit date
- Presence and type of tobacco use
- Arrangement of follow up
- Demographic information
- Family history/ pedigree

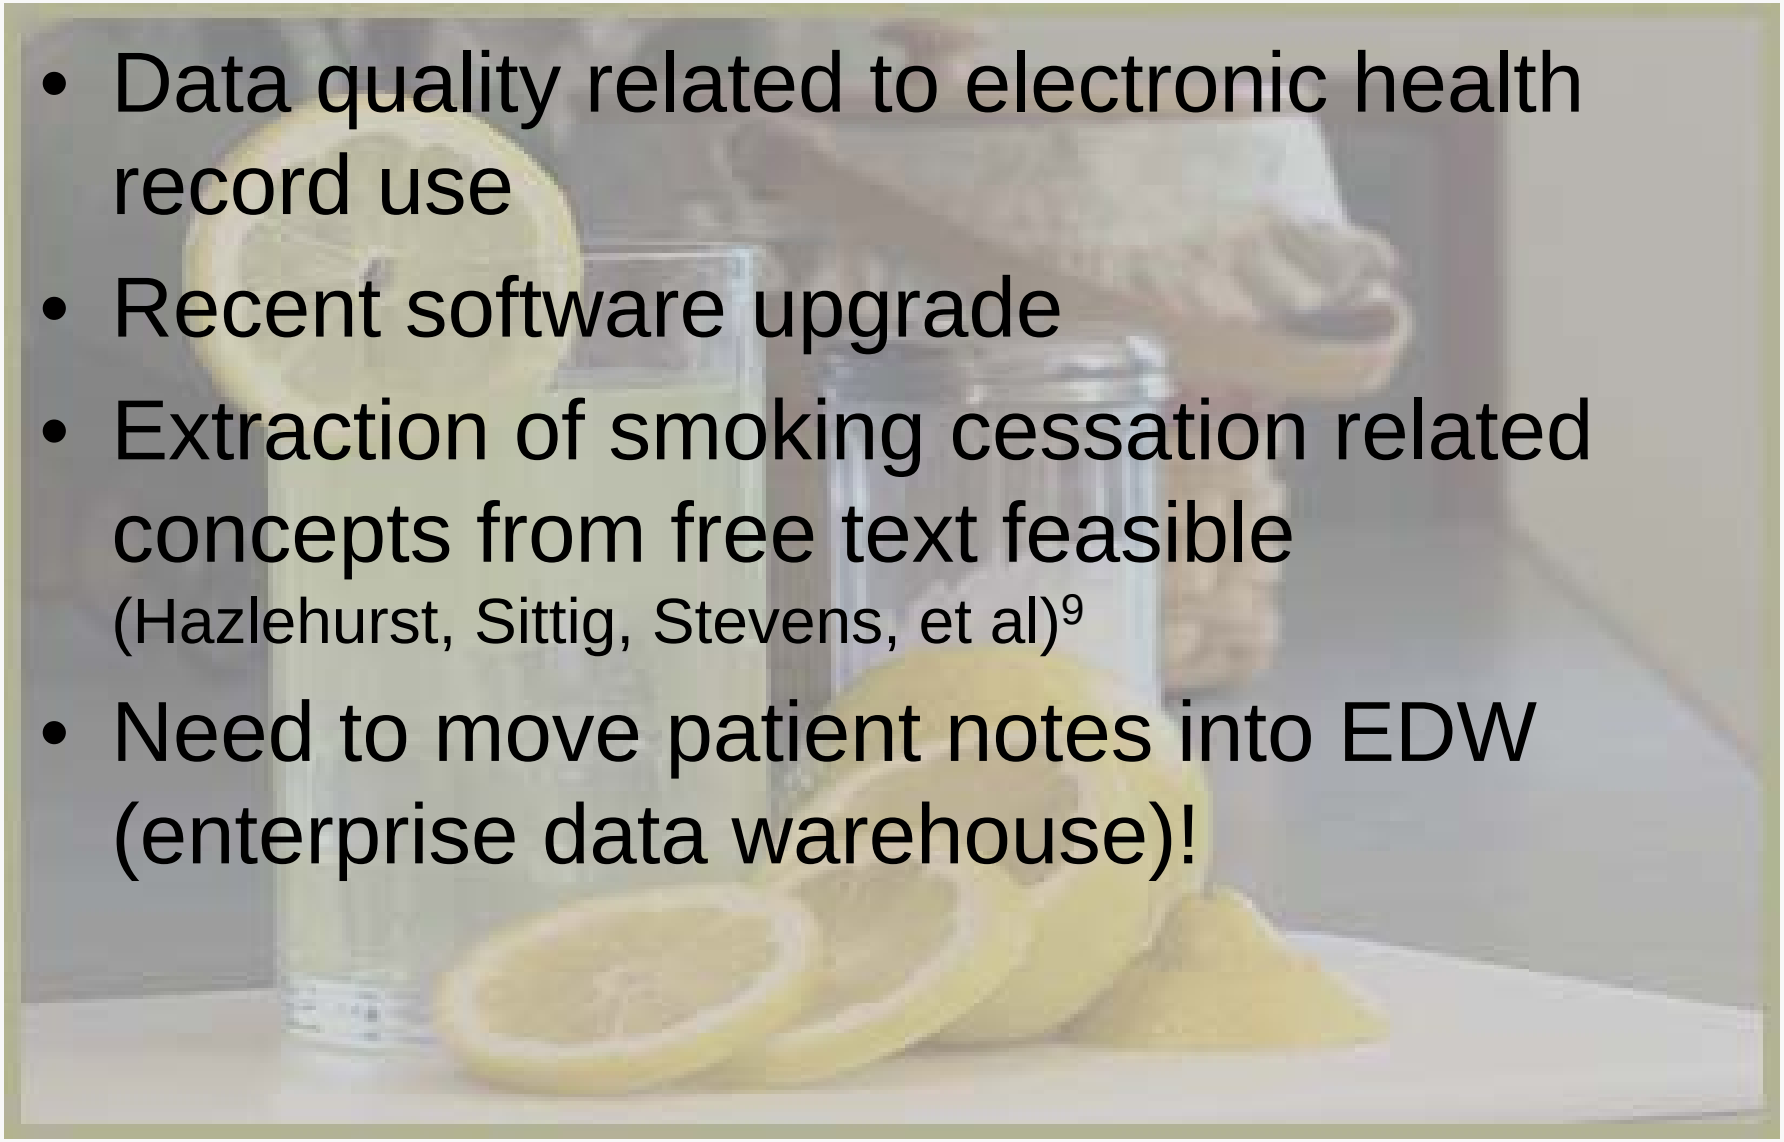
Concept Representation: Gaps

- Advice/counseling to quit
- Educational intervention
- Self-help materials
- Referral to external counseling/ treatment programs
- Type/ characteristics of program
- OTC nicotine replacement
- Social support

Conclusions

- Coded attributes capture some (but not all) concepts relevant to smoking cessation.
- Data assay indicates substantial data quality issues in coded data elements related to smoking cessation.
- Free text patient notes necessary to assess/ describe primary care management of smoking/ tobacco use. (Coded data *not* sufficient).

