Evaluation of Rheumatoid Information Providing Web Site on the Internet

Jae Hyun Lee[a], Myonghwa Park[b]

[a]*Health Care Information and Technology Center, Keimyung University, Korea*
[b] *College of Nursing, Keimyung University, Korea*

Abstract and objective

The purpose of this study was to analyze and evaluate internet web sites about rheumatic arthritis in Korea. The results indicated the need of regular and reliable monitoring of the health information websites.

Keywords:

rheumatoid arthritis, information, internet

Introduction

The increasing health information on the web indicates the need of monitoring and evaluation of the quality of web based health information.

Methods

One hundred forty eight sites of general/university hospitals were searched through domestic search engines and included in the 1st analysis. Eleven websites which are entirely developed for RA information, were selected and secondly analyzed using web evaluation tools developed by Kim(2003)[1)].

Results

In the 148 web sites of general/university hospitals, there were 60 sites(40.5%) with bulletin board, 107 sites(73.6%) with web master contact information, 115 sites(79.1%) with the site maps for the convenient search, 136 sites(92.6%) with search function, and 106 sites(71.6%) with customer service functions. Second analysis of selected 11 web sites which are developed entirely for health information about rheumatoid arthritis, showed high scores in the website purpose items(purpose and target users are indicated clearly), and reliability items(developer information and contact information are clearly provided) but resulted in relatively low scores in source of references(36.4%), site maps/outlines(45.5%), how-to-use/help function(18.2%).

Conclusion

The results from this study indicated that internet information about rheumatoid arthritis were not enough quantitatively and qualitatively[2)]. It is necessary to improve the understandability of information for consumers, and provide the reference sources to improve the reliability of health information.

Experiences and Insights from the Development of a Mobile Self Management System for Cystic Fibrosis Sufferers in Tasmania.

Stephen Chau[1,3], Elizabeth Cummings[1,2], Paul Turner[1,2]

[1] University Tasmania, School of Information Systems, Australia
[2] Smart Internet Technology Co-operative Research Centre
[3] Verdant Health

Abstract

Among approaches aimed at addressing chronic illness are a number advocating the improvement of patient self-management and self-efficacy skills as a means of improving health outcomes. While comparison between these approaches is difficult, most report benefits. It is clear however that considerable uncertainty remains over the best methods for supporting patient self-management.

For sufferers of Cystic Fibrosis (CF) a major challenge in this regard is how to effectively support a transition from a model of care that is heavily reliant on specialists and parental control to one supporting self-guided management, particularly amongst adolescents and young adults.

This paper explores these issues in the context of experiences and insights emerging from the development of a mobile self-management system for cystic fibrosis patients' across Tasmania. Based on case study research within the CF community, initial insights highlight how patients involved with the mobile self-management system have readily accepted it and actively incorporated it into their daily routine.

Keywords:

self management, self efficacy, computer communication networks, mobile phone

Introduction

This paper presents experiences and insights from a project exploring how mobile technologies can be used to support the development of self-management and self-efficacy amongst cystic fibrosis (CF) sufferers across Tasmania. While supporting self-management and self-efficacy amongst the chronically ill has been shown to have benefit, the role that information and communication technologies (ICTs) can play remains under-researched. There are currently few systems that allow patients to remotely monitor and self-manage their health conditions in a non-obtrusive and cost effective manner. More significantly, many of the systems that do exist, fail to acknowledge the conceptual and practical difficulties of avoiding simply replacing dependency on health professionals for dependency on technology.

Information systems (IS) clearly have a role to play in enabling home based medical systems. Indeed, some research points to positive outcomes for patients with chronic illness in self–managing their conditions with ICTs. It is acknowledged that computer based support systems can be valuable tools to assist with the management, education and ongoing care of a patient's chronic illnesses. In particular, wireless mobile technologies are well suited to support the remote self-management and self-monitoring of a chronic health condition with patient cohorts that are geographically dispersed or where cross-infection is a clinical risk. Other considerations include fees and costs associated with any telemedicine system. Internet based systems rely heavily on connectivity, access speeds, suitable ICTs in the home . There is also a need to consider the nature of the information to be made available to the health care team and the patients. If mentors supporting patients are better informed their ability to monitor and assess patient's progress with goals and action plans can be more improved . The remainder of the paper explores these issues.

Aims / objectives

The overall aim of this research project is to determine the impact of a mobile system on CF patient's ability to self manage and monitor their condition. The project also aims to examine the effectiveness of communication between patient's and health professionals through this mobile system.

The objectives of this research are;

1. To explore how effective the use of mobile technology is in supporting self-management and self-efficacy amongst CF patients.
2. To determine if the use of mobile technology improves information access and communication with specialised health care providers.
3. To capture any perceived or realised benefits gained by patient's from using the mobile system.

Methods

This research adopted a case study methodology and recruited participants from within the Tasmanian CF community. All potential participants received a letter outlining the study and asking for volunteers. Respondents willing to participate then attended their regular CF clinic for consent, baseline measurements and randomization. Recruitment was undertaken within the following selection criteria.

Information systems development

The mobile self-management system was developed to enable participants to closely monitor their own disease through an electronic patient diary and respond to changes based on self-efficacy skills learned through a mentoring process at the beginning of the trial. The intention is to conduct comparisons between participants in the intervention arms and those who have received usual care. There will also be comparison made between the two intervention arms, i.e. outcomes in those with the IT tool versus those without. This will allow determination of whether mentoring alone is sufficient to enhance self-efficacy or whether additional tools such as IT provision value add to the process, or even whether the IT tool itself is what most effectively facilitates self-efficacy and self-management.

This project develops a model of integrated care that promotes patient self-management and self-efficacy supported by an information system. It is anticipated that this will promote the participant's active involvement in their own management, health care decisions and improve quality of life for adolescents and adults with CF. The anticipation is that in the long-term, this will result in better and sustainable outcomes.

System development

The design of the mobile system was broken down into three core components.

1. The development of a suitable mobile phone application that captures and renders clinical information from patients.
2. The development of a mobile phone server application to capture and send clinical information to each patient involved with the mobile phone trial.
3. The development of a database with a web-based interface to store all phone data, action plans and progress notes.

Every day CF patients are asked to run a customise CF application on their mobile phones that poses a set of questions forming a daily symptom diary. Some questions were randomly generated to improve data quality. On average it takes a patient four minutes to complete the diary. A data packet is then sent to a messaging server for capture and passed on to a database for consolidation and interpretation. Mentors and researchers are able to access a real time feeds of the information as it is sent via an online interface. This means that mentors and patients can be located remotely from the data service but still interact with the system in real time. CF patients also have the facility to gain a summary of key data elements to provide indicative progress with their condition and to use for reflection and response as part of their development of self-management and self-efficacy skills. Mentors are able to review their patients remotely and are able to contact patients directly to review or revise action plans and goals.

Experiences and insights to date

To date a number of experiences and insights have been generated by this on-going project:

- The time required to capture daily symptom information is relatively short and the mobile system supports the rendering of progress information in real time.
- The messaging of clinical information via SMS is very cost effective and sustainable.
- The interface used in the mobile phone application is highly intuitive and has incurred only limited time and training cost with this patient cohort.
- The use of mobile phones does not inhibit the scope of the patient's daily activities and is successfully integrated into their other use of the phone.
- Patients enjoy the flexibility of being able to complete or review data as and when it is convenient for them.
- Early indications are that self-management will be improved in both active arms of the trial. It remains too early to make specific remarks about the impact of the mobile system per se.

Conclusion

This paper has presented some of the initial experiences and insights gained whilst developing and implementing technology for a project exploring how mobile technologies can be used to support the development of self-management and self-efficacy amongst cystic fibrosis (CF) sufferers across Tasmania. The project is ongoing and so the final results are pending.

Local Medical System for Searching Medical Institutes and Communication

Katsuya Yahata[a], Yoshitaka Gohara[b], Michie Koga[c], Tetsuro Hada[c]

[b] *Zenrin Datacom co. Ltd.*
c HumanMedia Creation Center /Kyushu

Abstract

Developments in the Internet environment have led to the creation of the Web2.0. Nowadays updating information is as easy as blogging and information can be automatically dispatched to selected websites through the simple use of RSS technology. We developed an information retrieval system for local medical institutions which allows them to offer a push-type information system as well as a map information system. Together these create a dynamic flow of information communication between medical institutions as providers and local residents as users.

Keywords:

medical information search, RSS, intenet communication

Introduction

We recently developed a Contents Management System (CMS) which uses RSS and we added an automatic mail system and a website offering push-type information communication. Any medical institution can now easily update information is automatically forwarded to related websites using RSS technology.

Materials and methods

System outline

A medical institution information retrieval function and a map function were made using XOOPS with CMS as an open source of this basic system. XOOPS has a bulletin board, a notice function, and automatic connection function using RSS. Therefore, when it is necessary to add or update information, mail and websites can be automatically informed.

Not only is the location of a specific medical institution indicated on a map system related to Googlemap but information on other medical institutions in the area is also indicated.

Results

Because the information is offered by the medical institutes themselves and promptly disseminated automatically, it is possible to provide the public with timely information on season-related illnesses, etc. It is easier for the local residents to get accurate information on their local medical institutes from the top page.

Discussion

Information offered on the Internet is recognized as a public notice though there are legal regulations governing the advertisement of medical institutions in Japan

There were some issues in the update of the information on the homepage and the bulletin board. We could improve the convenience of the medical information system and the medical institutions' ability to offer greater information by developing it further in the Web2.0 and building it around a CMS.

An Instrument for Consumers to Discriminate Inaccurate Information on the Internet

Shinichi Okamura[a], Elmer V. Bernstam[b]

[a] *Department of Medical Informatics and Decision Sciences, Gunma University, Gunma, Japan*
[b] *School of Health Information Sciences, The University of Texas Health Science Center, Houston, TX, USA*

Abstract

People retrieve health information from the Internet that is unfiltered and not always accurate. In order to assist health care consumers, we tried to develop a simple instrument to discriminate inaccurate information. We hypothesized that accurate statements were likely to be repeated and inaccurate statements were likely to be refuted when multiple results from the same search were reviewed. We investigated information on irritable bowel syndrome (IBS), which is common around the world. We identified inaccurate statements on websites displaying information about this syndrome and counted the number of websites supporting and refuting each inaccurate statement. For each inaccurate statement displayed on English and Japanese sites, there were more refuting sites than supporting sites retrieved by the same search (0.93 vs. 0.0 in English sites and 0.15 vs. 3.35 for Japanese sites).This indicates that health care consumers can confirm online information by comparing multiple sites found on the same search.

Keywords:

irritable bowel syndrome, internet, medical informatics, patient satisfaction

Introduction

Thirty two percent of patients in the United States [1] and 22% of patients in Japan retrieved health information from the Internet [2]. Information on the Internet affected the decision making of 70% of patients in the United States in 2000 [3]. However, information on the Internet lacks peer-review and is not always accurate. Thirty two percent of bladder cancer websites [4] and 14% of melanoma sites [5] were found to be inaccurate. One quarter of complementary alternative medicine sites displayed information that could lead to physical harm if acted upon [6]. Quality assessment instruments such as DISCERN and QUICK attempt to help users identify false or misleading health information online. However, none of them can help a user determine whether a specific statement is true or false. Lay persons cannot be expected to determine whether a particular statement is true and may act based on false or inaccurate information resulting in poor outcomes such as delay of diagnosis or refusal of conventional treatment.

We hypothesized that false information displayed by a website was likely to be refuted by other websites identified by the same consumer search. If our hypothesis is correct, then consumers can be taught to validate facts by looking for confirmation on a sample of websites rather than a single site. We investigated information on irritable bowel syndrome (IBS), a common condition around the world.

Methods

Keyword and website selection

The English and Japanese keywords related to IBS most frequently used by consumers searching for health information online in June 2006 were selected using the Overture keyword tools. Websites were identified using Google between 12 July and 9 August 2006. Twelve keywords in English and Japanese were selected. Since consumers are most likely to review only the first page of results [8], only the top 10 websites were reviewed for each keyword.

Numbers of websites that support and refute inaccurate statements

Statements were considered inaccurate if they contradicted the published literature [9-12]. The numbers of websites that supported and refuted each inaccurate statement were counted.

Statistics

Differences between the numbers of websites that support and refute each inaccurate statement were tested by two-sided Wilcoxon`s rank test on Statcel2 (OMS publishing Inc., Saitama, Japan). Difference with $p < 0.05$ was considered significant.

Results

After exclusion of duplicates, inaccessible, irrelevant, testimonial advertising, and foreign language sites, 48 English and 31 Japanese websites were extracted.

Definitely inaccurate statements were identified: 13 statements from 9 English sites in categories of diagnosis (7 statements), signs/symptoms (2), and treatment (4); 12 statements from 11 Japanese sites in categories of epidemi-

ology (1), pathophysiology (6), diagnosis (2), signs/ symptoms (1), prognosis (1), and treatment (1). For each inaccurate statement in both language sites, there were more refuting sites than supporting sites in the selected sites as well as in the same search results (Table 1).

Table 1 - Number of sites supporting and refuting each innaccurate statement

	(mean ± SD)	
	Supporting sites	**Refuting sites**
In the selected sites:		
English 48 sites	0.77 ± 0.73	5.07 ± 1.85
Japanese 31 sites	1.00 ± 1.48	11.75 ± 8.75
In the same search results:		
English sites	0.00 ± 0.00	0.93 ± 0.16
Japanese sites	0.15 ± 0.05	3.35 ± 2.12

Discussion

We found that websites are likely to confirm accurate information and refute inaccurate information. We have shown here, for the first time, that the number of websites supporting each inaccurate statement is smaller than that of websites refuting it. Our result indicates that lay persons can precisely assess the accuracy of a specific statement on the Internet by looking for confirmation by other sites within the same set of search results. Consumers cannot identify a specific inaccurate statement even using conventional quality assessment instruments such as DISCERN because they apply to whole websites rather than to individual statements.

Since we studied a single health topic (IBS), using a single search engine (Google), our findings must be considered preliminary and require confirmation. However, Google is the most popular search engine in the English-speaking world and is widely used in Japan: suggesting that our findings apply to typical searches requested by consumers in English and Japanese. Further, Overture keyword tools report the actual frequency with which keywords are used to search. Since we selected the most commonly used keywords, we retrieved websites that are likely to be encountered by lay persons.

Conclusion

Consumers may be able to validate statements by looking at websites retrieved by the same search. Statements with more refuting sites than supporting sites will be inaccurate.

An instrument for consumers to discriminate inaccurate information on the Internet

Shinichi Okamura[a], Elmer V. Bernstam[b]

[a] *Department of Medical Informatics and Decision Sciences, Gunma University, Gunma, Japan*
[b] *School of Health Information Sciences, The University of Texas Health Science Center, Houston, TX, USA*

Abstract

People retrieve health information from the Internet that is unfiltered and not always accurate. To assist health care consumers, we tried to develop a simple instrument to discriminate inaccurate information. We hypothesized that accurate statements were likely to be repeated and inaccurate statements were likely to be refuted when multiple results from the same search were reviewed. We investigated information on irritable bowel syndrome (IBS), which is common around the world. We identified inaccurate statements on websites displaying information about IBS. The numbers of websites supportive for and opposed to each inaccurate statement were counted. The former was smaller than the latter in each inaccurate statement in both English and Japanese websites. This indicates that health care consumers can confirm online information by comparing multiple sites found on the same search.

Introduction (1)

Health information on the Internet is important

- ✧ Accounted 2% of all websites (http://www.nua/surveys/how_many_online/index.html 2002)
- ✧ Retrieved by 32% of patients in US and 22% of patients in Japan (J Med Internet Res 2001)
- ✧ Affected the decision making of 70% of patients in the US (Pew Charitable Trusts 2000)

The Internet contains inaccurate information

- ✧32% of bladder cancer sites (J Urol 2003)
- ✧6% of sarcoma sites (Cancer 1999)
- ✧14% of melanoma sites (J Clin Oncol 2002)

Introduction (2)

1. Existing quality assessment tools can not help consumers determine whether a specific statement is true or false.

2. To support consumers, we tried to develop a simple instrument to discriminate inaccurate information.

Methods

1. **Keywords related to IBS**

   selected by Overture keyword tools (English and Japanese)

2. **Websites**

   collected each top 10 sites retrieved by Google and selected

3. **Inaccurate statements**

   extracted from the websites above using published literature[1-5] as a standard

4. **Numbers of websites that support and refute each inaccurate statement**

   counted in the websites above as well as in the same search results

Table 1

Websites selection

	English sites	Japanese sites
Retrieved by Google	**120**	**120**
– **selected**	**48**	**31**
– **excluded**	**72**	**89**
• duplicated	45	55
• inaccessible	7	11
• irrelevant	11	15
• anecdotal information / testimonial advertising	5	3
• link page	2	1
• foreign language	2	4

Table 2

IBS information covered by websites and inaccurate statements

(# websites with inaccurate statements; # inaccurate statements)

	English 48 sites	Japanese 31 sites
Epidemiology	31 (0; 0)	11 (1; 1)
Pathophysiology	31 (0; 0)	28 (5; 6)
Diagnosis	20 (5; 7)	11 (2; 2)
Signs/symptoms	32 (3; 3)	30 (1; 1)
Prognosis	26 (0; 0)	8 (1; 1)
Treatment	41 (2; 3)	21 (1; 1)

Table 3

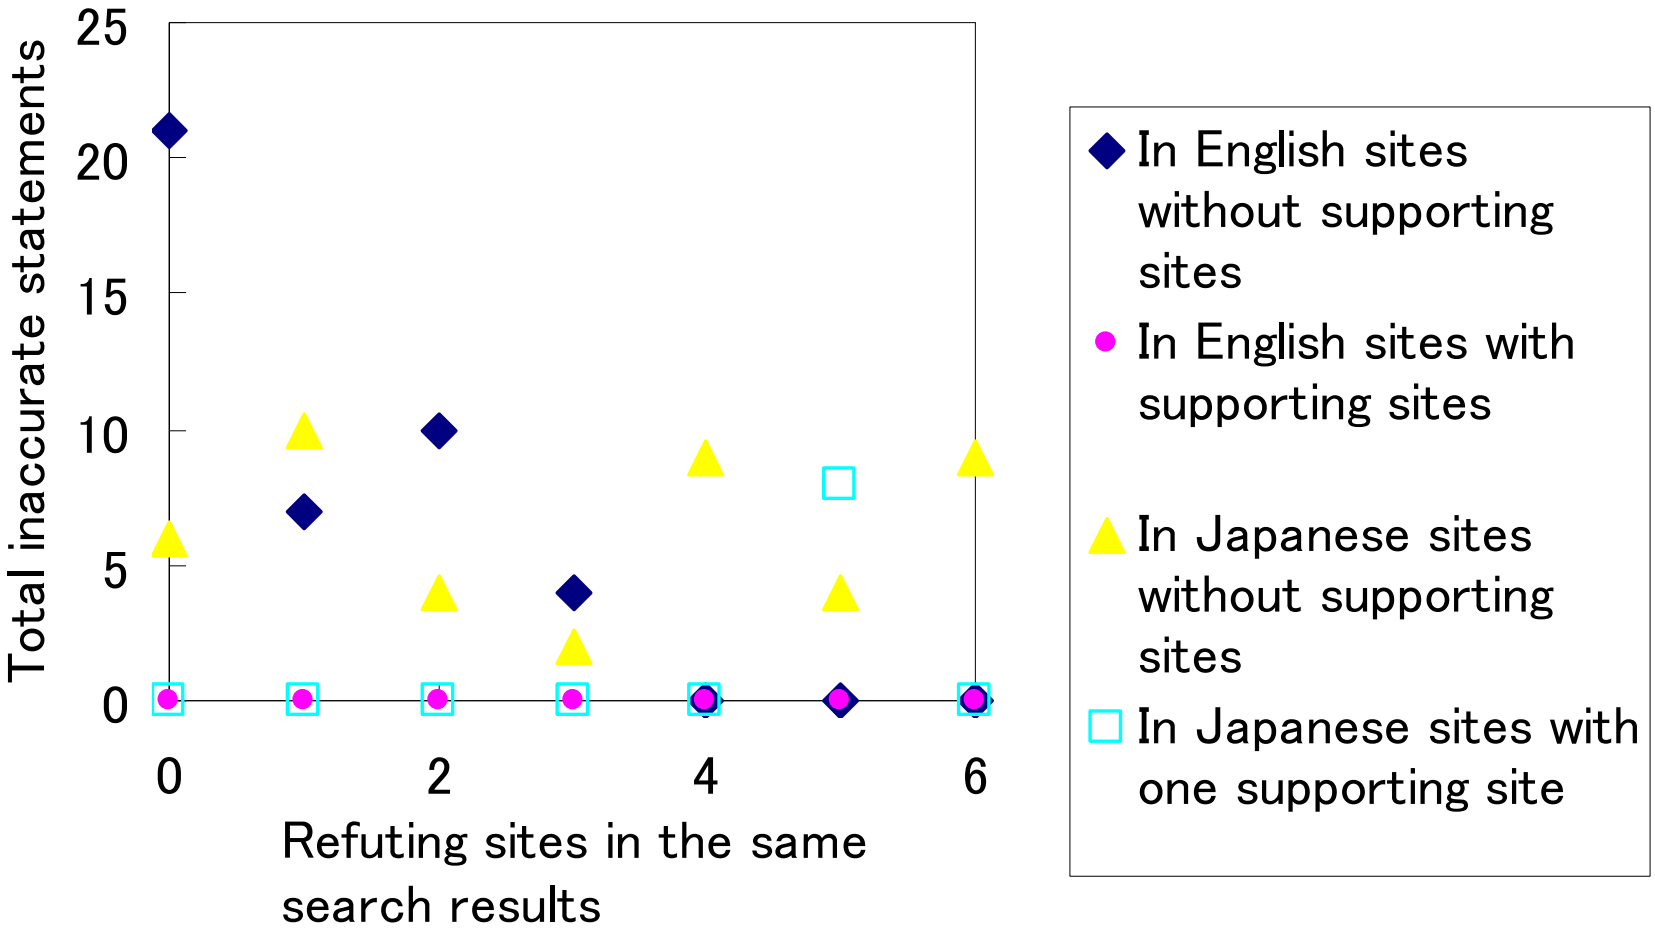
Number of sites supporting and refuting each inaccurate statement (mean ± SD)

	Supporting sites	Refuting sites
In the selected sites:		
English 48 sites*	0.77 ± 0.73	5.07 ± 1.85
Japanese 31 sites*	1.00 ± 1.48	11.75 ± 8.75
In the same search results:		
English sites*	0.00 ± 0.00	0.93 ± 0.16
Japanese sites*	0.15 ± 0.05	3.35 ± 2.12

* $P < 0.01$, difference between numbers of supporting and refuting sites (two-sided Wilcoxon`s rank test)

Figure 1

Inaccurate statements and refuting sites in the same search results



Results

1. From 120 sites each, 48 English and 31 Japanese sites were extracted for evaluation.
2. A total of 13 and 12 inaccurate statements were respectively contained in English and Japanese sites. At least one inaccurate statement was found at 20.8% of English and 35.5% of Japanese sites evaluated.
3. For each inaccurate statement, there were more refuting sites than supporting sites retrieved by the same search: 0.93 vs. 0.0 in English sites and 0.15 vs. 3.35 in Japanese sites.

Conclusion

Consumers may be able to validate statements by looking at websites retrieved by the same search. Statements with more refuting sites than supporting sites will be inaccurate.

eHealth Consumer Attitudes in Greece and Denmark

E. Orphanoudaki [a], H. Voss [b], A. Kouroubali [a], T. Roumeliotaki [a], L. Esterle [a], C.E. Chronaki [a]

[a] *Institute of Computer Science, FORTH, Heraklion, Crete,* [b] *Danish Center for Health Telematics, Odense, Denmark*

Abstract

This study examines the attitudes of people in Greece and Denmark towards innovative eHealth services. Although Internet use in general and more specifically Internet use for Health and Illness (H&I) is higher in Denmark than in Greece, survey data shows that people are equally interested in accessing their Electronic Health Record (EHR) online. Different attitudes between Greeks and Danes in regards to telemedicine and second opinion could be attributed to different levels of Internet maturity.

Keywords:

telemedicine, eHealth consumer trends, medical records, public acceptance of health care, public opinion

Methodology

An eHealth Consumer Trends Survey that investigates perceptions and attitudes towards use of the Internet for H&I began in 2005 and will be repeated in 2007 in order to establish eHealth consumer trends across Europe. The participating countries are Norway, Latvia, Germany, Denmark, Portugal, Greece and Poland. In telephone interviews conducted in October 2005, 1000 men and women from each country between ages 15-80 expressed their opinion on the use of the Internet for H&I. The sample was stratified for age, occupation, and residence. The questionnaire, based on earlier Norwegian surveys (2000-2002), was translated into national languages using the dual focus method. Additional questions, designed specifically for Greece and Denmark, explore the acceptance of innovative eHealth services: telemedicine, remote medical visits, teleradiology, and online access to one's personal EHR. Willingness to pay for eHealth was also considered in Greece.

Results

The attitudes towards telemedicine and second opinion in Greece and Demark differ considerably. 41% of the Danish respondents reacted positively to the idea of telemedicine in comparison to a mere 25% of the Greek respondents. 70% of the Greek respondents favourable to telemedicine, were willing to pay 10 euros for a remote medical visit by computer or video phone. When asked if they would be willing to grant remote access to their medical data in order to expedite diagnosis, more than half of the Greek respondents were hesitant, with just 44% willing to grant access to their test results. When the Danish respondents were asked a similar question, 73% pointed out that they would agree to have their xrays sent abroad for analysis by foreign doctors if this action meant they would receive a faster and more precise diagnosis and treatment. These attitudes can be explained by the different levels of Internet use (42,2% in Greece vs. 80,1% in Denmark) and of Internet use for H&I (22,9% in Greece vs. 60% in Denmark). According to the results of the survey, access to one's EHR appears to be the most attractive online service related to H&I. When asked if they would go online to access their EHR assuming they were given the opportunity, 61.7% of the Greek respondents were affirmative. It is worth noting that one third of all respondents in Greece are even willing to pay for such a service. Similar conclusions are drawn from observing the corresponding results of the Danish survey with 58% of the respondents interested in the EHR service. It is clear that there is a positive attitude among citizens in Greece and Denmark towards accessing their EHR online. Despite the positive perception of the Greek respondents, such services are not yet widely available in Greece. In Denmark, the Danish eHealth Portal was launched in 2003 to serve as a gateway to the public healthcare sector for patients and health professionals. Cooperation between health professionals across institutional borders is facilitated whereas patients have the ability to interact with health professionals as well as access phone numbers, waiting lists, and their own EHR data. 53.2% of Danish respondents were not aware of the portal's existence, thus suggesting that the campaign has not yet had the intended effect and more efforts towards raising awareness are required.

Conclusions

The presented results reflect the growing trend to use the Internet as a source of information on H&I, as a means to interact with health professionals to expedite diagnosis or to access one's own personal EHR. Different levels of Internet use and Internet use for H&I explain the different attitudes towards eHealth services in Greece and Denmark. People are inclined to access their EHR, but reluctant towards telemedicine and second opinion, perhaps due to their lack of experience with eHealth. The progress already made towards eHealth addressing current and future needs is a sign that the innovative ideas are being applied and in time accepted.

Application of a Web-based System to Screen for Hidden Depressive Patients

[d] *Institute of Biomedical Informatics, National Yang-Ming University*
[e] *Department of Psychiatry, Taipei Veterans General Hospital*
[f] *Department of Psychiatry, Yuli Veterans Hospital*

Abstract and Objective

Although depression has been regarded as a major public health problem, many individuals with depression still remain undetected or untreated. The Internet may help to detect the hidden depressive patients. The study used the Internet-based Self-assessment Program for Depression (ISP-D) for people to freely screen depressive disorder online. The results showed that 73.9% of 1656 participants had some kind of depressive disorders and 56.2% of them never sought for professional help. We concluded that Web-based tools could help screen the hidden depressive disorders for whom could assess the Internet.

Keywords: Information Services, Psychiatric Status Rating Scales, Internet, Depression

Introduction

The World Health Organization Global Burden of Disease study in 1997 predicted that clinical depression will be the second most burdensome illness in the world by the year 2020. The prevalence of depressive symptoms is high, ranging from 20% to 41% of the total population. However, many individuals with depression remain undetected or go untreated. Computer-administered depression assessment programs have been developed to facilitate the administration and screening of depression, but they still require that people come to a clinical setting to take the test. The Internet provides advantages that may greatly improve the utility of computer-administered diagnostic programs and detecting hidden depressive patients.

In the present study, we used the Internet-based Self-assessment Program for Depression (ISP-D) for people to screen depressive disorders online and analyzed the results.

Methods

ISP-D was designed to detect major depressive disorder (MDD), minor depressive disorder (MinD), and subsyndromal depressive symptoms (SSD). Previous studies found that the test-retest reliability of the ISP-D was good within a 2-week interval and its criterion validity was comparable to that observed with written tests. The current study provided online ISP-D service for Internet users to assess depression by oneself in a short amount of time. The ISP-D can provide a continuously available depression screening method that is accessible to a large number of individuals across a broad geographic area. We analyzed the test results between Jan 2001 and Jan 2002 to understand the effect of ISP-D in the detection of people with hidden depressive disorders.

Results

There were 1656 tests performed during the period. The mean age for the participants was 25.3 ± 7.3 years and their mean education level was 14.7 ± 2.5 years. Most of the participants were female (75.1%), and single or separate (84.5%). The distributions of MDD, MinD, SSD, and no depression were 37.9% (n = 627), 12.9% (n = 213), 23.2% (n = 384), and 26.1% (n = 432), respectively. The mean Internet test time was 8.7 ± 6.4 minutes. Among the participant, 56.2% of them never sought for professional help.

We compared the participants who ever sought for professional help and those who never sought for professional help. We found that those who ever sought for professional help were significantly older, with higher educational level, with more depressive symptoms, with more comorbid medical conditions, with more family history of mental illness and more females than those who never sought for professional help.

Conclusion

In our one-year survey, more than 70% of people who performed the ISP-D tests were screened as having depressive disorders. More than half of them never sought professional help before. Therefore, Web-based screening tools may greatly facilitate people to detect the hidden depressive disorders.

Value Added: Needs, Motivations, Hopes and Fears of Argentine Patients About the Development of their Personal Health Records

Alejandro Mauro[a], Analía Baum[a], Carlos Galarza[a], Paula Otero[a], Daniel Luna[a]

[a] *Department of Medical Informatics, Hospital Italiano de Buenos Aires, Argentina*

Abstract and objective

The objective of the present work was to evaluate the needs, motivations, hopes and fears of argentine patients for a patient-centred personal health record development. Using inquiry methods and paper prototyping, we evaluated the different types of needs of 23 patients who were invited to take part in this study. Investigators grouped patients' needs into 11 categories. The meeting with final users developed a clear shared vision of the purpose of the product and brought new insight and clarity concerning the informatics needs of health consumers. The Group Discussion technique permits that, at very early stages of the development process, users' needs can be perceived and that this, conducted before the stage of initial design, results in high performance and low costs.

Keywords:

medical records systems, computerized; needs assessment; user-computer interface; software design; patient access to records; attitude to health

Introduction

Since Hurricane Katrina battered the Gulf Coast, more health care organizations have begun to think about PHRs as the best way to make personal health information portable. As an example The Centers for Medicare & Medicaid Services are exploring the creation of a national PHR for Medicare beneficiaries[1].

The Italian Hospital of Buenos Aires has developed a full scale Health Information System (HIS) has been gradually implemented, including ambulatory Electronic Medical Record (EMR), inpatient discharge summaries, administrative systems, scheduling systems, inpatient tracking systems, pharmacy systems and complementary studies report and visualization [2].

Currently we are working on the development of a PHR to support patient's access to different functionalities and services from HIS. To develop a product which will comply with the criteria of usability[3] you have to know, understand and work with the people who represent the current or potential users of the product[4, 5].

The purpose of the study was to understand those aspects of the product that are of most interest to and need for our users.

Materials and methods

We based our work on methods of contextual inquiry[4]. These techniques offer the possibility of generating ideas and taking user participation into account..

We invited patients of the HMO to participate in the activity "Internet Use: can it improve your health care?"

Two activities were carried out in two hours. After a brief introduction in which it was explained to the participants what a Personal Health Record (PHR) is, they were divided into groups so that at the end each of the groups told the others of its results.

To carry out the second activity, each group was given a canvas in the form of a monitor screen, and materials (scissors, markers, papers, cardboard, and stickers) and they were asked to design a portal which would provide the services and information listed in the previous activity. When they finished, each group presented its portal, explaining each of the components chosen and the function and/or information which each component should offer.

Finally, each patient completed an anonymous survey for us to get to know details of gender, age, educational level, access to Internet, and the perceived usefulness of the patient portal components which the literature suggests, on a Likert scale of 5 points.

Results

23 people voluntarily attended, of whom 16 (69.6%) were women and 7 (30.4%) men. Only 17 people fulfilled the survey. The average age was 60.4 years and 65% had completed university studies. 88% had a personal computer with Internet access in their homes, and 86.6% use it for work, communication or topics research. 76.6% at some time sought information on health on the Internet.

During the framework analysis of the collected data, investigators identified patients' needs and grouped them in the following 11categories.

1. Integrated information. The members of one group

proposed that the portal should be problem-oriented.

2. Interface flexibility. One of the groups insisted that guides or aids should be developed to help in navigating.

3. Immunization control. All the groups suggested having an age-based vaccination calendar.

4. Warnings, recommendations and reminders. All the groups agreed that having a space with recommendations on preventative practices and specific controls for each illness was fundamental.

5. Access to information sources. There was also agreement about having access to sources of contextualized information.

6. Communication. All the means of communication of information technologies were mentioned.

7. My medicines. All the participants reiterated underlined the need to be able to have access to a section with information about the medicines that each one is using, and be able to know about adverse effects and contraindications.

8. My results. All participants proposed the visualization of the results of complementary studies.

9. My records. Among the functions suggested, in two groups the idea came up of a space where they could see the records vital signs with the possibility of being able to complete the record with data obtained by the patients from controls in their home or in a pharmacy.

10. Accessibility. In this section we group participants' suggestions which might help to optimize patient flow in the health system and service accessibility.

11. Access to clinical histories, and data privacy. Naturally, the topic of confidentiality and privacy of data did not fail to come up.

The paper prototypes that the participants designed reflected the needs of the categories which we have mentioned. All the groups used the color red to make the categories Warnings, Reminders, Recommendations and Immunological Controls stand out. In spite of having been given several sheets of paper to simulate different windows, all the groups concentrated all the information on the initial screen.

Discussion

A meeting with the main stakeholders develops a clear, shared vision of the purposes of the product, brings new insights and clarity to the informatics needs of health consumers, such as access to reminders, recommendations, alerts, immunizations, medication, notes and vital signs, and even schedules and referenced maps.

The data gathered in the Discussion Group are consistent with the standard recommendations found in the literature on the functionality of PHR. However, consumers' needs, motivations, hopes and fears add a value necessary for any successful implementation[6].

This methodology is easy to put into practice, does not need too many resources, and is very valuable in that it contributes to an amplification of perspectives and a deepening in a variety of considerations that, at times, pass the software designer unnoticed. In future work, we plan to design and develop a PHR that will fulfill consumers' expectations, and to invite a wide range of people to test its usability.

Conclusion

Using simple methodology we have been able to identify the needs, motivations, hopes and fears of our patients in relation to PHR and to learn some principles for the design of this new tool. But we need more research to verify how it will be used and if we can meet our usability goals.

- They reflected the needs of the categories mentioned.
- Red Color for

  →Warnings, Reminders, Recommendations and Immunological Controls .
- Icons for web actions
- Online Help button always available

Discussion

- Meeting the main stakeholders develops a clear, shared vision of the purposes of the product, brings new insights and clarity to the informatics needs of health consumers.
- The data gathered in the Discussion Group are consistent with the standard recommendations found in the literature on the functionality of PHR. [3]

Conclusion

- Using a simple methodology we have been able to identify the needs, motivations, hopes and fears of our patients in relation to PHRs and to learn some principles for the design of this new tool.
- More research is needed to verify how it will be used and if usability goals were met.

Privacy and Security Issues in E-Health Services: a Review of HON Sites

Yi Hong[a,b], Timothy B. Patrick[c]

[a] *Medical College of Wisconsin, Milwaukee, Wisconsin, USA*
[b] *College of Engineering and Applied Science, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, USA*
[c] *College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, USA*

Abstract

E-Health involves new forms of patient-physician interaction and poses new ethical challenges and threats to patient privacy. This paper reviews HONcode accredited e-Health websites that provide online appointment services for compliance with basic principles of security and privacy. We selected the HONcode websites with online appointment service in the U.S.A to do the analysis. We found that 20 of 30 HON sites we reviewed are secure sites but only 9 of 20 secure sites state that it is secure. Most HON sites require patients to submit confidential data. 10 of 30 websites do not display privacy notice or statement of privacy policy on the web appointment request page. Even though there is a privacy notice, the reading level might be a problem for the patients who have lower education background. Regulations and guidelines do not ensure that privacy protection and data security is done appropriately or well. More attention to measures and procedures are needed to safeguard patients' privacy right.

Keywords:

health services, internet, privacy, confidentiality, computer security, ethical analysis, Health Insurance Portability and Accountability Act

Introduction

E-Health and Consumer Privacy

E-Health is "…the application of Internet and other related technologies in the healthcare industry to improve the access, efficiency, effectiveness, and quality of clinical and business processes utilized by healthcare organizations, practitioners, patients, and consumers in an effort to improve the health status of patients." [1] E-Health can provide healthcare consumers with opportunities to interact with their healthcare systems online and can provide new forms of patient-physician interaction.

Despite its advantages for healthcare consumers, e-Health poses new challenges and threats to their privacy. Many healthcare consumers are not aware that their use of Healthcare resources on the Internet may be tracked. Consumers may also not be aware of the personal information gathered about them when visiting a Web site [2]. For example, consumers may not be aware that their personal information may be collected without acknowledgment by cookies, nor how it may be used when it is collected by other mechanisms such as online surveys and assessments.

The HON Code of Conduct (HONcode)

The Health On the Net Foundation (HON) was founded in 1995 to promote "…the effective and reliable use of the new technologies for telemedicine in healthcare around the world."[3] The HON Code of Conduct (HONcode) was developed …to help standardise the reliability of medical and health information available on the World-Wide Web.

The HONcode is not an award system, nor does it intend to rate the quality of the information provided by a Web site. It only defines a set of rules to:

- hold Web site developers to basic ethical standards in the presentation of information;
- help make sure readers always know the source and the purpose of the data they are reading. [4]

Currently there are more than 120,000 health-related web sites that are HONcode accredited. [5] The HONcode principle regarding privacy and confidentiality states that

Your site must describe how you treat confidential, private or semi-private information such as email addresses and the content of emails received from or sent to your visitors. You must inform your visitors whether their data will be recorded in your own database, who can access this database (others, only you, nobody), if this information is used for your own statistics (anonymous or not), or if these statistics are used by third party or other companies.

A statement or a privacy policy page regarding confidentiality of data must be clearly displayed. [6]

Purpose of the Study

Rating and accreditation standards such as HONcode are critical to the success of e-Health. This study reviews HONcode accredited websites that provide online appointment services for compliance with basic principles of security and privacy.

Methods

We searched for HONcode accredited sites using the HON search engine [7] with the query "web appointment request" on Nov 16 2006 . The search retrieved 170 HONcode accredited sites. We reviewed the 30 USA websites that actually provided online appointment services. The 30 sites are listed in **Table 1**.

We reviewed each of the 30 sites to determine:
(1) Is it a secure site?
(2) Does it include a statement regarding its status as a secure site?
(3) Does it request confidential data elements from the user making an appointment?
(4) Does it include a privacy notice or statement of privacy policy?
(5) What is the reading level of the privacy notice or statement of privacy policy?

We considered a site to be secure if it used HTTPS, which is a "…combination of a normal HTTP interaction over an encrypted Secure Sockets Layer (SSL) or Transport Layer Security (TLS) transport mechanism." [8]

We used the SMOG Calculator [9] to assess the educational level needed to fully understand the text of the privacy notice or statement of privacy policy. We coded SMOG grade <12 (high school level) as low level (l), SMOG grade 12-16 (college level) as medium level (m), SMOG grade >16 (university degree) as high level (h).

Results

Table 1 shows the results of the review.

(1) Is it a secure site?
Among the 30 HON sites, 20 sites are secure sites, 10 are not.

(2) Does it include a statement regarding its status as a secure site?

Among the 20 secure sites, only 9 of them state that they are secure.

(3) Does it request confidential data elements from the user making an appointment?

Most HON sites require patients to submit confidential data such as Social Security number, date of birth, medical record number, medical information, insurance information, etc. Almost all of them require patients to provide birth date information. 6 of them require Social Security Number (SSN) along with birthday. The secure sites require more confidential data than non-secure sites.

(4) Does it include a privacy notice or statement of privacy policy?

10 of 30 websites do not display a privacy notice or statement of privacy policy, or a link to such a statement, on the web appointment request page.

(5) What is the reading level of the privacy notice or statement of privacy policy?

Among 20 websites that have a privacy notice or statement of privacy policy on their appointment page, 19 of them need higher than high school level to fully understand the privacy statement while 6 of them need higher than college level to figure out what the privacy statement means, only one needs high school or lower level to understand.

Discussion

Persons who use the Internet for health-related reasons have the right to expect that personal data they provide will be kept confidential and also have the right to be informed that personal data may be gathered, and to choose whether they will allow their personal data to be collected and whether they will allow it to be used or shared. The study of HONcode accredited medical and health Web sites reveals the gap between ideal and reality. In our sample, 1/3 of the HONcode accredited sites that provide online appointment service are not secure.

Including a privacy notice or statement of privacy policy on a site is very important. However, even though a site adopts security procedures and displays a privacy policy, users might still not trust it or may be misled unless there is a brief and understandable statement of security and privacy displayed on the site. In our study, we regarded the websites that have "https" within their URLs as secure sites as information exchanged with any address beginning with https is encrypted using Secure Sockets Layer (SSL) before transmission, but very few lay users realize the difference between "http" and "https". It is thus necessary to show that the Web site is secure by either displaying a secured seal or a brief statement. This is especially important for the users with lower education background, particularly when the site requires users to submit confidential data such as Social Security number, date of birth, medical record number, medical information, or insurance information.

Table 1 - Review of the HONcode accredited websites for compliance with basic principles of security and privacy.

Criteria:
1: Is it a secure site?
2: Does it include a statement regarding its status as a secure site?
3: Does it request confidential data elements from the user making an appointment?
4: Does it include a privacy notice or statement of privacy policy?
5: What is the reading level of the privacy notice or statement of privacy policy? (SMOG grade)

Conclusion

Security, privacy, and confidentiality are major concerns in e-Health services. Health Insurance Portability and Accountability Act (HIPAA) regulations, eHealth Code of Ethics, HON principles, and other guidelines do not ensure that privacy protection and data security is done appropriately or well. There is a gap between ideal and reality. More attention to the spirit of existing measures and procedures are needed to safeguard patients' privacy rights.

To deal with the challenges to manage and ensure individual privacy, the following steps should be taken to maintain the Web site visitor's rights to privacy and the confidentiality of personal information:

1. Secure Web sites with user ID and password or using SSL Certificate Encryption and display the Secured Seal to let the user know that his or her transactions are secure.

2. Provide a statement or a link to the privacy policy of the Web site on the home page or the site navigational bar that is easily accessible and understandable to the user.

3. Do not collect name, birthday, phone number, e-mail address, or any other personal information unless voluntarily provided by the visitor after the visitor is informed about the potential use of such information.

4. Do not collect SSN, personal medical information (medical conditions, health-seeking behaviors and questions, and use of or requests for information about drugs, therapies, or medical devices) and other sensitive personal information without the express consent of the site visitor after explanation of the potential uses of such information.

Online Survey of Consumer Health Information Privacy in Korea

Jeongeun Kim[a,b], Sukwha Kim[c]

[a] *College of Nursing Seoul National University, Korea*
[b] *Research Institute of Nursing Science, Korea*
[c] *College of Medicine Seoul National University, Korea*

Abstract and objective

Health information should be acquired, disclosed and used only in ways that respect consumer's privacy & rights. The online survey on the consumers' attitudes towards health information privacy was done, and revealed the unique result that is somewhat different from Americans'. The consumers' need should be incorporated to the constitution.