Discussion



- Data quality related to electronic health record use
- Recent software upgrade
- Extraction of smoking cessation related concepts from free text feasible (Hazlehurst, Sittig, Stevens, et al)[9]
- Need to move patient notes into EDW (enterprise data warehouse)!

[c] *Department of Welfare and Medical Intelligence, Chiba University Hospital, Chiba, Japan*

Abstract

We analyzed electronic discharge summaries by text mining and demonstrated its potential to make an automatical diagnosis and classification. We extracted diagnosis related terminological information by morphological analysis from 4,784 discharge summaries of 14 representative diseases applying vector space model. We calculated the weights of each term for individual diseases and obtained each vector for 14 diseases by tf-idf and entropy methods. The index terms extracted from the discharge summary showed the features of the disease. In comparing tf-idf and entropy methods, the ranking of importance of the terms were different but the extracted terms were approximately the same. When applying these data to new cases, more than 96% of the correct diagnoses could be obtained by both methods. The classification by the clustering showed clear accordance with the code of ICD-9. These results suggest the possibility to classify diseases from medical documents automatically by using the text mining technique.

Keywords:

text mining, discharge summary,
electronic medical record

Introduction

Recently in Japan, the electronic medical record has become popular, and electronic data has been accumulated in great quantities. At Chiba University Hospital, more than 30,000 electronic discharge summaries are stored. We showed the possibility of disease judgement and extraction of the index terms that characterize diseases by applying the vector space model to the discharge summary [1]. In addition, expansion of the target diseases and plural methods of weighting were requested. Therefore we increased the number of target diseases, and added the entropy method to compare. Moreover, we performed cluster analysis by similarity computation, and tried automatic classification of the disease.

Methods

Discharge Ssmmary

The full text computerization of the discharge summary began at Chiba University Hospital in 1999. A total of 36,335 summaries were registered in four years by May, 2003. Free text which described the history of the present illness was used for analysis in this research. All the cases have been extracted from representative diseases that consisted of more than 100 cases individually. These diseases were selected from diverse fields (Table 1). Subsequently, we selected 4,784 discharge summaries from 14 diseases.

Morphological analysis

Morphological analysis that resolves the character string to the element like a noun, an adjective, and a particle, etc. is necessary for the analysis of a Japanese natural sentence. In this research, we used the "ChaSen" that was developed as a morphological analysis system [2]. The PHYXAM dictionary was used as a medical technical dictionary [3].

Vector space model

We calculated the weights of each term for every disease and obtained each vector for 14 diseases by the vector space model [4]. In this research, we compared two weighting methods (tf-idf and entropy methods).

Tf-idf method

In tf-idf method, weight *ij* is shown by *ij=(lij×gi)/nj*. *lij* is the local weight, and a big value is given to the index term that appears frequently in the document. *gi* is global weight, and a big value is given to the term that appears only in a specific document. *nj* is a document normalization coefficient to which removes the influence by the length of documents.

$$\alpha_{ij} = \frac{l_{ij} g_i}{n_j}$$

tf $l_{ij} = log(1 + f_{ij})$ idf $g_i = log(\frac{n}{n_i})$

$n_j = \sqrt{\sum_{i=1}^{m} (l_{ij} g_i)^2}$

f_{ij} ··· Frequency of term w_i in disease d_j
n ··· Total number of the diseases in discharge summary
n_i ··· Number of the diseases which include the term w_i

Entropy method

Entropy decreases when each event occurs in equal probability. The value of *Hi*/log is close to 1 when the index

term appeared in each document at an equal probability, therefore, the following expressions can be used as global weight of an index term.

$$g_i = 1 - H_i = 1 + \frac{1}{\log n} \sum_{j=1}^{n} \frac{f_{ij}}{F_i} \log \frac{f_{ij}}{F_i}$$

Disease judgment

We testify to the diseases from a discharge summary based on the calculated vector of the 14 diseases. First of all, we selected 10 cases of discharge summaries from 14 diseases that were not used to make the vectors, in total 140 cases as test cases. Next, similarity computation between the test case and each of the14 diseases were calculated by inner products. When the disease showed the highest similarity computation corresponding to the correct diagnosis, it was set to "matched".

Cluster analysis

We substituted similarity between the diseases for the distance of the Euclidean square, and performed the cluster analysis by the furthest neighbor method.

Results

Extraction of the index term

8,375 index terms have been extracted from the discharge summary set which is composed of 4,783 cases. Table 2 shows the result of permuting the extracted index term of each disease in order of weight. It seems that the index term characterizing each disease was extracted from among the terms actually used in the hospital. No significant difference was found about medical validity observed in both methods. The correlation coefficient of the weight of all the index terms between both methods indicated a very high value (0.95).

Disease judgment

As shown in Table 3, 137 cases were correctly diagnosed out of 140 cases (98%) by entropy methods and 135 cases (96%) by tf-idf method. There were no significant differences between both methods. All the cases misjudged here were those with ancillary diagnosis and computer selected a complication as a main diagnosis.

Cluster analysis of 14 diseases

The results of the classification by clustering were almost the same order of the code system of ICD-9, and showed good accordance from a medical viewpoint.

Discussion

We identified diseases even though we expanded the number of diseases. Furthermore, we experimentally analyzed the discharge summaries of other hospitals, and we could identify the diseases as well as the summaries at our hospital (Data not shown). We believe that this technique is universal when target diseases and facilities expand in the future, and the universal vector data is obtained. In comparing the methods of calculating weights, the difference was seen in the order, however extracted terms and phrases were almost the same between the tf-idf method and the entropy method. Furthermore, clear superiority was not observed about medical validity between both methods. In identifying diseases, there were no significant differences.