Keywords:

privacy, consumer, health information

Introduction

Korean government recently announced that the master plan for the National Health Information Infrastructure will be on the way, and will set the Health Information Privacy Protection Law which is in equivalent to the HIPAA as soon as possible. The purposes of this research are: to survey the consumers' opinions about the health information privacy, to understand the consumers' privacy-protective behaviors out of the concern about the privacy breaches, to know the consumers' recognition about the constitution of the health information privacy law, to know the consumers' willingness to share their personal medical information.

Methods

The authors conducted the online survey. The questionnaire developed and conducted by the California HealthCare Foundation (CHCF) on "National Consumer Health Privacy Survey" was translated into Korean and reviewed by the authors to conform to the Korean situation. It was made as an online survey form, and uploaded, solicited the participation of the website visitors of a tertiary teaching hospital in Korea, and 281 responses were collected online. The results were analyzed for the descriptive statistics.

Results

- Consumers concerned about the privacy of their personal health information. 79% were concerned about the privacy, and this was higher percentage than the US consumers' which was 67%.
- Recent privacy breaches have raised the level of concern. 56% of Korean respondents were aware of such privacy breaches, which was also higher than that of the US consumers' of 24%.
- Consumers are unfamiliar with health information privacy law. Only 37% were aware of the related law, and 80% didn't have a chance of notification that there are such laws.
- Consumers think that the paper medical records are more secure than electronic medical records.
- Employees concern about the misuse of medical claim information. Sixty percent of the respondents concerned about the disclosure of their medical information to their employers.
- Privacy-protective behaviors exist, however, not so much as US consumers. Not so many Korean consumers practice the privacy-protective behaviors even though they worry about the misuse of the health information.
- Consumers will share their personal medical information with limited others such as family members and physicians involved in their care. In contrast, they are not willing to share their health information with drug companies, government agencies or employers.

Conclusions

Most of the consumers answered that the information could be shared when necessary, however, the ownership and the right to decide the disclosure should belong to patient, and patient should be allowed to access their own information with certain degree of regulation. These kind of awareness were strengthened by the implementation of EHR. In detail comparative analysis between Korean and American consumers' attitudes will be done if the American data be available.

Patient Empowerment: A Measure of Patient Empowerment Received by the German Health Card

Katharina Spitalewsky[a], Stefan Skonetzki[b], Maria Pritsch[c], Christian Kohl[d], Petra Knaup[d]

[a] *Medical Informatics, University of Heidelberg, Germany*
[b] *Institute for Medical Informatics, Erlangen, Germany*
[c] *Department of Medical Biometry, University of Heidelberg, Germany*
[d] *Department of Medical Informatics, University of Heidelberg, Germany*

Abstract

Problem: Patient Empowerment is a major aim of the German Health Card project. Up to now, it is unclear how patient empowerment can be measured. Methods: Literature review, development of patient empowerment indicators (PEI), design of a questionnaire to measure PEI for electronic prescription, validation of the questionnaire, analysis of indicators that can be determined by Health Card Terminals (HCT). Results: Six basic requirements for patient empowerment. and a questionnaire with 39 items. Conclusions: Patient Empowerment is difficult to measure. The suggested questionnaire has to be validated again by a representative sample. Then it can be used for a pilot study.

Keywords:

patient empowerment, measurement, qualitative research, electronic prescription, patient behaviour

Introduction

"To empower" means to give (someone) the power or legal right to do something[1]. Known empowerment concepts base on the principle of strengthening the mental power of the individual. The approach is already realised in disciplines like sociology, psychiatry or marketing. Empowerment is also a major aim of Germany's electronic health card project. The patient is enabled to continuously check all medical data on the card with the help so called Health Card Terminal (HCT). The objective of the paper is to define indicators for patient empowerment in the context of electronic prescription on the German Electronic Health Card (GEHC) and to introduce methods to measure them.

Materials and Methods

The aim of patient empowerment is to better integrate the patient in decisions e.g. by providing more individualized information. He is better involved in his treatment and more responsible for his health. Our working definition is based on Gibsons definition: „empowerment is a process of helping people to assert control over the factors which affect their lives. This encompasses both the individual responsibility in health care and the broader institutional, organizational or societal responsibilities in enabling people to assume responsibility for their own health." [1]. In addition we use the dimensions of empowerment developed by Zenz in his paper "Evaluating Empowerment: The world vision area development programme"[2].

We developed a process model for the prescription process and carefully analysed sub-processes in which the patient can be involved. To identify items that characterise patient empowerment in each of the processes we conducted a moderated brainwriting with 16 scientists. We enhanced the resulting item list by patient empowerment indicators (PEI) from literature e.g. "Satisfaction with quality of care" or "Desire for more information" and by technology acceptance indicators e.g. "Response time" and "Compatibility". We developed a 39-item questionnaire and performed a first iterative validation with more than 30 participants.

Results

The Dimensions of patient empowerment

We matched Gibson's definition with Zenz's model [2] to make sure that it can be used for the patient empowerment problem. Applying Zenz's statement in health care resulted in four our basic requirements for patient empowerment: Literacy, creative power, independence, self-efficacy. They apply, when the patient has access to his medical data by his GEHC.

Modelling the prescription process

Modelling the workflow of prescriptions we defined seven processes: Consulting the physician, Patient deletes the prescription (Action at the HCT), Patient hides or reveals the prescription (Action at the HCT), Dispensation, Reading prescription (Action at the HCT), No action, (the prescription is not valid any longer after a certain time span.), Advice (pharmacy). This process is not necessarily

1 Longman Dictionary of Contemporary English DCE, 1987

linear. Functions can be omitted or can be performed repeatedly.

Items for describing empowerment and IT-acceptance

We conducted a brainwriting to analyse for each step in the process, which decisions of a patient could be expected and which influence patient empowerment would have. We matched all answers with our four core requirements. The Matching resulted in two new requirements: exogenous empowerment, endogenous empowerment.

In a final step the resulting items were completed by items for measuring IT-acceptance, known in the literature [2]-[13]. We organised our item list in four tables: a) Description of the population, b) Description of medical background, and c.) descriptive data of terminal use and usage. The fourth table contains the six prerequisites mentioned above.

Measuring empowerment

Planning controlled trials for measuring patient empowerment should first of all start with determining the inclusion criteria, like that the patient is an owner of a GEHC. For measuring the items introduced in table a)-c) different methods have to be used. Items which are part of the Health Card data (e.g. age, sex) could be collected in a log file, if data protection laws are followed. as well as data like length of HCT consultation. Other items cannot be measured objectively, but have to be investigated by questioning patients. We designed a questionnaire for patient attitudes with four parts and 39 items. Part A is demographic data of table 1, Part B Medical Background – table 2, Part C is attitude towards HCT and Part D is behaviour. Some items in the questionnaire are requested by statements to be judged by the patient. For this personal judgement the 4-point Likert-Scale is used for questions like ‘by using a HCT I feel more independent from the general practioner and the pharmacist’.In a first validation phase, the questionnaire was validated by 30 participants.

Discussion

A potential of the HCT is that additional information about the prescribed drug can be presented. If this is formulated in a way, which can be well understood by the patient, this could positively influence patient compliance [14]. Nevertheless we can cannot guarantee that the empowered patient makes clinically sound decisions.

We will validate our approach in the real setting of patients using the HCT, when the GEHC and the terminals are available. For this it is necessary that the patients have their own cards and used the HCT. Questions about the satisfaction with the functionality can be used to improve the system. The aim of our further research is to present individualized information about the drugs during HCT encounter and to analyse if the patient is empowered by this.

Conclusion

To measure patient empowerment precisely and to finally define the indicators that determine patient empowerment, further research is necessary. Our questionnaire is a first step and considers the problems patients may have with Health Card Terminals. It can be adapted to other telematics applications and may hopefully lead to empowered patients and accepted technologies in healthcare.

Patient Empowerment

A measure of patient empowerment received by the German Health Card

Katharina Spitalewsky, Medical Informatics of Heidelberg, Germany
Stefan Skonetzki, dmc digital media center GmbH, Germany
Maria Pritsch, Department of Medical Biometry, University of Heidelberg, Germany
Christian Kohl and **Petra Knaup**, Department of Medical Informatics, University of Heidelberg, Germany

Background: German Health Card

The patient is enabled to continuously check the data on the card. For this the introduction of the so called Health Card Terminal (HTC) is necessary.

Aims of the project:

- improving the communication between all partners in health care (faster access, trans-institutional provision of data, better access for patients)
- lowering costs (easier workflow for prescription, reducing prescription errors, avoiding double measures and faster access to emergency data)
- **empowering the patient**.

→ It is unclear how patient empowerment can be measured.

Empowerment

Definition

Gibson (1991):

„empowerment is a process of helping people to assert control over the factors which affect their lives. This encompasses both the individual responsibility in health care and the broader institutional, organizational or societal responsibilities in enabling people to assume responsibility for their own health.” [1]

Dimensions

Zenz developed 2001 a model of empowerment. It consist of four dimensions[2]. For our research we adapted it to **patient** empowerment:

Dimensions of Patient Empowerment

- Literacy

  competency which comprises several skills, which enable the individual patient to handle information competent, efficiently and responsibly. The patient can identify relevant information for his health in different contexts, he can understand, interpret and communicate this information.

- Creative power

  competency which enables to define individual aims, define strategies to reach these aims and to act according to these strategies. I.e. that the patient can influence decisions, discussion results or general changes.

- Independence

  Independence is the ability of a patient to make decisions concerning his health state and health care on his own.

- Self-efficacy

  With self-efficacy the patient is able to believe in skills to act independently with regard to his health

→ **Our core requirements for patient empowerment**

Prescription process

Involved processes (patient view):

- Consulting the physician
- Patient deletes the prescription - Action at the HTC
- Patient hides or reveals the prescription - Action at the HTC
- Reading prescription - Action at the HTC
- Dispensation
- No action
- Advice

→ The modelled process is not necessarily linear. Functions can be omitted or can be performed repeatedly

Workshop

Analysing the modelled process in a moderated workshop:

→ Which decisions of a patient could be expected?

→ Which influence have patient empowerment?

Matching the answers with the our core requirements resulted in two new requirements:

- Exogenous Empowerment

  Did the behaviour of the health care professional towards the empowered patient?

- Endogenous Empowerment

  How sustainable is the empowerment of a patient and is the patient motivated to critically reflect the treatment results.

IT-acceptance

The HCT is a new technology for the patient. Functionality or ease of use can improve the patient‘s behaviour and empowerment at the first time.

Items taken from the literature[3]:

- Compatibility
- Ease of use
- Information
- Perceived usefulness
- Relative advantage
- Satisfaction
- Voluntariness

Items for describing patient empowerment

The items resulting from the analysis in the workshop and items for measuring IT-acceptance were completed by items in the literature [4]-[15] and organised in four tables:

- Table A. Description of the population
  - e.g. gender, age, education, IT knowledge
- Table B. Description of medical background
  - e.g. satisfaction with quality of care, desire for more information
- Table C. Descriptive data of terminal use and usage
  - e.g. ease of use, respond time, no. of errors, compatibility
- Table D. Expected Empowerment
  - contains the six prerequisites

We divided the resulting list of indicators in two parts:

- objective data which can be assessed by analysing the **logfiles** of health card terminals
- subjective data from **questionnaire**

Questionnaire

For items witch cannot be measured objectively a questionnaire was designed. It consists of four parts and 39 items:

- Part A is demographic data of table 1,
- Part B Medical Background – table 2,
- Part C is attitude towards HCT and
- Part D is behaviour.

Most of the items of the questionnaire are requested by statements to be judged by the patient. For this personal judgement the 4-point Likert-Scale is used:

I agree - ... - I do not agree.

e.g. “I haven’t any problems to access my data.“

Measuring patient empowerment at the HCT

Summary:

- Controlled randomised trial
- Inclusion criteria e.g.
  - patient is older than 18 years
  - patient had not been deprived of his right of decision
- Two methods are used to measuring the items
  - Logfile
  - Questionnaire
    - was validated by 30 students and scientist which resulted in a reworked version of the questionnaire

Discussion

- A potential of the HCT...

  ...is that additional information about the prescribed drug can be presented. If this information is presented and formulated in a way, which can be well understood by the patient, this could positively influence patient compliance [15].

- But...

  of course, a restriction of our measuring methods is, that we can cannot guarantee that the empowered patient makes clinically sound decisions.

- Next valuation phase:

  When the German Health Card and the terminals are available we will validate our approach in the real setting of patients using the HTC.

- The aim of our further research is to present individualized information about the drugs during HTC encounter and to analyse if the patient is empowered by this.

→ **To measure patient empowerment precisely and to finally define the indicators that determine patient empowerment, further research is necessary.**

Goal-Oriented Blogging: A Case Study of a Dutch Commercial Website For Tracking Weight Loss Online

Samantha A. Adams

Erasmus University Medical Center, Rotterdam, the Netherlands

Abstract

Blogs, short for "web logs," together with podcasts and wikis are currently important foci of internet research. These three applications are often addressed together as comprising "Web 2.0." Within the area of health care, however, little attention has been devoted to understanding these technologies and how they are being used by lay health publics. In this article, I will discuss the idea of "goal-oriented" blogging using the case of a Dutch commercial weight loss website. Because this research project is still in preliminary phases, I will address the topic based on an analysis of the website and discuss the relevant informatics questions that such a case raises.

Keywords:

blogs, Web 2.0, patients, lay health practices, health promotion

Introduction

Web applications such as podcasts, wikis and online web logs (more commonly referred to as "blogs") are currently important foci of internet research. These types of web-based applications (collectively dubbed "Web 2.0") are considered to give credence to well-known claims about the democratizing nature of internet technologies because they give users easy avenues to produce/publish information, experiences, opinions, etc. and reflect bottom-up regulation of that published information. Within the area of health care, however, little attention has been devoted to understanding these technologies and how they are being used by lay health publics. Discussants in both the Consumer Health Informatics and Knowledge in Motion Working Groups at the AMIA 2006 Annual Symposium pinpointed the need for more research devoted to alternative avenues for managing both information and experiences with respect to individual health.

Although much has been published on blogs, bloggers and the practice of blogging more generally, the literature on blogs with respect to health care has been quite limited. Most of what has been written are editorials, are written from the perspective of doctors who are blogging, or are discussing the potential roles for blogs in educating nurses and medical students.[1-3] Little attention has been given to how patients blog with respect to their health.

The closest relation is found in work on Personal Health Information Management, such as the studies conducted by Pratt et al. [4] As Pratt et al discuss, Patients are increasingly expected to play a more active role as managers in their own care. The central role afforded to patients means that they must store, maintain and retrieve many different kinds of information from different sources using different media. Pratt et al suggest that patients need tools that address information gathering and sharing challenges, thereby enabling them to be more involved in their health care. Specifically, they emphasize the need to create tools that are easy to use *and* allow for the integration of different information interfaces in one.

Although health-related blogs do not completely meet the idea of integration, they do allow patients to utilize open space to actively manage their own care. They can assemble information from different sources as they choose and repackage it for others, who not only read the blog posts, but also have a chance to respond. This latter function also helps patients to communicate any news or developments they want to share with those in their readership communities. Investigating under which circumstances individuals do or do not choose to use this broadcast format could provide helpful insights into how individuals use technology to resolve the communication difficulties to which Pratt et al refer. Under the idea of "push button publishing" (all you have to do is fill in a text box and click submit), blogs are incredibly easy for individuals in the general public to use, thereby further lowering the barriers to publication/ distribution of various types of information.

Blogs are generally defined as personal web sites with content displayed in reverse-chronological order. [5] They can deal with personal or private issues or aim to situate themselves within the public discourse on a given topic. [6] New posts are placed at the top of the page instead of the bottom, making changes easily identifiable. They generally have an identifiable author, sometimes even with pictures. Site visitors can usually leave comments for others to see. Blogs are loosely joined to each other through hyperlinks and the global network of blogs is referred to as the "blogosphere". [5] Blogs are often thought of as analogous to online diaries, but this is a misconception. [7] Blogs began as lists of links to (or web logs of) other interesting web content but have evolved to include many different forms of multimedia content, including combina-

tions of links, text, photographs and other web materials. The format and tools used to produce the blog are more defining than the content itself. [7-8]

Information about an individual's health care can be both implicit and explicit in existing personal blogs. Implicit would refer to texts that are on general topics or consist of links to different types of websites, but that refer to health-related issues or practices as part of a larger body of topics. In this case, one would have to search blogs for instances of links, thoughts or experiences related to health care. Explicit would refer to blogs that are set-up with a particular health situation in mind. An example would be coping with a chronic disease such as leukemia, self-management of a disease such as diabetes[9], documenting a specific (limited) trajectory such as pregnancy, or to support attempts to achieve specific health care goals such as losing weight or smoking cessation.[1]

In this article, I will discuss the idea of "goal-oriented" blogging using the case of the Dutch-based "valt af" ("is losing weight") website. This commercial website allows individuals to keep an online journal, collect and/or register information and other resources, and communicate with others through discussion boards and chats on the parent site and through a function that allows readers to post responses to individual blog posts on personal sites. This space enables users to use their blogs to document the process of achieving a specific health goal. After describing the features of the site, I will use the discussion to raise important questions that are relevant for future informatics research.

Materials and methods

This is a case study description of the Dutch-based, Dutch-language commercial website, Valtaf.nl. It is based on a content analysis of the website and also garners information from the website of the company that provides the commercial site.[2] This website is an interesting case because it has received a lot of attention in the popular press and because it represents a unique approach to helping people achieve difficult health goals.

1 Combinations of implicit and explicit are also possible. An example of a hybrid of these two types of health representation is the blog maintained by sociologist and internet researcher Eszter Hargittai. [10] Hargittai posts interesting links with comments, and also tells about her personal life and experiences in journal format. The archives of her posts are tagged according to topic. The part of her blog tagged for "health and fitness" refers to a post about her goal to run a 5K marathon

2 Interviews with users are currently being conducted. However, not enough interviews have been completed to allow using that data and making any detailed claims here.

Results

The Valtaf website is provided by a commercial company, Sofit Wellness, which develops software and content about healthy habits, nutrition and exercise. Sofit Wellness provides Valtaf.nl for Dutch users and Valtaf.be for Flemish-speaking Belgian users. On its corporate site [11], Sofit also explains that the valtaf sites are an example of the software and content services they provide – in this case, the technological basis for companies interested in establishing a weight loss portal under the brand name of said company for use by customers, readers or employees. The websites provide "personal web pages" to individual users and includes diverse automatic content and social support functions that support participants in the weight loss process.

The parent page for valtaf.nl provides general information about the site. It begins with the claim, "Lose Weight Online!" and contains a sentence in the web-browser that identifies the site as "Your free, personal weight graph and food diary." It informs site visitors that "Losing weight on the internet really works! If you participate with www.valtaf.nl , then you'll receive your own website where you can keep track of what you weigh, what you've eaten and how much you still have to lose in order to reach your target weight." It continues, "Thanks to the support and encouragement you'll receive from buddies and thanks to the professional supervision from a nutrition expert and dietitian, you can successfully lose weight and keep it off."

Through their links to the parent website, these "personal web pages" offered to individuals who join contain more content options than do blogs, but the individual pages are be built, at least partially, with the same easy-to-use functions as popular blogging websites and they include the unique combination of materials that is common to present-day web logs. In addition to submitting data about their daily food intake and exercise, weight, fat percentage, BMI, and physical measurements using a form that allows push button publishing, users can also post personal photo's and write journal entries with (animated) emoticons. The journal entries are listed in reverse chronological order, with the newest on top, and allow for commentary from others. Their other entries are then repackaged in helpful charts and graphs that track progress over time, while the journal provides a compendium for understanding the trends reflected in the graphics by providing insight into specific factors in their daily lives that may have affected eating/exercise habits.

Users also have contact with buddies they have met (mostly) through the site and they can also join clubs with similar characteristics (live in the same city, are in the same age group) or with similar sub-goals (such as losing weight following a certain diet program or losing weight and remaining smoke free). Once on the site, they can eas-

ily see who is actively participating (that is, which sites were recently updated), who is online at the same time that they are and what each participant's individual progress is. In the general participation list, weight loss is signified with a green arrow pointing down while weight gain is signified with a red arrow pointing up. New users are easily identifiable because they haven't yet entered enough information to indicate weight gain or loss.

The personal web pages are interlinked with the primary valtaf website, which offers both asynchronous discussion boards and real-time chat, as well as articles from the experts behind the site. It also contains its own separate blog, which presents news and other relevant materials related to weight loss. The parent site also has direct communication with individual users. Submission of measurements and data is supported with e-mail reminders and all participants also receive weekly newsletters. For a fee, users can receive personal supervision with one of the health care consultants that works with the site.

A final interesting aspect of the site is the personal nature of the information that individuals choose to display. Web-based communication is often thought of as anonymous and faceless. This is called into question with applications such as blogs. In the case of valtaf, users generally register with a pseudonym as their user name, but their websites are not necessarily private/protected or anonymous (although they can be either or both). Many users write an introductory text wherein they reveal their name (at least their first name) and then reveal more personal information as they document their daily lives. Furthermore, the photograph policy on the sites requires that the photos be of the user and pictures of others can only be included when the registered user is also in the picture. Thus, a blog about an otherwise private and personal health issue becomes a public, social activity.[12]

Discussion

The different features offered by the valtaf website transcend different web categories (home pages, discussion boards, chat, text, video, pictures, news, opinion, experience, etc.) and broadcast genres (one to one, one to many, many to many, etc). Bridging different genres has been argued as one of the important defining elements of blogs. [13] Because of the nature of the personal sites and the structure of the journals that are located on these sites, I would argue that the individual pages are incorrectly labeled as personal home pages and should be considered as health-related, goal-oriented blogs.

Herring et al [13] suggest the importance of documenting the individual characteristics of journal authors, the purpose of keeping the blog, a structural analysis of the blog, and temporal information for when specific information is added to a blog. Additionally, I suggest it is important to understand how blogging as an activity fits into an individual's past and present uses of other documentation and communication media, both in general and specifically with respect to health. For example, is an online journal easy to use because the person has kept journals in the past – or is there no discernable relationship? Has blogging for health care purposes led to other online practices? Understanding how users utilize (or have utilized) related on- and offline tools enables us to answer the question of where can blogs be placed in relationship to other methods of keeping records, such as diaries and autobiograhies and other forms of support, such as online and offline groups.

Because sites such as valtaf are gaining recognition in the popular press in the Netherlands, it will be important and interesting to examine from a user's perspective what aspects of the blogging tools and site options are most important and why/how these are effective. This indicates the need to typify who exactly is using these commercial sites, as well as why and how different individuals use various options they offer. It also raises the question of whether online tools are as effective as they are portrayed in popular media to be, which points to the need for quantitative studies in addition to qualitative studies.

Many users keep a daily or weekly chronicle of their experiences, which is a rich source of data about how individuals construct their own (health) identities. How does keeping an online record of one's progress motivate users to stick to the routines that are necessary to achieving their personal goals? Because interactions are not limited to online instances but also reflect blending with respect to online and offline communication, another important question which deserves more attention is one that leads to understanding how Web 2.0 technologies are configured within existing and new (health) networks. Where are the lines between online and offline relationships and how do these shift when patients begin documenting specific health care practices for which they need support?

One final area of interest is learning from users how they integrate their blogging practices into encounters with health care professionals. Do they utilize the services offered by the professionals that support the site? Do they discuss their attempts to lose weight, their blogging activity to this effect or the issues that they document in their online journal with their personal physicians? How does using such a tool "democratize" the health care process? What is the relationship between lay and expert knowledge on such a site and how do individual users view the expert opinions and advice vis-à-vis information they receive from buddies or other peers who share the same space? Related to this is investigating whether they would like to receive a similar service from their own health care provider organization in addition to or rather than a commercial website. Investigating these points could be

useful to health care institutions that are looking for new avenues for reaching their users for promotion and prevention purposes.

Conclusion

New and emergent technologies and tools are important topics of discussion. New applications that are available via the still very much rapidly changing internet are of special importance. In many respects the technologies and ideas discussed here are not exactly new. Certain categories of patients have been encouraged to keep diaries for years and more recent research has shown the effectiveness of, for example, online discussion boards as support groups. The uniqueness of these technologies comes, of course, in the fact that so many different tools are being blended together in and through one easy-to-use interface and that information retrieval and management are combined with interactive communication with both peer and expert contacts. In this paper I have used a single case study to identify several important questions that can be raised about these new combinations and applications. In the next phases of my research among individuals who explicitly blog for their health, I will address these questions more thoroughly.

In the United States, much research interest has been devoted to usable, functional Personal Health Records provided from Health Care Providers/Institutions. In the Netherlands, this has been much less of an issue, although one hospital is currently exploring what the creation of this type of tool would mean for its consumers. However, private companies are providing individuals with defined space on the internet that combines the idea of personal websites with easy to use blogging tools. Although these are not the same as personal health records, they can arguably be seen as fulfilling a similar function, at least with respect to specified health goals. What can we learn from the fact that patients are taking it upon themselves to utilize these publicly available (commercial) technologies for health purposes? More research is needed into these sites and the respective practices of the individuals who use them. This line of research is important for increasing our understanding of how "new" and "alternative" avenues for managing health information fosters healthy practices and how health care providers can capitalize on these easy-to-use applications in patient education or disease prevention and health promotion.

A Study of the Decision-making Process of the Medical Consumer based on Description Analysis of Personal Experiences of Illness

Mariko Iwasawa[a], Michiko Nishiyama[a], Yoichi Nakamura[b]

[a] *Graduate School of Library, Information and Media Studies, University of Tsukuba, Japan*
[b] *Ibaraki Prefectural University of Health Sciences, Japan*

Abstract and objective

Medical professionals offer medical information to the medical consumer in various forms. However, the medical consumer is considered to be isolated from such medical information before and after medical treatment. This research aimed to examine medical consumer's decision about whether to seek a medical consultation by performing description analysis of the personal experiences of illness. It became clear that there were various thought patterns, which deny their certain symptom. It became clear that the viewpoint, which pushes out the medical consumer to medical consultation, is indispensable at offer of medical information to them.

Keywords:

decision-making, narration, negation, patients

Introduction

It is thought there are fundamental differences in the types of disease information needed by the consumer. Here, we analyzed medical consumers' own descriptions of their decision-making processes in cases of rectal neoplasms.

Methods

We examined patients' own accounts of their struggles against rectal neoplasms. As consumers of medical information, they described their thought processes from the onset of symptoms, before they had decided whether or not to seek medical advice. We unified descriptions based on "The Merck Manual of Diagnosis and Therapy", and analyzed:

- the time when the symptoms had appeared, and the condition of the patient at that time

- the use of logic to deny recognition of the condition

- the action taken to search information in order to resolve their uneasiness

- the point at which the patient sought medical consultation

We used the following books as the information source of the personal experiences of illness:

Books; Toubyo-ki (described the thought process before a medical consultation)

Records; 24 gross records from 12 books by 24 patients

Illness; rectal neoplasms

Author; medical consumers (excluded medical professionals), Japanese

Results

The typical symptoms of rectal neoplasms were frequently extracted as shown in Figure 1. A lot of patients recorded initial and typical symptoms in their descriptions before medical consultation. For example, "bleeding with defecation", "stool frequency", and "constipation". Such three symptoms had become the key symptoms led to consultation behavior. Common symptoms like "nausea" and "weight loss" were also extracted from descriptions.

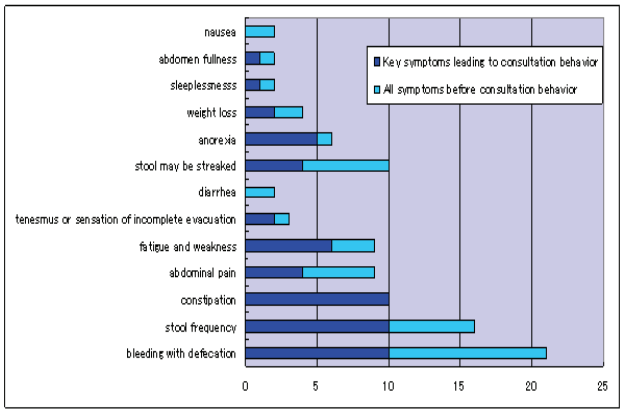

Figure 1 - Key symptoms of patients in all symptoms

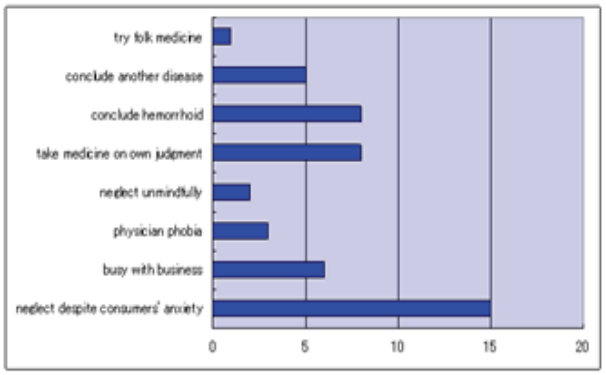
The reason that these symptoms were neglected was shown in Figure 2. These were able to be greatly divided into two groups based on the reason and action. The first group consisted of patients who do no action irrespective of the existence of a reason, though it felt nervous on their symptoms. The second group consisted of patients who devised the disposal of their own judgment, without receiving medical consultation. Furthermore, informational participation was also accepted as a trigger to take

medical consultation behavior. Their information sources were poster, library, newspaper, or friends.

Figure 2 - Reasons for neglect symptoms and action



The decision-making actions taken by medical consumers are shown in Figure 3. The Figure shows the types of thought processes used to deny the symptom and also the initial triggers for seeking a consultation behavior.

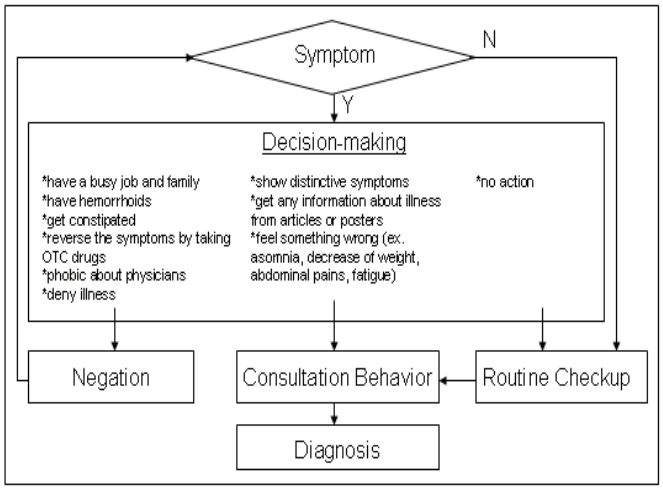


Figure 3 - Decision-making actions of medical consumers

Conclusion

Currently, medical information is offered mainly at the time of medical treatment, and the medical consumer is isolated from medical information before and after medical treatment. However, consumers need to make decisions by using information-seeking behavior before treatment. This need to seek prior information is thought to be a serious consequence of consumers' isolation from medical information.

In this research, from patients' personal experiences of illness we extracted their illusions and the causes in relation with medical consultation. We also illustrated the process of decision-making used by the medical consumer before medical consultation. By using these results to develop ways in which medical information is offered to medical consumers, we should be able to prevent problems such as delays in initiation of medical treatment, or the misguided use of folk remedies, in advance. These points are valuable to such research.

- Interpret the behaviors

3. Methods

Symptoms and Signs

The right colon has a large caliber, thin wall and its contents are liquid; thus, obstruction is a late event. Bleeding is usually occult. Fatigue and weakness caused by severe anemia may be the only complaints. Tumors sometimes grow large enough to be palpable through the abdominal wall before other symptoms appear.

The left colon has a smaller lumen, the feces are semisolid, and cancer tends to encircle the bowel, causing alternating constipation and increased stool frequency or diarrhea. Partial obstruction with colicky abdominal pain or complete obstruction may be the presenting picture. The stool may be streaked or mixed with blood. Some patients present with symptoms of perforation, usually walled off (focal pain and tenderness), or rarely with diffuse peritonitis.

In rectal cancer, the most common presenting symptom is bleeding with defecation. Whenever rectal bleeding occurs, even with obvious hemorrhoids or known diverticular disease, coexisting cancer must be ruled out. Tenesmus or a sensation of incomplete evacuation may be present. Pain is common with perirectal involvement.

Assessing the "Hyvis" Enquiry Service by Applying the Process Model of Information Management

Virpi Jylhä[a], Liisa Klemola[a], Kaija Saranto[a]

[a] *Department of Health Policy and Management, University of Kuopio, Finland*

Abstract

Internet-based services in the field of health care are one potential response to technological development. Nowadays people of different ages use the Internet to seek health-related information. The aim of this study was to assess how well the "Hyvis" Enquiry Service fulfils users' information needs, and also how the Hyvis Enquiry Service impacts on the use of health care services, by applying Choo`s Process Model of Information Management. A qualitative approach was used and the data were collected using semi-structured interviews (n=14). The results of this study show that in the view of both health care professionals and users, the Enquiry Service fulfils users´ needs, and that users usually obtain the specific information they require for the problem they have. Further, health care professionals believe that the information is accurate for the answer and is filtered by a health care professional before delivering the information to the users. These were also the expectations of the users who decided on using the Enquiry Service.

***Keywords**:*

delivery of health care, internet, consumer participation

Introduction

The number of Internet users in Finland has been growing rapidly, and people of different ages increasingly use Internet services in their daily life. As use of the Internet has become more popular among health care users, the Internet has also had an effect on the delivery of health care services. According to Åkesson et al. technical interventions provide the users with support, help and information. Although information and communication technology can enhance the nurse – patient relationship, it cannot entirely replace it. [1] The traditional 'office visit' model used in health care fails to meet clients´ heterogeneous needs. Nowadays, services should be delivered by offering multiple entry paths into health care services. [2] Consequently, new ways of accessing health services and information should be introduced.

Internet-based services, such as the "Hyvis" portal, are relevant options. The Hyvis portal is a free Internet-based service, intended for inhabitants of the Etelä-Savo Hospital District, that complements regional health services and promotes the welfare of inhabitants by offering information about health and health care services. An enquiry service for users to consult a health care professional is included in the portal. Questions can be presented either in the portal's public forum, allowing universal access to the information, or in a private forum access to which is secure and only the person who asks the question can read the answer. Clients usually, receive their answer within one or two days. [3]

The process model of information management

The process model of information management is a continuous cycle of six closely related activities: identification of information needs, information acquisition, information organization and storage, development of information products and services, information distribution and information use. [4]

The aim of this study was to assess how well the Hyvis Enquiry Service fulfils users' information needs and also how the Hyvis Enquiry Service impacts on the use of health care services, by applying Choo`s information management model.

Methods

This study employed a qualitative approach. The data were collected through semi-structured interviews. Five users of the Hyvis Enquiry Service and all the nine health care professionals who answer users' questions via the Internet were interviewed for this study. Six of the interviews were carried out by telephone. The users of this service were requested to participate in the study by advertising the study on the front page of the Hyvis portal. All the interviews were tape-recorded, and the researcher also took notes. The interviews were typed up and the data analysed by using inductive content analysis. [5]

Results

The results of this study will be presented in the order followed in the Information Management Model applied.

Information needs

The users of the service expect to obtain reliable information filtered by a health care professional. Frequently asked questions are problem-based questions relating to

health, diseases or the health care services. Also, self-care for a specific disease is often enquired about. Typically, the information is needed to support users' decision-making processes.

Answers given by health care professionals are based on the information given in the question. Sometimes the user fails to give enough background information, or the question is very wide and general. In such cases it is almost impossible to give a specific answer in writing. For that reason part of the users and the health care professionals thought that structured questionnaire might be helpful in formulating a question.

Information acquisition

All health care professionals use electronic databases for seeking information. The most widely used database is a portal called 'Terveysportti' [Health portal]. Interviewed professionals also mentioned evidence-based recommendations as a means of applying information. In addition, health care professionals use their own experience and tacit knowledge in formulating the answer to the users´ enquiries.

Users of the service initially search for health-related information by using search engines such as Google. Three interviewees mentioned that they seek information from reliable Internet pages such as the Hyvis portal. In seeking information, users and health care professionals use different primary sources, but according to the health care professionals, users may still find the same information on the Internet. However, the selection of accurate information and sources, and also the application of the information to the user's own situation, are problematic without the relevant experience and education.

Information use

In this study, four of the five users obtained the required information. Although users trust the information received from the Enquiry Service, and most of the users received assistance with their problems, more specific answers were desired. At present, some of the answers are presented too generally, and the information offered in the answer would have been easily available from other sources. However, most users felt that they had been given the answers to their questions, and that the enquiry service helped users to make decisions about whether to visit a doctor immediately or to treat themselves.

Adaptive behaviour of the users

At present, the Enquiry Service complements health care services by offering easily available health-related information, but does not substantially reduce the use of health care services. Even through the service offers useful information to the users, some of the five interviewees contacted the health care call-centre or health care organization to make an appointment because self-care failed to bring relief. Both users and health care professionals are of the opinion that the Enquiry Service has a positive effect on users' self-care habits, and assists users to take care of their health. According to the users, the information received from the Enquiry Service has enhanced their knowledge of health and disease.

Conclusions

The results of this study suggest that the Hyvis Enquiry Service benefits some inhabitants and that users usually obtain the information they need. According to Choo´s applied information management model, identification of information needs is vital, as information needs form the basis for information acquisition. When communication between inhabitants and professionals is based on typed text, there also exist certain threats with respect to the identification of users' health-related needs. Firstly, health care professionals can interpret questions in a different way from what was intended, which leads to the user not receiving the information required. Secondly, users sometimes fail to supply all the necessary background information which should be taken into account in the answer. Accordingly, the information in the answer may be inappropriate, and the user still needs to contact the health services by telephone and make an appointment. For users who need less urgent help and do not want to spend time in a telephone queue, this will be a useful service model in the future providing that the problems concerning the identification of information needs are solved. According to this study, one option for the future could be structured questionnaires, which would help users to formulate their questions.

Combining Web, Email and Telephone Counseling for Behavioral Change

Leslie A Lenert,[a,c], Shu-hong Zhu [a,c], Carrie Kirby [b], Carrie Koon [b], and Ricky Huang[c]

[a]*Departments of Medicine and Family and Community Medicine, University of California San Diego, La Jolla, California, USA*
[b] *California Smokers Helpline, University of California San Diego, La Jolla, California USA*
[c]*Veterans' Medical Research Foundation, San Diego, San Diego, California, USA*

Abstract and objective

Proactive telephone counseling is one of the most effective non-pharmacological approaches for smoking cessation. This study examines the effectiveness of combining proactive telephone counseling with web/email counseling to improve efficiency and reduce costs. In a randomized trial of 219 smokers with Internet and email access at home and interested in web based support, we observed low rates of use of Internet methods in practice (45%) but no statistically significant difference quit rates (31% at 6 months among respondents.)

Keywords:

smoking cessation, computers, telephone, Internet, counseling, behavior therapy, randomized trial

Introduction

Proactive telephone counseling is one of the most effective tools available for smoking cessation. However, this approach is expensive. Proactive methods require counselors to repeated initiate calls to smokers, many of which are missed, incomplete, etc. Even so, a large part of the effectiveness of proactive protocols is this outreach and the sense of accountability it creates in clients. The purpose of this study was, within the established workflow of a busy telephone helpline, to create an integrated system web-based and email methods with telephone counseling, in the hopes of improve efficiency.

Methods

We created series of web based systems including a client site, a counselor site, and an automated email messaging system to alerted was designed to present a tailored experience to the client based on the stage of their smoking cessation effort. To support modular and reusable systems for tailoring of web sites to clients in a federated environment, we created middleware for dynamic assembly of web pages. The specifications for tailoring of the site, including tailoring based on data in either of the two databases, were represented in XML in an external file. This approach allowed us to rapidly change the nature of interactions on the site without rebuilding all of the linkages and other tools for state maintenance. The counselor site was design allowed counselors to review their panel of assigned clients on the left hand bar, and activities on the right-hand side. This included automated email messages that could to be edited before delivery by system, messages from clients, and scheduled appointments with clients. Counselors would be able to view and edit these messages for 24 hours before delivery. When a message was delivered to a client or counselor, they were notified by open email (nonsecure) of the message. They could then log into the web site and read the message on the secure email server portion of the site and then respond.

Results

219 smokers were randomized to receive either Web/email only follow up counseling, ad hoc telephone/web, or telephone counseling. The demographics of enrollees were surprisingly similar to Internet studies with a high educational level among participants (70% with some college education), a preponderance of female subjects (69%), and of younger subjects (64% under 45 years of age). Among smokers randomized to web access, about 45% logged in and access web/email tools for smoking cessation and communications with counselors. Amongst enrollees, 67% responded to request for follow up information 6 months after enrollment in the program. Only a few participants had used other web based cessation services (11%). Most subjects reported being satisfied with services received (more than 75%). Smokers receiving Internet counseling tended to believe that the right mix was a equal proportion Internet and telephone counseling (50% of respondents) The overall quit rate among respondents was 31% and there were not statistically significant differences between groups.

Discussion

This study was among the first studies to attempt to combine web/email and telephone counseling. It was difficult toconvert helpline callers Internet communications with counselors. However, most participants thought that telephone counseling had a place in communications (even though they may not have used it). While this study was not powered to detect small differences in quit rates, com-

bined modality counseling appeared as effective as telephone counseling alone.

XML Data Structures for Tailoring of Web Sites to Promote Behavioral Change

Leslie A Lenert,[a,b] Steven Skoczen,[b] and Ricky Huang[b]

[a]Department of Medicine, University of California San Diego, La Jolla, California, USA
[b]Veterans' Medical Research Foundation, San Diego, California, USA

Abstract

Web sites should use theoretically-based individually tailored content to maximize their effectiveness in promotion of behavioral change, Personal tailoring of content is difficult in computer systems and infrequently linked to theoretical models. This poster describes an approach for creating tailored content that combines an external XML representation of the tailoring process with a run time interpreter and content management system. The approach offers a robust and explicit method for personalization of the content of web sites.

Keywords:

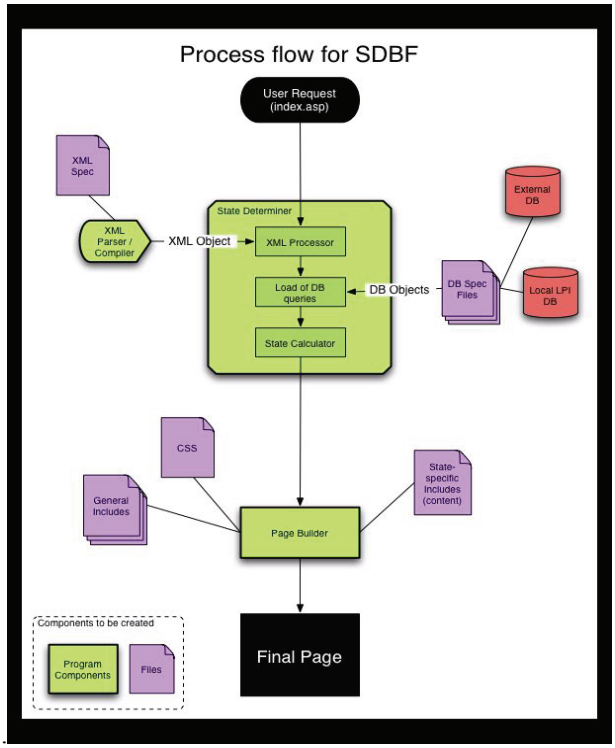
internet, behavioral medicine, Extended Markup Language (XML), content management system

Introduction

A large body of research has shown that personally tailored educational materials are far more effective in the promotion of behavioral change than untailored materials, regardless of the underlying theories for tailoring (Stages of Change, Health Belief Model, Motivational Interviewing, etc.). Tailoring of the content of web sites is a difficult task and the specific strategies for tailoring, along with linkages to formal models, are rarely described. In this paper we describe an approach for explicit representation of tailoring protocols that separates the knowledge and algorithm for tailoring from its implementation.