The research on the medical technical term using the vector space model is performed. We analyzed the documents in Japanese, however, similar results can be expected in English, because we only used the index terms and their weighting for analysis from the characteristics of language. Takemura et al. are experimenting with the automatic diagnosis of the diseases from text mining of the radiograph report [5]. Text mining seems to be applied to all medical documents in the future.

[1]

Table 1 - 14 diseases and number of case

Disease	organ	ICD-9	Case
gastric cancer	GI tract	151	524
hepatoma	liver	155	483
lung cancer	respiratory	162	687
mammary cancer	mamma	174	363
prostatic carcinoma	genital organ	185	340
renal carcinoma	renal	189	158
malignant lymphoma	hematology	202	153
diabetes Mellitus	endocrine	250	293
schizophrenia	psychiatric	295	104
cataract	eye	366	777
angina	circulatory	413	467
asthma	allergy	493	114
scar contracture	skin	709	133
osteoarthritis	motor organ	715	188

Table 2 - Top 5 list of index term order by severity (abstract)

	gastric cancer		hepatoma		Angina	
	tf-idf	entropy	Tf-idf	entropy	tf-idf	entropy
1					(exertional chest pain)	
2						
3					(acetyl-choline)	
4					(Q wave)	(chest pain)
5	(total gas-trectomy)	(gastric cancer)	Angio -CT			(nitro)

Table 3 - Judgment result of each disease

disease	ICD-9	tf-idf	entropy
gastric cancer	151	9	9
Hepatoma	155	10	10
lung cancer	162	10	10
Mammary cancer	174	9	10
prostatic carcinoma	185	10	10
renal carcinoma	189	9	9
Malignant lymphoma	202	10	10
Diabetes Mellitus	250	9	9
Schizophrenia	295	10	10
Cataract	366	10	10
Angina	413	10	10
Asthma	493	10	10
scar contracture	709	9	10
Osteoarthritis	715	10	10
Accuracy		96%	98%

Conclusion

We extracted the index terms that characterize diseases, and by using them identified more than 96% out of 140 discharge summaries. There were no significant differences between the tf-idf method and the entropy method. The classification by the clustering showed good accordance with the code of ICD-9.

Angina	circulatory	413	467
Asthma	allergy	493	114
scar contracture	skin	709	133
osteoarthritis	motor organ	715	188

Methods

1. **Obtained vector for discharge summary**

   We extracted diagnosis related terminological information from 4,784 discharge summaries by morphological analysis that resolves the character string to the element like a noun, an adjective, and a particle, etc. is necessary for the analysis of a Japanese natural sentence.
   We used the “ChaSen” that was developed as a morphological analysis system [2]
   The PHYXAM dictionary was used as a medical technical dictionary [3],
   We calculated the weights of each term for individual diseases and obtained each vector for 14 diseases by tf-idf and entropy methods.

2. **Disease judgment**

   We testify to the diseases from a discharge summary based on the calculated vector of the 14 diseases. First of all, we selected 10 cases of discharge summaries from 14 diseases, in total 140 cases as test cases. These summaries were not used to make the vectors according to disease.
   Next, similarity computation between the test case and each of the 14 diseases were calculated by inner products, and visualized by the radar chart. When the disease showed the highest similarity computation corresponding to the correct diagnosis, it was set to "matched".

3. **Cluster analysis**

   We substituted similarity between the diseases for the distance of the Euclidean square, and performed the cluster analysis by the furthest neighbor method.

Vector space model

- We calculated the weights of each term for every disease and obtained each vector for 14 diseases by the vector space model. The vector space model is a technique widely used in the field of information retrieval, which changes the characteristic of the document into the multidimensional vector. [4] In this research, we compared two weighting method (tf-idf and entropy methods).

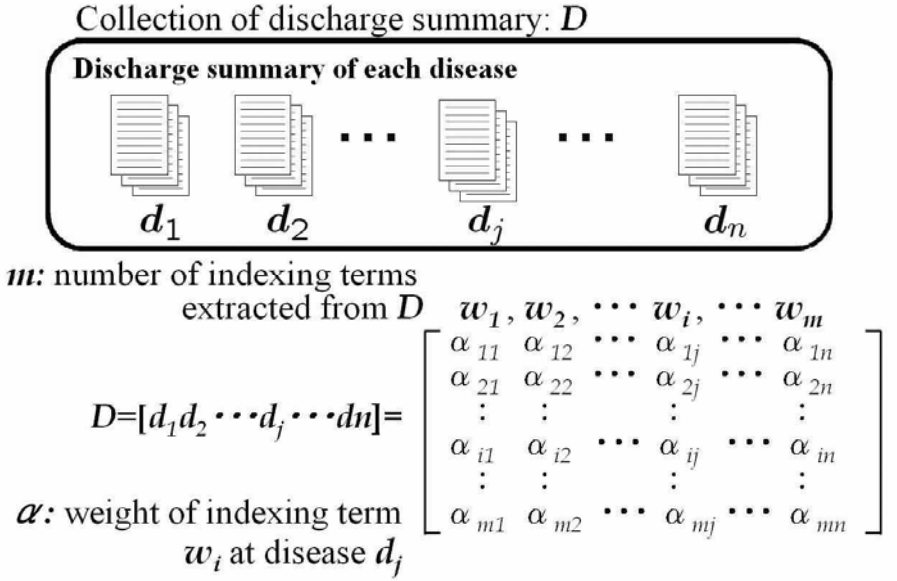

Figure 1- Vector space model

The total targeted discharge summary set is assumed to be D, and discharge summary sets of each disease are assumed to be $d1, d2, \cdots, dj, \cdots, dn$. Next, the m pieces of index term extracted from D are assumed to be $w1, w2, \cdots, wi, \cdots, wm$. Weight of index term wi in the discharge summary dj is assumed to be αij. As a result, the discharge summary dj is expressible by the vector that consisted of the m pieces of element α, and defined this as the discharge summary vector of disease j.

Weight of the index term

- tf-idf method
  - In tf-idf method, weight α_{ij} is shown by $\alpha_{ij}=(l_{ij} * g_i)/n_j$.
  - l_{ij} is the local weight, and a big value is given to the index term that appears frequently in the document. g_i is global weight, and a big value is given to the term that appears only in a specific document. n_j is a document normalization coefficient to which removes the influence by the length of documents.

$$\alpha_{ij} = \frac{l_{ij} g_i}{n_j}$$

tf $$l_{ij} = log(1 + f_{ij})$$

idf $$g_i = log(\frac{n}{n_i})$$

$$n_j = \sqrt{\sum_{i=1}^{m} (l_{ij} g_i)^2}$$

f_{ij} ・・・ Frequency of term w_i in disease d_j
n ・・・ Total number of the diseases in discharge summary
n_i ・・・ Number of the diseases which include the term w_i

- Entropy method
  - Entropy decreases when each event occurs in equal probability. The value of H_i/log is close to 1 when the index term appeared in each document at an equal probability, while it closes to 0 when it appeared only in limited documents. Therefore, the following expressions can be used as global weight of an index term w_i.

$$g_i = 1 - H_i = 1 + \frac{1}{\log n} \sum_{j=1}^{n} \frac{f_{ij}}{F_i} \log \frac{f_{ij}}{F_i}$$

Results: Extraction of the index term

- We extracted 8,375 index terms from the discharge summary set D which is composed of 4,783 cases. The summaries of 14 diseases were vectorized by using the weight of the index term. Table 2 shows the result of permuting the extracted index term of each disease in order of weight. It seems that the index term characterizing each disease was extracted from among the terms actually used in the hospital. tf-idf method and entropy method were compared in each disease. No significant difference was found about medical validity observed in both methods. The correlation coefficient of the weight of all the index terms between both methods indicated a very high value (0.95).

Table 2. Top 10 list of index term order by severity (abstract)

	gastric cancer		hepatoma		Angina

Results: Disease judgment

- As shown in Table 3, 137 cases were correctly diagnosed out of 140 cases (98%) by entropy methods and 135 cases (96%) by tf-idf method. There were no significant differences between both methods. All the cases misjudged here were those with ancillary diagnosis and computer selected a complication as a main diagnosis.

Table 3. Judgment result of each disease

disease	ICD-9	tf-idf	entropy
gastric cancer	151	9	9
Hepatoma	155	10	10
lung cancer	162	10	10
Mammary cancer	174	9	10
prostatic carcinoma	185	10	10
renal carcinoma	189	9	9
Malignant lymphoma	202	10	10
Diabetes Mellitus	250	9	9
Schizophrenia	295	10	10
Cataract	366	10	10
Angina	413	10	10
Asthma	493	10	10
scar contracture	709	9	10
Osteoarthritis	715	10	10
Accuracy	709	96%	98%

Results: Cluster analysis of 14 diseases

- We performed cluster analysis from similarity computations between 14 calculated diseases by the nearest-neighborhood method, and visualized it by the dendrogram. According to these results, three diseases became complicated such as diabetes, angina, and cataracts and malignant tumors such as stomach carcinomas and liver carcinomas were established in the small groups.

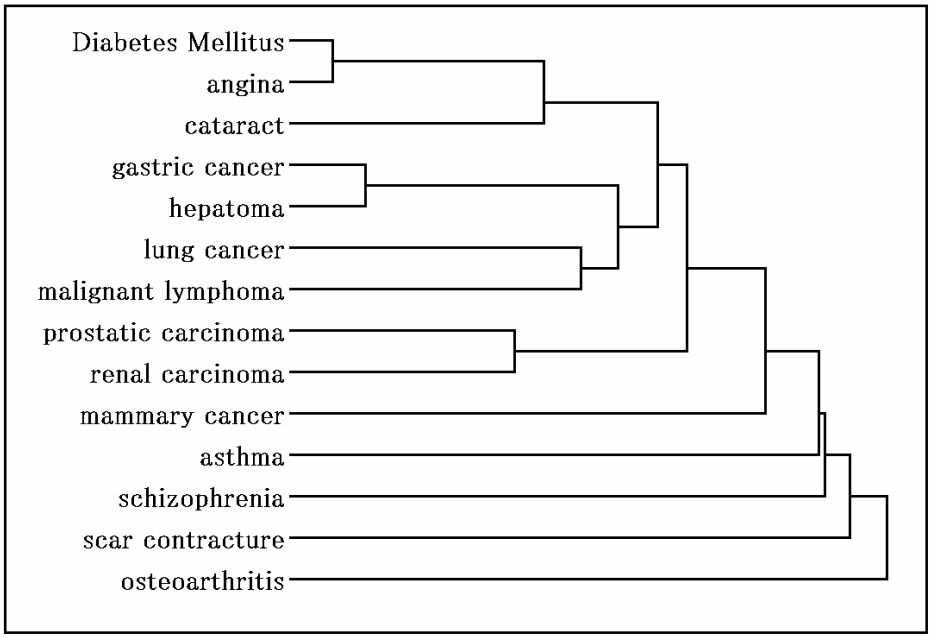

Figure 3- Cluster analysis of 14 diseases

The group that was the furthest from others was osteoarthritis. The results of the classification by clustering were almost the same order of the code system of ICD-9, and showed good accordance from a medical viewpoint.

Discussion & Conclusion

- **Discussion**

  We showed the extraction of the linguistic information and by using it we made a diagnosis of the discharge summary by the vector space model, in Medinfo 2004. [1] However, the some questions arose. Firstly it happens to work only in the combination of specific diseases and did not function when other kinds of diseases were added, such as circulatory diseases. Secondly, since there are various techniques for weighting the index terms, therefore it would be more effective than the tf-idf method.

  We identified diseases even though we expanded the number of diseases. Furthermore, we experimentally analyzed the discharge summaries of other hospitals, and we could identify the diseases as well as the summaries at our hospital. (Data not shown) We believe that this technique is universal when target diseases and facilities expand in the future, and the universal vector data is obtained. In comparing the methods of calculating weights, extracted terms and phrases were almost the same between the tf-idf method and the entropy method. In identifying diseases, there were no significant differences. Furthermore, clear superiority was not observed about medical validity between both methods.

  The research on the medical technical term using the vector space model is performed. We analyzed the documents in Japanese, however, similar results can be expected in English, because we only used the index terms and their weighting for analysis from the characteristics of language. Takemura et al. are experimenting with the automatic diagnosis of the diseases from text mining of the radiograph report [5] and Iwahashi et al. are also researching automatic classification of an incident report [6]. Text mining seems to be applied to all medical documents in the future.

- **Conclusion**

  We extracted the index terms that characterize diseases, and by using them identified more than 96% out of 140 discharge summaries. There were no significant differences between the tf-idf method and the entropy method. The classification by the clustering showed good accordance with the code of ICD-9.