Methods

We designed a system where the complete specifications for tailoring of a web site, including tailoring based on personal data multiple external databases and tailoring the stage of an experimental protocol, were represented in XML in an external file. This approach allowed designers to rapidly change the nature of interactions on the site without rebuilding all of the linkages and other tools for state maintenance. Under this architecture, when a user requests a page, the XML specification for was read in, parsed by a compiler program creating an XML object. The XML object included specifications for database transactions with both of the project databases to compute the state of the system for tailoring. Based on the XML instructions and queries to the external databases, the appropriate state for the web site was computed. Based on the state, a software module called the page building assembled a tailored web page using cascading style sheets, html components, and custom built programmable Flash (Macromedia) objects. This final page was presented to the user. The advantage of this system is that the entire process for tailoring is explicitly represented within the external XML file. This explicit process may aid linkage to the web site with an ontology representing the interventions used in the web site. It also reduces maintenance effort.



The approach combines the explicitness of XML representations with the robustness of a content management system. Using this model, we created a large web site for a randomized trial of web based communications intervention for smoking cessation. Performance on a Linux APACHE P4 Pentium web server was not an obstacle for a research scale (n=220 subject) implementation.

AboutKidsHealth: A Unique Initiative in Pediatric Consumer Health Informatics

Ross Hetherington [1, 3, 4], Andrew James [1, 2], Kimberly Meighan[1], Angela O'Neill[1], Brian Shaw, [1, 3, 4, 5] for the AboutKidsHealth Team

[1]AboutKidsHealth, The Hospital for Sick Children, Toronto, and the Departments of [2]Paediatrics, [3]Psychology, [4]Public Health Science, and [5]Psychiatry, University of Toronto, Toronto, Ontario, Canada

Abstract

The Hospital for Sick Children, Toronto (SickKids), has launched AboutKidsHealth, a project that promotes and delivers evidence-based information and programs according to a determinants of health model arising from the understanding that health extends beyond the absence of disease. Accordingly, AboutKidsHealth takes an inclusive approach to the enhancement of quality of life that embraces the home, the greater community, the education system, and the health system. The project employs innovative communication strategies supported by state-of-the-art technology to deliver evidence-based information and programs in all major areas influencing child health and family quality of life. The web-based infrastructure is also used to provide enhanced communication for families of children with complex conditions and health professionals, and to develop web-based research projects in collaboration with SickKids scientists.

Keywords:

consumer health informatics, parents' health information needs, sources of health information, typically developing children

Introduction

Consumers of online health information are concerned with issues of quality and trust. No sites presently offer comprehensive child health information and tools for families seeking solutions to complex questions that may involve disease, lifestyle, behavioral, and educational issues. Parents of children with complex health issues, as well as parents of typically developing children, need a trusted, comprehensive online resource to inform and guide.

Families of children with complex conditions frequently have unmet needs for trusted health information. A large gift to The Hospital for Sick Children from TD Securities, a Canadian investment bank, made possible a unique initiative in consumer health informatics that would strive to meet the information needs of these families.

Methods

In recognition of families' concern with psychosocial and adult outcomes of complex

paediatric conditions in addition to their needs for reliable medical information concerning diagnosis and evidence-based treatment, we hypothesized that a determinants of health model would best meet their needs. We tested this model and an information architecture based on the concept of a family journey.

We conducted initial proof-of-concept and needs assessment qualitative research with families and clinicians concerning the online information needs of families of children with complex conditions. Subsequently, we used wire frames to assess the proposed information architecture and content of resource centres with families and clinicians.

In collaboration with clinical programs, we developed resource centres for Brain Tumour, Diabetes, and Heart Conditions. We describe the initial research and development of the centres, and usability testing conducted after launch.

Initial qualitative research

We conducted unstructured interviews with clinicians, observed families interacting with caregivers in clinic, and conducted unstructured interviews with families.

A series of initial proof-of-concept, semi-structured interviews with site schematics was performed with parents of children with complex conditions in Toronto, and parents with typically developing children in Toronto, Atlanta, and Portland, Oregon.

A second set of semi-structured interviews with wire frame schematics of resource centres for brain tumour, diabetes, and heart conditions was conducted with families and clinicians.

Development of the resource centres

The resource centres were built with five main sections: About (Condition), Understanding Diagnosis, Treatment, At Home, and Looking Ahead. Creating each resource centre represented an 18- to 24-month collaborative effort

among the medical writers, medical illustrators, designers and developers of the AboutKidsHealth team and the health professionals of The Hospital for Sick Children clinical programs. As part of the development process, original narrated animations concerning anatomy, disease knowledge and management, and health for children and youth were created to support each resource centre.

In December 2003, the hospital launched the first phase of AboutKidsHealth. This phase included The Family Health Centre, a 1000 square foot site supporting families' health information and medical decision making needs. The site, staffed by trained health professionals and volunteers, includes a library of books, brochures, and multimedia resources, 12 computers, and two multimedia/counseling rooms equipped to handle telehealth consultations. A 50 inch plasma monitor and 10 foot pixel board facilitates coordination of messaging and campaigns with AboutKidsHealth.

In June 2004, three resource centres were published as the initial web component of the AboutKidsHealth: Brain Tumour, Heart Conditions, and Diabetes. Additional resource centres that have been published include Pain, Epilepsy, Pregnancy & Babies, Premature Babies, Attention Deficit Hyperactivity Disorder, and Learning Disorders. Other resources include the A-Z Health Library, News (Online magazine), How the Body Works (Child Physiology), and Just for Kids.

Usability testing

Usability testing of the initial three resource centres was conducted with 12 families. Following an initial interview with a questionnaire to gather demographic information and patterns of internet use, parents completed a 1.5 hour, task-based, think-aloud protocol in a usability laboratory followed by a 24-item evaluative questionnaire containing questions with a 7-point Likert scale.

Results

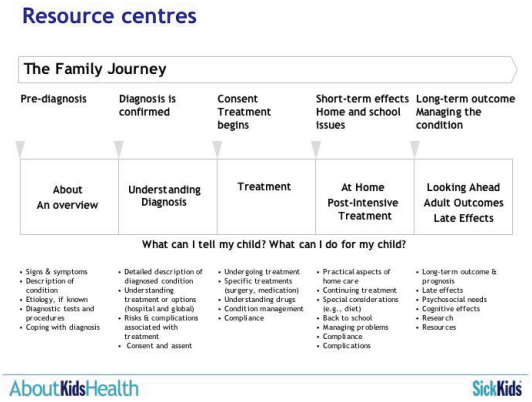
Initial qualitative research

Results of the initial qualitative research supported the utility of a determinants of health model for meeting families' health information needs. Furthermore, an information architecture for resource centres based on the family journey from the time a child was diagnosed with a complex condition through adult outcomes was seen as appropriate and useful by both parents and clinicians.

Resource centres

Each AboutKidsHealth resource centre consists of 45,000 to 325,000 words of level I content and 5000 to 1000 words of level II content. There are over 160 original medical illustrations, animations and other images. The material is comprehensive, incorporating not only medical information, but also addressing safety, nutrition, psychosocial, educational, and quality of life issues.

The resource centres are complemented with tools for families with typically developing children and



a range of articles on general child health issues. These articles focus on child and youth health from a determinants of health perspective and feature articles, expert columns, and series concerning healthy living and prevention, family living skills, understanding and managing common and complex conditions, safety, community-based systems and advocacy, and learning and education.

The A-Z Health Library contains 575 everyday health topics written at less than grade 7 reading level. This syndicated material has been reviewed by SickKids staff and complemented with original illustrations.

News comprises series, feature articles, news items and columns. Approximately 10,000 words are published each month.

How the Body Works contains interactive, animated illustrations that describe the brain, the heart and sexual development.

Just for Kids contains over 150 minutes of original narrated animations for children and youth. There are downloadable materials including games. Just for Kids supports all resource centres and provides general heatlth and safety information as well.

Usability testing

The overall mean response (6.1/7) to the questionnaire and analysis of qualitative responses indicated a very positive response to the design and utility of the resource centres and AboutKidsHealth.ca overall.

Conclusion

AboutKidsHealth is an innovative and unique paediatric consumer health informatics initiative from several perspectives: utilization of a hybrid public/private business model within the Canadian health care system; integration of a physical site for families with a virtual child and youth

health site and telehealth capacity; development of programs in the context of a comprehensive, determinants of health model; and the use of offline, social marketing campaigns to increase traffic to the online site while promoting awareness of child and youth health issues.

AboutKidsHealth: A unique initiative in paediatric consumer health informatics

Ross Hetherington PhD, Andrew James MBChB MBI, Kimberly Meighan RN, Angela O'Neill, Brian Shaw PhD for the AboutKidsHealth Team

Medinfo 2007, Brisbane, Australia

AboutKidsHealth: Mission statement

We will work to improve child and youth health and quality of life for families around the world. We will accomplish this working within a determinants of health model, using state-of-the-art information design and communication strategies to ensure effective transfer of evidence-based information and tools.

"Quality of health information sites on the Internet; however, has less to do with whether the sites meet a list of static criteria. Rather, quality can be understood as the degree to which Web health information positively affects a user's health outcomes, quality of life, or disease-specific clinical endpoints."

Risk & Patterson, *Journal of the American Medical Association, 2002*

Initial qualitative research: methods

- Unstructured interviews with clinicians
- Observations in clinic and unstructured interviews with families
- Initial proof-of-concept, semi-structured interviews with site schematics
- Second set of semi-structured interviews with schematics of resource centres for brain tumour, diabetes, and heart conditions
  - Clinicians (2 from each of 3 programs)
  - Families (3 from each of 3 programs)

Patient family comments and questions: Diabetes as an example

- "A central place to go and look up information [would be] great."
- "Tell me in plain English what's going to happen."
- "When you're upset, you don't retain it all. It's good to have a place to go to get all the information after the diagnosis."

Common questions included:

What is insulin?
How does the pancreas function?
What are the long term effects of the condition?
What lifestyle changes will be required?

- Despite oral instruction in clinic, parents needed to know:

What signs and symptoms should we watch for?
How do you treat high and low blood sugar?
What are appropriate insulin doses and injection techniques?
What are insulin pumps and how do we use them?

Resource centres: information architecture

The Family Journey

Pre-diagnosis	Diagnosis is confirmed	Consent Treatment begins	Short-term effects Home and school issues	Long-term outcome Managing the condition
About *An overview*	**Understanding Diagnosis**	**Treatment**	**At Home** *Post-Intensive Treatment*	**Looking Ahead** *Adult Outcomes Late Effects*

What can I tell my child? What can I do for my child?

- Signs & symptoms
- Description of condition
- Etiology, if known
- Diagnostic tests and procedures
- Coping with diagnosis

- Detailed description of diagnosed condition
- Understanding treatment or options (hospital and global)
- Risks & complications associated with treatment
- Consent and assent

- Undergoing treatment
- Specific treatments (surgery, medication)
- Understanding drugs
- Condition management
- Compliance

- Practical aspects of home care
- Continuing treatment
- Special considerations (e.g., diet)
- Back to school
- Managing problems
- Compliance
- Complications

- Long-term outcome & prognosis
- Late effects
- Psychosocial needs
- Cognitive effects
- Research
- Resources

Resource centre: content characteristics

- Level I content
  - less than Grade 10 reading level (accuracy *vs* readability), Browsealoud enabled
  - supported with glossary and illustrations
  - secondary and tertiary sources
  - process: consult -> write -> review -> revise -> review -> revise -> QA
- Level II content
  - plain language treatment of current research from primary sources
  - 600 – 1200 words each
  - review and comment on relevance by clinician

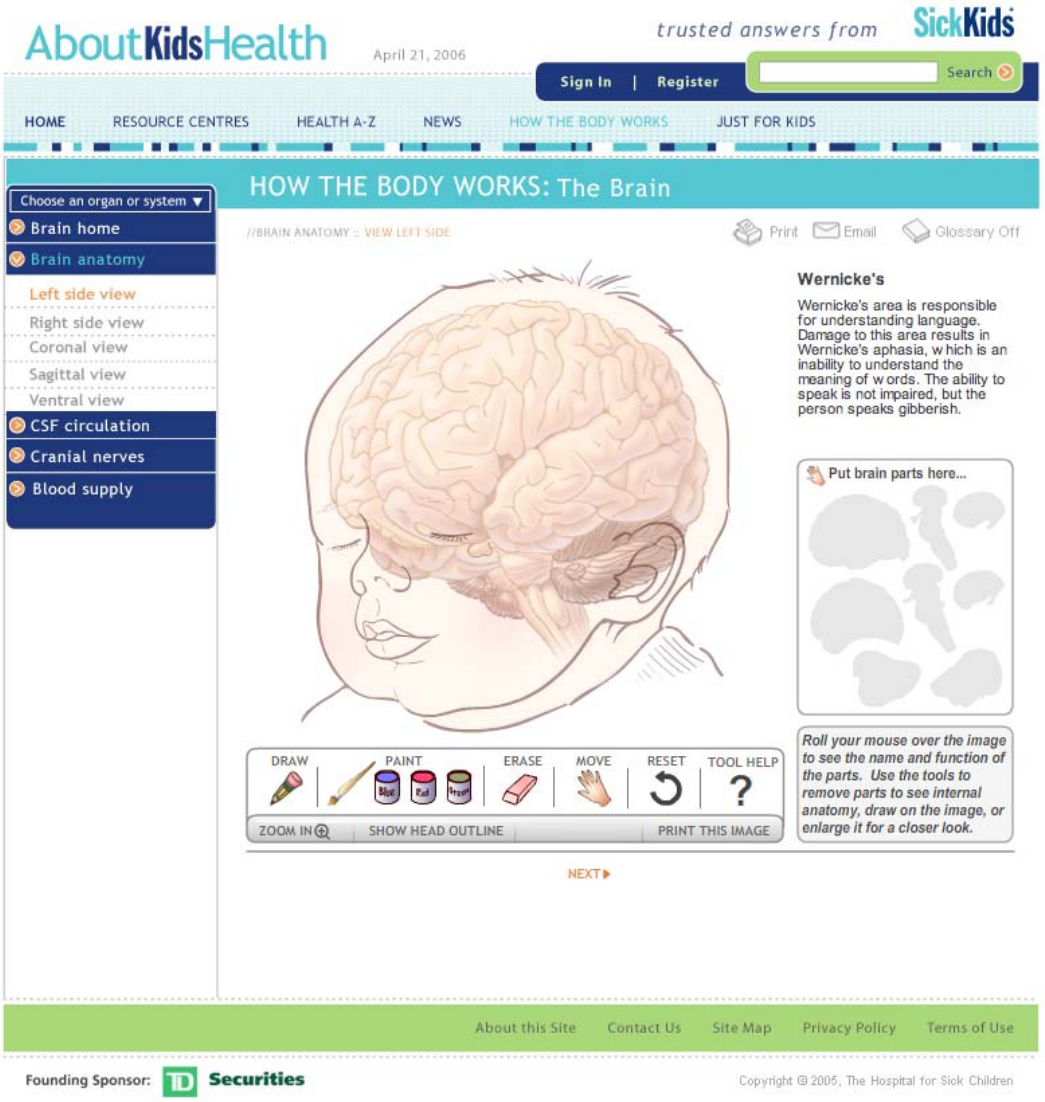
Content and features: Resource Centres

- Seven Resource Centres: Brain Tumour, Diabetes, Epilepsy, Heart Conditions, Pain, Pregnancy & Babies, Premature Babies
- 45,000 to 325,000 words of Level I content
- 5000 to 15,000 words of Level II content
- Over 160 original medical illustrations, animations, and other images
- Comprehensive, interactive, family focused

Content and features: A-Z Health Library

- **A-Z Health library**
  - 575 everyday health topics
  - less than Grade 7 reading level
  - Syndicated content but reviewed and revised by SickKids staff — original illustrations added
  - Complete rewrite currently underway
- **Online magazine**
  - Publish ~10,000 words/month
  - Series, feature articles, news items, and columns

Content and features: How the body works



Content and features: Just for Kids

- Over 150 minutes of original narrated animations for children and youth
- Downloadable material: desktops, games
- Supports all Resource Centres with condition management information and tools
- General health and safety information as well
- Just for Kids was recently re-designed, 3 new modules launched

Usability testing

- Parents of 12 children with complex conditions
- 1.5 hour, task-based, think-aloud protocol
  - "Can you please find information on how to adjust the insulin dose?"
  - Semi-structured interview sought qualitative information on content and design during testing
- Post-test site evaluation questionnaire — 24 questions, seven point Likert scale from 1 (strongly disagree) to 7 (strongly agree)
- Overall response was 6.1

Sustainable Caregiving Families: Addressing the Ethno-Cultural-Linguistic Needs of Chinese Immigrant Caregivers for a Web-based Support Portal

Teresa Chiu [a,b,c], Gunther Eysenbach [a,d]

[a] *Department. Of Health Policy, Management, and Evaluation, University of Toronto, Canada*
[b] *COTA Health, Toronto, Canada*
[c] *Occupational Science and Occupational Therapy Department, University of Toronto, Canada*
[d] *Centre for Global eHealth Innovation, University Health Network, Toronto General Hospital, Toronto, Canada*

Abstract

Background: Family caregivers are fundamental members of a sustainable health care system. In a multicultural society, family caregivers have different ethnic, cultural, and linguistic support needs. Purpose: To develop and evaluate the design enhancements of a Personalized Support for Family Caregivers (PSFC) web-based portal for Chinese families. Method: Through the portal, 33 participants received caregiver-therapist email support and had access to an information website. After in-depth interviews of 10 users, data were analyzed using qualitative thematic, user profile and requirement analyses to conceptualize the redesign. Results: Traditional family values, information needs, familiarity with English and computer literacy had an impact on the usage of the PSFC. The portal functions was enhanced by: 1) building a sense of presence of the PSFC, 2) engaging more members in a family rather than only a primary caregiver, 3) assisting users with English communication, and 4) delivering information in the form of narratives. Conclusion: Information communication technologies, when well designed and implemented, can meet the ethno-cultural-linguistic needs of caregiving families in a multicultural society.

Keywords:

alzheimer disease, clinical informatics, Canada, Chinese, culture, family caregivers

Introduction

Family caregivers are fundamental members in a sustainable healthcare system. In a multicultural society, the pluralistic ethnic, cultural, and linguistic landscape creates many different caring environments. A number of studies have evaluated the use of communication technologies to support family caregivers [1-4], but few investigated ethno-cultural-linguistic barriers to accessing technology-based support programs. This paper will report on the ethno-cultural-linguistic ehealth needs of Chinese Canadian family caregivers and the design enhancements of a web-based portal that offers Personalized Support for Family Caregivers Support (PSFC) to them.

Methods

This research is a substudy of a larger research being undertaken [5]. The main study provided caregiver support through a web-based portal in both Chinese and English. The portal consisted of 1) a 400-page caregiving information website and 2) a personalized caregiver-therapist email support.

A mixed methods design was used in this substudy. We selected a purposive sample of ten participants from the main study. The sample had varied caregiving characteristics and usage patterns of the caregiver portal. Participants were interviewed by phone or in-person, in a language of their choice (90% in Chinese). The in-depth interviews were audio-taped, translated, and transcribed verbatim. The data were coded, and a thematic analysis conducted [6].

A user-centered design methodology [7] was used to develop the design concept. There were five processes: 1) thematic analysis of the interview data, 2) the construction of user profiles, 3) the stakeholder analysis, 4) the requirement analysis, and 5) the conceptualization of the system enhancements.

Results

The caregiving context and usage experiences

The participants provided care in a caregiving context that had the following salient themes: 1) embracing the traditional family values, 2) living with worries and emotional struggles, 3) seeking external help and reflecting on self, and 4) sharing the care while caring for the family.

Within this caregiving context, the participants had varying usage experiences of the caregiver portal. They 1) talked in Chinese, typed in English, and preferred to hear stories, 2) needed help to access their accounts in an unfamiliar portal, 3) ranged from liking all information in one place to favouring human contacts, and 4) ranged from expressing self freely to not knowing what to say in an email

Enhancement requirement analysis

The requirement analysis [7] focused on the unmet needs of participants who were occasional or non-users. The results showed that these non-adopters typically:

- were not fluent in written English
- did not know what to ask; were unsure which problems were part of the illness
- did not know how to ask; unsure how much to tell
- preferred learning from stories of other caregivers
- preferred notifications and reminders; forgot the user name and password
- felt that they could manage the care on their own
- had difficulty expressing in an email
- felt that going to a support group, asking the doctor, browsing the internet, or reading a book was better

Conceptual design of an enhanced system

The non-adopter characteristics, thematic analysis and requirement analysis were used to conceptualize the redesign. The enhanced system, called PSFC, expanded the original functions to include four new features:

1. Building a sense of presence of the PSFC
2. Expanding from a primary caregiver to a caregiving family
3. Using narratives to inform and educate
4. Addressing multilingual needs with a digital solution

Figure 1 - Screen shots of Short Stories (Chinese version), Family Forum; and Telling More

Conclusion

Ethno-cultural-linguistic needs of family caregivers are complex. Information communication technologies, when well designed and implemented, have the capacity to address the special needs of these caregivers who live in a multicultural society. This study illustrates the iterative design and redesign of such an application based on usage experiences and user preferences. The redesign is currently being evaluated using usability testing and a quantitative analysis of user engagement. The concepts, if proven to be useful, could benefit families from other ethnic or cultural groups that value close family relations, needs assistance in English communication, and prefer narratives to receive information. If caregivers are better supported, caregiving families can be sustained, which in turn can contribute to sustainable health care systems in the 21st century.

Sustainable Caregiving Families:
Addressing the Ethno-Cultural-Linguistic Needs of Chinese Immigrant Caregivers for a Web-based Support Portal

Teresa Chiu [a,b,c], **Gunther Eysenbach** [a,d]

a *Department. Of Health Policy, Management, and Evaluation, University of Toronto, Canada*

b *COTA Health, Toronto, Canada*

c *Occupational Science and Occupational Therapy Department, University of Toronto, Canada*

d *Centre for Global eHealth Innovation, University Health Network, Toronto General Hospital, Toronto, Canada*

Purpose

- This paper will report on
  - the ethno-cultural-linguistic ehealth needs of Chinese Canadian family caregivers
  - the design enhancements of a web-based portal that offers Personalized Support for Family Caregivers Support (PSFC) to them

Background

- Family caregivers are fundamental members in a sustainable healthcare system
- In a multicultural society, the pluralistic ethnic, cultural, and linguistic landscape creates many different caring environments
- A number of studies have evaluated the use of communication technologies to support family caregivers [1-4]
- But few investigated ethno-cultural-linguistic barriers to accessing technology-based support programs

A Mixed Methods Evaluative Study

- A substudy of a larger research that provides caregiver support through a web-based portal [5].
- The portal
  - Offers in both Chinese and English
  - Is consisted of 1) a 400-page caregiving information website and 2) a personalized caregiver-therapist email support.
- A mixed methods evaluative design
  - In-depth interview
  - User-centered design

In-depth Interview

- A purposive sample of 10 participants from the main study was selected
- The sample had varied caregiving characteristics and usage patterns of the caregiver portal
- Participants were interviewed by phone or in-person, in a language of their choice (90% in Chinese)
- The in-depth interviews were audio-taped, translated, and transcribed verbatim. The data were coded, and a thematic analysis conducted [6]

User-centered design

- The portal redesign was conceptualized using a user-centred design method [7]:

1. thematic analysis of the interview data
2. the construction of user profiles
3. the stakeholder analysis
4. the requirement analysis
5. the conceptualization of the system enhancements

Results:
Caregiving Context & Usage Experiences

- Caregiving context:
  - embracing the traditional family values
  - living with worries and emotional struggles
  - seeking external help and reflecting on self
  - sharing the care while caring for the family.
- Usage experiences of the caregiver portal:
  - talked in Chinese, typed in English, and preferred to hear stories
  - needed help to access their accounts in an unfamiliar portal
  - ranged from liking all information in one place to favouring human contacts
  - ranged from expressing self freely to not knowing what to say in an email

Results:
Enhancement Requirement Analysis

Participants who were occasional or non-users typically:

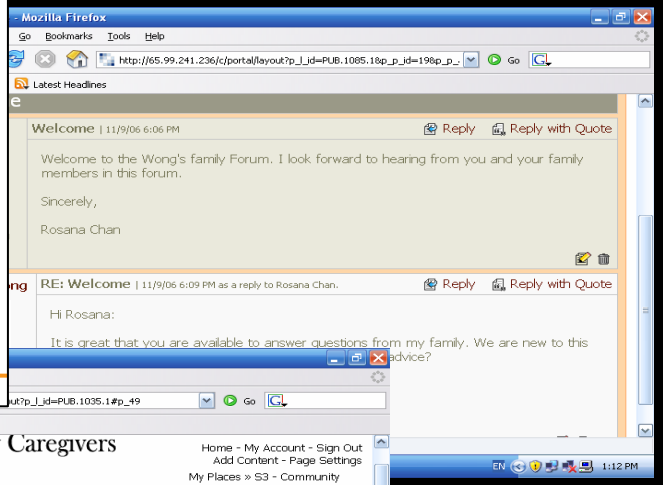
- were not fluent in written English
- did not know what to ask; were unsure which problems were part of the illness
- did not know how to ask; unsure how much to tell
- preferred learning from stories of other caregivers
- preferred notifications and reminders; forgot the user name and password
- felt that they could manage the care on their own
- had difficulty expressing in an email
- felt that going to a support group, asking the doctor, browsing the internet, or reading a book was better

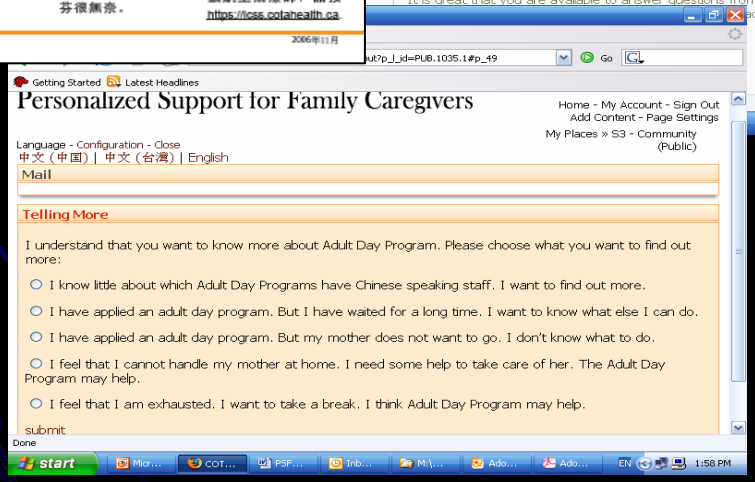
Results:

Conceptual Design of an Enhanced System

- The non-adopter characteristics, thematic analysis and requirement analysis were used to conceptualize the redesign
- The enhanced system, called PSFC, expanded the original functions to include four new features:
  1. Building a sense of presence of the PSFC
  2. Expanding from a primary caregiver to a caregiving family
  3. Using narratives to inform and educate
  4. Addressing multilingual needs with a digital solution

Screenshots of the Enhanced Features





Conclusion

- Ethno-cultural-linguistic needs of family caregivers are complex
- ICT has the capacity to address the special needs of these caregivers
- This study illustrates the redesign process of a caregiver portal based on user preferences and usage experiences
- The redesign is currently being evaluated using usability testing and a quantitative analysis of user engagement
- The design concepts may benefit families from other ethnic or cultural groups that value close family relations, needs assistance in English communication, and prefer narratives to receive information
- If caregivers are better supported, caregiving families can be sustained, which in turn can contribute to sustainable health care systems in the 21st century.

Three Month Trial of Networked System that Improves Quality of Life of the Elderly

Kaori Fujimura[a], Tatsuaki Ito[a], Setsuko Murata[b], and Toshiaki Tsuboi[c]

[a] *NTT Cyber Solutions Laboratories, Nippon Telegraph and Telephone Co., Japan*
[b] *Department III, Nippon Telegraph and Telephone Co., Japan*[c] *Health Care Systems Division, NTT IT Co., Japan*

Abstract

Japan has a rapidly aging population, and is now facing various problems related to nursing care. One key problem, the rapid increase in insurance payments for long-term care, was tackled by reforming the insurance system to emphasize preventative care in April, 2006. It has become increasingly urgent to prevent elderly people from falling ill or needing nursing care, and thereby reduce doctor visits, and ultimately to contain the expenditure on medical care for the elderly. However, we don't have enough preventative-care specialists. In order to offset the shortage of these specialists, we have developed a support system to provide the elderly with scientifically proven instruction using broadband and video-communication technologies. A three month trial of the system at a day-care center for the elderly people in need of care is described. The results show that the support system provides effective exercise guidance.

Keywords:

nursing care, prevention, Internet, video-communication

Introduction

Japan's aging society continues to grow. Last year, the number of people 65 or older reached 25.60 million or 20.04％of the population [1] . It has become increasingly urgent to prevent elderly people from falling ill or needing nursing care. However, we don't have enough preventative-care specialists.

The proposed system aims to prevent the elderly from becoming bedridden due to the "old-age syndrome", which frequently triggers falls, broken bones, poor nutrition, incontinence, and home confinement[2]. The shortage of care-givers means that only a small percentage of the elderly are receiving the support they need. In response, we had developed a support system that exploits the features of video-related technologies including video streaming and multipoint videoconferencing. This system is an extension of a home-participation type care-prevention system developed in 2003 that was geared to self-sufficient elderly persons. The effectiveness and usefulness of the system led to the work described in this paper.

Methods

The support system

The support system consists of the care-prevention servers and the client PCs (including PC for management). The servers include a database server (A), a content-storage server (b), a WWW server (C), a video –delivery server (D), and a Video conferencing server (E), as in Fig. 1. Scientifically proven instruction contents are stored in the content-storage server and delivered to each client by the video-delivery server over the Internet at the appointed time.

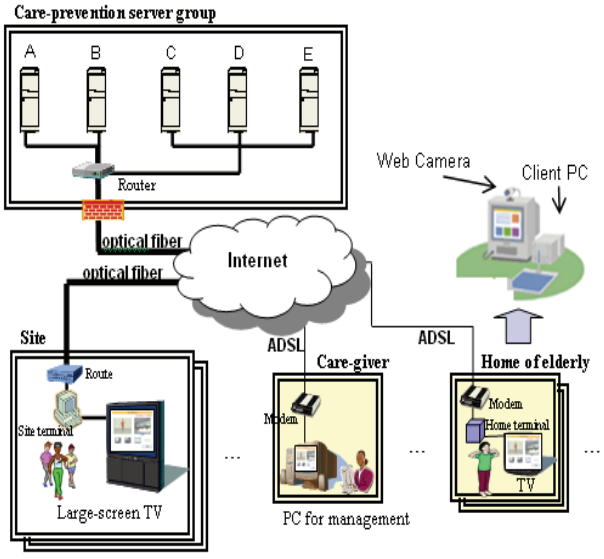

Figure 1 - Configuration of the system

The exercise for people requiring nursing care has 8 levels. The initial level is very relaxed, and the increments in difficulty are small. This allows training without strain.

1 http://www8.cao.go.jp/kourei/english/annualreport/2006/06wp-e.html

2 S. Murata, T. Tsuboi,T. Ito, K. Fujimura and H. Sato, " Development of System for Reducing the Need for Nursing Care," NTT Technical Review, Vol. 4, No. 2, p.60, 2006

The exercise contents are tagged with metadata enabling the exercise scenarios delivered to each site to be optimized to suit the current physical condition of the participant. In particular, the system can ask each participant for back pain, knee pain, and pain in the thighbone before the exercise session and then select exercises that do not overburden the knee, for example, for individuals experiencing knee pain. It can also deliver content with commentary targeting individuals or sites that desire more detailed exercise scenarios.

The client system consists of a web camera, a microphone, a speaker, and a PC. The web camera is used not only for video-conferencing but for recording of the user's movements. The recorded video is sent to the database server when the PC is shut off. Care-givers at remote locations can monitor the exercise classes and review the exercise videos of participants so they can offer them encouragement or tips via net-consultation or video mail.

Sometimes, elderly people or care-givers are not accustomed to PCs. To solve usability problems, the client system starts automatically when the user powers up the client PC. In addition, most operations require only simple button pushing.

Three month trial

To test the effectiveness of the system, we held a three month trial. Trial participants were the attendees of a day-care center, Care Port Yahata, Shizuoka, Japan. The 20 minute classes were held after lunch and each class consisted of exercises that were to be performed while sitting on a chair.

Check-up items were as follows:

1. Measurement of physical fitness:
- grip strength
- balance on one foot (with eyes open)
- walking speed (5 meters)
- knee extension power
- functional reach

2. Interview: iADL according to the Tokyo Metropolitan Institute of Gerontology Index of Competence (TMIG Index of Competence[3])
- Basic self-sufficiency: the ability to go out by bus or by train alone, buy articles for daily use, prepare a meal, pay bills, deposit and withdraw money
- Intellectual activities: the ability to fill out forms, on a routine basis, read newspapers, read books or magazines, and demonstrate interest in TV programs or news articles on health issues.
- Social role: visit people, offer advice to family and friends, go to see someone in the hospital, speak to younger people.

Results

Outline

Forty seven people (men and women) participated; they were given check-ups before and after the trial. Over the 3 month trial, the average participant used the support system 12.6 times (about once a week).

Results of the measurement of physical fitness

There was a significant improvement in leg strength (knee extension power). Leg strength improved by 30% on average; about 60% of the participants showed some improvement. Fig. 2 shows the results of the measurement.

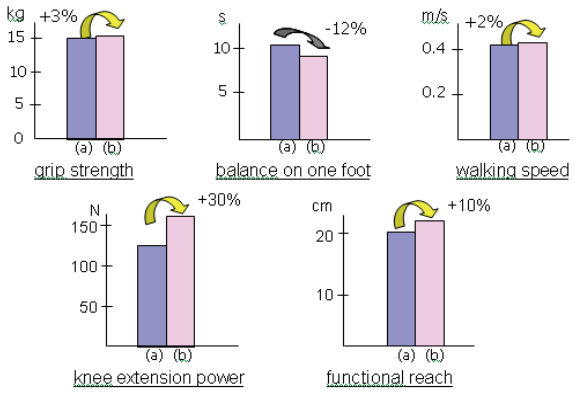

Figure 2 - Results of the measurement of physical fitness

Results of the interview (iADL)

Almost all interview items showed some improvement as shown in Fig. 3; the improvement in intellectual activities was significant at 13%.

3 Koyano W, Shibata H, Nakazato K, Haga H, Suyama Y, "Measurement of competence: reliability and validity of the TMIG Index of Competence." Arch Gerontol Geriatr, 13: 103-116,1991

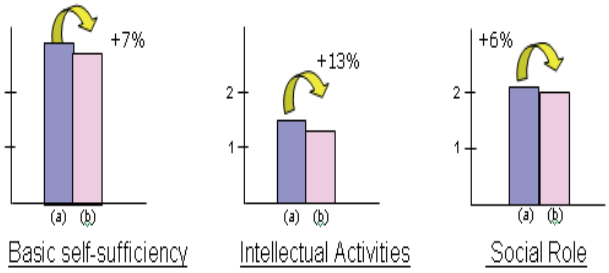

Figure 3 - Results of iADL

Conclusion

While it is hard for the elderly who need nursing care to keep up their strength, the results demonstrated a significant improvement in leg strength and iADL after the three month exercise.

The proposed support system has been proven to be effective for those who need nursing care. It can be expected to not only solve the shortage of preventative-care specialists but also reduce the need for and costs of nursing care.

The Factors Influencing Intention to Use Ubiquitous Healthcare Services[1]

Hye-Jeong Jeong[a], Nam-Hyun Kim[a]

[a] *Department of Medical Engineering, College of Medicine Yonsei University, Korea*

Abstract

Through the investigation into the studies of information technology acceptance and human act theory, the factors influencing in using the Ubiquitous Healthcare Service (UHS) are clarified and the relationship of them are empirically verified. As a result of analyzing a total of 760 effective sample groups, Perceived Risk, Perceived Cost, Perceived Usefulness, Perceived Ease of use, Social Influence, and Personal Character have shown to influence noticeably for the UHS Intention to Use. This paper's significance lies in producing a theoretic model must be contemplated while developing a new service. UHS's success is not guaranteed without consideration of social behavioral factors.

Keywords:

healthcare service, ubiquitous, intention to use, perceived risk, TAM, TRA

Introduction

Ubiquitous healthcare that improves the personal health at anytime and anywhere, manages the chronic diseases while forecasting the acute disease is expected to take the core part of the next generation health medical informatization that there are active undertakings of information technology including the infra of national wide projects, development of essential technology and others. Notwithstanding such a social and technological demand, it is true that the health medical informatization has been assessed as relatively vulnerable. There are various analyses for the causes, but one of the main causes has been the neglect of user based approach that reflects the unique characteristics of health medical in the development and accommodation of the new information technology. In fact, it is evident from the fact that there are numerous cases where many costs and hours are invested to realize great medical information system yet to have users and medical staffs turning away from them. With the development of the information technology, the needs of individual change ceaselessly that the core of success is to find out the demand of customers promptly or anticipate in advance providing the system and service accordingly. Therefore, in this study, the analysis is to be made for what factors influence on the socio-behavior point of view as well as the acceptance of the information technology in determining the services provided under the u-healthcare environment in a way of presenting the theoretical foundation in service development later.

Materials and methods

The ubiquitous computing is a new concept advocated by Mark Weiser in his thesis of 1991 that has relatively short history. Most of the study is focused on the technology development basis that the research outcome based on the consumer recognition or behavior is relatively insufficient. Therefore, through the survey analysis process that included the existing studies on the relationship of the e-service use and the attitude or recognition of users, the review on adaptability under the ubiquitous service environment was made. Davis proposed the technology accommodating model to describe the service factors of the information system and as the important factors to use the information technology for users; it presented perceived ease of use and perceived usefulness. Fishbein and Ajzen is the model that describes the relationship among behavior, behavior intention, attitude, subjective norm, and belief, and in this model, the behavior is caused by the behavior intention, and the behavior intention is determined by the attitude factor and social factor. In another study, Dodds and Monroe presented the theoretical model to select the product for users on the basis of the Means-Ends Chain Theory that describe the recognized action of human of Tolman. According to their studies, the concept of value presented by Tolman is defined by the objective evaluation used by users in selecting the product, measured by the perceived value, and influenced by the perceived sacrifice to obtain the desired product of customers for the perceived value, and influenced on the behavior pattern, and it presented the theory for influencing on the willingness to pay. In the meantime, T.M. Lee has proven the influence of the variables in ubiquitous connectivity, contextual offer, perceived usefulness, and perceived ease of use makes the influence on the attempt of accommodating the ubiquitous mobile commerce in his study. There are various advance studies on the perceived risk of users and service use, and according to Bauer who first introduced the concept of risk perception on the user behavior field, the perceived risk is distinguished from the objective and probable risk that it is the risk perceived by

1 Corresponding Author: Nam-Hyun Kim

user under the situations like trademark selection, store selection, purchase method selection and others.

On the basis of the above theoretical contemplation, the model proposed under this study is shown on Figure 1.

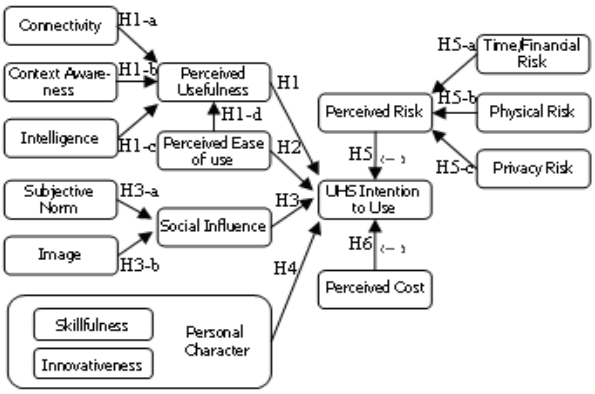

Figure 1- Research model

The questionnaire survey was implemented from Aug. 15, 2006 to Sep. 14 with 789 copies of questionnaires distributed and 784 copies recovered. A total of 760 copies was selected as the final valid sample group, and by using SPSS 12.0, the frequency analysis and factor analysis for reasonableness proof, reliability analysis, and regression analysis for hypothetical proof have been implemented.

Results

For the hypothetical proof of this study, the multiple regression analysis by using the enter method was implemented. This work was undertaken in the total of four stages as follow, and the outcome is specified in the following Table 3.

Table 3 – Outcome of hypothetical proof

Model		Beta	Sig.	Hypothetical proof
1	Context-Intelligence	.099	.000	Selection
	Connectivity	.119	.000	Selection
	Perceived Ease of Use	.639	.000	Selection
*Dependent Variable: Perceived Usefulness				
2	Subjective Norm	.588	.000	Selection
	Image	.254	.000	Selection
*Dependent Variable: Social Influence				
3	Time/Financial Risk	.290	.000	Selection
	Physical Risk	.140	.000	Selection
	Privacy Risk	.744	.000	Selection
*Dependent Variable: Perceived Risk				
4	Perceived Usefulness	.186	.000	Selection
	Perceived Ease of Use	.159	.000	Selection
	Social Influence	.400	.000	Selection
	Personal Character	.374	.000	Selection
	Perceived Risk	-.299	.000	Selection
	Perceived Cost	-.230	.000	Selection
*Dependent Variable: UHS Intention to Use				

Discussion & conclusion

As a result of formulating the factors influencing on the intent for use and its empirical verification for the ubiquitous healthcare service, Perceived Usefulness, Perceived Ease of Use, Social Influence, Personal Character, Perceived Risk, and Perceived Cost have been showing the influence noticeably for the intent of use. Several discussed matters are mentioned herein as follows. First, as a result of fact analysis, the Context Awareness and the Intelligence variable are combined as one variable as Context Awareness-Intelligence. Second, for the Perceived Risk, the influence of private risk was shown to be 74% or higher compared to that of Time/Financial Risk or Physical Risk that there is a high demand and concern on the medical information protection that if these problems are not resolved, it would be a basis of unclear future of the u-healthcare industry. Third, in the willing to accept UHS, the social influence from the people around and others, or the personal character that displays the personal skill of information technology or innovative tendency of individual impact more than the concern on information disclosure or costs, service usefulness, convenience and the like.

This study was undertaken based on the questionnaire survey with the targeting on the UHS yet to be generalized, and it has the innate problems of lack of advanced research outcome, generalized reasonableness of the u-healthcare scenario, level of understanding by the respondents and others. Notwithstanding such problems, the verification of various factors influencing on the intend of use for the UHS would bring the implication in having the research on the point of view of user, and it is expected that this

research outcome will be the useful data for the actual service development and the business strategy for the success in u-health industry.

Developing a Taxonomy to Categorize Patient Falls

Juliana J. Brixey PhD, MPH, RN

Judith Warren PhD, RN

James P. Turley PhD, RN

KU SCHOOL OF NURSING
The University of Kansas

The University of Texas
School of Health Information Sciences at Houston

Abstract

A patient fall can result in life-threatening injuries. In order to reduce or mitigate the negative impact of patient falls, a number of risk assessment tools have been developed to identify patients who are likely to sustain a fall. The following study describes the development of the KU Patient Fall Taxonomy. It was derived from four patient fall risk assessment tools. Nine concepts emerged from the fall assessment tools as specific risk factors. Formation of the taxonomy hierarchy is based on Rosch's three-tiered hierarchy of events. The taxonomy will be utilized to systematically analyze patient fall error reports. The taxonomy is the first step in developing an ontology of patient falls.

KU SCHOOL OF NURSING
The University of Kansas

The University of Texas
School of Health Information Sciences at Houston

Background

- Patient falls in hospitals continues to be a patient safety issue.
- A fall in any setting is a life-threatening event for an older person because of the catastrophic consequences such as fractures or death.
- In an effort to reduce falls, a number of fall risk assessment tools have been developed to prospectively identify patients at risk to sustain a fall.
- Therefore the purpose of this study was to develop a patient fall taxonomy derived from the four risk assessment tools.

Background

Morse Fall Risk, Morse 1985	Fall Risk Assessment Tool (FRAT), Peninsula Health Fall Prevention Service, 1999	Hendrich II Hendrich, Bender, Nyhuis, 2003	STRATIFY, Oliver, Britton, Seed, Martin, Hopper, 1997
History of falling immediate or within the last 3 months	Recent falls	Confusion/ Dis-orientation	Did the patient present to hospital with a fall or has fallen or has she or he fallen on the ward since admission?
Presence of secondary diagnosis	Medications	Depression	Do you think the patient is agitated?
Use of ambulatory aid	Psychological	Altered elimination	Visually impaired to the extent that everyday function is affected?
IV/Heparin lock	Cognitive Status	Dizziness/ vertigo	In need of especially frequent toileting
Gait/ Trans-ferring	Vision	Gender (male)	Transfer and mobility score of 3 or 4?
Mental status	Mobility	Any administered antiepileptics (anti-convulsants)	
	Behaviors	Any prescribed benzo-diazapenes	
	Activities of daily living (A.D.L.) Environment Continence Other	Get-up-and-go Test	

KU SCHOOL OF NURSING
The University of Kansas

THE UNIVERSITY of TEXAS
SCHOOL OF HEALTH INFORMATION SCIENCES AT HOUSTON

Methods

- Design: A retrospective analysis of four previously published risk assessment tools.
- Data Analysis: Each criterion was inductively analyzed using line-by-line coding and constant comparison.
  - Data analysis was supported using NVivo.
  - If a new risk concept was identified it was coded and added to the list of categories.
  - The iterative process was carried out until no new risk concepts were identified.

Findings

- Nine concepts emerged from the fall assessment tools as specific risk factors.
- The categories of risk factors are as listed:
  - History of fall
  - Cognitive status
  - Psychological status
  - Medical conditions
  - Medications
  - Body system involvement
  - Personal independence
  - Environmental conditions

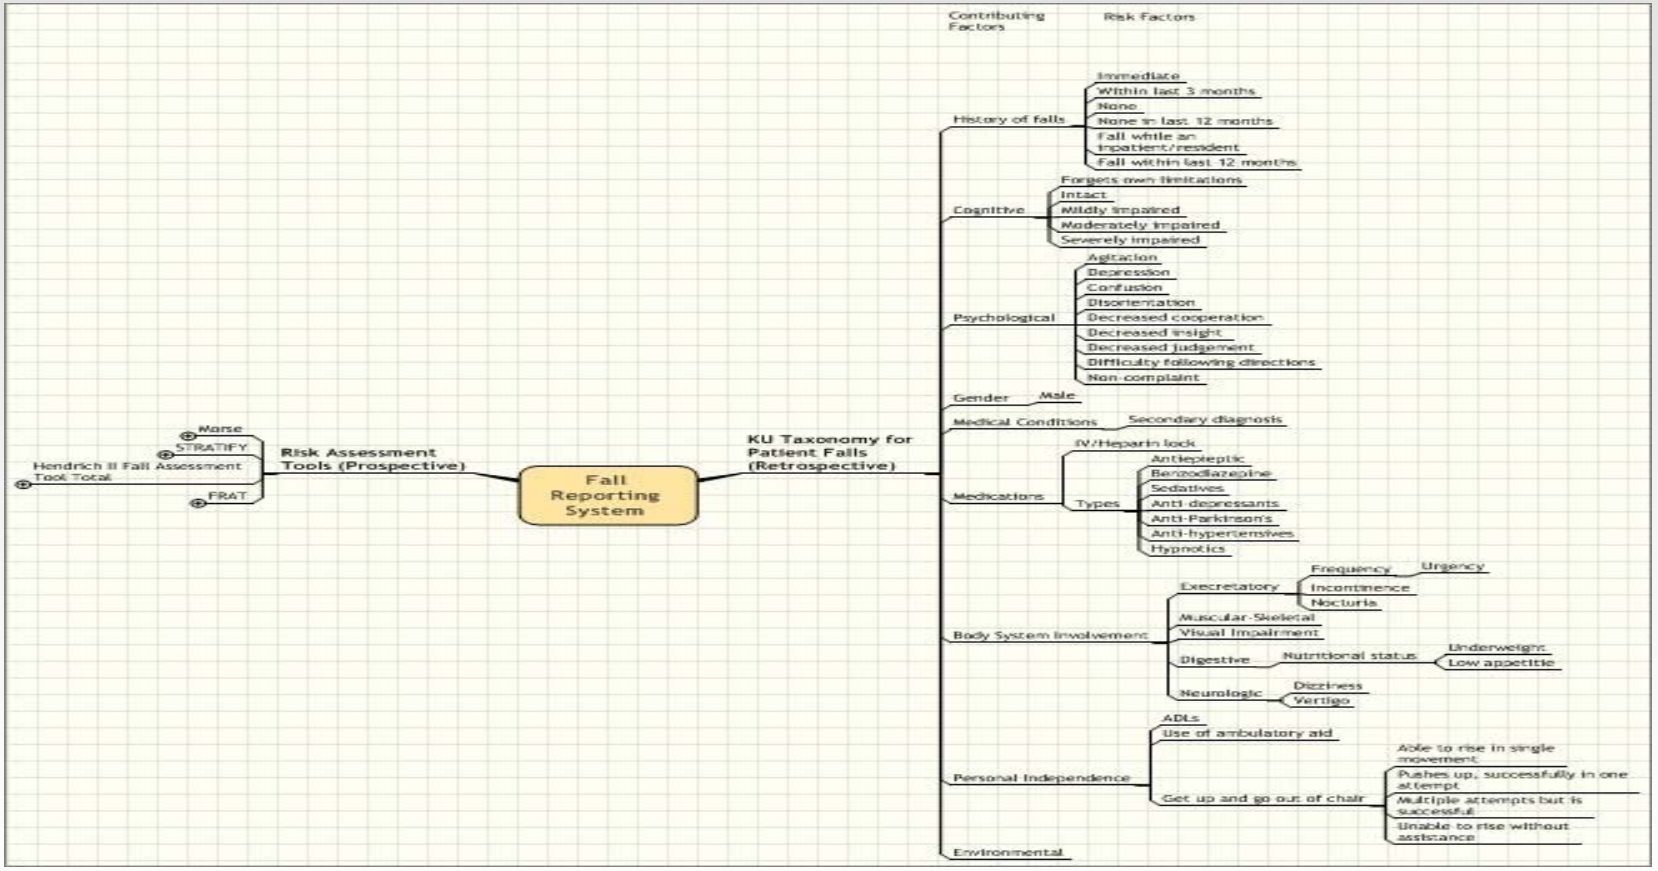
KU Patient Fall Taxonomy

Contributing Factors	Risk Factors
History of Falls	Immediate Within last 3 months None Home in last 3 months Fall while an inpatient/resident Fall within last 12 months
Cognitive	Forgets own limitations Intact Mildly impaired Moderately impaired Severely impaired
Psychological	Agitation Depression Confusion Disorientation Decreased cooperation Decreased insight Decreased judgment Difficulty following directions Non compliant
Gender	Male
Medical Conditions	Secondary diagnosis
Medications	IV/heparin lock Type
Body System Involvement	Excretory Musculo-Skeletal Visual impairment Digestive Neurologic
Personal Independence	ADLs Use of ambulatory aid Get up and go out of chair
Environmental	

KU SCHOOL OF NURSING
The University of Kansas

The University of Texas
School of Health Information Sciences at Houston

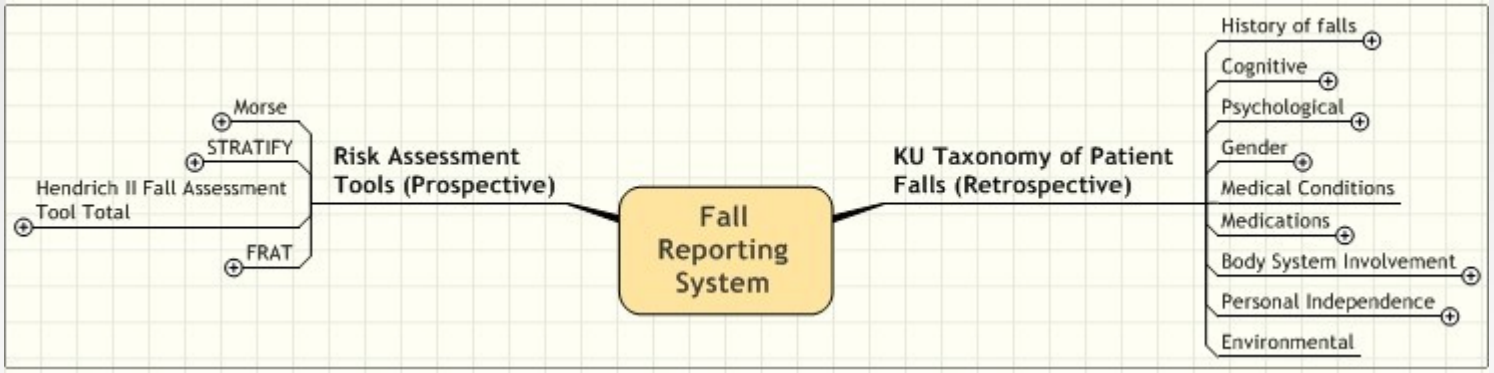
Patient Fall Risk Taxonomy



KU SCHOOL OF NURSING
The University of Kansas

THE UNIVERSITY of TEXAS
SCHOOL OF HEALTH INFORMATION SCIENCES AT HOUSTON

Future Studies: Patient Fall Reporting System



Discussion

- An inductive method of identifying and structuring the risk factors categories into a taxonomy was enhanced using Rosch's hierarchical structure for concepts.
- The hierarchy is a two dimensional structure composed of:
  - a vertical axis which corresponds to the level of abstraction.
  - a horizontal axis depicts the typicality of members represented in the category.

Conclusion

- Nine concepts emerged from the fall assessment tools as specific risk factors.
- The taxonomy is the first step in developing an ontology of patient falls.
- The taxonomy would be utilized to systematically analyze patient fall error reports.

Developing a Taxonomy to Categorize Patient Falls

Juliana J. Brixey [a,b], Judith Warren [a], James P. Turley [b]

[a] *University of Kansas School of Nursing, Kansas City, KS, USA*
[b] *University of Texas Health Science Center at Houston, School of Health Information Sciences, Houston, TX, USA*

Abstract

The KU Patient Fall Taxonomy was derived from four patient fall risk assessment tools. Nine concepts emerged from the fall assessment tools as specific fall risk factors. The taxonomy will be utilized to systematically analyze patient fall error reports.

Keywords:

taxonomy, patient falls, risk assessment

Introduction

Patient falls in hospitals continues to be a patient safety issue. [1] In an effort to reduce falls, a number of fall risk assessment tools such as those in Table 1, have been developed to prospectively identify patients at risk to sustain a fall. [2-5]Each tool is designed to assess a patient and calculate a risk score. Using the risk score, interventions are implemented to reduce or mitigate the likelihood that the patient will experience a fall. In spite of these efforts, falls continue to occur. The purpose of this study was to develop a patient fall taxonomy derived from four risk assessment tools.

Table 1 - Previously published patient fall risk assessment tools

Morse Fall Risk, Morse 1985	Fall Risk Assessment Tool (FRAT), Peninsula Health Fall Prevention Service, 1999	Hendrich II Hendrich, Bender, Nyhuis, 2003	STRATIFY, Oliver, Britton, Seed, Martin, Hopper, 1997
History of falling immediate or within the last 3 months	Recent falls	Confusion/ Dis-orientation	Did the patient present to hospital with a fall or has fallen or has she or he fallen on the ward since admission?
Presence of secondary diagnosis	Medications	Depression	Do you think the patient is agitated?
Use of ambulatory aid	Psychological	Altered elimination	Visually impaired to the extent that everyday function is affected?
IV/Heparin lock	Cognitive Status	Dizziness/ vertigo	In need of especially frequent toileting
Gait/ Transferring	Vision	Gender (male)	Transfer and mobility score of 3 or 4?
Mental status	Mobility	Any administered antiepileptics (anticonvulsants)	
	Behaviors	Any prescribed benzodiazapenes	
	Activities of daily living (A.D.L.)	Get-up-and-go Test	
	Environment		
	Continence		
	Other		

Methods

Design A retrospective analysis of four previously published risk assessment tools using techniques of line-by-line coding and constant comparison. [6]

Findings

Nine concepts emerged from the fall risk assessment tools. The concepts were arranged as categories using Rosch's three-tiered hierarchical structure for concepts (Fig 2).[7]

Figure 2 – KU Patient Fall Taxonomy

Contributing Factors	Risk Factors
History of Falls	Immediate
	Within last 3 months
	None
	Home in last 3 months
	Fall while an inpatient/resident
	Fall within last 12 months
Cognitive	Forgets own limitations
	Intact
	Mildly impaired
	Moderately impaired
	Severely impaired
Psychological	Agitation
	Depression
	Confusion
	Disorientation
	Decreased cooperation
	Decreased insight
	Decreased judgment
	Difficulty following directions
	Non compliant
Gender	Male
Medical Conditions	Secondary diagnosis
Medications	IV/heparin lock
	Type
Body System Involvement	Excretory
	Musculo-Skeletal
	Visual impairment
	Digestive
	Neurologic
Personal Independence	ADLs
	Use of ambulatory aid
	Get up and go out of chair
Environmental	

Discussion

An inductive method of identifying and structuring the risk factors categories into a taxonomy was enhanced using Rosch's hierarchical structure for concepts. The hierarchy is a two dimensional structure composed of a vertical and a horizontal axis. The vertical axis corresponds to the level of abstraction. The horizontal axis corresponds to the typicality of members represented in the category.

Conclusion

The KU Patient Fall Taxonomy was derived and grounded in the risk assessment tools. The taxonomy provides a consistent set of categories and attributes by which will be used in future research to retrospectively code patient fall error reports.

Initiators of Interruption in Workflow: The Role of MDs and RNs

Juliana J. Brixey[a,b], David J. Robinson[b], James P. Turley[b], Jiajie Zhang[b]

[a] *University of Kansas School of Nursing, Kansas City, KS, USA*
[b] *University of Texas Health Science Center at Houston, School of Health Information Sciences, Houston, TX, USA*

Abstract

The healthcare environment has been characterized as interrupt-driven with medical doctors (MDs) and registered nurses (RNs) receiving many interruptions during a shift. Previous research studies have focused on the recipient because of the negative impact on task performance. It is equally important to understand the initiator of an interruption to help design strategies to lessen the number of interruptions and the possible negatives consequences. The purpose of this instrumental study was to examine MDs and RNs as initiators of interruptions. Results of this study indicate that MDs and RNs initiate interruptions most often through face-to-face situations and use of the telephone. Strategies to successfully manage interruptions must consider both the role of initiator as well as the recipient in an interruption event.

Keywords:

Interruption, workflow, emergency medicine

Introduction

The healthcare environment has been characterized as interrupt-driven. An interruption is defined as a break in the performance of a human activity initiated by a source internal or external to the recipient, with occurrence situated within the context of a setting or a location. This break results in the suspension of the initial task by initiating the performance of an unplanned task with the assumption that the initial task will be resumed. [1] Medical doctors (MDs) and registered nurses (RNs) are the recipients of many interruptions during a shift resulting from face-to-face conversations with co-workers, telephone calls, email messages, and alarms and alerts from medical devices. These examples depict a role-based event between a recipient and an initiator. The recipient takes the role of accepting the interruption. Consequently, the recipient is affected by the interruption event because of the unexpected intrusion of a secondary task. For that reason, research studies in healthcare have examined the role of recipient because of the negative impact on task performance. [2-6] Moreover, the Joint Commission for Accreditation of Healthcare Organizations (JCAHO) [7-9], the Institutes of Medicine (IOM) [10, 11] and Morbidity and Mortality [12] report that interruptions contribute to preventable medical errors. It is equally important to understand the role of the initiator.

The initiator has the role of originating the interruption in workflow. Hence, they play an active role in the event. Moreover, the successful delivery of an interruption entails that the initiator forms the intent to interrupt and that the interruption be announced by some physical signal. That physical signal must pass a threshold test of detection by the recipient's sensory system so that the recipient is stimulated to respond to the initiator. Therefore, a successful interruption depends on the detection and acceptance of the impending interruption task by the recipient. [1]

A review of the literature found a limited number of studies that considered the role of initiator in an interruption event. [3, 4, 13, 14] Coiera and Tombs categorized a communication event as either sent or received for nine different MD and RN clinical roles. Findings from the study showed RNs initiated more paging and telephone calls than they received. In contrast, MDs initiated almost all communication events using the telephone. Medical doctors designated as house officers initiated more telephone calls when compared to consultants, senior registrars, or senior house officers. Specifically in the ED, Spencer and Logan categorized a communication event as sent or received by the MDs and RNs. [3] The MDs were classified as either registrars or junior medical officers. Registered nurses were categorized as either coordinators or having a patient load. [15] This study is limited to attending MDs and staff RNs. Therefore, the purpose of this instrumental study was to examine the role of MDs and RNs working in a level one trauma center as initiators of interruptions. An understanding of the initiator will help in the design of strategies to reduce or mitigate the negative outcomes of interruptions.

Methods

Study Design: The design was an instrumental case study. An instrumental case study is used to gain an in-depth understanding of a phenomenon as well as to generalize from an observational, inductive approach. [16]

Subjects: A convenience sample of MDs and RNs in a level one trauma center. Participation was voluntary and written consent and community consent was obtained.

Setting: All observations were made in the trauma section of a large teaching hospital. The hospital is part of a major medical center located in the Gulf Coast region of the United States of America (USA). The Emergency Department occupies 51,000 square feet (4738 square meters) and contains major trauma and cardiac resuscitation rooms. Annually, the organization provides care to approximately 52,000 patients.

Study Protocol: The MDs and RNs were shadowed with observations being recorded on a minute-by-minute basis using an automated semi-structured field note form.

Data Collection: Observers typically worked in teams of two and recorded their observations using a semi-structured field note form implemented on Tablet PCs. Subjects were shadowed for a minimum of 2 hours but not more than 12 hours. Recording of observations began when the subject had completed the informed consent. Observations were recorded on a minute-by-minute basis.

Data Analysis: Data analysis of the field notes was supported using NVivo© [17] and MacSHAPA [18].
The data was analyzed using the Hybrid Method to Categorize Interruptions and Activities (HyMCIA). [19] HyMCIA was developed through the hybridization of a deductive *a priori* classification framework with the provision of adding new categories discovered inductively in the data using grounded theory [20]. Two coders analyzed the data for agreement of tasks and interruptions. A percent agreement score was calculated.

Results

Demographics: Five attending trauma physicians were observed for a total of 29 hours, 31 minutes. The physicians were pre-selected based on scheduling and a willingness to participate. Observations were made on either the 0700–1500 or the 1500-2300 shift. These shifts were selected because they were known to be periods of time characterized as high activity.

Eight RNs were shadowed for a total of 40 hours 9 minutes. Observations were made on either the 0700–1500 or the 1500-2300 shift. The charge nurse for the shift preselected which subject would participate in the observation and the willingness of the subject to participate.

Roles in the interruption event: The major roles of initiator and recipient of an interruption emerged during categorization of the field notes. The following examples are taken from the coded field notes:

Initiator – RN initiates a telephone call.

Initiator Blocked – RN initiates a telephone call but no answer.

Initiator Delayed – RN initiates a telephone call and put on hold.

Intended Recipient – MD paged for new trauma patient

Indirect Recipient – MD talking with resident when resident is interrupted to speak with the RN.

Unintended Recipient – MD answers telephone but call is for the RN.

Recipient Delayed – Nurse practitioner waits until MD acknowledges her to receive report for a patient.

Recipient Blocked – RN waits to talk with MD but leaves after a few minutes. MD did not acknowledge.

The precise roles that were identified within the categories are shown in Table 1.

Table 1 - A Role-Based Taxonomy of Interruption

Initiator	Recipient
Initiator – a person who initiates an interruption	**Intended Recipient** - the person to be interrupted
Initiator Blocked - the initiator is blocked from initiating an interruption	**Indirect Recipient** – the incidental recipient of an interruption; i.e., talking with another in conversation when the intended recipient suspends the original activity
Initiator Delayed – the initiator is delayed in initiating an interruption	**Unintended Recipient** - not the intended recipient of an interruption; i.e., receiving a phone call that was incorrectly dialed
	Recipient Delayed – the intended recipient postpones an interruption
	Recipient Blocked – the intended recipient does not accept the interruption

As each new category was identified from the field notes, all previously coded data was reviewed. If an instance of the new category was identified the observation was coded

to the new category. This iterative process ensured that all observations recorded in the field notes were accurately coded. These categories formed a role-based taxonomy of interruptions derived from the data.

Medical doctors initiated 2.1 interruptions per hour. However, as the recipient of an interruption, MDs were found to have 25.19% of all activities interrupted. Consequently, MDs received 10.58 interruptions per hours. As shown in Figure 1, MDs were more likely to be the recipient of an interruption compared to the initiator.

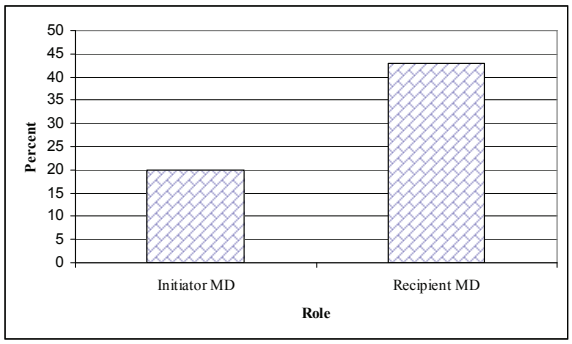

Figure 1 - Role for MDs in the interruption event

Similarly, RNs were more likely to be the recipient of an interruption rather than the initiator as reported in Figure 2.

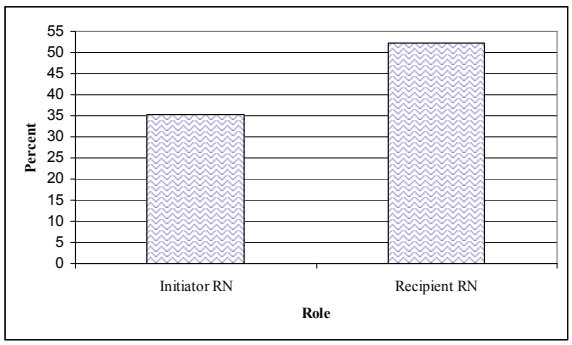

Figure 2 - Role for RNs the interruption event

In contrast, 16.45% of all RN activities were interrupted. What's more, RNs were interrupted at a rate of 11.65 per hour. When compared to MDs, RNs were more likely to initiate an interruption. This could be attributed to difference in role responsibilities. For instance, RNs may initiate an interruption to give report to another nurse when transferring a patient to another unit or when requesting a physician assess a patient because of a change in condition.

Analysis of the field notes indicated that MDs and RNs most often used face-to-face encounters to initiate an interruption. The telephone was also used as a medium to deliver an interruption. Mobile telephones were used by MDs in addition to traditional land-line telephones. Mobile telephones were not available for use by staff RNs. Therefore, RNs used only land-line telephones to initiate an interruption.

Discussion

This study systematically identified and studied the role of initiator for MDs and RNs in an interruption event. Findings from this study indicate that MDs initiated an interruption less often than receiving an interruption. Similarly, RNs took the role as initiator of an interruption less often than that of recipient. However, both MDs and RNs most often initiated an interruption as a communication event in a face-to-face encounter. The telephone was found to be the second most often used medium through which to deliver an interruption. Telephones included both land-line and mobile telephones.

It should be understood that some interruptions are necessary in the ED to deliver critical information to the MD or RN via technology. Moreover, the initiator needs to know when and how to deliver the interruption to lessen the negative impact on task performance for the recipient. This is an emerging challenge as mobile technology such as mobile telephones and personal digital assistants (PDAs) become more common in the ED. In a recent study, mobile telephones were reported as improving patient safety through the rapid delivery of communication between MDs. [21] However, the study did not report how the delivery of information via a mobile telephone interrupted the recipient's workflow.

The initiation of interruptions is not limited to mobile technologies. Real-time clinical notification systems can initiate interruptions for the MD or RN. Delivery of a notification such as a laboratory value is initiated by set of rules. Once a threshold is met the rule fires and the notification is sent regardless of the recipient's workload.

The recipient of an interruption has few choices in how to manage the instant accessibility as mobile technologies may have few features to delay receiving the interruption as opposed to older technologies such as pagers and land-line telephones. The mobile telephone lacks a voice mail feature which would allow the recipient to delay the interrupting telephone call. With a pager, the recipient page did not need to need to immediately attend to the page message as it was stored in memory of the devices. A clerical person is usually designated to answer the land-line telephone. This person could intercept the interruption by taking a message or possibly provide information to the initiator of the call. In this study only MDs had mobile telephones in contrast the RNs did not. However, as mobile technology comes into widespread use in the clini-

cal setting, there will be a need to study the roles of initiator and recipient in the interruption event.

Research is needed to understand how the new types of interruptions change workflow for MDs and RNs. It is imperative that future research studies identify the types and consequences of interruptions introduced by technology. It is suggested the role based taxonomy presented in this paper be used to classify interruptions in future studies. Findings from the studies can be used to design strategies to mitigate or decrease the negative effects of interruptions must consider the role of the initiator.

Conclusion

A role-based taxonomy of interruption was derived from the recorded field notes using grounded theory. The categories within the taxonomy show that MDs and RNs initiate interruptions as well as receive them.

This study suggests the need to develop strategies to decrease or mitigate the negative effects of interruptions and must consider the interaction between the initiator and the recipient of an interruption. Failure to consider why the interruption was initiated will lead to the formulation of ineffective strategies to manage interruptions. The introduction and use of technology in the clinical setting to manage interruptions must be critically evaluated so that MDs and RNs do not initiate unnecessary interruptions.

Abstract

The healthcare environment has been characterized as interrupt-driven with medical doctors (MDs) and registered nurses (RNs) receiving many interruptions during a shift. Previous research studies have focused on the recipient because of the negative impact on task performance. It is equally important to understand the initiator of an interruption to help design strategies to lessen the number and the possible negatives effects of interruptions. The purpose of this instrumental study was to examine MDs and RNs as initiators of interruptions. Results of this study indicate that MDs and RNs initiate interruptions most often through face-to-face situations and the telephone. Strategies to successfully manage interruptions must consider both the role of initiator as well as the recipient in an interruption event.

Background

- The healthcare environment has been characterized as interrupt-driven.
- MDs and RNs are the recipients of interruptions through:
    - face-to-face conversations
    - with co-workers
    - telephone calls
    - email messages
    - alarms and alerts from medical devices.
- Research studies have examined the role of recipient because of the negative impact on task performance.

Purpose

- To examine the role of MDs and RNs working in a level one trauma center as initiators of interruptions.

Methods

- Study Design: The design was an instrumental case study.
  - An instrumental case study is an inductive approach used to gain an in-depth understanding of a phenomenon.
- Subjects: A convenience sample of MDs and RNs.
  - Participation was voluntary.
  - Written consent and community consent was obtained.
- Setting: All observations were made in the trauma section of a large urban teaching hospital.
- Study Protocol: The MDs and RNs were shadowed with observations being recorded on a minute-by-minute basis.
  - Observations automated using a semi-structured field note.

Methods

- Data Analysis: Data analysis of the field notes was supported using NVivo© and MacSHAPA.
- The data was analyzed using the Hybrid Method to Categorize Interruptions and Activities (HyMCIA).
  - HyMCIA was developed through the hybridization of a deductive *a priori* classification framework with the provision of adding new categories discovered inductively in the data using grounded theory.
- Two coders analyzed the data for agreement of tasks and interruptions. A percent agreement score was calculated.

Methods

- Data Collection: Observers typically worked in teams of two and recorded their observations using a semi-structured field note form implemented on Tablet PCs.
- Subjects were shadowed for a minimum of 2 hours but not more than 12 hours.
- Recording of observations began when the subject had completed the informed consent.
- Observations were recorded on a minute-by-minute basis.

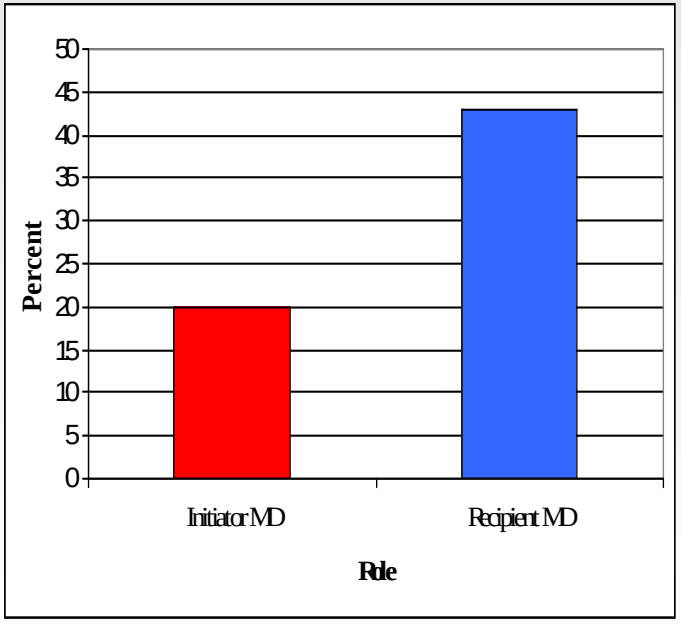
Findings

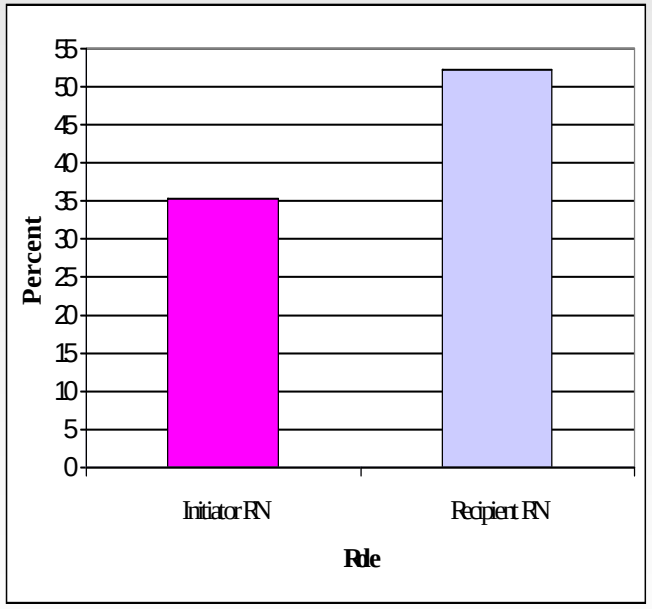
- Five attending trauma physicians were observed for a total of 29 hours, 31 minutes.

- Eight RNs were shadowed for a total of 40 hours, 9 minutes.

Findings

Initiators and Recipients of an Interruption





KU SCHOOL OF NURSING

Identifying Potential Human Errors in the Medication Label Reading Process using FMEA

Jennifer Jeon [a], Sylvia Hyland [b], Catherine M. Burns [a], Kathryn Momtahan [c]

[a] *Department of Systems Design Engineering, University of Waterloo, Canada*
[b] *Institute for Safe Medication Practices Canada, Canada*
[c] *The Ottawa Hospital, Canada*

Abstract

Poor labelling is a contributing factor of medication errors. To predict potential human errors in the process of reading the container labels for injectable medications, Failure Mode and Effects Analysis (FMEA) was applied to the label reading process. The implementation of FMEA involved various challenges including difficulties in representing a context-sensitive process, defining the failure modes, their causes and effects and developing rating scales for criticality. The identified failure modes were rated via a focus group of healthcare professionals. The results of the FMEA will be applied to improve existing label designs to prevent potential medication errors that may result from human errors in the label reading process.

Keywords:

medication errors, drug labelling, risk assessment, FMEA

Introduction

Medication errors leading to harm are a significant cause of adverse medical events [1, 2]. Poor labelling of injectable medications can be a contributing factor to medication errors. According to a survey of 687 anesthetologists in Canada, the misidentification of the drug ampoule or vial was cited as one of the most common causes of medication error (46.8%) [3]. To identify potential human errors that can arise in the label reading process, their causes, their effects and possible interventions, modified process Failure Mode and Effects Analysis (FMEA) was applied to the label reading process. FMEA is a proactive technique designed for predicting potential system failures, their causes and effects for developing mediations to prevent the failures.

Methodology

The research team consisted of a pharmacist, a nurse/ human factors psychologist, a human factors engineer, and a graduate student in human factors engineering.

The FMEA methodology developed by the Institute for Safe Medication Practices Canada (ISMP Canada), for use in healthcare, was selected as the basic framework. First, the label reading process was defined and flowcharted. There is no single established procedure for optimal reading of labels by healthcare professionals, and the process is fluid depending on the context. Therefore, an "ideal" label reading process was developed in consultation with practicing nurses. Secondly, the research team identified failure modes and their effects. The failure modes were defined as any failure in the human user's perception/cognition when reading the labels, and their effects were defined as potential types of medication errors that could result from the failure modes. Plausible causes of the failure modes were then identified with a focus on the users and existing label designs. To prioritize the failure modes, the failure modes were ranked by a focus group of 9 healthcare professionals: 6 pharmacists, 1 registered nurse, 1 educator in medication safety and 1 administrative staff in healthcare. The failure modes were rated in terms of their severity, frequency, and detectability, the rating scales for which were derived by integrating the rating scales from the Health Care Failure Mode and Effects Analysis [4] and a medication error category index [5]. For each failure mode, the median value of each type of the criticality ratings was calculated from the aggregated participant results. The three median values were multiplied together to derive a Risk Priority Number (RPN) value for each failure mode. The higher the RPN value, the more critical is the failure mode.

Results and discussion

A total of 24 failure modes were identified for the label reading process. The criticality ratings from two participants were excluded from the analysis; one pharmacist's ratings were incomplete, and the administrative staff's expertise was inadequate for the purposes of the study. The criticality ratings from the remaining 7 participants yielded RPN values ranging from 12 to 45 with an average of 30.

The process of reading the drug brand name, common name, concentration, total amount of drug ingredient per total volume and route of administration had associated failure modes with relatively high RPN values (30 or

higher) as shown in Table 1. The standard for Labelling of Drug Ampoules, Vials, and prefilled syringes developed

Table 1 – Failure modes with RPN values of 30 or higher

Failure Mode Description	RPN
User misperceives the brand name of a wrong drug as the common name of the correct drug.	45
User misperceives a different common name as the correct common name.	45
User misperceives the concentration as the total amount of the drug ingredient or vice versa.	45
User misperceives the values of the concentration/ total amount of the drug ingredient.	45
User does not read the route of administration.	45
User does not read the common name.	36
User does not read the multi-dose information.	36
User does not read the formulation type.	36
User does not read non-medicinal ingredient	36
User cannot read the concentration or the total amount of the drug ingredient.	30
User cannot read the route of administration.	30

by the Canadian Standards Association International defines the first three items as 'critical information', and a large portion of the standard is devoted to ensuring the legibility of these label contents [6]. Although not defined as critical information in the standard, route of administration is important for injectable drug use. Medication errors involving wrong route of administration were found to be the second-highest type of medication errors causing harm in the USP MEDMARX analysis of reported medication errors in 2003.[7].

In general, the participants found it difficult to rate the failure modes without a specific scenario. The detectability of failure modes, in particular, is highly dependant on the stage in the medication use process (e.g. dispensing, administration) where the failure mode occurs.

Conclusion

Applying FMEA to predict potential human errors in the process for reading the container labels for injectable pharmaceuticals required the use of a combination of several existing FMEA frameworks. Defining the failure modes, their causes and their effects was challenged by the cognitive/perceptual nature of the reading process and the fact that it is only a small link in the complex chain of events in the medication delivery process. Nevertheless, the criticality ratings of the failure modes collected via a focus group of healthcare professionals identified contents on the label that are important to end users in order to safely deliver medication to patients. The results of the analysis are being applied to improve existing label designs as interventions to reduce the likelihood of medication errors that may result from the identified critical human errors.

Objectives

- Identify potential human errors in the process of reading the container labels for injectable pharmaceuticals
- Prioritize potential failures in terms of their criticality
- Address critical failures by redesigning existing labels

Method - FMEA

- Prospective analysis technique to identify and avoid potential failures from a system or a product
- A reliability engineering technique
- Becoming widely accepted in healthcare

Method

1. Define & flowchart the label reading process
2. Brainstorm for potential failure modes and their effects.
3. Identify causes of failure modes.
4. Rate & prioritize the failure modes
5. Develop mediations for failures modes with high priority.

ismp CANADA

INSTITUT DE CARDIOLOGIE
DE L'UNIVERSITÉ D'OTTAWA

Results

- 24 failure modes identified
- Severity, frequency, and detectability ratings for each failure mode from a focus group of healthcare professionals
- Risk Priority Number (RPN) values derived from the criticality ratings

Results

Table 1: Failure modes with the highest RPN value

Failure Mode Description	RPN
User misperceives the brand name of a wrong drug as the common name of the correct drug.	45
User misperceives a different common name as the correct common name.	45
User misperceives the concentration as the total amount of the drug ingredient or vice versa.	45
User misperceives the values of the concentration/ total amount of the drug ingredient.	45
User does not read the route of administration.	45

Discussion

Label contents related to high RPN values

- Brand name
- Common name
- Concentration & total amount of drug ingredient

Defined as critical information in the CSA Standard [4]

- Route of administration → **Critical for proper administration**

Discussion

Challenges with applying FMEA

- Difficulties in
  - representing a context-sensitive process
  - defining the failure modes, and their causes & effects
- Customized rating scales developed from an existing FMEA framework & a medication error category index

ismp CANADA

Examining Senior Residents' Willingness to Adopt Smart Home Sensor Technologies

George Demiris[a], Brian K. Hensel[b], Marjorie Skubic[b], Marilyn Rantz[b], Myra Aud[b]

[a] *Biomedical and Health Informatics, University of Washington, Seattle, WA, USA,*
[b] *University of Missouri-Columbia, Columbia, MO, USA*

Abstract

The goal of meeting the desire of older adults to remain independent in their home setting while controlling health care costs has led to the conceptualization of "smart homes." A smart home is a residence equipped with technology that enhances safety of residents and monitors their health conditions. The study aim is to assess older adults' perceptions of specific smart home technologies (i.e., a bed sensor, gait monitor, stove sensor, motion sensor, and video sensor). The study setting is TigerPlace, a retirement community designed according to the Aging in Place model. Three focus group sessions with 14 participants were conducted to assess perceived advantages and concerns associated with specific applications, and preferences for recipients of sensor-generated information pertaining to residents' activity levels, sleep patterns and potential emergencies. The findings indicate an overall positive attitude towards sensor technologies for non-obtrusive monitoring. However, specific concerns about privacy and usability were also raised.

Keywords:

home care services, frail elderly, telemedicine, telemetry

Introduction

The ongoing growth of the elderly population and increase in life expectancy have led to new models of positive aging, empowering older adults to longer maintain functionality, autonomy and higher quality of life. Independence is a critical issue for many older adults as they age and face health-related challenges such as falls, sensory impairment, immobility, and isolation. The twin goals of meeting the desire of older adults to remain independent in the home setting while controlling health care costs has led to the conceptualization of "smart homes." A smart home is a residence equipped with technology that enhances safety of patients at home and monitors their health conditions.

Worldwide, smart home initiatives are demonstrating the potential of technology to support aging. The Aware Home developed by Georgia Tech in the US, for example, is a project developed in two identical independent living spaces that allow for controlled experiments with technology and enable inhabitants to live on one floor while demonstrating prototypes of assistive technologies on the other floor[1]. In Sweden, the SmartBo project explores technology for elders with mobility impairments and cognitive disabilities, such as dementia and developmental disability. Devices and sensors are tested that control lighting, windows, doors, locks, water outlets, electrical power, and stoves. The project also explores visual and tactile signaling devices, speech synthesizers, and Braille displays[2]. The PROSAFE project in France utilizes devices and infrared sensors to identify abnormal behavior that can be interpreted as an accident and to collect representative data on Alzheimer's patients' nocturnal and daily activity[3]. The "Hospital Without Walls" in Australia is a project that includes a wireless fall monitoring system in which patients at home wear small sensors that measure heart rate and body movement[4].

The study presented here is part of the TigerPlace project. This project is facilitated by the framework of Aging in Place, a new model of long-term care for older adults[5]. This model aims to allow older adults to age in the least restrictive environment of their choice. Clients' needs determine the timing and intensity of health and personal care services, delivered to them in their residence. Unlike the traditional continuum of care model, where clients move to progressively more intensive health care settings, in the aging in place model the health system organizes delivery of services to the client in his or her residence. Home health, community-based clinics, and other health system services allow clients to 'age in place.' A demonstration site of this model is Tiger Place, a 34,000 square foot facility in Columbia, Missouri, developed by the University of Missouri-Columbia with Americare Systems, Inc., of Sikeston, Missouri. TigerPlace opened in Spring 2004 and includes 32 apartments. Emphasis has been placed on a state of the art building and apartment design that supports independence, therefore helping residents to age at home and not in a nursing facility[6]. This paper is a part of a larger investigation of the use of smart home technologies in this setting as tools that can support the Aging in Place model. The focus of the larger project within TigerPlace is to investigate the use of sensors to monitor and assess potential problems in mobility and cognition of elders in their home. The emphasis is on sensing alert con-

ditions such as falls, and changes in daily patterns that may indicate problems. The components of the system include an in-home monitoring system, an event-driven anonymized video-sensor network, and a component for activity analysis and behavior reasoning.

The In-Home Monitoring System (IMS)[7] consists of a set of wireless infrared proximity sensors that detect motion, and pressure switch pads (sensor mats) that can be used to infer specific activities. Furthermore, a stove temperature sensor and switches on cabinet doors are being used. The system is also augmented with a bed sensor capable of detecting presence, respiration (normal/ abnormal), pulse (low, normal or high) and movement in the bed. Finally, the system includes a passive gait monitor that relies on a highly sensitive displacement sensor which can detect small deflections in the floor induced by a person walking up to ten feet away from the sensor on both carpeted and uncarpeted wooden and concrete floors. The gait monitor processes the raw vibration signal and extracts features of significance. It also provides basic gait characteristics by analyzing the extracted data[8].

The event-driven anonymized video sensor network complements the IMS as the visual information helps reduce false alarms generated by the motion sensor or gait monitor. In order preserve the privacy of the residents, algorithms are used to identify a person in the image and extract a silhouette[9] and inanimate objects are tracked that are manipulated by the residents.

The final component of the system is an activity analysis and behavioral reasoning system that distinguishes a typical pattern for an individual from an abnormal pattern. In this context, we are investigating Hidden Markov Models (HMMs) for learning and recognizing short-term activity patterns. The output of each Activity Analysis process is a descriptor or a set of descriptors that report the likelihood of an activity.

In previous work[10], the research team investigated older adults' attitudes and perceptions of smart home technologies in general, asking older adults in the community (not TigerPlace residents) to identify what activities of daily living could be enhanced by technology; what types of technologies they were familiar with; and what technologies they would be willing to accept. This work indicated that older adults were concerned about falls and that they perceived technologies that monitor activity levels and sleep patterns as useful. They emphasized the need for non-obtrusive systems. This work informed the design of specific technologies that were chosen to be installed in the TigerPlace apartments.

The study presented here is a follow-up of this previous work and is aimed at investigating the following: older adults' perceptions of the specific smart home technologies employed by the TigerPlace project (i.e., a bed sensor, gait monitor, stove sensor, motion sensor, and video sensor); perceived advantages and concerns associated with these types of technology; willingness to adopt such technologies in their own residence; and preferences about recipients of sensor-generated information pertaining to their activity levels, sleep patterns and potential emergencies. This study provides insight into older adults' attitudes towards specific sensor technologies and captures the level of willingness to allow installation of such technologies and to share associated personal data with other stakeholders.

Materials and methods

We conducted a series of focus group sessions to assess older adults' perceptions and expectations of specific smart home technologies, including perceived advantages and disadvantages and degree of willingness to adopt such technologies in their homes. The sessions were facilitated by members of the research team and followed facilitation guidelines for focus groups by Krueger[11]. Special considerations for elderly focus group participants as suggested by Barrett and Kirk[12] were followed. In order to avoid fatiguing participants and conflicts with their usual activities, the sessions were scheduled to last approximately one hour. At the beginning of each session, the facilitator introduced the purpose of the study. The sessions were audiotaped for later analysis by team members. We used purposeful sampling in the recruitment of focus group participants. An invitation to participate was placed in residents' individual mailboxes and posted at several locations within TigerPlace.