  By collecting discharge summaries in many facilities, we can obtain universal vectors, characteristics for every disease and analysis through for electronic medical records by textmining, therefore we can expect to discover new medical knowledge.

A Text Mining Approach to Explain What Being Actively Engaged in Life Means

Richi Nayak[a], Laurie Buys[b]

[a]*Faculty of Information Technology,*
[b]*Centre for Social Change Research Queensland University of Technology, Brisbane, Australia*

Abstract

This paper shows the findings and analysis of a national survey data on 'Active Ageing'. We examine the applicants responses on "what being actively engaged in life means to you?" with the text mining approach. The analysis shows that the 'Family', 'Friend' and 'Activity' were the most important concepts appearing across all age groups and both genders.

Keywords:

text mining, data mining, active ageing

Introduction

It is widely accepted that many first world countries are experiencing extended life expectancies and reduced fertility rates, which is resulting in an ageing population. A definition of active ageing is "the process of optimizing opportunities for physical, social, and mental well-being throughout life in order to extend healthy life expectancy [2]. The Australian Active Ageing (Triple A) study at the Queensland University of Technology (QUT) has conducted a national-wide postal survey to collect the responses of older people on a wide range of questions related to 'work', 'learning', 'social', 'spiritual', 'emotional', 'health and home', 'life events' and 'demographics'. The survey also included an open-ended question that the applicants responded to was "Briefly describe what being actively engaged in life means to you?". The purpose of this paper is to present the findings and analysis of the open-ended question in the survey using the text mining techniques [1]. This paper attempts to gain a better understanding of the impact of aging upon older Australians' engagement in society and their sense of well being. The findings and analysis are based on the responses from 2645 (45% response rate) participants over the age of 50 years residing across Australia.

Method: text mining

Text mining extracts the important concepts and emerging themes from the collection of text sources using computation linguistics, machine learning and information science methods [1,3]. We utilize the Leximancer text mining application [3] to extract relationships from the text data. It is based on the bayesian theory using the words which make up a sentence to predict the concepts being discussed. Each *term* appearing in the text data is analyzed to form a *concept* and then many concepts are put together to form a *theme* based on the co-occurrence of terms and concepts in the text.

Data: The Triple A study data includes responses of 2645 members of a large Australia wide seniors organization on a wide range of questions related to their life. The survey includes 178 questions grouped into 8 sections covering the life aspects of social, health and home, emotional etc and an open-ended question. The sample included a reasonable balance of gender (57% female) and state representation (NSW: 32%, Vic: 24% and Qld: 20%). The respondents were quite comfortable financially, well educated and majority were living with a companion, in their own home in a metropolitan area.

Table 1 - Categorization by age and gender

Grouping	Category	Qty
All comments		1964
Grouped by age	55-64	1252
	65-74	474
	75 & over	238
Grouped by gender	Male	870
	Female	1094
Males grouped by age	55-64	523
	65-74	230
	75 & over	117
Females grouped by age	55-64	729
	65-74	244
	75 & over	121

Process: Preprocessing such as (1) removal of surveys (instances) that did not have sufficient information of age, gender etc, (2) application of spelling and grammar checking function in Excel in order to locate and correct the misspell words, incorrect abbreviations and slang, and (3) stop word removal and stemming were performed. The data file was then arranged and split into categories of both Age and Gender that allowed us to thoroughly compare and contrast the different combinations of categories (Table1).

Results and discussion

Comparison by age groups

Age group 55 – 64: The most significant concept and theme is 'Family'. 'Life' and 'Active' are next in the level of frequency. There is an integral relationship between 'family' and 'time' as well as having close ties with the 'enjoy' entity. 'Work' is considered a significant concept ranking highly for both males and females. 'Work' and 'Active' aspects comes to the fore in Males whereas 'Health' and 'Social' aspects are more frequent in the Females. This may indicate that Males place a greater importance in physically active aspects while Females signal social themes as figuring in their perception of active ageing.

Age group 65 – 74: This age group shows that they consider an active life to being engaged in it, living a full life, having a life with purpose and friendship in terms such as visit, involvement and participation. In this age group, males considered 'work' a more important concept than females. Both males and females emphasize on Family. However the terms that form the 'Family' concept in both groups differ. The females were concerned with interaction with emphasis on meeting, touching, visiting, whereas the males, although the terms indicate a need to be interactive, are less personal. Their terms include social, involved, community, and activities. Although it is a subtle difference, it could possibly indicate that for males, family is also a source of activity or social events. Whereas with the females, it could be perceived as a more emotional connection as opposed to as a source of activities or social connectivity.

Age group 75+: Ageing is perceived as having a close association with family and friends and maintaining an engagement in life through activities with these people. The concept of 'health' emerges as a significant concept, more highly ranked by the males than the females. This differs from the prior age groups indicating that this group may be considering health issues more frequently in relation to active ageing.

A very interesting difference that appears between male and female of this age group is the 'enjoy' concept. Female associate enjoy with life concept. However, male segregate the enjoy concept from either of family or active concept. Male population subtly emphasizes more on 'active' concept in comparison to female. Male population being actively means being involved with people. The female population seems to relate being actively with being involved with their loved ones, friends and social groups such as church.

Comparison by gender

All Females: Ageing is perceived as having a close association with family and friends and enjoying the activities with these people. Ageing is also perceived as being active in life through the time based work activities.

All Male: Ageing is perceived as being active in life and spending time with family and friends.

The most significant difference between the results of the males and females, are that where the females population were concentrated around 'Life', 'Family' and 'Friends', the male population seems to include a wider range of concepts including 'Active' and 'Work' as heavily weighted.

Using the whole population

To understand the behavior of the whole population including various age groups and all gender, we grouped the respondents according to the way they reflect active ageing using the clustering method [4]. This method also utilizes the computation linguistics to analyses the terms that mainly form a theme and consequently puts them into the same group. All respondents are grouped into 6 clusters. Following is the detail of each cluster including the few top-most terms due to which the respondents were put together in same group along with number of similar respondents in that cluster according to the written response.