The focus group protocol included questions about participants' perceptions of the usefulness of specific devices and sensors. These included a bed sensor, a motion sensor, a gait monitor developed by the University of Virginia, a kitchen sensor and a video based fall detection sensor. Table 1 depicts examples of these sensors and describes their intended use and Table 2 depicts the gait monitor and describes its use. For each sensor the facilitator explained briefly its purpose by describing its function and providing an example of usage. The facilitator showed and passed around the actual sensors, allowing participants to touch and directly observe the devices. The examples used by the facilitators were chosen to increase understanding as recognition, comprehension and memory for information in older people have been shown to benefit from prior context cues[13]. Questions pertained to perceived advantages and disadvantages associated with the usage of such systems, participants' willingness to allow installation in their residence, and opinions about who should be receive the data produced by the sensors.

In order to ensure the protocol's validity, the questions were reviewed by a team consisting of researchers experienced in instrument development and knowledgeable about health care providers. The protocol was also pilot-tested for readability with a senior resident in a different facility following Krueger's recommendation to test the wording of questions with people similar to the target participants[11].

The audiotapes were transcribed and a content analysis was performed. The content analysis was data-driven; thus, a pre-determined coding scheme was not used for coding the data[14]. Data codes were inductively generated by the data collected. The goal of the qualitative content analysis was to summarize the information gleaned from the analyses of the content. Analyses were performed by assigned members of the research team and consensus in interpretations was achieved through discussion between these members. The validity of interpretations was then discussed and agreed upon with other members of the research team[15].

Table 1 - Assistive Technologies used in this study

Type of Technology	Description/ Intended Use
Bed sensor 	Bed sensors are designed to monitor heart rate, respiration, and restlessness and compare readings with personal norms.
Kitchen sensor 	Kitchen or stove top sensors are designed to detect when a stove burner has been left on accidentally when no one is present in the kitchen. This sensor combines a heat sensor with a motion sensor
Motion sensor 	Motion sensors are designed to detect motion within a room. One potential use could be detecting increases in nocturnal trips to the bathroom.
Video sensor (Fall detection) 	Video-based fall detection sensors are designed to recognized different patterns of resident movement including walking, falling down, staying down and getting up. These patterns are recognized from residents' silhouettes. Messages sent from these sensors do not contain image data.

Table 2 - The Gait Monitor

Gait monitor 	The Medical Automation Research Center (MARC), at the University of Virginia developed a passive Gait Monitoring Device that comprises a highly sensitive and selective sensor technology that is capable of measuring footfalls on the floor. The sensor's output signal creates a unique signature based in part on the individual's weight, gait, stride and average pace. Analysis and comparison of gait patterns can be made over time.

Results

A total of 14 older adults over the age of 65 participated in three focus group sessions (4 in the first, 3 in the second, and 7 in the third session). Each session lasted approximately one hour (the average length was 64 minutes). Five participants were male and nine were female. All participants were older than 65 years of age.

The bed sensor was perceived overall as useful. Two participants asked questions about the installation on top of the mattress. One participant stated that she relied on her spouse to detect restlessness or problems during the night and felt no need for technology-based monitoring. The stove sensor was perceived by some participants as useful, but most responded that they do not use the stove as they receive meals prepared by the facility and, therefore, are not concerned about accidentally leaving the stove turned on. The sensor mat was also perceived as useful by most participants. The motion sensor was perceived as an application that could provide ease of mind. Participants focused primarily on the usefulness of such a device in

detecting intruders and thus providing additional security, more so than on its usefulness in monitoring their activity levels. The gait monitor was perceived overall as very useful, as most participants expressed concerns about falling and being helpless or not detected in a timely manner. Finally, the video sensor was seen as beneficial in detecting health emergencies, particularly falls, but raised greater privacy concerns than the other technologies. Ten participants stated that they would not want to have a video sensor installed in their residence.

Findings suggest that participants focused on the potential of smart home features to detect emergency situations rather than their potential for prevention through early detection of potential health problems. Their comments emphasized the technologies' function of emergency detection rather than their function of proactive monitoring. Some participants addressed the issue of stigmatization resulting from installing the technology. One participant stated *"as long as it is installed in the others' [apartments], as long as it would be something they were going to use all over and I would not be different…"*

Many subjects found the technology useful for residents with greater levels of frailty than themselves. One participant stated, *"I don't need this now, but perhaps at a later point-I have friends who'd benefit from this a great deal, I am not there yet...."* In this context, readiness to adopt the technology resulted from perceived need and some participants found that their functional and physical status was such that there was no need for monitoring at the time.

Two participants expressed concerns about privacy violation resulting from the use of the technology. One subject stated *"I don't like for anyone to know that I went out and didn't get back until midnight or something like that-I don't think anyone needs to know that."*

When asked who should have access to the data generated by the sensors, participants stated that they would want their health care providers to receive this information. Six participants also added that they would like their close family members to be recipients of the datasets. Four participants said that they, themselves, would like to see the information. One participant followed up indicated that residents should have control of the amount and frequency of information distribution, stating that he would *"need to see the information first, before anybody else is bothered"*.

Preferences for specific sensors were based on different criteria. For some participants the size of the device played a role. One participant made a comment about the motion sensor:

"I like this one the best; it's so small, really not intrusive…" Other participants determined the usefulness of the devices based on previous personal adverse health events. One participant stated, "If you had told me two months ago [about these technologies] I'd say who needs it, but after what I have been through, I see the benefits." This participant had experienced a fall in the apartment and had felt helpless until someone discovered the event. Participants also addressed the issue of integration of the technology in the residence and its degree of visibility to visitors. One participant stated, "If you can hide them and you don't really see them but you know that they are there, that would be my preference."

Two participants expressed concerns about the accuracy of the devices. One of them specifically addressed the issue of false alarms that could prove burdensome to both residents and facility staff members. Other participants, however, expressed the need to balance safety with privacy and that they would be willing to allow others to monitor their activity levels if that provided an added layer of safety and enhanced their well-being.

Discussion

Overall, participants had a positive attitude towards smart home technologies in general. As previously stated, their perceptions of the potential of the technology focused on a reactive role (detecting emergencies) rather than a proactive one (monitoring a situation to detect trends or predict issues or concerns). Fall detection was a function that appeared to be uniformly supported as important. Participants felt that none of the technologies presented to them would interfere with daily activities. Half of all participants (seven) specifically stated that they would agree to having these technologies installed in their own apartment. Most participants deemed the technologies useful for other older adults with greater levels of frailty than themselves.

Overall, participants saw a balance to be struck between the benefits of such monitoring, determined by level of need, and the concomitant perceived intrusion into privacy at home. Participants also emphasized the need to customize how the information resulting from the monitoring systems would be handled (who and how often would be receiving the data).

From a methodological point of view, our study confirms the challenges of conducting focus groups with older adults, identified by Barrett and Kirk[12]. These include the fact that older people show a lowered ability to focus attention over longer periods of time, or to suppress irrelevant information[13,16]. Our protocol was designed so as not to overload the working memory of older adults during the sessions since these require simultaneous maintenance and manipulation of spoken information[13].

This study provides useful feedback about specific smart home sensor technologies that can be organized into general themes. This research also suggests additional, potentially fruitful areas of inquiry. For example, was the

participants' focus on the technologies' benefit in reaction over prevention, a basic orientation or a matter of not having learned or considered enough about the potential preventive benefit? The potential mediating role of control also poses interesting questions, such as, does perceived control (e.g., ability to turn technology off) mediate the level of privacy concern? Finally, the question of what is perceived as "obtrusive" in these types of technologies presents a fertile area of study.

A Study of Nurses' Interaction with an Alerts and Reminders System of a Nursing Documentation Application

José A. Borges, Néstor J. Rodríguez, Carlos Pérez, Gilberto Crespo,Carlos Martinez, Celia R. Colón-Rivera

Center for Industrial Software Development (InduSoft),
Institute for Computing and Informatics Studies, University of Puerto Rico - Mayagüez

Abstract

Alerts and reminders can keep nurses aware of pending actions or procedures for patients and provide warnings on abnormal conditions or potential health hazards for patients. An alerts and reminders system can provide added value to an electronic medical records system (EMR) facilitating its adoption. This paper describes a study of nurses' interaction with an alerts and reminders system of a nursing documentation application. The system provides alerts on critical patients' conditions and reminders on pending nursing activities such as medication administration, physician orders and patient treatments. The nurses' interaction was analyzed in terms of task completion times, number of items found and subjective user satisfaction. Results revealed a wide variability in nurses' completion times which correlated with nurses' age. Younger nurses exhibit better performance than older nurses. Nurses are able to identify most alerts and pending activities on the system. However, the lack of experience with the system is a factor that affects their ability to identify some alerts and pending services. Nurses were very satisfied with the system and demonstrated a strong preference for it over the traditional paper-based system.

Keywords:

electronic medical record systems, nursing documentation, alerts and reminders, usability engineering

Introduction

The benefits of Electronic Medical Records (EMR) are well established and documented. Successful implementations of such systems have shown to improve patient care in terms of safety, effectiveness, and efficiency. However, in spite of the proven and potential benefits of electronic medical records, paper-based records are still predominant. The reasons for the lack of a widespread adoption of electronic medical record systems are also well documented in the literature. Factors such as cost, user resistance, complexity and poor usability, have contributed to the slow implantation of these systems.

The design, development, and deployment of an electronic medical record is a complex endeavor. An EMR must integrate the unpredictable, complex, and information intensive nature of the health care environment into the clinician workflow in a timely, easy to use, and effective manner [1]. Knowing this, it then becomes important to research mechanisms and alternatives that facilitate the adoption of these support systems.

Alerts and reminders can be an added value to an EMR system that can facilitate its adoption. Alerts and reminders are typically useful to inform clinicians of events, such as the correct time to administer medication, the arrival of test results, or other more urgent events such as an overdue procedure [2]. The key is in providing these alerts in an intuitive manner, one that is tailored to the clinician using the system. The systems display must be straightforward, offering as much useful information as possible without being cluttered or awkward.

A study by Krall [3] determined that physicians are most concerned with efficiency, usefulness, information content, user interface and workflow when asked about an alerts and reminders system. Efficiency was found to be the most important and fundamental criterion for success as perceived by the physicians. A similar study [4] used questionnaires sent out to community family physicians to determine their needs regarding electronic medical records. The topic of interest from the results of this study were the respondent's comments regarding what information is important enough to be included in the electronic records' "front page". Most mentioned among the replies were laboratory results, medication information, consultations, hospital follow-up and health maintenance. More specific atoms of information that were deemed important included allergies, flags for abnormal lab results, patient age, an active problem list, notifications if any screening procedures were recommended, and other data.

Usability [5] is one of the most important considerations in the design of any electronic health care system. It can has a significant impact on the acceptance, learnability, efficiency, and satisfaction of the users. Conducting usability tests with users is the most effective mechanism to evaluate the usability of a system. This is precisely

what this paper is about. It presents a usability study in which nurses interacted with the alerts and reminders system of a nursing documentation application of a prototype of an EMR. This alerts and reminders system evolved from a system called SAAS [6], conceived to track patients in an Emergency Room setting and provide status information about pending services for each patient. The study focuses on the usability attributes of learnability, efficiency and subjective user satisfaction.

The alerts and reminders system

The alerts and reminders system described in this section is part of the nursing documentation module of a prototype of an EMR system called hPad. The system allows efficient navigation between patient records, reduces nurses' memory load, and serves as a workflow management tool. The categories or selection of alerts, reminders, warnings, messages, pending services, and any other item of information to be referenced in this system could be customized for the specific needs of a particular health organization. Potentially, the system could be the basis to manage and assist in other health environment concerns mentioned in the medical literature. It could be used to assist the patient transfer or sign-out process [7,8], to enhance the adherence to guidelines [9] and documentation, and to provide timely information for clinical decision making [10].

The initial interface of the nursing documentation module is presented in Figure 1. The user is identified at the top left of the header of the user interface. A dropdown menu at the top right allows the user to select the clinical area in which she/he will be working. However, the system starts by default with the clinical area normally assigned to the nurse. A list of the patients in the clinical area selected is displayed below the header. Each entry of the list provides the name of the patient and his/her room number. Alerts and reminders for a specific patient are indicated with circular or oval icons to the right of the room number in the patient's row. These icons are aligned in columns and each column represents a specific type of reminder or an alert. The type of alert or reminder is specified with the pictorial icons at the heading of the table. The pad with the blue strip refers to physicians' orders reminders, the capsule to medication reminders, the test tubes to laboratory reminders, the chest x-ray to diagnostic studies reminders, the phone to physician consultations reminders, the yellow pad to pending documentation reminders, and the yellow triangle to general alerts.

Figure 1 - Initial Interface of the Nursing Documentation Module

The level of urgency of an alert or reminder is indicated with the icon color as well as its shape. These two ways of distinguishing the urgency of an alert or reminder were adopted to support colorblind users. The green circle indicates the lowest level of urgency. It means that a service or an action needs to be performed soon. The small yellow oval indicates that a service or an action is reaching the time it needs to be performed. The large red oval indicates that a pending service or action has exceeded the time when it should had been performed. In cases when there are more than one instances of a specific alert or reminder for a patient a number is displayed inside the corresponding icon indicating the number of instances. Placing the pointer over an alert or reminder icon for a few seconds activates a small tool tip-type window that provides additional information about the alert or reminder.

A double click on a patient's name opens a nursing documentation window like the one shown in Figure 2. This window facilitates the documentation of typical nursing tasks such as handling physicians' orders, medication administration, drip type medication administration, taking vital signs, writing nursing notes, performing daily assessment, collecting I/O measurements and assessment of pain. Access to a specific documentation category is accomplished by clicking on the corresponding keyword of the tab bar provided on the window. By default the nursing documentation window opens on the physicians orders tab when a patients name is double clicked on the window that lists the patients and the pending alerts and reminders (see Figure 1). However, if the user clicks on one of the alerts or reminders icons on the patients' lists window, the nursing documentation window will open on the documentation tab that corresponds to the particular alert or reminder.

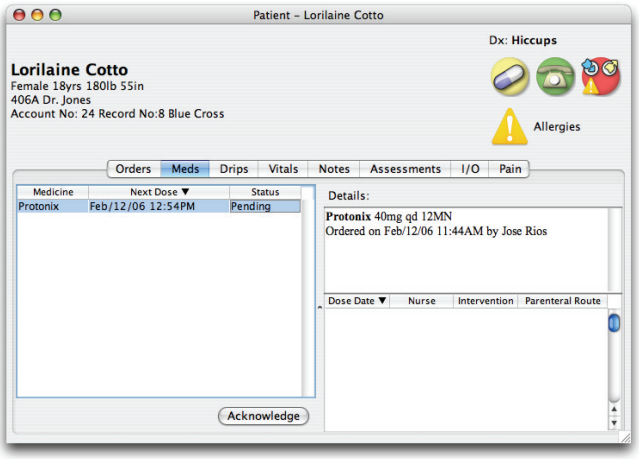

Figure 2 - Nursing Documentation Window

The nursing documentation window indicates the name of the patient and some relevant information at the top left side. Pictorial icons with a circular background are displayed at the top right of the window. These icons correspond to the pending alerts and reminders for the patient. The color of the circular background indicates the urgency of the alert or reminder. Double clicking on a pictorial alert or reminder icon will open the documentation tab on which the alert or reminder can be managed. The pictorial icons will disappear from the nursing documentation window as soon as the pending action or service that it represents is performed and documented. Similarly, the corresponding circular or oval icon will disappear from the patients' list window.

The alerts and reminders system allows efficient navigation between patient records and between specific items requiring attention. At a glance, the system provides a snapshot of the specific ward or floor, which can help nurses coordinate and manage their activities.

Methods

Participants

Twenty staff nurses from a hospital serving only a cardiovascular clientele participated in the study. They were selected on a first-come first-serve basis from those that responded a call for participation and were compensated for their participation. Their experience as staff nurses ranged from 0.2 to 27.4 years (M=8.5 years). Experience with computers ranged from 0 to 28 years (M=3.5 years). None had prior experience with the hPad system, nor with any other electronic patient record system.

The tasks

Each participant was asked to perform the nine tasks listed below on the hPad system. All the tasks began with the hPad system displaying the patients' list window (figure 1).

1.Indicate the patients with pending lab orders.

2.Indicate the pending alerts and reminders for a specific patient.

3.Indicate the pending services for a specific patient.

4.Determine the time a physician submitted a consult order for a specific patient.

5.Acknowledge the consult orders for a specific patient.

6.Open a pending note for a specific patient, add a specific text to it and save it.

7.Acknowledge the pending reminders for a specific patient.

8.Identify the rooms in which there are patients with pending medication orders.

9.Acknowledge all pending medication for the patients in the clinical area.

During the execution of task 9 one new alert and one new reminder is generated.

Research design

Before proceeding with the test the, participants were asked to sign consent forms and fill out a background questionnaire. All received a short tutorial of about 15 minutes on the hPad system. The participants were asked to perform the nine tasks indicated in the previous section. The patients' records used in the study were realistic in terms of their content but did not belong to real patients.

After performing the tasks the participants were asked to fill out a subjective user satisfaction questionnaire. The questionnaire asked them to rate five aspects of the hPad system using a 1-5 scale (see Table 3). The participants were also asked to indicate their system preference for the hPad or the traditional paper-based system.

Data analysis

Descriptive statistics were used to analyze the results. Average, standard deviations, maximum and minimum values were used for analyzing the completion times of all the tasks. Percentages were used to analyze the number of items asked to identify or act on by nurses while performing tasks 1, 2, 3, 8, and 9. Average ratings were used to analyze the users' responses to the subjective satisfaction questionnaire.

Results

A summary of the completion time results for all the tasks is presented in Table 1. The table indicates the average completion time, standard deviation, and maximum and

minimum times recorded for each task. The results exhibit a very wide variability in completion times. In most of the cases the maximum time recorded was more than ten times the minimum recorded.

Table 1. Completion Time Results

	Average (seconds)	Std. Dev. (seconds)	Min (seconds)	Max (seconds)
Task 1	30.4	22.0	6	77
Task 2	39.5	21.5	11	90
Task 3	31.8	19.2	7	91
Task 4	26.2	29.5	6	120
Task 5	39.2	28.0	11	92
Task 6	83.7	61.5	13	253
Task 7	52.1	34.1	12	125
Task 8	34.7	19.5	9	70
Task 9	103.5	95.1	17	480

A summary of the percentages of items found in response to questions posed for tasks 1, 2, 3, 8, and 9 is presented in Table 2. The results show that the participants found the large majority of the items they were asked to look for.

Table 2 - Percentage of items found

	% Found
Task 1: *Patients that have pending lab orders*	73.3
Task 2: *Pending alerts and reminders for patient Lorilaine Cotto*	82.5
Task 3: *Services pending for patient Rafael Cajigas*	98.3
Task 8: *Rooms where patients await for pending medication*	86.7
Task 9: *Pending medication for the patients in the clinical area*	78.8

Table 3 provides a summary of the average ratings given by the participants to various aspects of the hPad system and their system preference (item 6). The ratings given to the different aspects were very favorable to the hPad system. The participants overwhelmingly preferred the hPad system over the traditional paper-based system.

Table 3 - User satisfaction results

Aspect	Meaning of scale	Rating
1. Did you understand the functionality of the system?	1= not understood 5= understood	4.85
2. How did you find the meaning of the icons?	1= very confuse 5= very clear	4.55
3. How easy was to find the patients requiring the most urgent attention?	1=very difficult 5= very easy	4.75
4. How easy was to find the pending actions of a patient?	1=very difficult 5= very easy	4.90
5. How easy was to handle the different windows of the program?	1=very difficult 5= very easy	4.55
6. Which system would you prefer, the hPad or the traditional paper-based system?	1= paper-based 5= hPad	4.80

Discussion

The results for task completion times exhibit a wide variability (see Table 1). These results suggest that there exists a notable difference in the participants' ability to perform the tasks. In order to understand what may account for the variability in the participants' performance a correlation analysis was performed between the overall completion time for each participant and the participants' age, work experience and computer experience. A correlation was found between the overall completion time and the participants' age but not with the participants' work experience or computer experience. A correlation analysis was also performed between individual task completion times and the participants' age, work experience and computer experience. Correlations were found only between the participants' age and the completion times for tasks 1,3,4,6 and 8. These results suggest that age is a key characteristic in the participants' ability to perform the tasks on the hPad system. In general younger nurses exhibit better performance than older nurses. Thus, special attention should be given to older nurses when training them to use the system.

For tasks 1, 2, 3, 8 and 9 participants were asked to find, identify or perform actions on several items present on the initial window of the hPad system. The results show that the participants were able to identify the majority of these items (see Table 2). However, under normal circumstances nurses should be able to find all these items. The fact that the participants did not have any experience with the system other than a 15 minutes tutorial certainly played an important roll on the participants' ability to identify the requested items. Nevertheless, given the lack of training and exposure to the systems the results are very encouraging.

Although the participants did not know the system very well they were very satisfied with it. The results for the user satisfaction questionnaire were very favorable for the hPad system. The participants gave relatively high ratings to all the aspect considered (items 1 to 5 of Table 3). They understood the functionality of the system and the meaning of the icons very well, and found the windows of the program very easy to handle. The participants' perception of the system is consistent with their observed interaction with the system. It was evident that the participants understood the functionality of the system because 95% of them were able to assess pending services without having to open the patient's record window. In addition all the participants clicked on the alerts or reminders icons instead of the patient's name in the initial window (see Figure 1) in order to open the documentation tab that corresponds to

the particular or alert or reminder. The participants also indicated that it was very easy for them to find the patients requiring urgent attention and to find the pending actions on a patient. In addition the participants indicated a strong preference for the hPad system over the traditional paper-based system used in the hospital (item 6 of Table 3).

Conclusion

Nurses exhibit a wide variability in performing tasks with the alerts and reminders system. This variability correlates with the age of the participants. In general, younger nurses exhibit better performance than older nurses. Thus, in order to learn to use a system like the hPad older nurses may required more training time than younger nurses.

Nurses are able to identify most alerts on pending activities and reminders on the system. However, the lack of experience with the system is a factor that affects their ability to find, identify or perform actions on several items present on the initial window of the system, but the fact that they were able to identify most of them is an encouraging result. With minimum training nurses should be able to identify all pending activities and alerts indicated by the system.

Even though nurses exhibit a wide variability in performing tasks on the alerts and reminder system they were very satisfied with it. They felt they understood the functionality of the system and the meaning of the icons, and found the windows of the systems very easy to handle. In addition, they felt it was very easy to find the patients requiring urgent attention and to find the pending actions on a patient. Nurses also evidenced a strong preference for the alerts and reminders system over the existing paper-based system.

Using PDA to transform the long MDS-HC evaluation form into a favored system

Chiao-Ling Hsu, Yu-Yin Kuo, MS, Polun Chang

Institute of Biomedical Informatics (formerly Health Informatics and Decision Making), National Yang-Ming University, Taiwan

Abstract

The MDS-HC has been an effective home care evaluation form. However it was not yet accepted in Taiwan because it is too long for our over-burdened home care nurses. We used a self-developed PDA information representation model to design the PDA MDS-HC support system and used the Technology Acceptance Model to examine its potential acceptability. The results showed a well-designed PDA could greatly improve the usability of a originally un-favored paper system.

Keywords:

MDS, home care, PDA, information representation

Introduction

The Resident Assessment Instrument, consisting of a Minimum Data Set (MDS) evaluation form, Client Assessment Protocols (CAPs) and Triggers, has been well internationally known, applied, and even used for the insurance claim, in the long term care [1]. The MDS-HC is vary complete and covers 17 main categories and as many as 64 evaluation items. However, currently its professional completeness doesn't make it a formal evaluation form for the home care in Taiwan because it is too long for our over-burdened home care nurses.

PDA has been a potentially useful tool for mobile nursing, especially for those in home care settings. But its interface features, such as difficult data entry in writing and small display screen, still confine its use. We developed a PDA information representation approach which had been practically proven to be easy to use by nurses [2][3]. A modified version was latter developed for the long forms.

The purpose of this study was to use the modified PDA information representation approach to design the PDA-based MDS home care evaluation support system and to examine the home care nurses' acceptance of the PDA-based MDS-HC system.

Methods

The modified PDA information representation approach is mainly composed of 4 principles:

1. The screen display area is separated into three sections for the users to clearly see and to easily navigate through the form.

2. User should be able to switch to any item in less than 3 taps.

3. The hand-writing should be replaced, if possible, by tapping for data entry.

4. User should be well reminded what tasks have been done.

A team of nursing user, nursing programmer and experienced PDA programmers was organized and the prototyping approach was used to develop the system. A convenient sample of 24 subjects, who were trained of the MDS, was used for testing. 3 representative home care scenarios were written for users to test the PDA system. Davis' Technology Acceptance Model was used to evaluate users' acceptance of the system in terms of their perceived ease of use and usefulness.

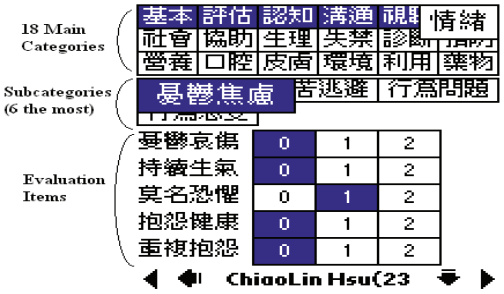

Figure 1. The representative screen shot.

Results

The representative PDA screen was shown in Figure 1, in which uses could navigate the system through tapping the upper main category and subcategory buttons, and enter data in the lower half data entry area. The highlighted buttons mean answered questions.

58% of subjects never used the MDS-HC form. Most of the subjects have BS degree and aged from 20-50. 100% agreed the system was easy to use and 92% agreed the system was useful.

Conclusions

Our study showed that a well-usability-engineered PDA system can well improve the usability of both the professional forms, which was too long to be practically accepted, and PDA, which small-display interface usually hinders its popularization.

Unanticipated Workflow Characteristics after Implementing a Computerized Vaccination Reminder System: A Case Study

Judith W Dexheimer[a], Dominik Aronsky[a,b]

[a] *Department of Biomedical Informatics, Vanderbilt University, Nashville, TN*
[b] *Department of Emergency Medicine, Vanderbilt University, Nashville, TN*

Abstract

Computerized reminder systems can increase vaccination rates in the outpatient setting. Achieving a high level of system integration may support busy clinicians and result in higher compliance. After successful implementation of a closed-loop, informatics-based pneumococcal vaccination reminder infrastructure in the ED, we discovered several, unanticipated workflow details that may have impacted the implementation approach. Despite the participation of the ED staff in designing the workflow of the vaccination reminder system, the workflow details would have been challenging to predict.

Keywords:

emergency medicine, pneumococcal vaccines, case reports

Introduction

Pneumococcal vaccination is recommended for all patients older than 65 years and those younger than 65 with a co-morbid illness. Current vaccination rates remain far below the Healthy People 2010 target of 90%. The Emergency Department (ED) has been suggested as a suitable environment to offer vaccination and feasibility has been demonstrated. We implemented an end-to-end computerized vaccination reminder system in the ED using four different information systems, including the ED triage application, the computerized provider order entry (CPOE), the order tracker system, and the longitudinal electronic medical record system (EMR).

Unanticipated workflow details

With close participation of the ED staff a workflow for the pneumococcal vaccination program was mapped out using flow diagrams, which were repeatedly reviewed and discussed during the weekly team meetings. To design a system that would fit into the existing ED workflow, our goal was to create a sustainable system that would require limited additional data entry by ED clinicians. As part of designing the system, we conducted a survey of ED physicians and nurses to evaluate their beliefs, opinions, and interest in a vaccination reminder system. The survey results helped us to identify clinician education foci and guide design aspects.

The initial implementation phase included observation periods to elicit complaints and discover system issues. We discovered several subtle process and procedure variations that were originally not accounted for: (a) Nurses were able to short-circuit the reminder system and preemptively order the vaccine with physician approval prior to the physician prompt. (b) As the reminder was tied to the first CPOE session, it occurred that physicians completed the first session prior or during the nurses vaccination screening task. (c) More patients than expected seemed to decline vaccination during the triage process, a result of triage nurses' workload leading the triage nurse to decline on behalf of the patient without completing the actual screening task. (d) Despite several educational communications with the physicians, they remained unclear that patients consent was already obtained at triage, which we were able to clarify with a small wording change in the physician reminder. (e) Some eligible patients consented to receiving the vaccine, but their reason for the ED visit did not require the use of the CPOE system. (f) During an information system upgrade, the infrastructure for capturing the physicians' refusal reasons got disconnected during a limited time period.

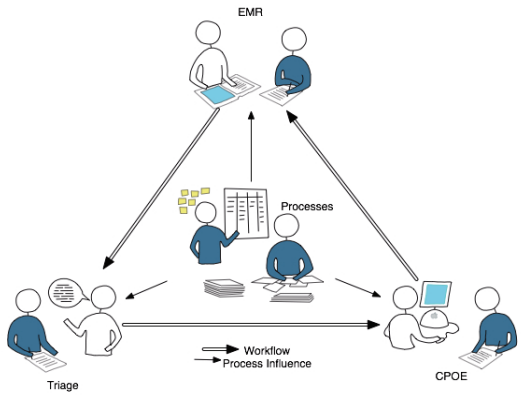

Figure 1 – System design and processes

Discussion

Although we discovered several unanticipated workflow details immediately after implementation, the close communication with the clinicians allowed us to modify the

system so that it remains part of the ED workflow. After 12 months the computerized reminder system seems to be a sustainable informatics approach improving vaccination rates in the ED.

User-Computer Interface Design of a Family Support Web-based Portal: The Use of Scenarios and Low Fidelity Prototype

Reza Samavi[a,b], Teresa Chiu[c,d,e]

[a] *Dept of Mechanical and Industrial Engineering, University of Toronto* [b] *Knowledge Media Design Institute, University of Toronto* [c] *Dept of Health Policy, Management, and Evaluation, University of Toronto* [d] *Occupational Science and Occupational Therapy Dept, University of Toronto,* [e] *COTA Health, Toronto, Canada*

Abstract

This paper describes the user interface design of a web-based portal for middle-aged novice internet users to receive multilingual family caregiver support. We used a scenario-based analysis technique and low fidelity prototype to create and iteratively refine 46 scenarios that characterized 4 portal functions, supporting 5 stakeholders and quality attributes. This technique has several advantages when applied to this case example: It enabled clinician participation, facilitated team communication, saved cost and time, sped up subsequent design steps, and validated assumptions in the user interface design process.

Keywords:

clinical informatics, Chinese, family caregivers, middle-aged, multilingualism,user-computer interface

Purpose

This paper describes the user interface (UI) design process of a web-based portal for middle-aged novice internet users who speak English as a second language to receive multilingual family caregiver support service [1]. The functions of the portal allow the caregivers to: (1) communicate with and support from health professionals online, (2) involve multiple family members in the communication process, (3) receive alerts to trigger usage of service, and (4) receive information needed to support their caregiver role. The portal consists of 4 features for use by 5 types of stakeholders.

Methods

We modified a standard requirement analysis practice to identify, specify, and validate the functions of the portal. The original version of the portal consisted of simple functions to provide information on web pages and therapist-caregiver email communication for personalized support. We collected field work data to determine the enhancement needs the original portal functions.

Enhancements of the functions were analyzed based on a stakeholder analysis (Fig. 1). Ten caregivers who had used the original version of the portal participated in in-depth interviews. They had been caring for their family member who had dementia for a range of 2 to more than 10 years. The interviews allowed us to understand the daily caregiving situation and their experiences of using the original basic portal design. The caregivers were typically female in their 40s and 50s and had other major roles in life such as being a mother, working full time.

Next, we used a scenario-based analysis technique to: 1) critically analyze the UI design, 2) bridge the design concepts to physical design, and 3) document the finalized design for implementation. Figure 1 shows how the scenario-based analysis, Step 2, is related to the other 4 UI design steps.

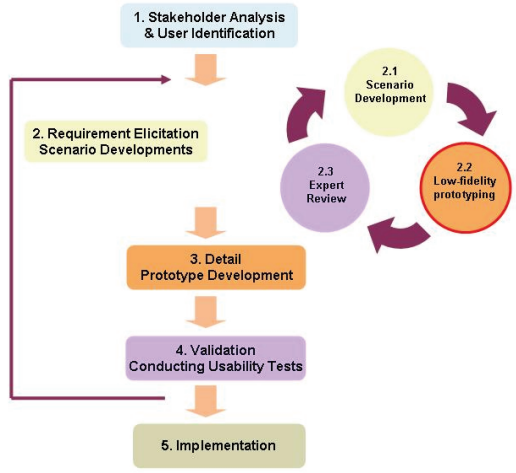

Figure 1 - Methodology for user interface design

In Step 2, we used an iterative process to (2.1) develop the scenarios, (2.2) create low fidelity prototype (LFP), and (2.3) conduct expert reviews. We created and iteratively refined 46 scenarios that elaborated the UI of all four portal features. The scenarios detailed the UI design that supported different stakeholders' needs and quality attributes such as usability, accessibility, performance, and security. The scenarios were built using LFP (Fig 2) in MS Word documents with a template and narratives. A heuristic evaluation was conducted using the LFP.

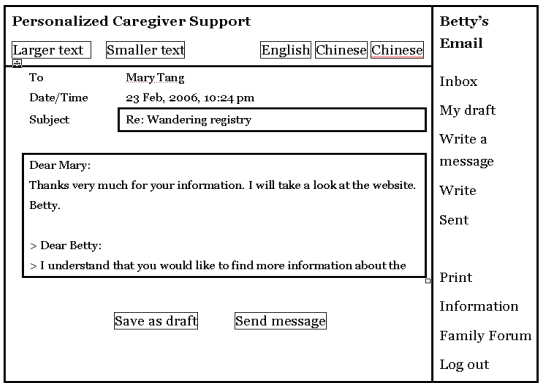

Figure 2 - Low Fidelity Protocol using MS Word Document

The scenarios were iteratively refined through these three sub-steps. The LFP facilitated the evaluation of the design against established usability standards, the validation of the design choices against functional requirements, and the identification of needs for improvements.

Results

The evaluation and analysis procedures resulted in eight important design decisions:

First, three functional enhancements to be added to the portal:

- a family message board to allow members in the same family besides the principal user to communicate with the online practitioner
- the use of narratives to describe issues in caregiving situations to increase the awareness of the caregivers to reflect on their own caregiving situations
- a tailored message to supports caregivers who do not know what to talk about to compose an email related to a specific topic more effectively and efficiently. The design would benefit caregivers who do not know medical terminologies in English (as a second language).

Second, emphasizing on analyzing stakeholders before any steps revealed crucial requirements for the system and helped to make and evaluate early design decisions.

Third, for users who are in their middle age and not technically savvy, using affordance familiar to them can improve the ease of use. For example adding buttons of "next page" and "previous page" helps with navigation like reading a book.

Fourth, buttons with only icons can be problematic for novice users. Icons with words can improve the understanding of semantic.

Fifth, users need to have control to change font size. This design decision requires special care of texts written on buttons, to resize all buttons when user changes the font size.

Sixth, to ensure security and confidentiality without compromising usability, a traditional email system design is used. The email module is used as an internal communication system; i.e., users cannot email to people not in the system.

Seventh, each family has one principal user and different collaborators and observers. The permission of each role is different. Various options of UI design was explored to examine the optimal way to present different combinations of permissions (i.e. full permission and read only). Tab sheets, toggle buttons listed in a row on the top of a window, are found useful to support this design decision.

Eighth, the portal requires supporting English, Traditional and Simplified Chinese. We chose to use language toggle buttons that allow the change of language in each page. We also have chosen a system that support Unicode encoding.

Discussion and conclusion

How to translate requirements of diverse users with competing special needs into UI design can be a challenge. Using scenarios in early design step is a well-established method in software design [2]. When applied in this case example, we have identified 5 advantages: 1) The LFP allowed team members who were clinicians and unfamiliar with advanced prototyping applications to actively take part in the process; 2) The scenarios facilitated the communication of the interdisciplinary multilingual team members; 3) The LFP allowed us to express each interaction explicitly at low cost and to quickly and easily apply the changes for expert review; 4) The iterative scenario development in Step 2 sped up the detail fidelity prototyping in Step 3; and 5) The detailed prototyping ensured the design would not use assumptions that may work in general practice but not the end users, e.g., buttons with icons preferred by experienced but not new users. The use of an inclusive, cost-effective UI design process can contribute to a sustainable ehealth practice in the long run.

User-Computer Interface Design of a Family Support Web-based Portal: The Use of Scenarios and Low Fidelity Prototype

Reza Samavi[a,b], Teresa Chiu[c,d,e]

[a] *Dept of Mechanical and Industrial Engineering, University of Toronto* [b] *Knowledge Media Design Institute, University of Toronto* [c] *Dept of Health Policy, Management, and Evaluation, University of Toronto* [d] *Occupational Science and Occupational Therapy Dept, University of Toronto,* [e] *COTA Health, Toronto, Canada*

Abstract

This paper describes the user interface design of a web-based portal for middle-aged novice internet users to receive multilingual family caregiver support. We used a scenario-based analysis technique and low fidelity prototype to create and iteratively refine 46 scenarios that characterized 4 portal functions, supporting 5 stakeholders and quality attributes. This technique has several advantages when applied to this case example: It enabled clinician participation, facilitated team communication, saved cost and time, sped up subsequent design steps, and validated assumptions in the user interface design process.

Keywords:

clinical informatics, Chinese, family caregivers, middle-aged, multilingualism,User-Computer Interface

Purpose

This paper describes the user interface (UI) design process of a web-based portal for middle-aged novice internet users who speak English as a second language to receive multilingual family caregiver support service [1]. The functions of the portal allow the caregivers to: (1) communicate with and support from health professionals online, (2) involve multiple family members in the communication process, (3) receive alerts to trigger usage of service, and (4) receive information needed to support their caregiver role. The portal consists of 4 features for use by 5 types of stakeholders.

Methods

We modified a standard requirement analysis practice to identify, specify, and validate the functions of the portal. The original version of the portal consisted of simple functions to provide information on web pages and therapist-caregiver email communication for personalized support. We collected field work data to determine the enhancement needs the original portal functions.

Enhancements of the functions were analyzed based on a stakeholder analysis (Fig. 1). Ten caregivers who had used the original version of the portal participated in in-depth interviews. They had been caring for their family member who had dementia for a range of 2 to more than 10 years. The interviews allowed us to understand the daily caregiving situation and their experiences of using the original basic portal design. The caregivers were typically female in their 40s and 50s and had other major roles in life such as being a mother, working full time.

Next, we used a scenario-based analysis technique to: 1) critically analyze the UI design, 2) bridge the design concepts to physical design, and 3) document the finalized design for implementation. Figure 1 shows how the scenario-based analysis, Step 2, is related to the other 4 UI design steps.

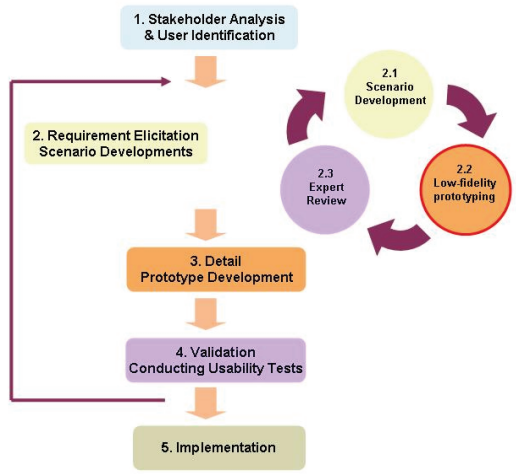

Figure 1 - Methodology for user interface design

In Step 2, we used an iterative process to (2.1) develop the scenarios, (2.2) create low fidelity prototype (LFP), and (2.3) conduct expert reviews. We created and iteratively refined 46 scenarios that elaborated the UI of all four portal features. The scenarios detailed the UI design that supported different stakeholders' needs and quality attributes such as usability, accessibility, performance, and security. The scenarios were built using LFP (Fig 2) in MS Word documents with a template and narratives. A heuristic evaluation was conducted using the LFP.

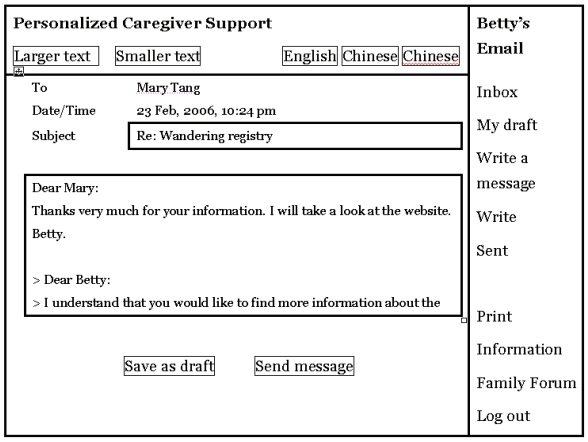

Figure 2 - Low fidelity protocol using MS word document

The scenarios were iteratively refined through these three sub-steps. The LFP facilitated the evaluation of the design against established usability standards, the validation of the design choices against functional requirements, and the identification of needs for improvements.

Results

The evaluation and analysis procedures resulted in eight important design decisions:

First, three functional enhancements to be added to the portal:

- a family message board to allow members in the same family besides the principal user to communicate with the online practitioner
- the use of narratives to describe issues in caregiving situations to increase the awareness of the caregivers to reflect on their own caregiving situations
- a tailored message to supports caregivers who do not know what to talk about to compose an email related to a specific topic more effectively and efficiently. The design would benefit caregivers who do not know medical terminologies in English (as a second language).

Second, emphasizing on analyzing stakeholders before any steps revealed crucial requirements for the system and helped to make and evaluate early design decisions.

Third, for users who are in their middle age and not technically savvy, using affordance familiar to them can improve the ease of use. For example adding buttons of "next page" and "previous page" helps with navigation like reading a book.

Fourth, buttons with only icons can be problematic for novice users. Icons with words can improve the understanding of semantic.

Fifth, users need to have control to change font size. This design decision requires special care of texts written on buttons, to resize all buttons when user changes the font size.

Sixth, to ensure security and confidentiality without compromising usability, a traditional email system design is used. The email module is used as an internal communication system; i.e., users cannot email to people not in the system.