Cluster 1: people, thing, good, new, health (1073)

Cluster 2: friend, social, work, child, grandchild (736)

Cluster 3: physical, mental, good, health, activity (175)

Cluster 4: mental, physical, happy, independent, family (136)

Cluster 5: help, other, helping, helping others (99)

Cluster 6: body, mind, help, good (89)

Cluster 1 is the biggest cluster in the dataset, which gives a general description for the meaning of active aging. The concepts covered are as follows: learning new things and skills, maintain good health, dealing with other people etc. Cluster 2 focuses more on the aspect of personal life, involves the family life, the friendship and the attitude to society. These respondents would like to enjoy with their family, look after their grandchild, stay with their friends, participate in social event and contribute to the society. Respondents in cluster 3 realize good health (mental and physical both) is the basis for happy life and are willing to participate in activities according to their health status. Cluster 4 respondents find the mental and physical health along with the family surroundings as key aspects for active ageing. People in cluster 5 wish to find out their personal values by helping others, in the aspect of daily life or whatever and wherever others need. The responders in cluster 6 wish to be interactive with other people to make their body and mind active as well as help the others.

These clusters show the various characteristic that each group of common respondents have. Further drilling to each group will identify more common concepts and themes.

Conclusion

A strong common themes across all groups, male, female and age groups were that 'Family', 'Friends' and 'Activities'. The younger age group considers 'Work' an important variable in active ageing, and this drops off to be important for only males in the next group, and is not ranked in the 75 and older group. Within the eldest group however, 'Health' emerges as an important concept, and given that this group is in a minority in the population as a whole, could explain that lack of representation overall of health concerns. These trends seem to indicate that the respondents are considering factors that are relevant to them in the immediate timeframe when responding to the question without consideration toward their future. There are various areas where these results may have impact and warrant some consideration such as future planning for government funding of community activities.

A Text Mining Approach to Explain What Being Actively Engaged in Life Means

Richi Nayak

School of Information Systems, Queensland University of Technology, Brisbane, Australia

Introduction

- It is widely accepted that many first world countries are experiencing extended life expectancies and reduced fertility rates, which is resulting in an ageing population.
  - A definition of active ageing is “the process of optimizing opportunities for physical, social, and mental well-being throughout life in order to extend healthy life expectancy.
- The Australian Active Ageing (Triple A) study at the Queensland University of Technology (QUT) has conducted a national-wide postal survey to collect the responses of older people on a wide range of questions related to ‘work’, ‘learning’, ‘social’, ‘spiritual’, ‘emotional’, ‘health and home’, ‘life events’ and ‘demographics’.
- The survey also included an open-ended question that the applicants responded to was “Briefly describe what being actively engaged in life means to you?”.
- The purpose of this paper is to present the findings and analysis of the open-ended question in the survey using the text mining techniques.
- This paper attempts to gain a better understanding of the impact of aging upon older Australians’ engagement in society and their sense of well being.

Method: Text Mining

- Text mining extracts the important concepts and emerging themes from the collection of text sources using computation linguistics, machine learning and information science methods.
- We utilize the Leximancer text mining application [3] to extract relationships from the text data.
  - It is based on the bayesian theory using the words which make up a sentence to predict the concepts being discussed.
  - Each *term* appearing in the text data is analyzed to form a *concept* and then many concepts are put together to form a *theme* based on the co-occurrence of terms and concepts in the text.

Data

- The Triple A study data includes responses of 2645 members (45% response rate) of a large Australia wide seniors organization on a wide range of questions related to their life.
- The survey includes 178 questions grouped into 8 sections covering the life aspects of social, health and home, emotional etc and an open-ended question.
- The sample included a reasonable balance of gender (57% female) and state representation (NSW: 32%, Vic: 24% and Qld: 20%).
- The respondents were quite comfortable financially, well educated and majority were living with a companion, in their own home in a metropolitan area.

Process

- Preprocessing steps were performed.
  - (1) removal of surveys (instances) that did not have sufficient information of age, gender etc,
  - (2) application of spelling and grammar checking function in Excel in order to locate and correct the misspell words, incorrect abbreviations and slang,
  - (3) stop word removal and stemming were performed.
- The data file was then arranged and split into categories of both Age and Gender that allowed us to thoroughly compare and contrast the different combinations of categories.

Combinations of categories for analysis

Grouping	Category	Qty
All comments		1964
Grouped by age	55-64	1252
	65-74	474
	75 & over	238
Grouped by gender	Male	870
	Female	1094
Males grouped by age	55-64	523
	65-74	230
	75 & over	117
Females grouped by age	55-64	729
	65-74	244
	75 & over	121

Comparison by Age Groups

Age group 55 – 64

- The most significant concept and theme is ‘Family’.
- ‘Life’ and ‘Active’ are next in the level of frequency.
- There is an integral relationship between ‘family’ and ‘time’ as well as having close ties with the ‘enjoy’ entity.
- ‘Work’ is considered a significant concept ranking highly for both males and females.
- ‘Work’ and ‘Active’ aspects comes to the fore in Males whereas ‘Health’ and ‘Social’ aspects are more frequent in the Females.
- This may indicate that Males place a greater importance in physically active aspects while Females signal social themes as figuring in their perception of active ageing.

Comparison by Age Groups

Age group 65 – 74

- This age group shows that they consider an active life to being engaged in it, living a full life, having a life with purpose and friendship in terms such as visit, involvement and participation.
- In this age group, males considered ‘work’ a more important concept than females.
- Both males and females emphasize on Family. However the terms that form the ‘Family’ concept in both groups differ.
  - The females were concerned with interaction with emphasis on meeting, touching, visiting, whereas the males, although the terms indicate a need to be interactive, are less personal.
  - Their terms include social, involved, community, and activities.
  - Although it is a subtle difference, it could possibly indicate that for males, family is also a source of activity or social events.
  - Whereas with females, it could be perceived as a more emotional connection as opposed to as a source of activities or social connectivity.

Comparison by Age Groups

Age group 74+

- Ageing is perceived as having a close association with family and friends and maintaining an engagement in life through activities with these people.
- The concept of ‘health’ emerges as a significant concept, more highly ranked by the males than the females.
  - This differs from the prior age groups indicating that this group may be considering health issues more frequently in relation to active ageing.
- A very interesting difference that appears between male and female of this age group is the ‘enjoy’ concept.
  - Female associate enjoy with life concept.
  - However, male segregate the enjoy concept from either of family or active concept.
  - Male population subtly emphasizes more on ‘active’ concept in comparison to female.
  - Male population being actively means being involved with people.
  - The female population seems to relate being actively with being involved with their loved ones, friends and social groups such as church.

Comparison by Gender

- All Females:
  - Ageing is perceived as having a close association with family and friends and enjoying the activities with these people.
  - Ageing is also perceived as being active in life through the time based work activities.
- All Male:
  - Ageing is perceived as being active in life and spending time with family and friends.
- The most significant difference between the results of the males and females, are that where the females population were concentrated around ‘Life’, ‘Family’ and ‘Friends’, the male population seems to include a wider range of concepts including ‘Active’ and ‘Work’ as heavily weighted.