MEDINFO 2007, Brisbane, Australia

Aug. 20-24, 2007

Purpose

- Describe the design process of the user interface (UI) of a web-based portal [1]

- Principal Portal users:
  - family caregivers of a family member who have dementia
  - middle-aged, novice internet users
  - speak English as a second language

Type of Portal Users

Principal users	• Daughters or sons of a person who has dementia • 40 to 50 y.o. • Working full time and very busy caregiving.
Collaborators	• Active caregivers • Collaborate with the Principal User to give care and to use the portal
Observers	• Family members who review the information posted on the portal • But do not actively participate in the communication
Practitioners	• Regulated professionals • Use the portal to communicate with and offer interventions to the family caregivers

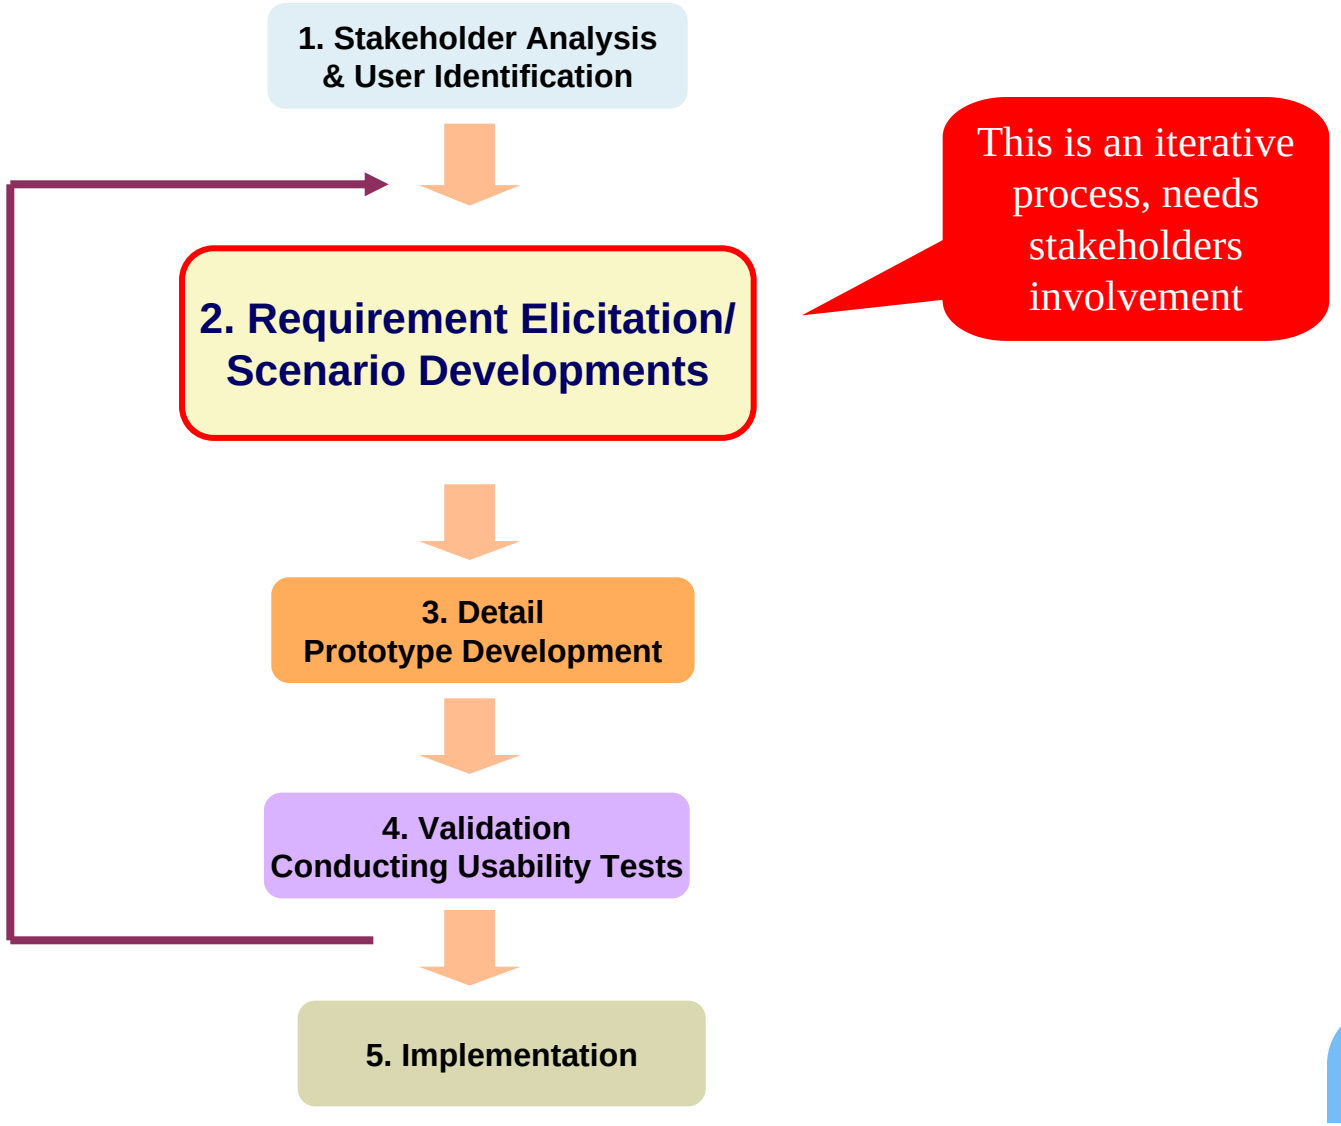
Portal Functions

- To support users to
  - Communicate with and support from health professionals online
  - Involve multiple family members in the communication process
  - Receive alerts to trigger usage of service
  - Receive information needed to support their caregiver role

Portal Features

1. Personalized Email Support	Allows the Principal Users to communicate with their Online Practitioner on a one-to-one basis
2. Family Message Board	Provides an online forum for principal users and family members to discuss caregiving issues
3. Short Stories	Provides narratives for family members to learn more about family caregiving
4. Telling More	Supports Principle Users to compose an email related to a specific topic

From stakeholders and functions to implementation – an Overview



The Extended Requirement Elicitation Process

- 2.1 Developed 46 scenarios
  - Elaborated scenarios of the 4 portal features
- 2.2 Created low fidelity prototype (LFP)
  - The scenarios were built using narratives and Low Fidelity Prototype in MS Word documents with a template
- 2.3 Incorporated expert review

Intensive, Iterative Requirement Elicitation

2. Requirement Elicitation/ Scenario Developments

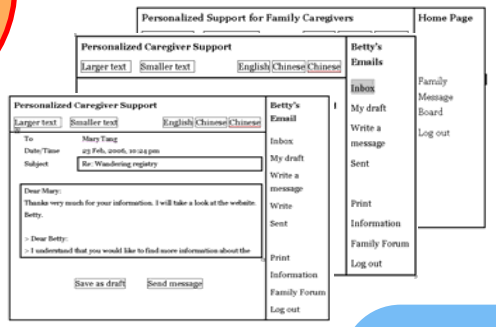
46 scenarios of

1. **Personalized Email**
2. **Family Forum**
3. **Short Stories**
4. **Telling More**

2.1 Scenario Development

2.2 Low-fidelity prototyping

2.3 Expert Review



Heuristic Evaluation & Iterative Refinements

- Heuristic Evaluation
  - The LFP scenarios were used to conduct expert reviews
- Iterative refinements:
  - Ensured that each function supported different stakeholders' needs
  - Checked quality attributes: usability, accessibility, performance, and security

5 Advantages of Scenario-based Design

1. The LFP allowed team members who were clinicians and unfamiliar with advanced prototyping applications to actively take part in the process
2. The scenarios facilitated the communication of the interdisciplinary multilingual team members
3. The LFP allowed us to express each interaction explicitly at low cost and to quickly and easily apply the changes for expert review
4. The iterative scenario development in Step 2 sped up the detail fidelity prototyping in Step 3
5. The detailed prototyping ensured the design would not use assumptions that may work in general practice but not the stakeholders

Conclusion

- This paper documented how to use scenarios and LFP to conduct an inclusive, cost-effective UI design
- Scenario-based design is a well-established method in software design [2]
- We have experienced several advantages after applying this technique to design the UI of a family caregiver portal
- The technique can contribute to a sustainable ehealth practice in the long run

A Model of Distributed Information Search on Relational Data

Yang Gong[a], Jiajie Zhang[b]

[a] *Department of Health Management and Informatics, School of Medicine, University of Missouri-Columbia, USA*
[b] *School of Health Information Sciences, University of Texas-Houston, USA*

Abstract

Searching relational data such as lab results in patients' chart can be a distributed search task where information is presented in different places and formats. Guided by a human-center process, we proposed a model of distributed information search for this type of data. In this model representation dimensions, data scales and search tasks types are the main factors considered for the search efficiency and effectiveness. The model is designed to serve as a foundation for the analysis of search tasks and effective design of search interface for relational data.

Keywords:

information search, lab result, information display

Model description

According to cognitive theory, the represented dimensions of a relational information display refer to the dimensions of an original domain in the world represented by various Relational Information Displays(RIDs). The representing dimensions refer to the physical dimensions of RIDs representing the dimensions of the original domain in the world. These two dimensions have to be matched in scales so as to guarantee the efficient and accurate representations between the display and the world. The information needed for carrying out a search task should also be matched in scales which are nominal, ordinal, interval and ratio and they have different strengths in operations. For example, if a search task is to find any abnormal triglyceride values on patient's chart, the representing dimension can be nominal scale; if a task is to find how much the patient's triglyceride is higher than normal, the representing dimension should be ratio scale.

Searching patients' records can be a comparison task within one patient or between different patients. The strategies are accordingly various if the search contents are different. A patient record contains both free text description and relational data which exists typically in the lab results section. The model contains localization, comparison and calculation, the three operations allowed by the properties of data scales. In this study, we employed lipid panel data to investigate the types of search tasks shown in the figure and the operations allowed by the power of data scales.

Discussion

For a type of clinical trial data, certain types of display are superior to other isomorphic representations in terms of search performance. A variety of studies have identified that the users such as clinicians and medical researchers may use the same data set in different ways. Search task efficiency can be improved by several factors that characterize human information behaviors. The focus of this research is on cognitive factors and their implications on human-computer interaction. Our model is particularly based on the interactions between user and computer-based information systems. This is because the computer system has the flexibility to generate isomorphic displays for the identical set of relation data.

There is no good display independent of tasks. The model with an inclusion of representation and tasks has its practical use for analyzing the search tasks of relational data. The analysis could provide a foundation for a better designed human-computer interface where data mapping, search content and search action are fully considered.

Understanding search task in scales helps explain task complexity, provide the proper representing data scales fornterface design and predict the search task feasibility on relational data.

A Classification of the Behaviours of Doctors, Patients and Computers in the Family Practice Consultation

Christopher Pearce[a], Kathryn Dwan[b], Christine Phillips[b], Michael Arnold[a] and Stephen Trumble[a]

[a] *University of Melbourne, Melbourne, Australia*
[b] *Australian National University, Canberra, Australia*

Abstract

General Practice (Family Practice) in Australia has rapidly computerised over the past ten years. Currently over 90% of General Practitioners (GPs) have a computer on their desk, and use it for clinical functions. One of the key elements of General Practice is the doctor-patient relationship, and survey work has suggested that both doctors and patients have concerns about the impact of computers on this relationship. This study describes how the doctor-patient-computer relationship is enacted in Australian General Practice. By dealing with the relationship as a triadic one we can see how the computer acts as an equal partner. As a precursor to more detailed analysis, we have described for each player in the consultation two overarching styles and three categories of behaviour exhibited at different times of the consultation. An understanding of these styles is needed before moving on to an analysis of the flow of information and power in the consultation.

Keywords:

computers, physician patient relationship, communication skills

Introduction

Computerisation of the general practice/primary care space is now almost complete in Australia, with 91% of doctors now using a computer on their desktop for prescribing. This is a figure that has come about rapidly, with only 60% reporting the same level of computing five years ago [1, 2]. computerisation occurred due to a combination of government initiatives and GP driven demand for computer prescribing [3]. This represents the most significant computerisation of the clinical encounter since the mass computerisation of the United Kingdoms National Health Service in the 1980's. Computers are now used in all facets of the consultation – prescribing, recall systems, progress notes and decision support [4]. Surprisingly, there is little literature on the direct effects of this computerisation on the doctor-patient relationship itself. Both surveys of the level of computerisation in Australia registered significant concerns by doctors to the effects of the presence of computers on the doctor-patient relationship [2, 5], although this concern is not necessarily reflected by patients [6, 7]. With a significant emphasis in primary care on the doctor-patient relationship[8, 9] , it is important the computers role in the relationship be studied.

Methods

The method has been described in detail elsewhere[10]. Twenty GPs generated 128 consultations for analysis.. The use of video allows the combining of both speech and body language in the analysis, as well as taking into account the interplay between all three players.

Results

We have been able to describe several classifications of behaviour across the various players (doctors, patients and computers) in the consultation. Central to the framework is the type of classificatins of the interaction provided by the players in the consultation. We described two for each player. The second element is the categories of behaviours exhibited during the consultation, which can occur independent of the classifications

The Classifications

Classifications apply overarching themes to the behaviours exhibited by the actants in the relationships (see table 1 for a summary). Doctors are either *Unipolar* or *Bipolar*. *Unipolar* doctors are characterised by the doctor seemingly being driven by the needs/presence of the computer. Their lower body orientation is predominantly towards the computer, and they often ask questions motivated by the computer or input information during the consultation. By contrast, *bipolar* doctors clearly indicate switches of focus with significant lower body shifts – using these shifts to indicate "computer" time vs. "patient " time. Patients are either *dyadic* (view the interaction with the doctor as prime, with the computer as a tool) or *triadic*, where the patient is happy to deal with the computer as an integral, if not equal, partner in the consultation. Similarly with the computer we can describe either *active* or *passive* styles of behaviour. Doctor styles generally remain consistent throughout each consultation and across consultations. Patients are only seen for one consultation, so although they are consistent across that consultation, no conclusion

can be made as to whether this is consistent across all consultations, either with that doctor or all doctors. The computer can change its style during the consultation, according to the directions of its programming.

The Conceptual Framework maps the overarching styles with the observed behaviour categories (or macro behaviours). An example of the framework in use is given in the example at the end of the paper..

The Behaviours

- Engaging behaviours: Refers to those behaviours when the doctor needs to engage with the patient in the consultation
- Disengaging behaviours; Conversely, refers to those behaviours when the doctor wishes to shift *away* from the patient, towards the computer.
- Cogitation: Refers to those behaviours related to the doctor staring at the computer for no clear reason. May include grazing (brief stares) to quite long periods of attention.
- Screen controlling: A patient behaviour where they try to bring the computer (through its surrogate, the screen) into play in the consultation. This is a more active process than the next category
- Screen watching: The patient uses the screen as a focus of attention in the consultation
- Screen excluding: Deals primarily with the doctor, not the computer, and may exhibit behaviours that actively excludes the computer.
- Informative: The first computer behaviour; where the computer provides important information for either patient or doctor.
- Distracter: Where an action by the computer (passive or active) acts to distract one of the other actants.
- Prompt: Where the computer acts to remind either of the actants of an action that needs to be attended toAuthor affiliations

Discusson

This classification of behaviours is similar in many ways to what has occurred in previous studies. Other work has taken a particularly doctor centric view, and had described specific doctor styles, such as managerial/interpersonal/informational [11] or behaviours such as “magic box”[12]. However my study extends on the previous work in several ways. I have attempted to be value neutral in my observations, I make no attempt to judge what may be “better” or “worse” in what is observed. Secondly, I am treating the relationship as an interaction between three players – describing and classifying not just doctor (the most usual observation) behaviour but also the patient and the computer. Patient centredness [9] requires us to take into account the patient perspective, therefore in the new consultation we should take into account the role and behaviours of the computer. Scott and Purves[13] have described the relationship as a triadic one, the sum of the interactions between three players. This work represents the first attempt to characterize the relationship from all three perspectives. This framework will allow further analysis/tagging of the video files. Thus a video of bipolar doctor/dyadic patient will be tagged according to the presence of screen watch behaviours, allowing a picture to be created as to what those behaviours are. This triadic perspective, and the application of the theoretical approach allows us to now take these classifications to the next step – reviewing the consultations to look at the flow of information in the consultation, how the triadic relationship works in the first minute, and the role of printing in the new consultation.

A Classification of the Behaviours of Doctors Patients and Computers in the Family Practice Consultation

Doctor's, Patients and Computers, The New Consultation

Dr Christopher Pearce PhD, MFM, MBBS, FRACGP, FACRRM

This Study:

20 GPs and 134 useable consultations
7% patient refusal
33% doctor refusal
20% lost due to technical reasons

- Rural and Urban
- Female and Male
- Solo and Group Practice
- *ALL* use computers for clinical functions and progress notes.

The Study used a hermeneutic framework, with Goffman's dramaturgy as a methodology, to underpin a video observation method. The 134 videos were viewed by two reseachers, and from those observations a classification framework was derived, and then tested on repeated viewings. Other researchers have attempted to classify some behaviours, usually from the doctor's perspective. This is the first time all three players in the consultation have been so viewed.

We view the consultation as a performance, in that both doctors and patients adopt specific roles. The computer also has quite specific roles, which invariably shape the consultation. Doctors are described on the basis of whether the pole of their lower body remains fixed on the computer (unipolar), or rotates between patient and computer (bipolar). Patients similarly are seen to be inclusive of the computer (triadic) or focused on the doctor (dyadic). Within the consultation the computer is passive, or active. Several classes of behaviours have also been described.

Consulting Styles vs Behaviours

Doctors

- **Styles**
  - Unipolar: always has lower pole of body facing computer
  - Bipolar: alternates lower pole of body between computer/patient
- **Behaviours**
  - Disengaging
  - Engaging
  - Cogitating

Consulting Styles vs Behaviours

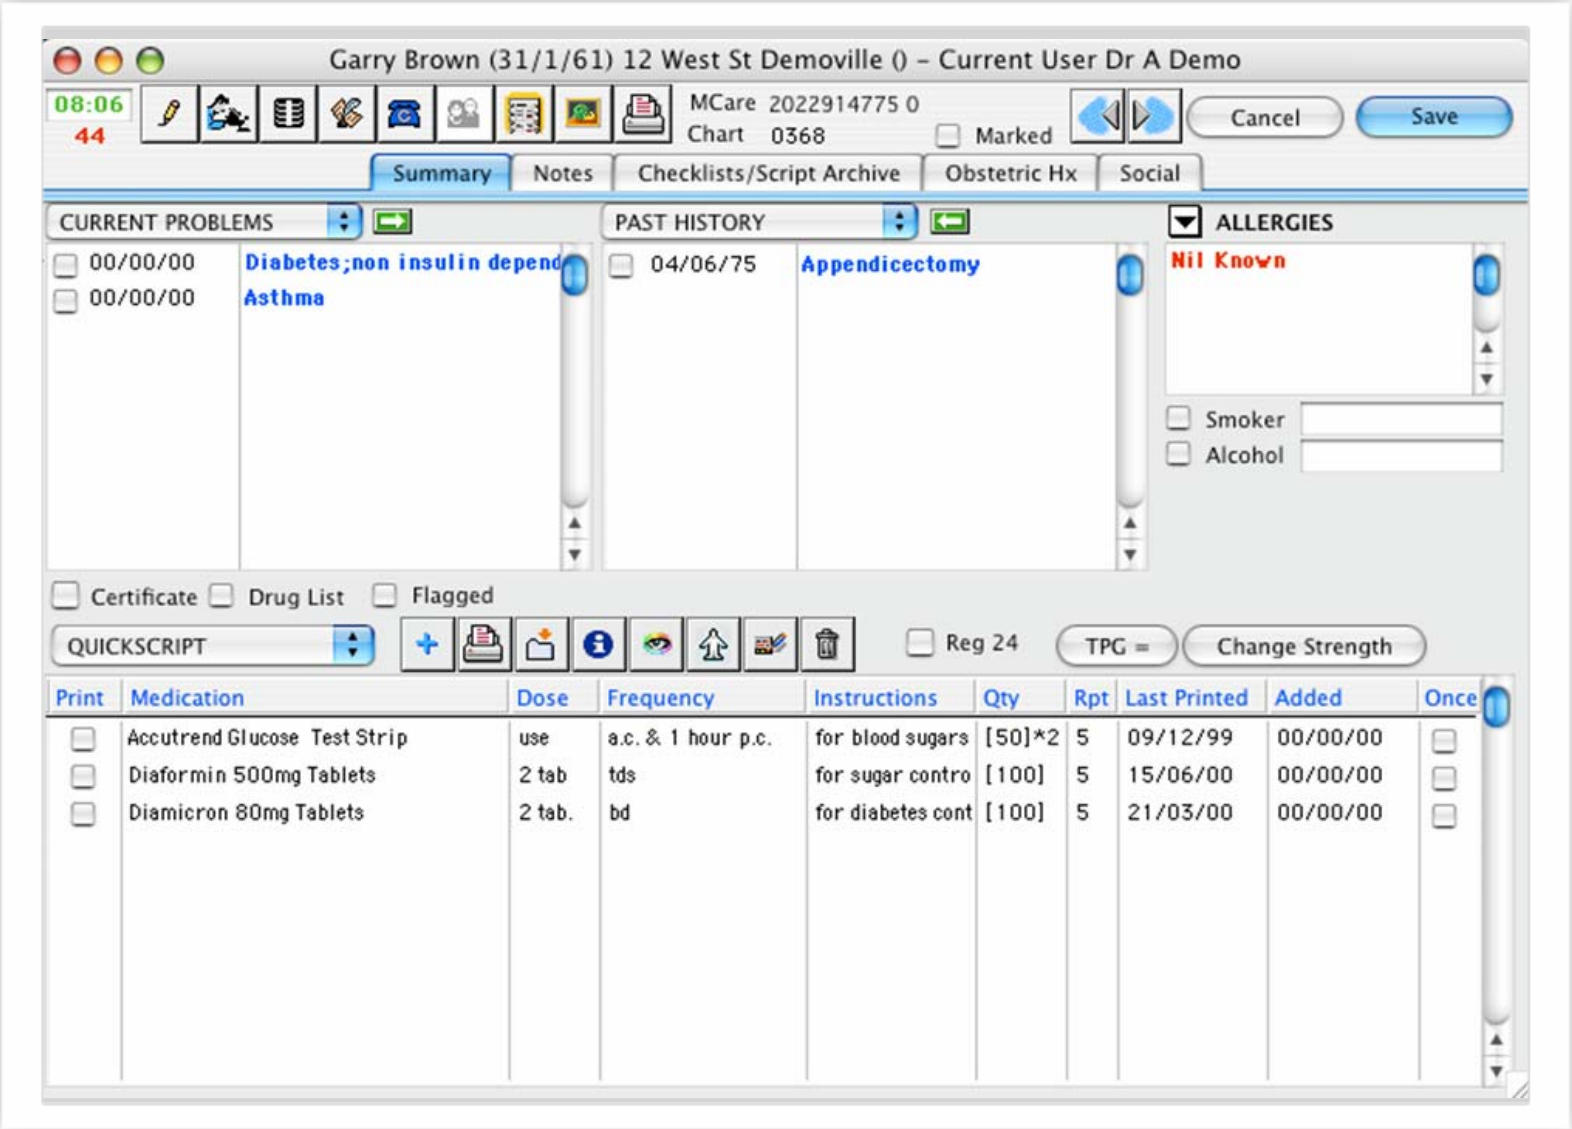
Patients

- **Styles**
  - Dyadic: inclusive of doctor
  - Triadic: inclusive of doctor *and* computer
- **Behaviours**
  - Screen-excluding
  - Screen-watching
  - Screen-controlling

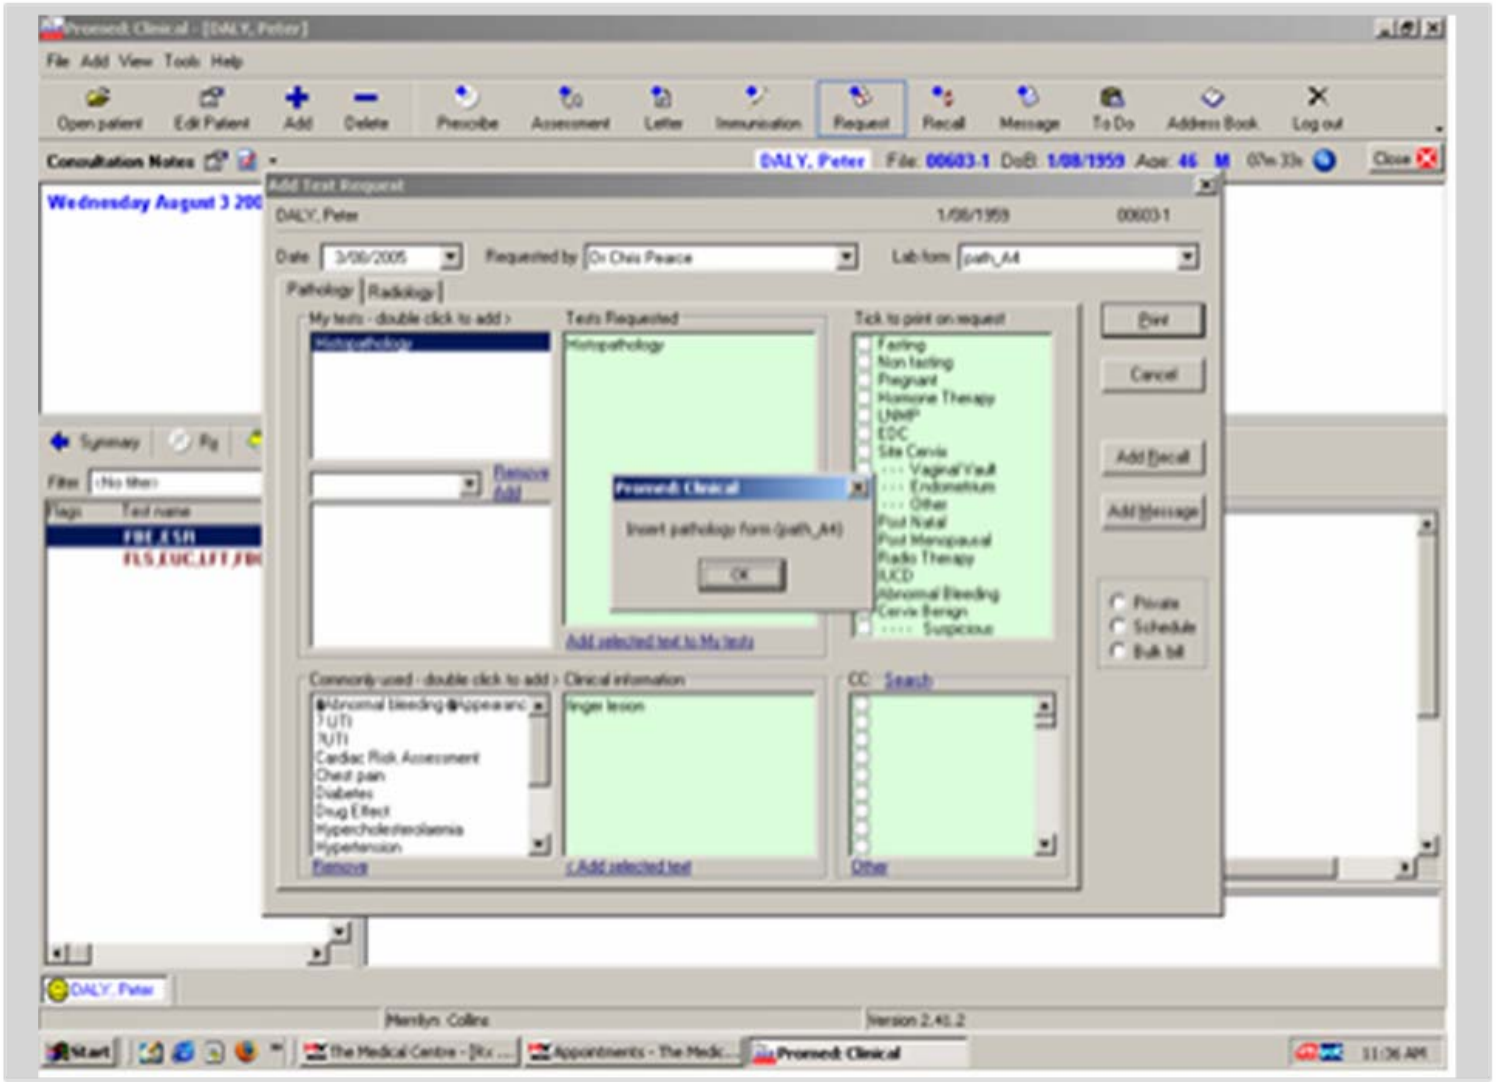
Consulting Styles vs Behaviours

Computers

- **Styles**
  - Active: forces the computer into consultation
  - Passive: Computer involved by humans.
- **Behaviours**
  - Prompting
  - Distracting
  - Informative



Passive Computer



Active Computer

DOCTORS	***Unipolar or Bipolar***
Engaging	*Engages the patient in the triad*
Disengaging	*Disengages the patient from the triad*
Cogitation/Evaluation	*Using computer as an aid*
PATIENTS	***Dyadic or Triadic***
Screen controlling	*Introduces computer into the consultation*
Screen watching	*Attends to the computer*
Screen excluding	*Ignores the computer*
COMPUTER	***Active or Passive***
Informative	*Provides Information into the consultation*
Prompt	*Reminders*
Distracter	*Distracts from the consultation*

Personalized Patient Education for Cardiovascular Risk Management: A Synergy of Behavioural Modelling, SCORE and Compositional Information Personalization Methods

Selena Davis, Syed SR. Abidi

NICHE Research Lab, Faculty of Computer Science, Dalhousie University, Halifax, Canada

Abstract

Personalized patient educational programs offer the opportunity to empower patients to self-manage Cardiovascular Disease (CVD) risk. In this paper, we present the PULSE project—Personalization Using Linkages of SCORE and behaviour change readiness to web-based Education—that provides personalized patient education for CVD risk management. Our personalization approach leverages behaviour modelling to ascertain the patient's readiness to uptake any educational interventions and behavioural attitudes towards self-management/improvement. The PULSE framework involves the calculation of the patient's CVD risk using the Systematic COronary Risk Evaluation (SCORE) algorithm, the estimation of readiness to change using the Transtheoretical Model (TTM) of intentional behaviour change, and the representation of personalization logic as Medical Logic Modules (MLM). The educational interventions were derived from evidence-based staged lifestyle modification materials and Canadian clinical guidelines for CVD risk management.

Keywords:

patient education, cardiovascular, risk assessment, behavior modelling, information personalization

Introduction

Patient education, especially for chronic health conditions, is an integral component of disease management at the patient level. In practice, patients are empowered through educational programs that enable them to make informed choices about therapeutic options, risk assessments and lifestyle modification to ensure healthy lives [1].

In general, patient education is practiced through the provision of 'generic' health educational material in the form of print materials (pamphlets or booklets) and/or Internet based health portals. However, despite both the perceived and demonstrated benefits of patient education, there is a noted lack of uptake of conventional patient education programs, despite the apparent ease of access, because the educational material is generally designed to cover the needs of a wider patient population. Patients prefer to receive information that is personalized to their individual needs and situation [1]. Personalized educational interventions are more likely to be read, remembered, experienced as personally relevant, and in turn are more effective in changing health outcomes [2].

We believe that personalized patient educational programs can be made more impacting if we take into account the patient's underlying (a) perceptions and attitudes towards his/her health risks; and (b) behavioural disposition towards the uptake of any risk modification information. Therefore, we argue that the personalization of patient education material should be guided by patient's behavioural readiness to uptake educational interventions (in addition to the patient's health profile). We pursue personalized patient education by (a) *determining* the patient's attitude towards his/her health condition and then establish their readiness level to make lifestyle changes to avoid risky behaviours; (b) *educating* the patient so that he/she contemplates lifestyle changes; and (c) *modifying* the patient's lifestyle through personalized educational material that targets both the patient's behaviour and health conditions.

Our research addresses the generation of personalized patient education programs for CVD risk management. The PULSE project personalizes educational material based on the patient's (a) 10-year risk of fatal CVD calculated using the SCORE algorithm [3]; and (b) readiness to change risky behaviour, which is determined using the TTM of intentional behaviour change, also known as Stages of Change [4]. We developed a novel compositional information personalization method that involves the dynamic composition of a personalized educational package by (i) systematically selecting multiple, topic-specific *snippets* of information based on the patient's behavioural and health profile [5]; and (ii) synthesizing the selected snippets based on a patient-specific presentation template. The personalization logic is derived from Canadian clinical guidelines and behaviour change literature, and is represented using MLMs. The educational material covers both medical and psychosocial aspects of CVD risk management, and is derived from a combination of staged lifestyle modification [6] and non-staged messages based on Canadian clinical guidelines. Finally, a web-based interface is used to present the personalized education material to the patient.

Materials and methods

We pursue fine-grained composition of a patient-specific educational package. Therefore, the entire educational material is decomposed into multiple individual educational messages, called *snippets*, where each snippet addresses a particular health issue, targets a specific set of patient parameters and is relevant to a specific Stage of Change. Our strategy is to construct a document by systematically selecting a set of snippets that are related to the patient's health conditions and behavioural Stage of Change. The patient-specific snippets are then intelligently synthesized to yield a seamless PDF-based personalized educational package. Our compositional information personalization strategy allows a fine distinction between patients and ensures that each patient receives educational interventions that are fine-tuned to his/her health needs and behavioural disposition towards risk management.

Behavior change model

We use the TTM [4] as it guides the patient through the process of modifying problem behaviour(s) and acquiring positive behaviours. We designed educational interventions that correspond to patient's needs at different Stages of Change.

Patient data capture template

The Data Capture Template (DCT) records patient information to guide the generation of personalized educational material. We used the Wellsource Coronary Risk Profile, with some modifications to meet (a) SCORE requirements, and (b) Canadian healthcare standards. The DCT was divided into four distinct sections: (1) Demographic Data; (2) Health History Data; (3) Clinical Data; and (4) Risk Behaviour Data.

Patient profile

The patient profile includes: (a) patient information collected via the DCT; (b) new patient information calculated using the DCT data; (c) the computed SCORE value; and (d) the patient's Stage of Change for each risk behaviour. The profile comprises three components: (i) CVD Risk Profile; (ii) Staged Risk Factor Profile and (iii) Non-staged Risk Factor Profile.

Message library

The message library contains a large volume of topic-specific educational interventions that are represented as 200 *snippets* of information, originating from multiple Canadian sources. At a highest level the snippets were categorized as staged and non-staged. At the next-level, the staged material was categorized into five categories, corresponding to the five Stages of Change. The non-staged material was categorized into six snippet categories—i.e. introductory (opening statements), informational (suitable action), definitional (meaning), motivational (incentive), factual (evidence), and gender-specific.

Personalization decision logic

The personalization decision logic determines the selection of the relevant snippets based on a given patient profile. To establish the decision logic, we first developed a mapping matrix that contained the 14 risk conditions identified in the DCT and potential messages targeting these risk conditions. Next, the matrix was translated into a set of symbolic decision rules—i.e. if-then statements—that map the profile elements in the IF part of the rule to specific messages in the THEN part of the rule. We used MLMs to represent the medical knowledge. In total, we developed around 300 rules and a forward reasoning rule-based engine to execute the rules.

Information presentation template

The information presentation template served as an information-structuring guide to determine the order in which the selected snippets are to be integrated. The template was divided into four sections: (1) The *Introductory* section providing patient's name, date, clinic name and the contents of the personalized document; (2) The *CVD Risk Profile* section providing both textual information and a graphical display of the patient's absolute CVD risk as computed by SCORE. (3) The *Progress* section provides a graphical display of changes in a patient's modifiable risk factor values over time; and (4) The *Risk Factor Management* section provides information on each risk factor relevant to the patient.

Delivery method

In PULSE, the educational material is presented as a PDF file that can be both viewed online (in a web browser) and printed as a document. Interaction with the PULSE system is initiated by a healthcare professional in a primary care setting. The practitioner enters the patient data into the DCT whilst consulting with the patient. Next, the PULSE system generates the personalized educational package for the patient.

Concluding remarks

The PULSE approach presents a personalized patient education system that purports a unique synergy between evidence-guided CVD risk assessment and the TTM for behaviour change readiness. We have developed a novel information personalization method that maps the patient profile to specialized educational interventions that correspond to the patient's physiological data, risk category and behavioural predisposition to lifestyle modifications. PULSE system has been qualitatively evaluated by CVD experts in a clinical setting.

Applying Tailoring Techniques for the Development of Consumer-focused and Clinician-focused Adult Depression Management Systems

[c] *Department of Biomedical Informatics, Columbia University, New York, NY, United States*

Abstract

This abstract describes the utilization of tailoring techniques for the development of evidence-based disease management systems for adult depression. TIDES is a consumer-focused system for self-care management of depressive symptoms. MODS-AD is a PDA system designed for clinicians to support depression screening and treatment planning decisions.

Keywords:

tailoring techniques, adult depression, self-care management

Introduction

With symptoms ranging from mild but chronic to more severe episodes, depression has been constantly reported as under-diagnosed and under-treated. The purpose of this abstract is to describe the application of tailoring techniques to develop two evidence-based adult depression management systems, tailored interventions for management of depression symptoms (TIDES) and mobile decision support for adult depression (MODS-AD), and to identify the important considerations while utilizing the same principles for system development.

Methods

TIDES and MODS-AD focus on different aspects of adult depression management. The development of these two programs has followed to the five steps of the tailoring process that were proposed by Kreuter and colleagues [1].

Results

1. Analyzing the problem and identifying determinants

TIDES is intended to assess the level of depressive symptoms of an individual while using the system independently. It helps to identify individuals at high risk and provide self-care management strategies for depressive symptoms. The program cannot make official psychiatric diagnoses. For MODS-AD, the program is designed to be used at the point of care in the clinical encounter in order to increase depression screening rates and adherence to guideline-based care. Clinicians have control over the final diagnostic decisions and treatment plans based on principles recommended by MODS-AD plus their clinical knowledge and experience.

2. Developing a program framework & assessment

The tailoring framework of TIDES was based on social cognitive theory [2]. The initial CES-D assessment divides TIDES users into three major groups using the cut-off points of 8 and 16 [3]. By comparing the score of the CES-D sub-scales, users with moderate risk are further divided into three groups. The secondary assessments were focused on physical activity, type of thoughts, or interpersonal relationships. On the other hand, MODS-AD is used to assist clinical depression screening and treatment planning. The framework is guideline-based [4, 5] and supported by recent published evidence. The two-step screening process (PHQ2 and PHQ9) is designed to fit into the busy clinical workflow and to avoid response burden of the patients.

3. Creating tailoring messages

The content readability and its length are two major considerations of the message composition for TIDES. In order to decrease the operational difficulties and assist the independent operation, the number of pages was increased. The prototype of TIDES consists of 74 messages with an average of 102 words per page at the readability level of 6.0. Regarding MODS-AD, because the plans of care that result from the tailoring process are designed for use by clinicians and implemented in PDA which has limited space for content presentation, they are composed in brief nursing/medical terms. Some parts provide more detailed information via help buttons.

4. Creating tailoring algorithm & automating the program

The tailoring algorithms reflect the key decision making points in the program. For TIDES, the user path has been tailored through the interactive assessment and goal-setting process. The linear design of TIDES limits the user's activity within the tailoring section. Individuals who may not fit into the purposes of TIDES are excluded at the

beginning of the system usage. The algorithm of MODS-AD includes the critical elements to reflect the clinical decision making flow of generating a depression-related diagnosis. Clinicians can choose the treatment plan options from the section tailored to a specific score on the PHQ9 plus level of functional impairment or suicidality.

5. Implementing the program and evaluation

TIDES is PC based and pilot tested with end-users. MODS-AD is PDA based and is under evaluation in a randomized control trial. The iteration of the program design is necessary to keep the information and tailoring rules updated.

Discussion

The definition of tailoring techniques highlights the two features that set it apart from other commonly used approaches to facilitate health care services. It is assessment-based at the individual level. As a result, the content of its communication can be highly individualized, going beyond risk status to develop personal plans to modify complex health problems by addressing the specific characteristics of an individual. Yet at the same time, it is truly a population approach with a potentially limitless reach for highly individualized communication among large populations.

In a recent series of well-designed studies, computer-assisted tailored programs have been shown to be more effective than conventional health communication approaches in helping some patients quit smoking, maintain balanced diet, increase their level of physical activity, and get mammograms and childhood immunizations [6-10]. The advances in information technology facilitate the utilization of tailoring information to meet the needs of individuals and health care providers. Consequently, the tailoring decision support system for clinicians in primary care settings (MODS-AD) and the tailoring self-care management system for consumers (TIDES) are possible adjunctive solutions for screening and management of adult depression.

However, although the assessment-feedback structure of tailoring programs makes them somewhat interactive, they don't come close to approximating the interactivity, intimacy, and immediacy of interpersonal communication. Tailoring communication programs such as TIDES should be viewed as complementary to the clinic encounters – a potentially powerful tool to enhance their work, not replace it. Similarly, MODS-AD was developed to assist the clinician in the detection and management of depression, not to replace clinical judgment.

Conclusion

In the area of mental health management, clinician encounters are usually the preferred service for improving health-related behaviors, due to the interpersonal contact, interactivity, and immediate feedback that can be provided with one-on-one counseling. However, the impact of such counseling on the health of populations is limited by cost and the relatively small number of individuals who can be reached by an even smaller number of trained professionals. Technology allows tailored communication programs to have broad reach and individual specificity, at a relatively low cost. As strategies for addressing low screening and treatment rates for depression, programs with tailored designs seek to identify alternative approaches that might be better suited to that person's needs or abilities and to assist primary care clinicians in achieving better health care quality.

Introduction

- Depression has been constantly reported as under-diagnosed and under-treated.
- Purpose of this paper:

  To describe the application of tailoring techniques to develop two evidence-based adult depression management systems and to identify the important considerations while utilizing the same principles for system development

  – TIDES: Tailored Interventions for management of DEpression Symptoms
  – MODS-AD: MObile Decision Support for Adult Depression

Methods

- Five Steps Tailoring Process: Kreuter and colleagues [4]

  1) Analyzing the health problem to be addressed and understanding its determinants

  2) Developing the program framework and an assessment tool to measure a person's status on these determinants

  3) Creating tailored messages that address individual variation of determinants of the problem

  4) Developing algorithms and a computer program that link responses from the assessment into specific tailored messages

  5) Implementing the program and evaluation

Results – I

Analyzing the problem and identifying determinants

- TIDES:
  - User: individual consumer
  - System operation: PC/Laptop independently at home/clinic
  - Purposes: enhance independent self-care management
    - assess the level of depressive symptoms
    - Identify individuals at high risk but cannot provide psychiatric diagnoses
    - Provide self-care suggestions
- MODS-AD:
  - User: clinician
  - System operation: PDA at the point of care
  - Purposes: increase depression screening rates and adherence to guideline-based care
    - have control over the final diagnostic decisions and treatment plans
    - based on principles recommended by MODS-AD plus their clinical knowledge and experience

Results - II

- **Developing a program framework & assessment**
- TIDES:
  - Framework: based on the social cognitive theory [2]
  - The initial assessment: CES-D
  - The secondary assessments:
    - Physical activity
    - Type of thoughts
    - Interpersonal relationships
- MODS-AD:
  - Framework: guideline-based [4, 5] and also supported by recent published evidence
  - Two-step screening process: PHQ2 and PHQ9
  - Other considerations:
    - Suicidal ideation
    - Functional impairment

Results - III

- **Creating tailoring messages**
- **TIDES**
  - **Content: readability level 6.0**
  - **Length: 74 messages with an average of 102 words per page**
- **MODS-AD**
  - **Content and length: brief medical and nursing terms**
  - **Some parts provide more detailed information via help buttons**

Results - IV

- **Creating tailoring algorithm & automating the program**
- TIDES:
  - Linear design of TIDES limits the user's activity within the tailoring section
  - No return back to the pre-assessment points
  - Goal setting through the interactive process
- MODS-AD:
  - Flexible multi-layered algorithm
  - Include the critical elements to reflect the real clinical decision making flow
  - Free choices of treatment planning options within the diagnosis section

Results -V

- **Implementing the program and evaluation**
- TIDES
  - PC based
  - Pilot tested with end-users in the usability lab
- MODS-AD
  - PDA based
  - Under evaluation in a randomized control trial

Discussion

- MODS-AD and TIDES are possible solutions for management of adult depression. Reasons include:
  - Through the multiple level assessments, the content of tailoring communication can be highly individualized.
  - It is truly a population approach with a potentially limitless reach for highly individualized communication among large populations.
  - Computer-assisted tailored programs have been shown to be more effective than conventional health communication approaches [6-10].
  - The advances in information technology facilitate the utilization of tailoring information to meet the needs of individuals and health care providers.

Limitations

- TIDES:

  To enhance the regular clinical work, not replace it
- MODS-AD:

  To assist the clinician in the detection and management of depression, not to replace clinical judgment

Conclusion

- Technology allows tailored communication programs to have broad reach and individual specificity, at a relatively low cost.
- Programs with tailored designs seek to identify alternative approaches that might be better suited to that person’s needs or abilities and to assist primary care clinicians in achieving better health care quality.

A Care Assessment System to Support Community-Based Healthcare

Mohan Karunanithi, Antti Sarela, Justin Boyle, Niranjan Bidargaddi, Anthony Maeder

E-Health Research Centre, CSIRO ICT Centre, Brisbane, Australia

Queensland Government

EHEALTH RESEARCH CENTRE

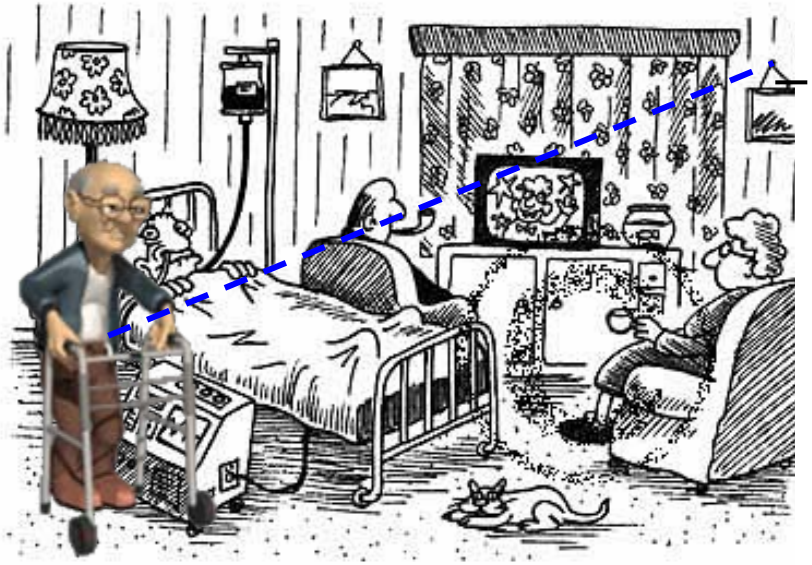
Background

- Pressures on health care delivery models because of:
  - Ageing population
  - Prevalence of chronic diseases
  - Diminished workforce

-> **Solution to improve care process :** Community based health care setting including multi-disciplinary care teams and detailed care plans

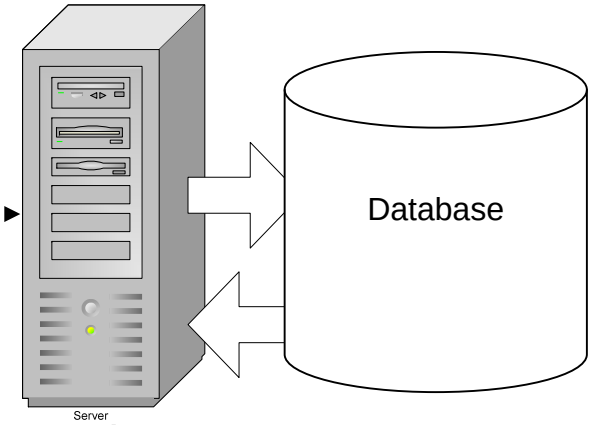
- Requirements:
  - Patient's health data should be collected and monitored also at home
  - Information on patient's health status should be available to care personnel at any time also outside the normal care circle

-> **Technology solution:** Software platform that provides monitoring and assessment information to the care team in the community care environment



Patient monitoring at home

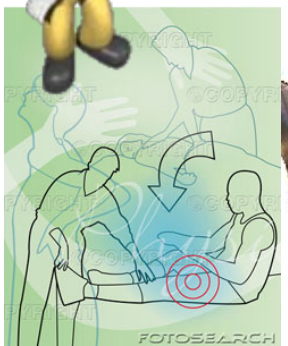
Health data transfer



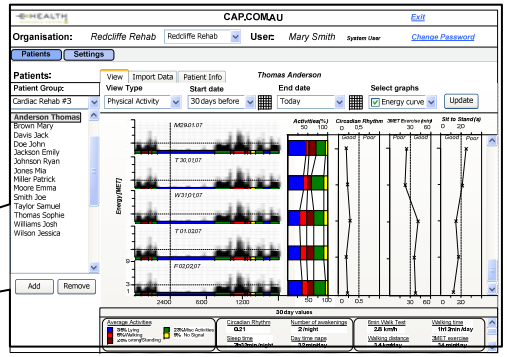
Centralized Server for data processing and storage

Community-based Healthcare

Assessment of patient condition and treatment



Web based GUI to display relevant health information to the care team

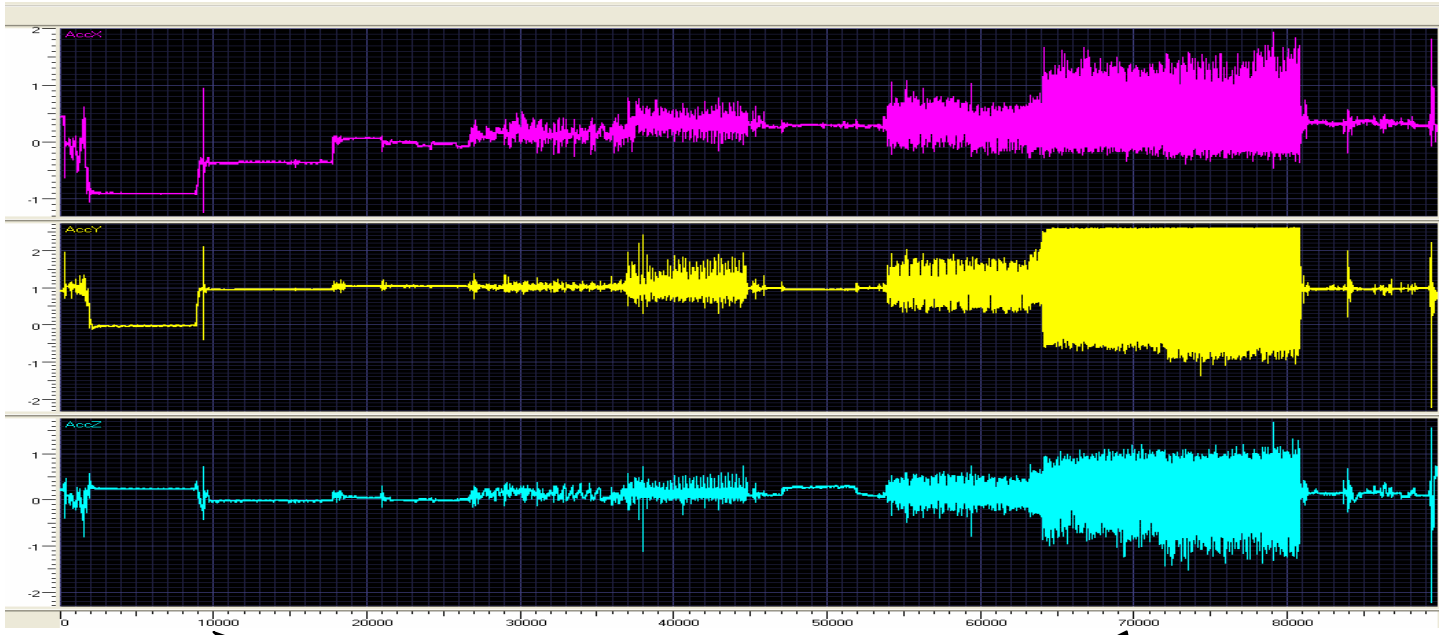


Methods

- Development of software platform technology that provides:
  - Ambulatory monitoring capabilities to collect patient data at home
    - Accelerometer, heart rate, and other health data
  - Calculation of clinically significant measures from the measured data to enable health assessment of the patients
  - Continuous availability of the measures for assessment to be performed at different time points and to monitor patient's progress according to their care plan
- Clinical trial to develop measures to assess patients with chronic diseases such as Cardiovascular Disease (CVD) and Chronic Obstructive Pulmonary Disease (COPD)
  - Trial employs ambulatory monitors worn by the patients to measure their physical movement activity and ECG
  - Measurement data is downloaded to a PC which analyses the data and displays clinically relevant information that the care team will use to assess the patient's condition

Ambulatory monitor: Waist worn accelerometer

Records X-, Y- and Z- axis acceleration



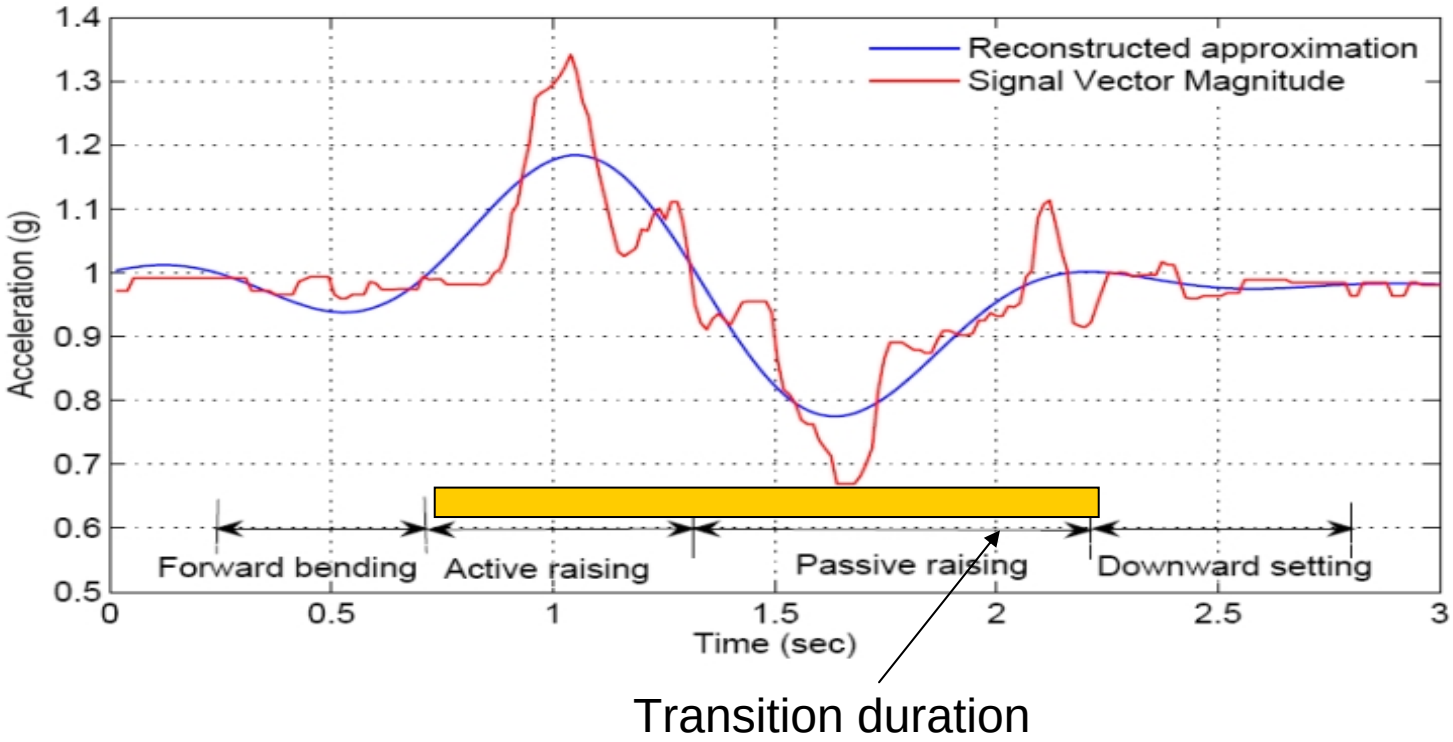
Movement patterns:

Sit to stand transition

Walking

Signal processing example

- Sit to stand transition duration can be calculated from accelerometer data by using wavelet transformation [1]



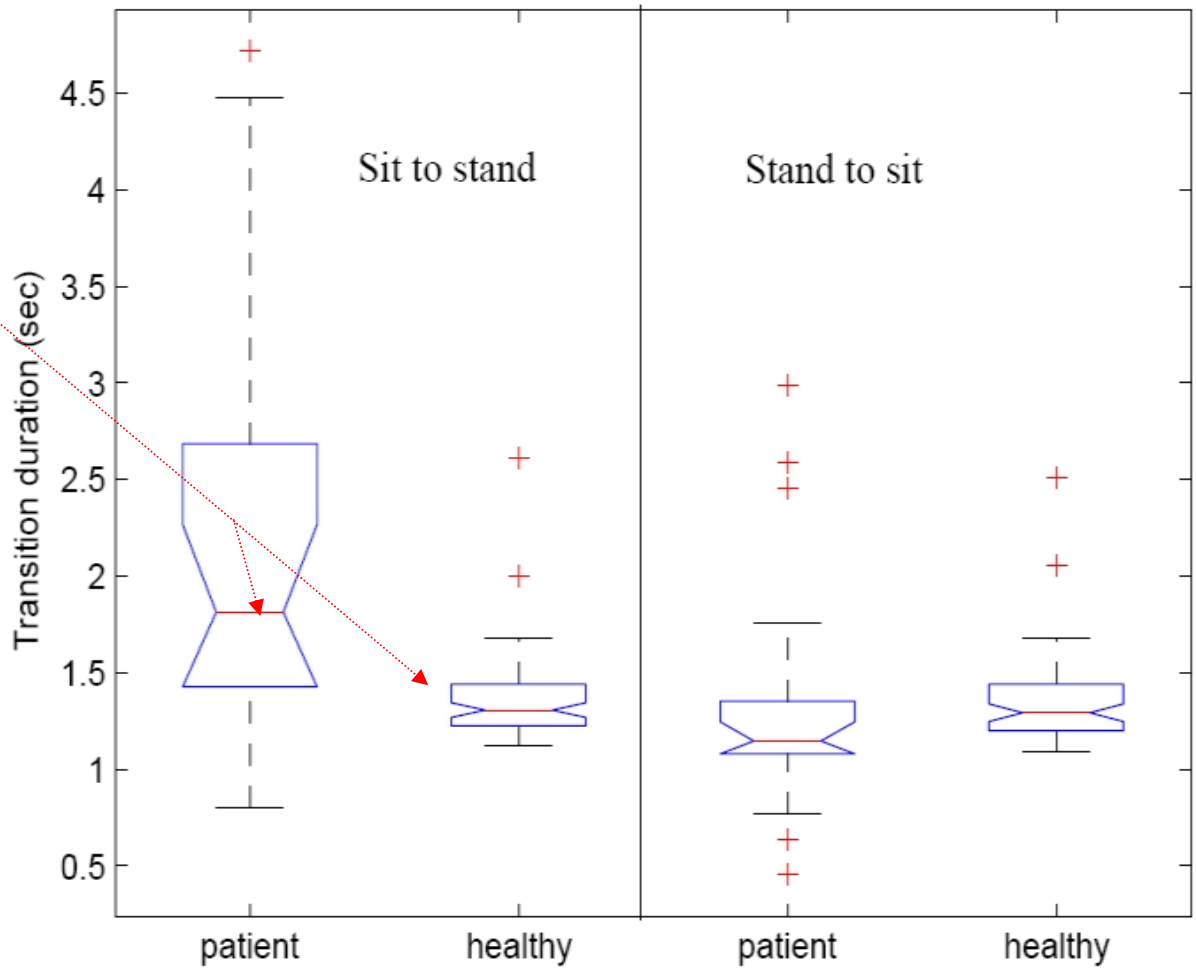
Transition duration significance

Sit to stand duration

- Statistically significant difference between healthy persons and elderly patients with medical conditions
- Sit to stand transition is also a good indicator to assess mobility of patients with heart diseases [2]

Stand to sit duration

- No significant difference observed

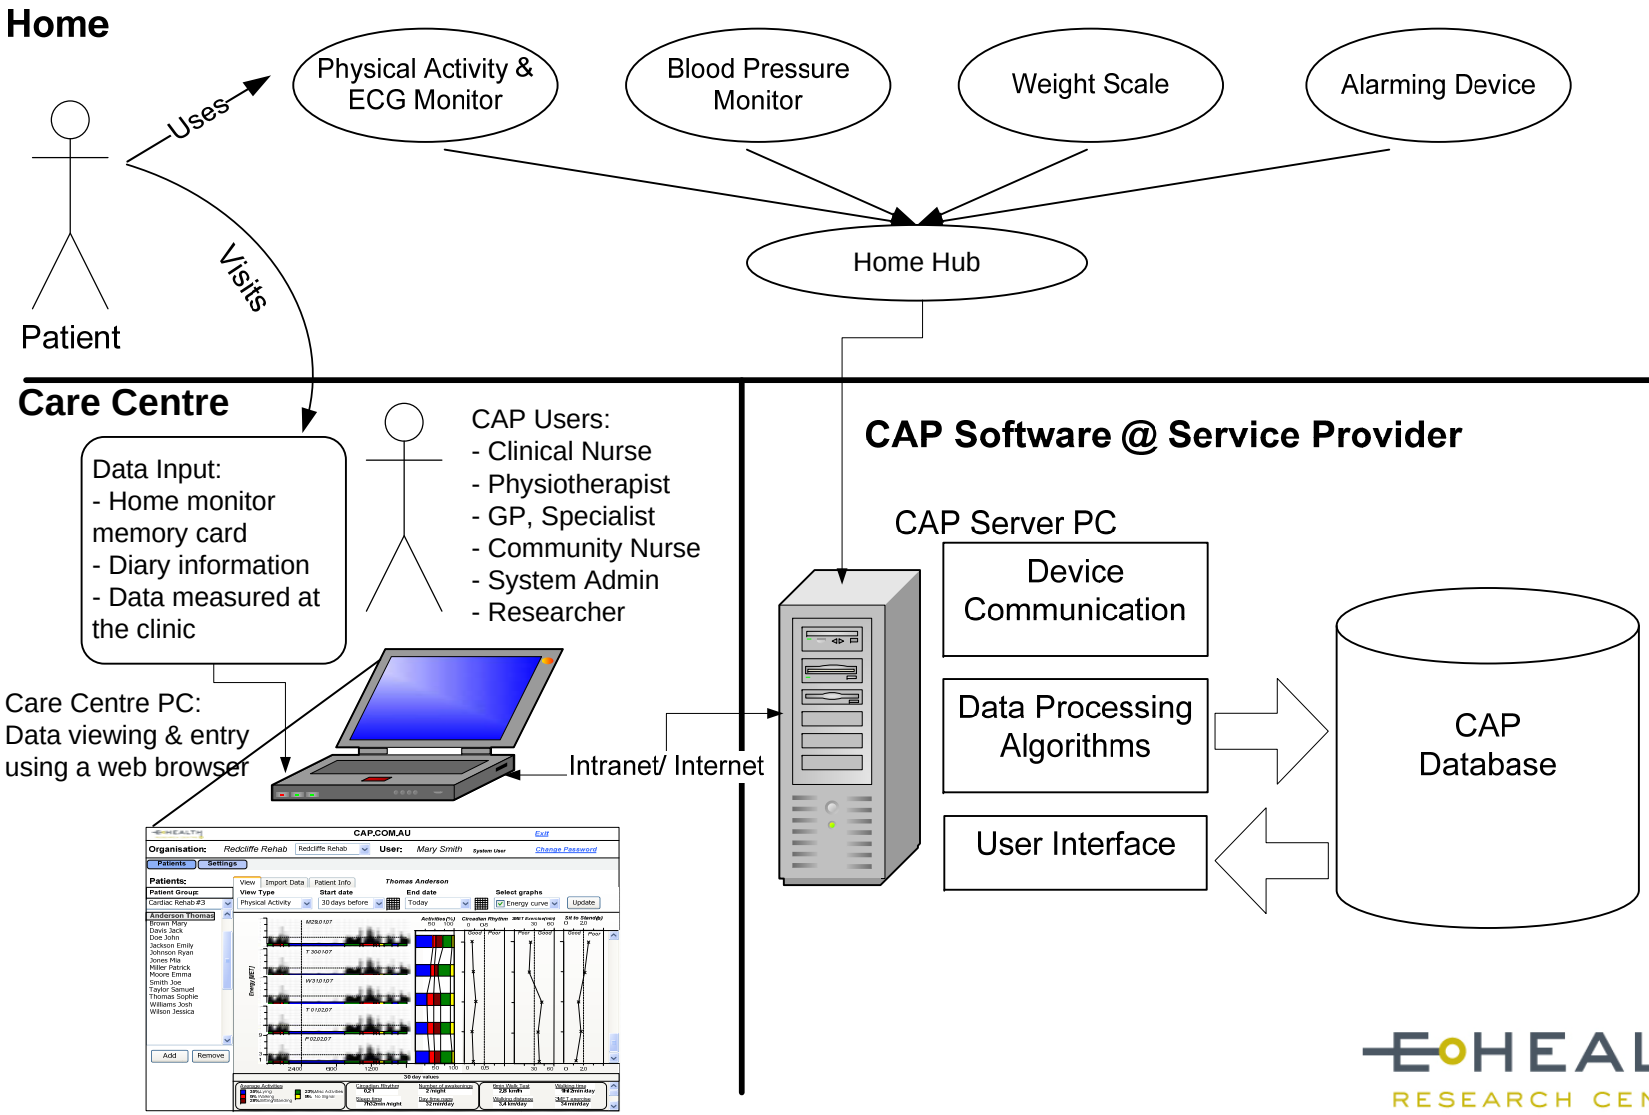


Data source: Princess Alexandra hospital, Brisbane

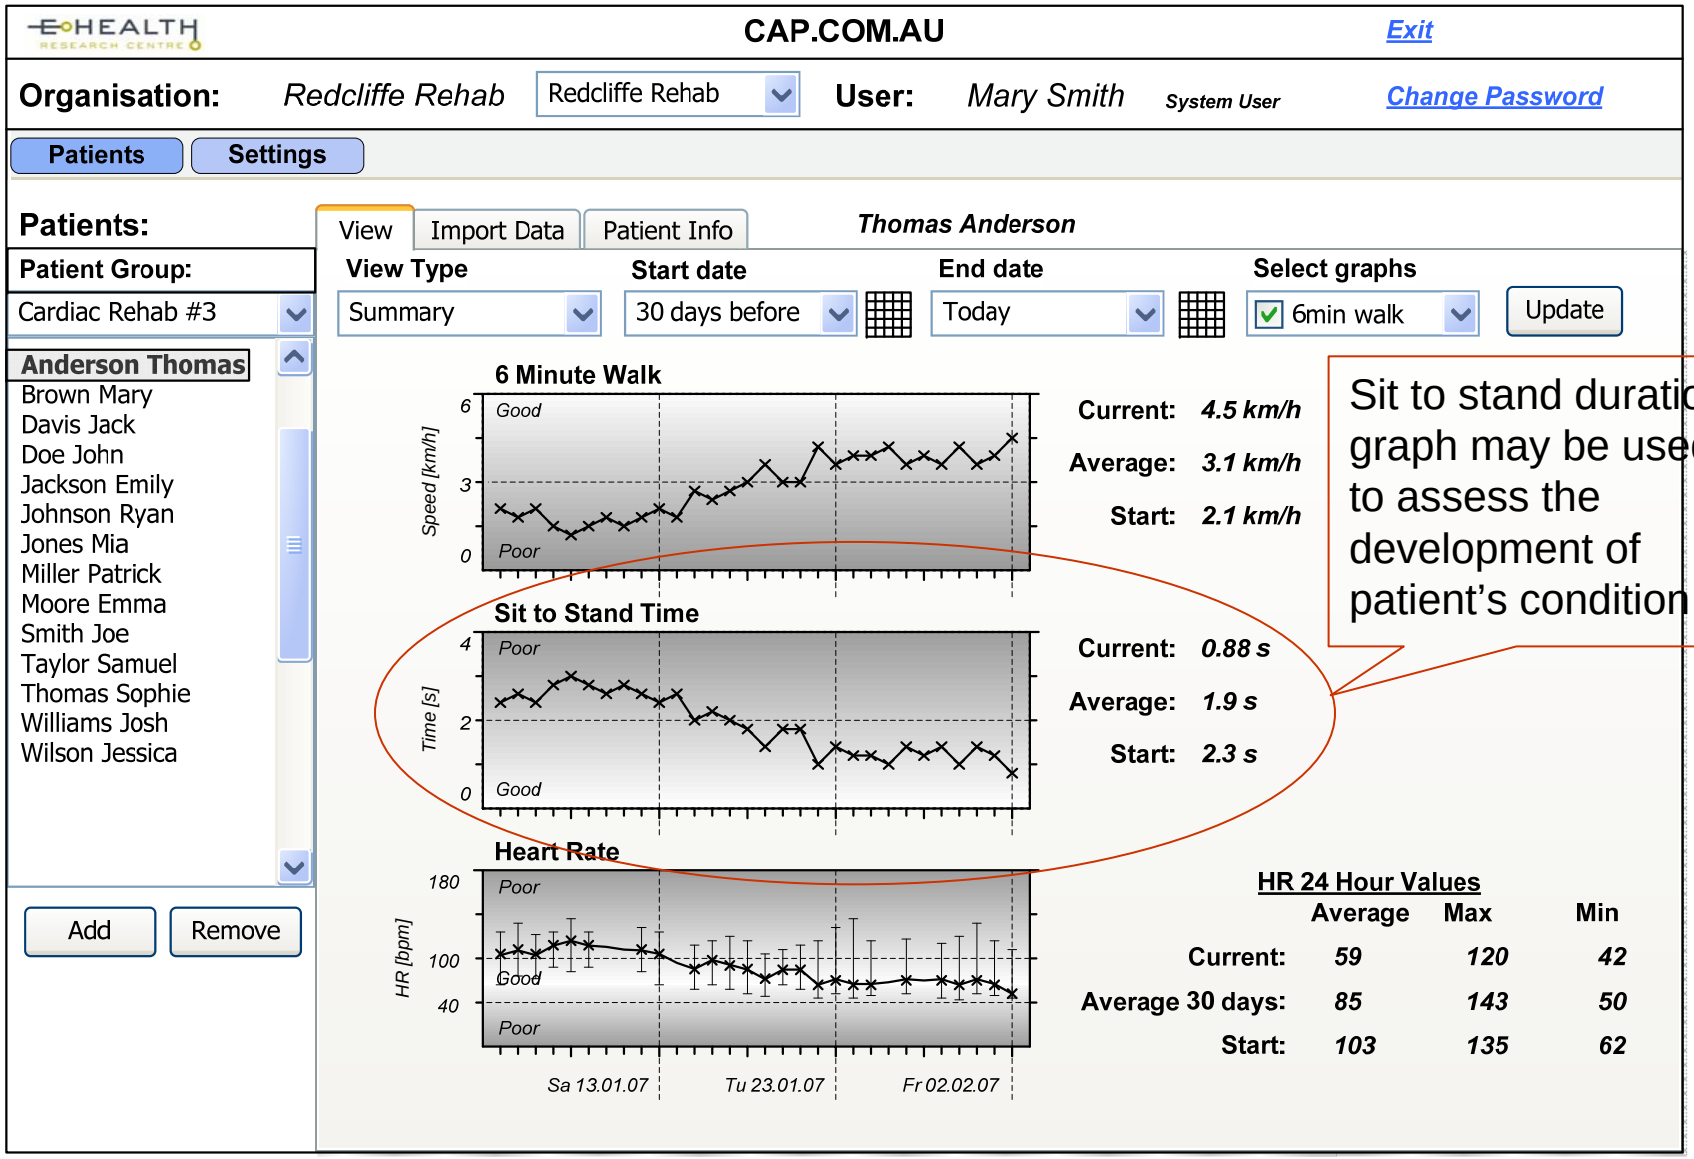
Care Assessment Platform (CAP) Software

- Main features
  - Convert and manage data form ambulatory devices fitted on patients
  - Perform data analysis to provide clinical measures that describe the patient's health condition
  - Store measurement data and related health information in a database
  - Provide a GUI for health care personnel to access the stored and analysed data
- Design principles
  - Open data exchange interfaces to connect various ambulatory monitoring devices
  - Highly modular structure to enable easy development of future applications and enhanced data analysis
  - GUI designed together with health care professionals to present clinically relevant information

CAP System Architecture



CAP GUI Summary View



Conclusion

- A care assessment software platform is being developed through a clinical trial conducted with ambulatory monitoring of COPD and CVD patients in a community care environment
- Clinical measures such as sit to stand transition time, metabolic expenditure and walking speed can be calculated and displayed to assist care team in assessment of patient's physical condition
- Future work:
  - Measure the effectiveness of the software platform in terms of health care benefits such as the ability to reduce hospital admissions
  - Incorporate the creation and monitoring of individual care plans to the software platform

A Care Assessment System Supporting Community-Based Healthcare Environment

Mohan Karunanithi, Antti Sarela, Justin Boyle, Niranjan Bidargaddi, Anthony Maeder

E-Health Rresearch Centre, ICT-Center, CSIRO,Brisbane, Australia

Abstract and objective

Due to the large demands on the health system caused by factors such as the ageing population, prevalence of chronic diseases and shortage of healthcare worker, the trend has been to move the healthcare system into the community. A community based care setting encompasses a multi-disciplinary care team who would need to interact regularly between themselves and with patients at home. To enable such interaction, monitoring of patients need to be made regular and assessments made from such monitoring need to be accessible to the respective member of the care team at different timepoints of their care. The aim of this project is to develop a software platform technology that would provide such monitoring and assessment information in a community care environment. The development will incorporate clinical trial in which patient activity and physiological measures will be monitored with ambulatory devices, and the information being processed by the software platform to provide clinical measures for assessment to the multi-disciplinary care team. The outcome of the trial will establish the effectiveness and the benefits in provide chronic disease management in community care setting.

Keywords:

community care, chronic diseases management, health assessment

Introduction

It is well established that there are severe current pressures on our health systems caused by diverse factors such as ageing population, burden of chronic diseases, shortage of resources, diminished health workforce. Changes in healthcare delivery mechanisms by adopting new workforce models and workplace practices have been widely advocated to ease these pressures. Recent trends towards making such changes include *patient-centric care models* incorporating extended carer teams and detailed care plans, an*d place-based care initiatives* which permit care delivery to be conducted in community-based settings away from hospitals.

These approaches present a number of challenges on the human front. They require learning of new skills and protocols involving coordination of a large and diverse group of participants, only some of whom will have team skills and health systems domain knowledge. They also require substantial amounts of health information on the patient to be gathered and monitored, to ensure that care is proceeding beneficially, and allowing adjustments to be made to the care plan on an individual patient level. In addition, they need to respond to an expectation that comprehensive, updated and reliable information on all aspects of the patient's care progress should be available in future episodes involving clinicians and facilities outside of the normal care circle.

Methods

All of the above human issues can be addressed in part by use of platform software technology that provides:

- Monitoring capabilities to assess patient/disease status.
- Clinical measures derived from monitoring to enable health assessment of patient and also generate care plans
- Availability of these clinical measures for assessment to be performed at different timepoints and monitor patient progress against their care plan.

Development of such software platform technology has been taken by our research center through a clinical trial being conducted at a Brisbane community-based care setting. The clinical trial focuses on two areas of chronic diseases: chronic obstructive pulmonary (COPD) and cardiovascular diseases (CVD), which are most prevalent to the community of that setting. The trial employs ambulatory monitors worn by these cohorts of patients to measure their physical activity and vital signs. Information is either downloaded or streamed wirelessly to a PC with the software platform, which analyses the data for clinical assessments of physical activity and vital signs such as heart rate and respiratory rate. These clinical assessments are made available to the multi-disciplinary care team involved in care of the patients being participating in the clinical trial. From the clinical assessments used to measure against the care plan, a more perceivable feedback will be provided to patient to enable self-management.

Results

In the course of the clinical trial, the software platform technology will derive and adopt:

- Computational tools for the relevant clinical measures which provide immediate feedback of patient assessment for clinical decision making.
- User interface for easy interaction by the multi-disciplinary team
- Information flow that adapts to existing workflow of the community-based healthcare setting
- Key performance indicators used to contributes to care planning and its progress.

Following the development of the platform, the trial will establish its effectiveness and the engagement of the multi-disciplinary care team in providing care to chronic disease patients at various points of care in the community care setting. It will also establish the effectiveness of the platform to provide chronic disease management at different levels of risks of the CVD and COPD diseases (primary prevention, secondary prevention, and tertiary prevention).

Conclusion

The shift in the current health system to community care requires a change in workforce, workflow and interaction with the patients at homes to provide better quality of care. To address this change, a care assessment software platform technology is being developed through a clinical trial conducted with ambulatory monitoring of COPD and CVD patients in a community care environment. The trial will establish the effectiveness of the software platform to provide: care assessment of COPD and CVD patients through ambulatory monitoring technology, the accessibility of clinical information to the respective members of the care team, and the capabilities to create and monitor care plans. This effectiveness will be measured in accordance with healthcare benefits such as the ability to reduce hospital admissions, individualized care plans, elimination of duplication of assessment, and encouraging self-management.

Prevention and Treatment of HIV/AIDS patients through ICT, A Pilot Study in AIIMS, New Delhi INDIA

Sushil K. Meher[a], **A. Biswas**[b]

[a] Department of Computer Facility, All India Institute of Medical Sciences, New Delhi, INDIA
[b] Department of Medicine, All India Institute of Medical Sciences, New Delhi, INDIA

Introduction

ICT is revolutionizing the medical science that tremendously improved the patient education as well as case and management system.. India is having 3.97 million people living with HIV/AIDS, which is 2nd height in the world next to South Africa. It has been seen that the HIV/AIDS patients are poor in knowledge about HIV/AIDS. We studied 150 HIV/AIDS patients in our medical clinic: where we observed that 90%(135) patients know what is Internet, 33.3%(50) uses the computer out of which 14.7%(22) patient uses in work place, 12%(18) at home and 6.6%(10) at cyber café. 3.3%(5) patients use Internet to update knowledge. 73.3%(110) patients want to communicate to the doctor through email. 93.3%(140) patients feel comfortable to communicate doctor through email. 80%(120) patients thinks that doctor/hospital visit could be reduce if the doctor's available or response in the internet or email So Information technology can help to reduce hospital visit, improve batter care and management of HIV/AIDS patients in developing country if proper recourses are provided to the institutions.

Multimedia effect on preoperative Knowledge and postoperative recovery of patients undergoing laparoscopic cholecystecomy

A.Stergiopoulou[a], K.Birbas[b], T.Katostaras[c], M. Diomidous[c], J.Mantas[a]

[α] *Laboratory of Health Informatics, Faculty of Nursing, National and Kapodistrian University of Athens, Athens, Greece*

[b] *Department of Surgery, Faculty of Nursing, National and Kapodistrian University of Athens, Athens, Greece*

[c] *Department of Public Health, Faculty of Nursing, National and Kapodistrian University of Athens, Greece*

Patient education

- Patient education is defined as the process of influencing patient behavior and producing the changes in knowledge, attitudes and skills necessary to maintain or improve health. The more educated a patient is, the more likely he is actively engaged in communication.
- Many different approaches to pre-operative education have been used including:

(a) group lectures,
(b) individual teaching,
(c) printed information,
(d) learning packages
(e) audio-visual presentations and
(f) combination of the above

Materials and Methods

- Aim of this study is the evaluation of of the impact of a multimedia CD (MCD) on patient's undergoing elective Laparoscopic Cholecystectomy preoperative knowledge, anxiety and postoperative recovery.
- One hundred and twenty consecutive candidates for elective LC were assigned randomly to four groups.

  (1)Group A included 30 patients preoperatively informed regarding LC through the MCD presented by Registered Nurse (RN).

  (2)Patients in group B (n=30) were informed through a leaflet.

  (3)Patients in group C (n=30) were informed verbally from a RN.

  (4)The control group D included 30 patients informed conventionally by the attending surgeon and anesthesiologist, as every other patient included in groups A, B, C.

The Multimedia CD

- The CD was designed in order to be flexible, dynamic, portable and cheap, permitting easy navigation even to someone unfamiliar to a computer machine. Screen design is consistent. Fast access to menus and screens are possible. Regarding controls, exit, backward, forward and skip functionality are available all the time.
- The multimedia program contains information concerning fundamental elements of bile anatomy and physiology, aspects of the disease (cholelithiasis), details on the procedure (LC), and the alternative options (open cholecystectomy), possible complications, duration of hospital stay and advices about recovery and life after LC.

Preoperative and Postoperative Questionnaire

- All patients after the structured informative session and before the operation fulfilled a preoperative questionnaire which contained eleven knowledge questions and an anxiety scale. All knowledge questions scored equally with others and the anxiety scale was conducted using the translated Amsterdam Preoperative Anxiety Scale and Information Scale (APAIS) on which scores could range from 6 to 30.
- As soon as the operation ended postoperative pain and nausea scores were measured using a Numerical Rating Scale (NRS) scale, 8 and 16 hours after the patient had returned to the wards.

Table 1 Multiple regression analysis for the variable “Knowledge score”.

Variable	Knowledge score P value (Adj.R^2) A, B(CI of B)
Group C	*0.009 (0.3)* *9.119,- 0,662 (-1.156_-0.168)*
Age	*0.05 (0.30)* *9.119,- 0.490 (-0.980_-0.0)*

Table 2 Multiple regression analysis for the variable "APAIS II".

Variable	APAIS II P value (Adj.R^2) A, B(CI of B)
Group C	*0.001 (0.206)* *2.697,-1,667 (-2.595_-0.739)*
Educational level	*0.001 (0.206)* *2.697, 0.331 (0.140_0.523)*

Table 3 Multiple regression analysis for the variable "APAIS ".

Variable	APAIS P value (Adj.R^2) A, B(CI of B)
Gender	*0.03 (0.133)* *19.279, -2.341 (-4.452_-0.23)*
Age	*0.007(0.133)* *19.279, -2.353(-4.064_0.642)*
Group D	*0.003 (0.133)* *19.279, 3.561 (1.215_5.907)*

Table 4 Multiple regression analysis for the variable "Pain score".

Variable	Pain score P value (Adj.R^2) A, B(CI of B)
Gender	*0.000 (0.147)* *4.028, -0.899 (-1.363_-0.434)*
Group D	*0.013(0.147)* *4.028, 0.658 (0.144_1.172)*

Conclusions of multiple regression analysis

- In the multiple regression analysis, structurally informed patients and specifically groups A and B, achieved a better knowledge score regarding LC, answering correctly to more questions comparing to study group C and of course control group D, ($p=0.009$), as it is shown in Table 1. This finding suggests that knowledge gain during conventional informative sessions is suboptimal.
- Not surprisingly, patients older in age, achieved lower knowledge score than younger patients independently of the educational tool used with $p=0.05$
- Our results, in the multiple regression analysis, proved that conventional information provided in patients of group D increases patient anxiety. Specifically, patients informed only by their doctor had a higher APAIS score than the patients of groups A, B, C ($p<0.05$, see Table 3). Also older and male patients expressed lower anxiety levels than the younger female ones with pvalue=0.007 and pvalue=0.03 respectively.

Conclusions of multiple regression analysis

- According to the study, patients who were informed verbally expressed a lower need for preoperative information comparing to the rest of the groups (p value=0,001) and this need is higher for patients who were better educated (p value=0,001)(Table 2). We can assume that at least in Greece, patient's preoperative need for information is not full filled during conventional informative sessions.
- Patients who were informed appeared to feel less pain than those who were informed conventionally (p value=0,013). Especially male patients found postoperative pain less disturbing and recovered faster than women who spent more time in bed (p value =0,000)(Table 4).

[c] *Department of Public Health, Faculty of Nursing, National and Kapodistrian University of Athens, Greece*

Abstract

Objective: Aim of this study is the evaluation of the impact of a multimedia CD (MCD) on patient's undergoing elective Laparoscopic Cholecystectomy (LC) preoperative knowledge, anxiety and postoperative recovery.

Methods: One hundred and twenty consecutive candidates for elective LC were randomly assigned to four groups. Group A included 30 patients preoperatively informed regarding LC through the MCD presented by a Registered Nurse (RN). Patients in group B (n=30) were informed through a leaflet. Patients in group C (n=30) were informed verbally from a RN. Finally, the control group D included 30 patients informed conventionally by the attending surgeon. Preoperative assessment of knowledge about LC was performed after each informative session through a questionnaire. Evaluation of preoperative anxiety was conducted using Amsterdam Preoperative Anxiety Scale (APAIS). Postoperative pain was measured using a Numerical Rating Scale (NRS).

Results: In multiple regression analysis, group C achieved the lower Knowledge score comparing with Group A and B ($p=0,009$ $r^2=0.3$).

Conclusions: It is believed that multimedia should be incorporated and not replace the traditional relationship between health professional and patient.

Keywords:

Laparoscopic Cholecystectomy, Multimedia CD, Patient education, Preoperative Information

Introduction

Patient education

Patient education is defined as the process of influencing patient behavior and producing the changes in knowledge, attitudes and skills necessary to maintain or improve health. As it is well known patients and their families express the need to communicate and understand the events that occur throughout the course of their disease as Hannah et al say.[1] The more educated a patient is, the more likely he is actively engaged in communication. [3],[4]. Patient education can empower patients to become full participants in their care through enhanced communication and a strong patient-provider relationship. Educational materials designed to deliver information and promote active participation in health care decisions can be effective tools for empowering patients. Consumers are faced with an economic climate that scrutinizes health care services in terms of their outcomes. [4],[5].

Materials and methods

Aim of this study is the evaluation of a structured informative session using a Multimedia CD (MCD) in patients undergoing elective LC. The study focuses on the impact of preoperative informing on (a) patient's preoperative anxiety and (b) patient's postoperative pain [6].

The multimedia CD

The Multimedia CD is a specifically developed multimedia health educational product based on Toolbook Asymetrix, version 8.5, Macromedia Company on an AMD 2000+ 1,6GHz multimedia computer under Windows XP professional. The preoperative session performed in the patient ward with the use of a laptop computer. The MCD contains animation, narration and photographs which can reinforce patient's understanding and decrease anxiety.

Participants and data collection

From July 2005 to July 2006, 120 consecutive patients, candidates to elective LC for cholelithiasis, were considered for enrolment in the trial. Exclusion criteria were: (a) patients older than 75 years and younger than 18, (b) patients with an American Society of Anaesthesiologists (ASA) physical status score greater than 2, (c) patients unable to understand Greek, (d) patients with serious sight and deaf impairment. Informed consent for participation in the trial was obtained and the trial was approved by the Administrative and Scientific Council of the Patras University Hospital, Patras, Greece and the "Attiko" University Hospital, Athens, Greece.

Patients were assigned randomly to four groups: **Group A** included 30 patients, preoperatively informed about the scheduled operation through the MCD, presented by the Registered Nurse (RN). **Group B** included 30 patients pre-

operatively informed through the leaflet which was delivered to the patients without the presence of the RN. In **Group C,** there were 30 patients who were informed verbally from the RN and finally, the control **Group D** included 30 patients, who had the conventional preoperative information by the attending surgeon and anesthesiologist, as every other patient included in groups A, B, C. The information leaflet and the MCD was available to patients for 20-30 minutes. Four hours after the completion of each informative session of each group, RN collected the completed patients' questionnaires which had given to them, earlier. Patients in group D fulfilled the same questionnaire. All the data were collected in a randomized way.

Assessment of preoperative knowledge about cholelithiasis and LC, was performed, using "closed, true-false" questionnaire, specifically developed. Each question was scored equally with the others yielding a maximum score of eleven. Evaluation of preoperative anxiety was conducted using the six items of the translated Amsterdam Preoperative Anxiety Scale and Information Scale (APAIS) – subdivided by Anxiety Scale (APAIS I) and the Need-for-Information Scale (APAIS II) [7],[8]. Postoperative pain score were measured using a Numerical Rating Scale (NRS) scale, 16 hours after the patient had returned to the wards. The NRS scale consists of 11-points (where 0 indicates no pain at all, and 10 the most severe pain imaginable) [9],[10].

Results

There were 77 (64,2 %) women and 43 (35,8 %) men enrolled in the trial. Eighty one patients (67,5%) had a previous operation in their history. Seventy nine (65.8%) patients with ASA I and 41 (34.2%) with ASA II were included in the study, respectively. The mean age of patients was 53.07 years (range: 18-75). Thirty six patients (30 %) were familiar with the use of computers. In multiple regression analysis, the dependent variables "Knowledge score", "APAIS II", "APAIS", "Pain Score", were inserted. Those dependent variables were related with the independent variables in order to seek for any statistical significance.