Summary

- A strong common themes across all groups, male, female and age groups were that ‘Family’, ‘Friends’ and ‘Activities’.
- The younger age group considers ‘Work’ an important variable in active ageing, and this drops off to be important for only males in the next group, and is not ranked in the 75 and older group.
- Within the eldest group however, ‘Health’ emerges as an important concept, and given that this group is in a minority in the population as a whole, could explain that lack of representation overall of health concerns.
- These trends seem to indicate that the respondents are considering factors that are relevant to them in the immediate timeframe when responding to the question without consideration toward their future.
- There are various areas where these results may have impact and warrant some consideration such as future planning for government funding of community activities.

Numerical Assessment of Blood Trauma in BiVentricular Assist Device (BVAD)

Dong Choon Sin[a], Andy CC Tan[a], Hyo Jung Kim[b], Won Cheol Kim[b]

[a] *Institute of Health and Biomedical Innovation, Queensland University of Technology, Australia*
[b] *School of Mechanical and Aerospace Engineering, Gyeongsang National University, Korea*

Abstract and objective

A CFD assessment of shear induced hemolysis in the early design phase of artificial prosthetics may decrease time and costs of development. Among the cardiac assist devices available, the BVAD has attracted worldwide interest because patients who received a left ventricular assist device (LVAD) have extended lives. However, some of them develop right heart failure syndrome, and these patients required a right ventricular assist device (RVAD). In this paper, a numerical analysis was performed to predict the share stresses which may allow possible blood trauma analysis in BVAD.

Keywords:

CFD, BVAD, blood trauma, Hemolysis

Introduction

Ventricular assist devices (VADs) have become widely used in bridging to heart transplantation, bridging to recovery, or destination therapy. However there is still insufficient understanding of fluid mechanics related issues in the clearance gap of the BVAD. The design nature of the pump requires sufficient washout in the clearance between the impeller and the stationary pump housing inner surface. In this paper, a numerical analysis was performed to predict the share stresses in the clearance regions of the BVAD.

Methods

The BVAD (Fig 1) is under development at the Queensland University of Technology in Brisbane, Australia.

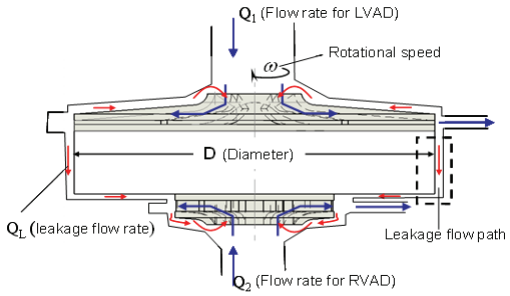

Figure 1 - The schematic drawing of the BVAD

The shear stress in blood is comprised of molecule viscosity stress and Reynolds stress components. A scalar stress value can be obtained according to Bludszuweit's stress formula[1]:

$$\sigma = \left[\frac{1}{6}\sum(\sigma_{ii} - \sigma_{jj})^2 + \sum\sigma_{ij}^2\right]^{\frac{1}{2}} \quad (1)$$

where σ is the scalar stress (pa) and σ_{ij} is the stress tensor. In order to predict the blood damage, it is necessary to define a threshold shear stress value leading to blood cell damage.

Results

Figure 2 shows the results of 2,200 rpm on the stress distribution. The maximum scalar stress value reached in the back region is 245 N/m2. The threshold levels of 500 Pa have been reported as the design condition in the development of centrifugal blood pump for exposure times of 0.1 s. [2]. Therefore, exposing the blood cells to such levels of fluid stress will not likely result in blood trauma based on these computational results.

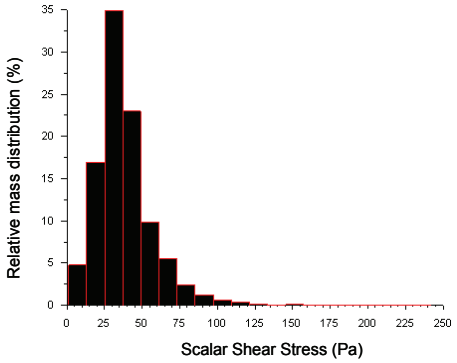

Figure 2 - Mass weighted distribution of scalar shear stress in clearance gap

In future studies, the CFD predictions will be compared quantitatively to data that are being obtained using PIV measurements.

Abstract

Computer-based approaches to clinical guidelines are gaining an increasing relevance within the medical community. We discuss the specific advantages of adopting the GLARE system

Introduction and background

Clinical guidelines are a means for specifying the "best" clinical procedures and for standardizing them. Several computer-based approaches have been introduced to overcome the gap between clinical guidelines as provided by standardization committees and their applicability in the clinical practice [1]. GLARE (Guideline Acquisition, Representation and Execution) is a system which has been built from 1997 in cooperation with Az. Osp. S. Giovanni Battista, Turin, Italy [2]. It is a domain-independent system to acquire, represent and execute clinical guidelines, which has been tested on several guidelines, including asthma, cardiac diseases, ischemic stroke.

Methods

GLARE has a three level architecture. At the highest level, it offers a high-level and easy-to-use interface to physicians. At the intermediate level, it has an acquisition module, to enter a new guideline, and an execution engine, to instantiate a guideline on a patient. At the lower level, it interacts with a DBMS to store clinical guidelines and to interact with patient records.

Results

The adoption of the GLARE system provides several main advantages. As regards the acquisition phase:

1. It provides a high-level graphical interface to introduce clinical guidelines by drawing graphs and filling slots
2. It provides automatic facilities to check the correctness of guidelines, including (i) a terminological check and a check on the correctness of the values of attributes, (ii) a check on the "logical" well-formedness of the graph (e.g., only decision actions may have more than one exiting arc), (iii) a check of the consistency of the temporal constraints in the guideline, based on the adoption of advanced Artificial Intelligence techniques [3]. Moreover, (iv) GLARE is integrated with the SPIN model-checker, to automatically check several kind of properties (e.g., the presence of a therapy with specific properties for a given patient).
3. It provides a module to contextualize a general guideline considering the local availability of resources

As regards the execution phase:

1. It interacts with the Patient DB, so that patients' data are automatically retrieved from it whenever needed
2. It adopts advanced Decision Theory techniques to assist physicians' decision making ("what if" analysis)
3. It checks whether the execution on a given patient is correct, in the sense that the actions in the guidelines are executed, and the temporal constraints in it are respected [3];
4. It provides a schedule of the set of actions to be executed in a given temporal window (e.g., in the next two days)

Knowledge Discovery Based on the Identification of Relationships Among Medical Concepts by Clustering Candidate Descriptors

Shizuka Yamazaki[a], Mariko Iwasawa[b], Shin-ichi Nakayama[b], Natsuo Onodera[b], and Yusuke Tanigawara[a]

[a] *Department of Pharmacy, School of Medicine, Keio University, Japan*
[b] *Graduate School of Library, Information and Media Studies, University of Tsukuba, Japan*

Abstract

The discovery of hidden connections within the medical literature could give new and plausible knowledge. This study proposes and examines a new methodology for hypothesis generation and knowledge discovery using cluster analysis. We obtained a knowledge overview from a network of medical concepts by clustering candidate descriptors.

Keywords:

cluster analysis, information storage and retrieval, medical subject headings

Introduction

It is important to obtain knowledge on relationships between various phenomena observed in clinical practice. All relationships are not always direct connections, however. The identification of relationships among medical concepts from the literature database could show such indirect connections.

Methods

Don R. Swanson, in his the ABC model, showed that unknown relationships between a chemical substance (A) and a disease (C) could be found by identifying a concept (B) that connects A and C in the literature (Figure 1) [1]. Closed and one-directional open discovery processes were reported by Marc Weeber et al. [2]. Most prior works used ranking based on term frequency. Such methodology may bring on only a part of the concepts. For effective discovery of useful relationships, we propose grouping candidate descriptors by means of hierarchical clustering. Three types of discovery processes were examined experimentally. In the closed process (a), the B terms were MeSH terms that co-occurred in the document sets A and C: these B terms were grouped into several clusters. In the one-directional open process (b), the B terms were MeSH terms in the set C: these B terms were grouped and the B terms in each group were used to extract set A from MEDLINE: the A terms were also grouped. In the two-directional open process (c), the A and C terms were MeSH terms in the set B: those terms were grouped. In each process, the stop list of MeSH terms used was similar to that applied in Swanson's method [3]. These processes were applied in an attempt to identify relationships between fish oil and Raynaud's disease from MEDLINE documents as an experimental test of Swanson's hypothesis. Additionally, we searched for particular terms with the relevant subheading: C-term(s)/th [therapy] - B-terms(s)/de [drug effect] - A-term(s)/tu [therapeutic use] OR A-term(s)/pd [pharmacology].

Results

In our experiment (a), 56 documents on "Raynaud Disease/th" and 40 on "Fish Oils/tu OR Fish Oils/pd" from 1983 to 1985 in MEDLINE had 29 co-occurring MeSH terms, included 7 B-terms/de. For example, "Platelet Aggregation/de" and "Blood Viscosity/de" were found among the MeSH terms (Figure 2). When we did not use subheadings in searching for documents, the document sets increased in size to 511 hits for "Raynaud Disease" and 262 for "Fish Oils", but the number of co-occurring terms was the same and the resulting knowledge overview was similar. In our experiment (b), MeSH terms appearing in 56 "Raynaud Disease/th" documents were clustered, which generated 5 groups of B terms (Figure 3). One of the groups of B terms facilitated the discovery of documents on Fish Oil. In addition, we got the relationships between Raynaud's disease and the serotonin reuptake inhibitor Fluoxetine, and also the calcium channel blocker Felodipine, Nisoldipine, Isradipine. In our experiment (c), the relationships between fish oil and variant angina pectoris were obtained (Figure 4).

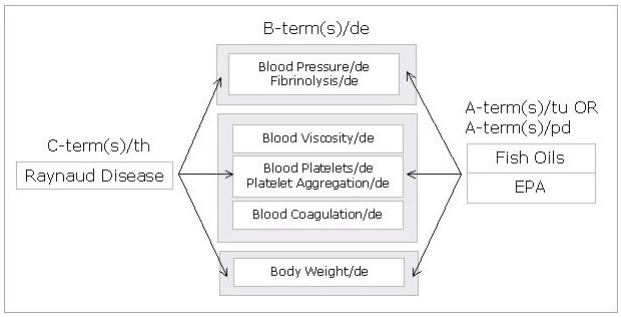

Figure 2 - Closed discovery process

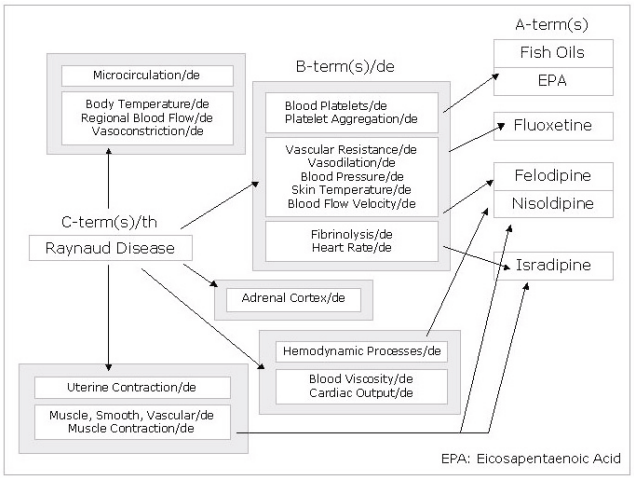

Figure 3 - One-directional open discovery process

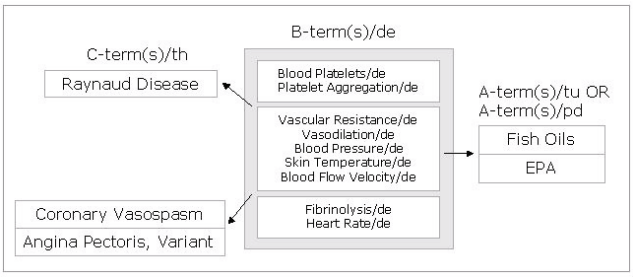

Figure 4 - Two-directional open discovery process

Conclusion

By grouping candidate descriptors using cluster analysis, we succeeded in detecting invisible connections between medical concepts. It is important to obtain knowledge on relationships between various phenomena observed in clinical practice. All relationships are not always direct connections, however. Our new methodology was effective in identifying hidden connections between medical concepts. The resulting knowledge overview could be helpful in clinical practice.