Discussion

Effective informative sessions provided by the health professional, require specifically developed educational tools. In this study, we investigate the effect of MCD on patient's postoperative recovery. In the multiple regression analysis, structurally informed patients and specifically groups A and B, achieved a better knowledge score regarding LC, answering correctly to more questions comparing to study group C and of course control group D, ($p<0.009$, $r^2=0.3$). This finding suggests that knowledge gain during conventional informative sessions is suboptimal. Not surprisingly, patients older in age, achieved lower knowledge score than younger patients independently of the educational tool used with p value=0.05 and $r^2=0.3$. In the current paper, there was no extra study for long-term benefits of patient education as it was believed that according to the study of Triggs et al, there would be none [11]. Patients who were younger in age and were informed by the leaflet and the MCD achieved greater knowledge score comparing with the older patients who were being informed by the doctor or only by the RN. Ng SKS et al[12] found that provision of preoperative information regarding the recovery process leads to significant anxiety reduction. It is also known that preoperative information would reduce preoperative anxiety[13]. Our results, in the multiple regression analysis, proved that conventional information provided in patients of group D increases patient anxiety. Specifically, patients informed only by their doctor had a higher APAIS score than the patients of groups A, B, C ($p<0.05$, $r^2=0.133$). Also older and male patients expressed lower anxiety levels than the younger female ones with p value=0.007 and p value=0.03 respectively. Higher APAIS score means that the patient felt more preoperative anxiety. Choi-Kwon et al [14] underlines in his study that health professionals do not know what exactly patients want to know about stroke. Specifically, the Need-for-Information Scale (APAIS II) is lower in patients informed verbally by the RN ($p=0.001$, $r^2=0.206$) and higher in patients who were better educated (pvalue=0.001, $r^2=0.206$). The patients with a high APAIS II score feel that they have not been informed adequately. In our study, patients who were informed through a structured informative session and especially patients in group C expressed smaller need for preoperative information than the patients of control group D. We can assume that at least in Greece, patient's preoperative need for information is not full filled during conventional informative sessions. It is widely accepted that preoperative information induces rapid postoperative recovery. Giraudet et al[15] reports a strong positive effect of patient education to the reduction of postoperative pain. In our study, patients in groups A, B, and C reported less postoperative pain during the first 16 hours ($p=0,013$ $r^2=0.147$). It is also mentioned that in multiple linear regression analysis men appear to feel less pain than women ($p<0.001$, $r^2=0.147$). This aspect is strongly suggested by Keogh et al[17] also confirming significant differences in pain responses regarding gender. Morin et al [16] has also shown that women seem to find post-operative pain more intense than males, although men are more disturbed than women by the low levels of persitent pain.

Conclusion

The multiple regression analysis did confirm the statistical knowledge significance for the MCD. It seems that both

MCD with the presence of the RN and the leaflet can improve the quality of health care increasing learning transfer. On the other hand, specifically developed MCDs for different populations (regarding gender, age or educational level) have to be tested in clinical practice to provide a therapeutic approach to personalised needs. However, the impact of MCD on preoperative anxiety and postoperative pain is less obvious. As this study has not finished yet, we feel that this significant relationship will become more evident in the near future.

Feasibility Study of Incorporating Personal Digital Assistants (PDAs) into a Problem-Based Learning Approach to Medical Education at the University of Wollongong

Rattiporn Luanrattana, Khin Than Win, John Fulcher

Health Informatics Research Centre, University of Wollongong, Northfields Avenue, NSW 2522, Australia

Abstract

Objective: To determine the key functionalities of personal digital assistants (PDAs) applicable to medical education. Study design: Interview and focus group were designed. The in-depth interviews were conducted with the medical school stakeholders in order to gather the needs and interpretation about the PDAs functionalities in medical education. Results: Based on a comprehensive review and findings from interviews, four significant functionalities of PDAs were found, these being (i) a clinical log, (ii) a personal portfolio (or e-portfolio), (iii) reference information, (iv) communication and connectivity. Conclusion: There is considerable potential for employing PDAs as a learning tool in medical education.

Keywords:

personal digital assistants, medical education, problem-based learning

Introduction

The University of Wollongong (UOW) established a Graduate Medical School (GSM) and accepted students for graduate entry in 2007. The medical curriculum was designed to use 93 clinical problems based on the contents of the core curriculum. The core delivery strategy is case-based learning by monitoring the students' progress through a whole course as an independent learning exercise. The use of IT is integrated into the course in order to assist in course delivery. Students start to practice in the regional area from year 1, and are required to practice in clinical placement in a rural setting for a 40-week period. IT will be integrated and facilitate learning while the students are practicing in the clinical placement.

The purpose of this research is to study the feasibility, applicability and functionalities of incorporating PDAs into medical education especially for the UOW GSM. Accordingly, the research question for this study is: what are the key functionalities of PDAs applicable for medical education in a problem-based learning (PBL) curriculum? To answer this, it is essential to understand the general context of PDAs, their functionalities, how they have been applied in the medical and nursing professions, and barriers to using such devices therein. It is necessary to understand the roles of using PDAs in medical and nursing curricula, how they have been used in medical and nursing curricula, and what functionalities have been integrated into medical education.

PDAs have been used for clinical references, tracking clinical encounters and clinical decision making and e-learning in medical education, and they can provide a user friendly interface and multimedia tools enabling students to learn at their own pace [1-3]. Furthermore, using PDAs as an educational tool has a high degree of acceptance from clinical students. The important barriers for incorporating PDAs into the healthcare sector are data security, patient privacy, privacy protection and interception [4-6]. Moreover, data access, data storage and retrieval and the loss of data [7] are major concerns in the use of PDAs in clinical practice. On the other hand, usability, interference and security are not a problem if the systems are well designed and free from the barriers previously mentioned [5]. Other important problems are interoperability, interference, patient privacy, scalability, and connectivity [5, 6, 8]. The use of PDAs in medical education can help medical faculty to monitor student performance and bridge the gap between student education and their clinical experiences, as students can take PDAs into clinical placements while having contacts with patients. Almost two-thirds of US medical schools integrate PDAs into residency programs [9]. Various uses of PDAs in medical education are student patient log systems, classroom assessment systems, teaching and interaction evaluation, objective structured clinical examinations (OSCE) and medical research [7, 9, 10].

Methods

Interviews and focus groups were designed accordingly. At this stage in-depth interviews with 15 stakeholders, have been undertaken; these aim to bring out information about the meaning, complication and interpretation from participants [11]. Moreover, they allow new understandings and theories to be formulated during the research process [11-13]. Results from these interviews have yet to be analyzed into different themes using `NVivo` software. These themes will then be used to conduct focus groups in the next phase of the project.

Interviews

Relevant medical stakeholders were contacted and interviewed face-to-face. The open-ended questions were asked about the appropriate PDA functionalities for students to use during their study years, what kind of information needed to be stored in the PDAs, how PDAs can be used in PBL approach, how to synchronize data back to servers, and what type of network connection is used. The interviews lasted approximately 30 minutes for each participant. All interviews were transcribed and analyzed based on content analysis [12, 13]. The interview answers were analyzed and categorized.

Results

Four major functions have been identified to date, these being: (i) clinical logs, (ii) personal portfolio (or e-portfolio), (iii) reference information, (iv) communication and connectivity.

Discussion

Mainly PDAs are to be used as a learning tool because of their portability and accessibility to information anywhere and anytime. The stakeholders express many needs of incorporating PDAs to GSM. Security and confidentiality are important concerns when using PDAs in the real world, particularly when recording patient logs and e-portfolios. Furthermore, stakeholders want PDAs to have the ability to access medical references. In addition, to fulfill the needs of using PDAs in medical education, PDAs must be well equipped with the standard IT systems, particularly for communication and data synchronization back to the central servers or data on demand (DOD) [14]. On the other hand, PDAs need to be connected to GSM systems for data transmission from remote locations to central servers. Currently UOW has access to medical databases such as AccessMedicine, MDConsult and Medline. Having PDAs in hand will assist students in referencing material.

Conclusion

PDAs can facilitate learning in medical education particularly in a PBL approach by using clinical logs and e-portfolios in order to keep track of students' progress. Wired or wireless PDA connectivity and communication functions would support and enhance students to learn as well as communicate with faculty while away in clinical placements. In the future, we plan to continue this study by conducting focus groups with medical, nursing and IT experts in order to gain a better understanding of how *best* to incorporate PDAs into a PBL-based medical curriculum.

Acknowledgements

The authors would like to gratefully acknowledge all interview participants, as well as the assistance of Prof. Don Iverson, Prof. Patrick Crookes, Dr. Lori Lockyer and Joann Joyce, and Assumption University for scholarship support.

Feasibility Study of Incorporating Personal Digital Assistants (PDAs) into a Problem-Based Learning Approach to Medical Education at the University of Wollongong

Introduction

Background

The University of Wollongong (UOW) established a Graduate Medical School (GSM) and accepted students for graduate entry in 2007.

The medical curriculum was designed to use 93 clinical problems based on the contents of the core curriculum.

The core delivery strategy is case-based learning by monitoring the students' progress through a whole course as an independent learning exercise.

The use of IT is integrated into the course in order to assist in course delivery. Students start to practice in the regional area from year 1, and are required to practice in clinical placement in a rural setting for a 40-week period.

IT will be integrated and facilitate learning while the students are practicing in the clinical placement.

Aim

To study the feasibility, applicability and functionalities of incorporating PDAs into medical education.

Research questions

What are the key functionalities of PDAs applicable for medical education in a problem-based learning (PBL) curriculum?

- How PDAs have been applied in the medical and nursing professions, and barriers to using such devices?
- What are the roles of using PDAs in medical and nursing curricula?
- How PDAs have been used in medical and nursing curricula?
- What functionalities have been integrated into medical education?

Introduction

PDAs have been applied in medical and nursing professions as well as medical education including

- clinical guidelines
- clinical references
- tracking clinical encounters and medical curriculum
- e-learning in medical education
- clinical decision making
- exchanging information between physicians during changeover of wards
- ordering additional clinical tests and checking test results
- Exchange information between physicians during changeover of wards
- ordering additional clinical tests and checking test results
- accessing medical images
- recording patient information [1-4]

Introduction

At present, many medical schools use PDAs in medical education, such as

- The Department of Family Medicine,
- University of Rochester,
- George Washington University,
- Johns Hopkins School of Medicine,
- Thomas Jefferson Medical College,
- Georgetown University,
- Columbia University,
- Stanford University,
- Medical College of Wisconsin and
- Wayne State University [5-12].

Example of how PDAs are used in medical professions.

PDAs have been used in various clinical placements such as the Canadian intensive care unit for wireless data transmission between the clinical staff, clinical data capture using pen-based PDAs [13], accessing medical images, clinical encounters and medical findings via their web-based interface [14].

Having medical information stored on PDAs means it is easy to use and access by clinicians and medical students at the point-of-care, moreover data can be downloaded to a central computer. Clinicians also use PDAs for recording patient information [15]. As a result, they can easily focus on their education [3, 6, 16].

Introduction

The roles of using PDAs in medical and nursing curricula

A major issue in the clinical area is errors in medication [15, 17].

Use of PDAs in the medical profession has the potential to decrease medical errors and increase efficiency [16].

Using PDAs to issue prescriptions result in less errors than with handwritten prescriptions. Therefore PDAs can play an important role in electronic prescription [15].

The Important Barriers for Incorporating PDAs into Healthcare Sector [4, 10, 13]		
• Data Security	• Patient Privacy	• Privacy Protection
• Interception	• Data Access	• Data Storage and Retrieval
• Loss of Data	• Usability	• Interference
• Interoperability	• Scalability	• Connectivity

Summary of PDA Applications in Medical Education [10, 18, 19]

- Student-patient Log
- Classroom assessment systems
- Gernal software applications
- Teaching and interactive evaluation
- Reference software applications
- Evaluation of medical training
- Communication software applications
- Monitoring clinical experiences of medical students
- Special software applications in other areas
- Objective structured clinical examinations (OSCE)

Methods

Methods

The objective of this study is to find the key functionalities of PDAs that are applicable for medical education. Interviews and focus groups were designed accordingly. In-depth interviews with 15 stakeholders, have been undertaken; these aim to bring out information about the meaning, complication and interpretation from participants [20].

Results from these interviews have yet to be analyzed into different themes using NVivo software. These themes will then be used to conduct focus groups in the next phase of the project.

Interviews

Relevant medical stakeholders were contacted and interviewed face-to-face. The open-ended questions were asked about …

- the appropriate PDA functionalities for students to use during their study years,
- what kind of information needed to be stored in the PDAs, how PDAs can be used in PBL approach,
- how to synchronize data back to servers, and what type of network connection is used.

The interviews lasted approximately 30 minutes for each participant. All interviews were transcribed and analyzed based on content analysis [21, 22]. The interview answers were analyzed and categorized.

Results

Four major functions have been identified to date, these being:

(i) Clinical logs,

(ii) Personal portfolio (or e-portfolio),

(iii) Reference information,

(iv) Communication and connectivity.

Clinical logs

Clinical logs contain patient contacts and information gathered over time.

The purpose of using a clinical log is to record the student interactions with patients during the four-years of their medical study.

For instance,

- Basic demographic information,
- Hospital locations where and when students see them,
- Signs and symptoms of clinical problems based on the 93-clincial problems,
- Medical treatments and physical examinations, and how comfortable patients are with what students have done with them.

Results

Four major functions have been identified to date, these being:

(i) Clinical logs,

(ii) Personal portfolio (or e-portfolio),

(iii) Reference information,

(iv) Communication and connectivity.

Personal portfolio (or e-portfolio)

The purpose of using an e-portfolio is to record student assessments, clinical attachments together with results of mini-examination, feedback, difficulties that students have encountered, learning needs and medical errors based on root-cause analysis.

Reference information

Reference information is an important functionality that students are able to have in PDAs, for instance

- Medical database
- Current clinical guidelines and
- Core medical textbooks.

Using available software applications can enhance students to access relevant clinical information any time while practicing in clinical setting in remote locations.

Results

Four major functions have been identified to date, these being:

(i) Clinical logs,

(ii) Personal portfolio (or e-portfolio),

(iii) Reference information,

(iv) Communication and connectivity.

Communication and connectivity

Communication and connectivity functionality is to be used for sending and receiving information, particularly for

- Clinical logs,
- e-portfolios,
- GSM weekly calendars,
- Changes in clinical placement and also including
- E-mail and Internet functions.

Discussion

We have studied the feasibility of incorporating PDAs into medical education.

Mainly PDAs are to be used as learning tool because of their portability and accessibility to information anywhere and anytime.

The stakeholders express many needs of incorporating PDAs to GSM.

Discussion

Security and confidentiality are the important concerns when using PDAs in the real world, particularly when recording patient logs and e-portfolios.

Furthermore, stakeholders want PDAs to have the ability to access medical references, e.g.

- medical dictionary,
- clinical guidelines,
- drug databases or even the core medical textbooks.

In addition, to fulfill the needs of using PDAs in medical education,

PDAs must be well equipped with the standard IT systems particularly for communication and data synchronization back to the central servers or data on demand (DOD) [23].

On the other hand, PDAs need to be connected to GSM systems for data transmission from remote location to central servers.

Currently UOW has access to medical databases such as AccessMedicine, MDConsult and to Medline. Having PDAs in hand will assist students in referencing material.

Conclusion

PDAs can facilitate learning in medical education particularly in a PBL approach by using clinical logs and e-portfolios in order to keep track of students' progress.

Wired or wireless PDA connectivity and communication functions would support and enhance students to learn as well as communicate with faculty while away in clinical placements.

In the future, we plan to continue this study by conducting focus groups with medical, nursing and IT experts in order to gain a better understanding of how *best* to incorporate PDAs into a PBL-based to medical curriculum.

Computer Assisted Learning is an Effective Way of Teaching and Learning in Medical Education

Lin Guo[a]

[a]*Centre for Adult and Paediatric Gastroenterology, Institute of Cell and Molecular Science, Queen Mary's School of Medicine and Dentistry, Barts and The London, Queen Mary, University of London, UK.*

Abstract

The aim of the study is to define computer assisted learning as the teaching and learning tool and environments facilitated through computers and to assess the effectiveness of teaching and learning by using computer assisted learning programme in medical education and computer assisted learning provides teachers with various teaching information when teaching medical students. Evaluation of CAL as an intervention is difficult, involving impact assessment studies of a variety of combined initiatives which seek to influence large and diverse populations. This is particularly true when evaluating attitude change and professional practice with a fast moving field like information technology. Computer assisted learning is an effective way of increasing knowledge in teaching medical students in medical education. In the future we will see more sophisticated software with virtual medical education who can communicate and interact with the medical students in a very realistic way.

Keywords:

computer assisted learning; medical education; information technology; multimedia; computer; training

Introduction

The aims of the study are to define computer assisted learning as the teaching and learning tool and environments facilitated through computers and to assess the effectiveness of teaching and learning by using computer assisted learning programme in medical education and computer assisted learning provides teachers with various teaching information when teaching medical students.

Design and methods

The design used for this study was a systematic review of published materials obtained from four large online databases, namely EMBASE, Blackwell Synergy, MEDLINE, and the *Cochrane Library* database. This review is largely a personal reflection on recent changes in computer assisted learning in medical education and demonstrates that the use of computer assisted learning programme is effective and easy to use. Research has been supplemented by email discussions with colleagues based in the United Kingdom.

Results

Computers have been available in medical education since the 1960s.[1] Computer assisted instruction enhances learning, allowing the student to decide content, time, place and pace of instruction. Evaluation of CAL as an intervention is difficult, involving impact assessment studies of a variety of combined initiatives which seek to influence large and diverse populations. This is particularly true when evaluating attitude change and professional practice with a fast moving field like information technology.[1, 2] It was shown that CAL provided the medical students with a popular and effective way of learning. Computer assisted learning systems' development in medical education in future years will be concentrated on the following areas:

- **Increasing systems' performances:** This includes higher speed of processing capacity and stronger computer software. This is a normal continuance to current computer assisted learning systems and their development's policy. [2, 3]
- **More distributed systems:** Nowadays modern world wide networks and high speed digital and mobile communications create a strong context for design and implementation of more distributed computer assisted learning systems. In the near future teleconferencing and non-centralised classrooms will be usual.[2]
- **Simulation and virtual reality:** New technology allows us to create 3 dimensional near-toreal environments for simulator systems. In practice, current applications of such systems are only on flight or sailing training systems. However, in the near future they will have a more important role, especially for blind and nearly blind people's education.[3]

Discussion

The quantity of applied research design and production of computer assisted learning application in medical field is growing rapidly and the quality is improving. There is good evidence supporting the use of computer assisted learning in medical education lowering all costs related to production and use. Development of guidelines and consensus statements issued by conventional medical organisations have recommended computer assisted learn-

ing application in medical education.[1] Computer assisted learning is increasingly practised in comparison of conventional teaching settings. There is a more open attitude to computer assisted learning application in medical education among conventional health professionals; this is partly explained by the rise of problem-based learning environment. Furthermore, the computer assisted learning should be seen as complementary to other traditional contact teaching, which may be more suited to clinical skills and attitudes.

Conclusion

Computer assisted learning is an effective way of increasing knowledge in teaching medical students in medical education. The potential of computer assisted learning is vast and its principles, application and practices need to be explored in detail. In the future we will see more sophisticated software with virtual medical education who can communicate and interact with the medical students in a very realistic way. However, at present computer assisted learning should not replace traditional medical education, but rather be used more as a supplement and for self-directed studies.

COMPUTER ASSISTED LEARNING IS AN EFFECTIVE WAY OF TEACHING AND LEARNING IN MEDICAL EDUCATION

Lin Guo

Centre for Adult and Paediatric Gastroenterology, Queen Mary's School of Medicine and Dentistry, Barts and the London, Queen Mary, University of London, London E1

Aims and Objectives

- To define computer assisted learning as the teaching and learning tool and environments facilitated through computers
- To assess the effectiveness of teaching and learning by using computer assisted learning programme in medical education
- To provide teachers with various teaching information when teaching medical students.

Methods

- **Systematic review of published materials obtained from four large online databases, namely EMBASE, Blackwell Synergy, MEDLINE, and the *Cochrane Library* database**

- **Personal reflection on recent changes in computer assisted learning in medical education and demonstrates that the use of computer assisted learning programme is effective and easy to use.**

- **Supplemented by email discussions with colleagues based in the United Kingdom.**

Results

- Computer assisted instruction enhances learning, allowing the student to decide content, time, place and pace of instruction.
- Evaluation of CAL as an intervention is difficult, involving impact assessment studies of a variety of combined initiatives which seek to influence large and diverse populations. [1]
- CAL provided the medical students with a popular and effective way of learning. Computer assisted learning systems' development in medical education

- **It would be concentrated on the following areas in the future years:**

  - **Increasing systems' performances:** This includes higher speed of processing capacity and stronger computer software. This is a normal continuance to current computer assisted learning systems and their development's policy. [2, 3]

  - **More distributed systems:** Nowadays modern world wide networks and high speed digital and mobile communications create a strong context for design and implementation of more distributed computer assisted learning systems. In the near future teleconferencing and non-centralised classrooms will be usual. [2]

  - **Simulation and virtual reality:** New technology allows us to create 3 dimensional near-toreal environments for simulator systems. In practice, current applications of such systems are only on flight or sailing training systems. However, in the near future they will have a more important role, especially for blind and nearly blind people's education. [3]

Table 1: Comparison between CAL and Traditional Teaching Methods in Medical Education

Tradition Model	Alternative Model	CAL Implications
Classroom lectures	Individual exploration	Networked PCs with access to information
Passive absorption	Apprenticeship	Requires skills development and simulations
Individual work	Team learning	Benefits from collaborative tools and e-mail
Omniscient work	Teacher as guide	Relies on access to experts over the network
Stable content	Fast changing content	Requires networks and publishing tools
Homogeneity	Diversity	Requires a variety of access tools and methods

RECENT PROGRESS AND ADVANCES

These are outlined CAL in medical education below:

- **The quantity of applied research design and production of CAL application in medical field is growing rapidly and the quality is improving**
- **There is good evidence supporting the use of CAL in medical education lowering all costs related to production and use**
- **Guidelines and consensus statements issued by conventional medical organisations have recommended CAL application in medical education**
- **CAL is increasingly practised in comparison of conventional teaching settings**
- **There is a more open attitude to CAL application in medical education among conventional health professionals; this is partly explained by the rise of problem-based learning (PBL) environment**

Discussion (1)

- The quantity of applied research design and production of computer assisted learning application in medical field is growing rapidly and the quality is improving.
- There is good evidence supporting the use of computer assisted learning in medical education lowering all costs related to production and use.
- Development of guidelines and consensus statements issued by conventional medical organisations have recommended computer assisted learning application in medical education.[1]

Figure 1: Details of Educational Institutions, which Offer Courses on CAL

- **Association for the Advancement of Computing in Education** The purpose of the AACE is to encourage scholarly inquiry related to information technology in education and the dissemination of research results and their applications through Publications, Conferences, Divisions/Societies/Chapters and Inter-Organizational Projects.
- **Support Initiative for Multimedia Applications (SIMA)** The Support Initiative for Multimedia Applications (SIMA) was funded by the JISC New Technologies Initiative through the Advisory Group on Computer Graphics (AGOCG). The initiative funded projects in a range of areas, demonstrating the use of new technology to the higher education community through example, setting up services, training, and dissemination of good practice.
- **Computers in Teaching Initiative (CTI)** The CTI (Computers in Teaching Initiative) comprises 24 subject-based centres working to encourage the use of learning technologies in UK higher education. The CTI Support Service, based at the University of Oxford, coordinates the work of the centres, and acts as a focal point for activities relating to the use of communications and information technology in university teaching.
- **Advisory Group on Computer Graphics (AGOCG)** The Advisory Group on Computer Graphics (AGOCG) is an initiative of the Joint Information System Committee (JISC) of the Higher Education Funding Councils and the Research Councils. AGOCG provides a single national focus for computer graphics, visualization, multimedia and virtual environments within the UK higher education community and is concerned with the handling and processing visual information in all its forms.
- **The British Computer Society** The Society is concerned with the development of computing and its effective application. Under its Royal Charter granted in 1984, it also has responsibilities for education and training, for public awareness, and above all for standards, quality and professionalism.
- **Computer Assisted Teaching and Learning: The CASTLE Project** "Providing freely available tools for creating on-line multi-media assessments quickly and easily. Requires no prior knowledge of HTML, CGI or other scripting or mark-up language".
- **Institute for Computer Based Learning** The Institutes overall objectives are to pursue research in computer-based learning and its impact on teaching and training; to develop computer based learning environments for use in teaching and training and to promote the transfer of technology-based training to industry and commerce.
- **Educational Technology Information and Resources** Edu-Tech is also growing in its sections for authoring resources, to aid awareness and use of multimedia/hypertext authoring software (such as ToolBook), HTML- the language for authoring WWW pages, and computer-assisted assessment.
- **Centre for Gastroenterology** Royal Free Hospital, the creation and implementation of a Computer-aided Learning platform called RadioVision, which is accessible by students using their home-based PC or suitable equipped university computers.
- **Epidemiology and Education Unit** Centre for Adult and Paediatric Gastroenterology, Barts and The London, Queen Mary's School of Medicine and Dentistry, Queen Mary, University of London

Discussion (2)

- Computer assisted learning is increasingly practised in comparison of conventional teaching settings.

- Furthermore, the computer assisted learning should be seen as complementary to other traditional contact teaching, which may be more suited to clinical skills and attitudes.

Conclusion

- Computer assisted learning is an effective way of increasing knowledge in teaching medical students in medical education.
- The potential is vast and its principles, application and practices need to be explored in detail.
- More sophisticated software with virtual medical education who can communicate and interact with the medical students in a very realistic way in the future.
- Be used more as a supplement and for self-directed studies.

[d] *Institute of Medical Informatics, University of Lübeck, Germany*
[e] *Deutsche Blindenstudienanstalt e.V. (blista), Marburg, Germany*
[f] *University of the West Indies Library, Mona, Kingston, Jamaica, W.I.*
[g] *Department of Oral Biology, Minia University, Egypt*

Abstract and objective

The prevalence of severely visually impairment (visus < 0,1) to the point of blindness (visus < 0.05) is in industrialised countries approx. 0.2%, i.e., in Germany approx. 160,000 people suffering from notable visual deficiency. 6% of the affected persons (approx. 8,700) are younger than 18 years, most of which attend school. The concept intuition is to provide visual information by tactile analogies. In the present study, a haptic device is used, i.e., a hardware device that helps present tactile information. A haptic device along with prototypical software (`make2Dhaptic`) is used to present tactile representation of geometric objects and physical bodies. First tests show that more than 50% of the blind and severely visually impaired students tested get an idea of the tactile representation when a haptic device is used. Approx. 25% prefer it over traditional „swell paper".

Keywords:

hapticrRendering, phantom device, visual impairment

Introduction

Carl-Strehl-Schule (Marburg, Germany) is one of the few schools providing an opportunity for blind and severely visually impaired students to get a boundless University-entrance Diploma ("Abitur"). For blind and severely visually impaired students the visual components must now be transferred to be interoperable with other senses, preferably the acoustical and touching sense.

Methods

Using one of the main common haptic-devices we take the PHANTOM® Desktop^{TM} Haptic Device (SensAble Technologies, Inc., Woburn, MA, USA) which possesses six degrees of freedom in its possibilities of movement (Fig. 1).

Figure 1 - PHANTOM® Desktop^{TM} Haptic Device (SensAble Technologies, Inc., Woburn, MA, USA)

This haptic device can represent kinaesthetics and tactility to feel the surface texture. The computation of the forces fed back by the device is essential. We use the ability of generating physical powers to guide the user through the scene. Respective requirements have been met by developing the prototypical software `make2Dhaptic`

(applicable to chemistry, physics, biology and mathematics; Fig. 2).

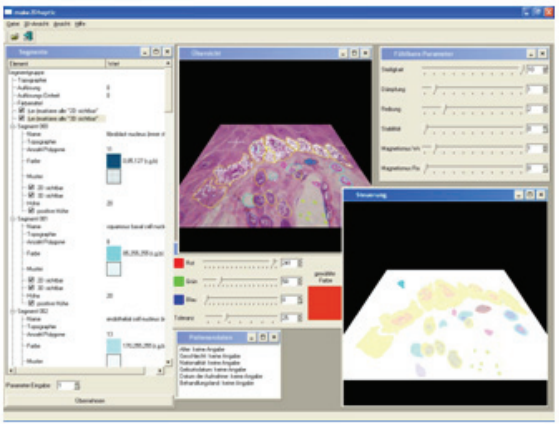

Figure 2 - The prototypical software make2Dhaptic (screenshot)

For a tactile representation of an output of a gas chromatograph (real time) the measured values are transferred into temporary or permanent forces. The values are represented as movements along the y-axis of the haptic device. In order to transform histological slides (medicine, biology) appropriately, the images were transferred into a 3D Surface Mesh, at which the spatial orientation (z-coordinate) is defined by the specific grayscale values of the image (Fig. 3).

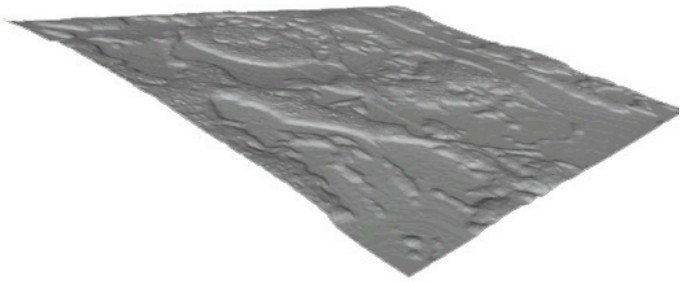

Fig. 3 - 3D Surface Mesh generated by make2Dhaptic

A gender mixed group of 21 sixth formers, who were partly blind from birth, were available for a trial. None of the group has ever used or touched a haptic device before. After the first

exploration of a standard parabola the users were asked to determine the form of the curve, and answered questions on the cells and the tissue samples presented to them. The replies of the users were mapped to a 1 to 6 Likert scale (1 = exactly right; 6 = absolutely wrong).

Results

For the graph, everyone answered directly “parabola”. 60% of the test persons billed the statement “I can follow the line without loosing contact.” with “1” and 40% with “2”. All persons approve the statement “More lead time is wise.” with 2 or higher. Approx. 25% prefer the haptic device over traditional „swell paper“. The representations of histological slides (medicine, biology) were judged similarly.

Discussion and conclusion

The current surface mesh is generated by interpreting the greyscale values as the spatial orientation (z-coordinate). By this, an extreme closed surface mesh is given and as a consequence the memory requirements for the mesh is proportional to dimension of histological slide but independent from the level of detail of the slide. Using a meshing algorithm based on the delaunay triangulation a more efficient representation is given. Another drawback of the current mesh is that it is only a pseudo 3D mesh.

Therefore the next step is to integrate an algorithm for generating a volume mesh of the histological slides. The advantage of this is the option to “manipulate” the slide, *e.g.*, cell division could be represented. This allows teaching blind and visually impaired people dynamic processes. Another drawback of many haptic systems, as well as the current is, that physical properties are not correct arranged. This means that it is typically impossible to differ between different materials in the haptic scene in a realistic way, *e.g.*, soft rubber feels like metal. To avoid this undifferentiated feeling we intend to build up a data base for different materials and their physical properties to adjust the settings of the haptic engine.

Beside these drawbacks a first exploration implies that already today students may benefit from the application of a haptic device along with the prototypical software `make2Dhaptic`. Further studies are needed for systematic evaluation.

The Need for Secure Computer-based Assessment-Software

Jörn Heid[a], Matthias Bauch[a], Sebastian Garde[b], Frank Hess[a], Martin Haag[a], Franz J. Leven[a]

[a] *Laboratory for Computer-based Training in Medicine, University of Heidelberg, Germany*[b] *Central Queensland University and Austin Health, Heidelberg Vic, Australia*

Abstract and objective

Most of the computer-based assessment software available is web-based. While there are many advantages, for instance the possibility to use the same software for learning and assessment, there are legal and technical risks with this approach such as a network failure or the missing proof for the correctness of the collected data. Therefore a new software was developed at the Heidelberg University Hospital focusing on fault-tolerance and certainty of law. It uses a client-server architecture for real-time result display but through using different layers of logging a failure of the server will neither end the test nor any data will be lost. The system has been used for testing students of medicine at the Heidelberg University Hospital since the end of 2004.

Keywords:

assessment, medical education, security

Introduction

In Germany computer-based tests of students of medicine are rare. The main problems are the missing amount of computers for the assessment and the certainty of law.

Accordingly, most of the exams are paper-based although the need for case-based testing and the possibility to use multimedia, the key feature approach [1] or advanced question types such as 'long menu' [2] or 'hotspot' is attractive for medical education.

Most of the computer based assessments have been carried out with browser-based assessment software such as WebCT [3], .LRN [4] or Ilias [5]. These are web-based learning management systems used in the student's everyday work. Despite advantages like familiarity and the absence of client-side software installation, this approach has many problems when using that software for official examinations.

One problem is that every data is collected at the server. If the connection between the client (browser) and the server breaks, data will be lost. Software bugs in the software, a server-side hardware failure or a corrupted database will end the examination and can cause a loss of data.

The second main problem is the missing certainty of law of the test. As all data is just collected digitally at the server, a bug in collecting the student's data or incorrect data storage cannot be verified afterwards. Some systems demand a student signature on a hardcopy afterwards but this will raise the time need and could lead to discussions between the examiner and the student.

Implementation of a secure assessment software

On top of the CAMPUS [6] e-learning shell, which offers a simulative and a card-based player for students of medicine, a separate software module was created using the same authoring system.

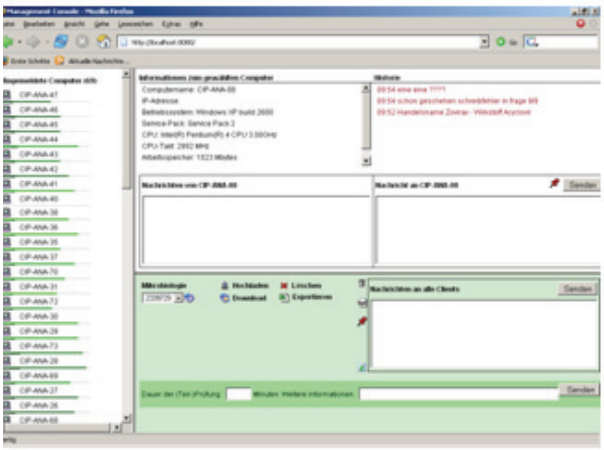

Figure 1 - The Management Console

The software consists of a PostgreSQL database, a server application, called "Management Console" (see Figure 1) and a client software (see Figure 2), all written in the Java programming language for best portability.

The Management Console is used by the examiner through a web-based interface. It controls the spreading of the test data and supervises the attached clients so that problems with them can be detected just in time. Additionally, a bidirectional messaging system can be used.

The client software acts as a normal desktop application (except it can be distributed and updated automatically via a webbrowser using the Java Webstart technology [7]). As it isn't bounded to the browser restrictions, the client can

be protected through an exclusive 'kiosk-mode' to prevent manipulation or fraud attempts using e.g. a chat.

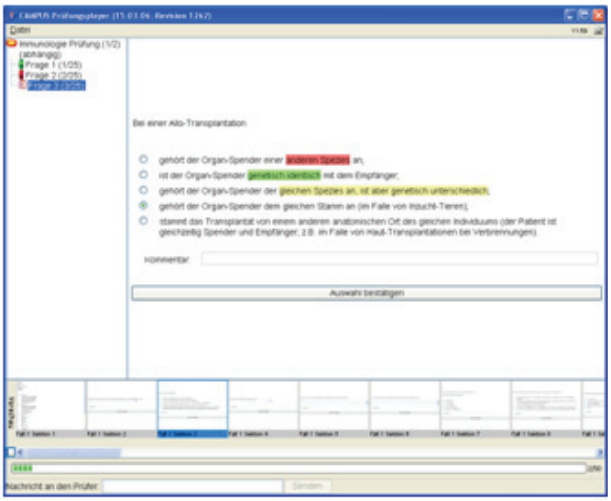

Figure 2 - The client software

Log files are created at every layer so that the test can be reconstructed even in case of a complete and permanent server failure. With this technology a breakdown of the server or a network failure is transparent to the client software – the test can be continued and the data can be synchronized later.

To ensure certainty of law, a screenshot, showing the unprocessed raw data of the examination, is taken each time a student commits an answer. Those screenshots are combined into a video which can be used to validate the result of the test afterwards.

To increase the confidence of the students in the results the video can be sent to a student's e-mail address after the test. This video is protected by a student's and an examiner's password so that both sides can prove its authenticity.

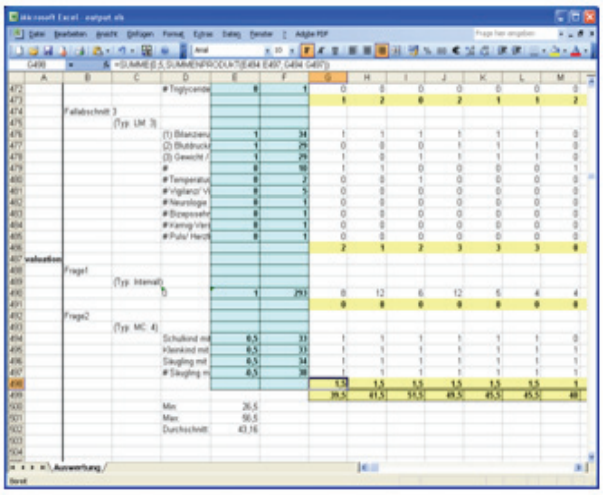

Figure 3 - Test results with adaptive formulas

The test result can be made available as HTML pages and a Microsoft Excel sheet with adaptive formulas (see Figure 3) where the examiner can modify the rating and sees the altered overall result just in time.

Results

The software has been used at the *Heidelberg University Hospital* successfully since 2004 with hundreds of students (up to 120 students at the same time). Although problems had occurred (for instance database problems), the videos and log files helped to reconstruct the corrupted or missing data completely.

The software has successfully addressed two of the main problems of computer-based assessment:

1. Prevention of having to abort an exam because of a network or server failure
2. Certainty of law for computer-based assessment by using unprocessed data shown as a video

Creating MP3 Audio Files from Scientific Articles

Chase L. Andreason[a], Scott L. DuVall[b]

[a] *Undergraduate Research Opportunity Program, University of Utah, United States of America*
[b] *Department of Biomedical Informatics, University of Utah, United States of America*

Abstract

Reviewing scientific literature is an important part of research and education. In the University of Utah Department of Biomedical Informatics published articles are assigned as required reading. As an alternative to reading these articles, students were given the opportunity to listen to audio reproductions of the articles. To create audio files from Portable Document Format (PDF) files took several steps and an average of two hours per article. Articles were converted from PDF files to plain text, reviewed for layout and text conversion errors, reviewed for pronunciation and word usage mistakes, adjusted for pace, and saved as Moving Picture Experts Group Audio Layer-3 (MP3) audio files. This process was used for converting weekly required reading articles for a fifteen week informatics course.

Keywords:

speech synthesizer, computer-assisted instruction, education

Introduction

In the course of training in the University of Utah Department of Biomedical Informatics scientific articles are referenced and given as required reading. In a fifteen week informatics course, an option was given to students to listen to the required reading articles as an alternative to reading them. Speech synthesis was used to convert Portable Document Format (PDF) files to Moving Picture Experts Group Audio Layer-3 (MP3) files.

Speech synthesis has been studied mostly in the realm of communication aids for the disabled.[1-3] Research has shown that non-technical, fictional literature is best understood by listeners.[3] Creating audio files from published literature will allow the Department to investigate the comprehension of technical concepts in a graduate school environment.

Methods

Scientific articles were acquired from journals as PDF files using the University of Utah institutional license. A commercial text-to-speech engine was used for converting PDF files into plain text. Special formatting, figures and tables, and peripheral page text caused the conversion to include artifacts or misinterpret page flow. Each article had to be reviewed for layout and text conversion errors. As expected, many medical and technical words were not in the text-to-speech application's dictionary and were pronounced incorrectly and needed to be spelled out phonetically. In addition, the pronunciation of heteronyms like "read" and "record" were determined automatically (sometimes unsuccessfully) from surrounding words. Human review was needed to ensure correct word usage. The text-to-speech engine had difficulty reading the complex, protracted sentences found in scientific literature. To correct issues with pace, sentences were divided up in to smaller parts and pauses were inserted. Article sections were individually converted into audio files as tracks for easier navigation. The commercial text-to-speech engine included the ability to save audio in the MP3 format. Tracks for each article were bundled in a compressed folder for distribution.

Results

Fifteen scientific papers were successfully converted from PDF files to MP3 audio files using the workflow described above. Each conversion took approximately two hours and resulted in a compressed folder of audio files.

Discussion

Scientific articles given in audio format was seen as a convenience and a time-saver for graduate students. The process of creating the audio files proved time consuming. While commercial products claim to enable conversion, layout and text conversion errors, pronunciation and word usage mistakes, and pace issues occurred.

Acknowledgments

This research was supported by a training grant from the National Library of Medicine and Robert Wood Johnson Foundation and funding support from the Jenifer C. DuVall Research Foundation.

Information Needs Associated with Hazard and Near Miss Reporting

Po-Yin Yen, MS[a], Suzanne Bakken, RN, DNSc[a,b]

[a] *School of Nursing, Columbia University, USA*
[b] *Department of Biomedical Informatics, Columbia University, USA*

Abstract

The purpose of this study was to understand the information needs of APN students related to hazards and near misses in order to expand a reporting system to provide Just-in-Time learning.

Keywords:

information needs, patient safety, adverse event

Introduction

As part of a patient safety curriculum for Advanced Practice Nurse (APN) students, a Hazard and Near Miss Reporting System (HNMRS) was developed for reporting of information on hazard (dangerous situations) and near misses (close calls) that occurred during students' clinical shifts. HNMRS includes 13 types of hazards and near misses: Accident (non-fall), Environment Hazard/Safety, Equipment/Device, Fall, Food/Nutrition, Infection, Laboratory, Medication, Patient Disappearance, Procedure/ Treatment, Restraint, Transfusion, and Other. We plan to extend the functionality of HNMRS beyond reporting to Just-in-Time learning by providing context-specific links to internal and external knowledge sources related to the type of hazard or near miss reported. Context-specific links have demonstrated utility in meeting information needs at the point of care. [1, 2] The purpose of this study was to understand the information needs of APN students related to hazards and near misses.

Methods

A focus group was conducted with four APN students in the baccalaureate year of a BS/MS curriculum. Students were asked to provide information about the hazards and near misses they had reported and their information needs related to particular types of hazards and near misses. Students were asked to express their information needs as questions. They were then analyzed and organized into the thirteen categories. Questions were classified into three information types: (S) subject-specific (i.e., patient-related data), (D) domain-specific, or (I) institution-specific.[3]

Results

The information needs were classified into the hazard and near miss categories and by type of information need (Table. 1). Information needs related to patient-specific data are not included because they would typically be answered by consulting an electronic health record, not through context-specific links to knowledge sources.

Conclusion

APN students experienced information needs related to hazards and near misses. Context-specific links to knowledge sources may help to prevent adverse events through Just-in-Time learning when a hazard or near miss occurs.

Table 1 - Information needs

Equipment/Device	Type
• How do I use the device?	D
• Who do I contact for replacement? (e.g., broken)	I
• How long should the device be in? Any protocol?	D
• Is there an institutional protocol for this device?	I
• How do I know if it placed correctly?	D
• What are normal and abnormal signs of function? (e.g., NG tube)	D
Fall	
• How do I prevent patient falls?	D
• Who do I contact for incident report?	I

Evaluation of Competency-Based Online Learning Modules for Nurses in Emergency Planning and Response

Linda Norman [a], Elizabeth Weiner [a], Margaret Irwin [b,] Jeffry Gordon [a], Lynn Slepski [c], Patricia Trangenstein [a]

[a] *Vanderbilt University School of Nursing, Nashville, TN USAc*
[b] *Independent Consultant, Nashville, TN, USA*
[c] *Department of Homeland Security, Washington, DC, USA*

Abstract and objective

Several grants have been received to develop an online curriculum for nurses in emergency preparedness using the competencies developed by the International Nursing Coalition for Mass Casualty Education (INCMCE). Another unique aspect of the development of these modules is that they reflect the "How People Learn Cycle" (HPL). This presentation will provide data to determine the effectiveness of learning programs designed to educate nurses volunteering for service in the US.

Educational informatics provides a model for learning that is based on resources that augment what the learner already knows. Using this more customized approach, learners can then integrate new knowledge within the context of their practice. The long term objective of this study is to provide quality educational materials for volunteer nurses.

Content validity was determined and design principles upheld for HPL. 953 learners were drawn from 33 Medical Reserve Units and from six states hosting volunteer nursing Registries. Data were collected after the third module was completed in the online series. Paired t-tests of pre-course and post-course total confidence scale scores indicated a significant increase in mean ratings, with the first 10 items being significant ($p < .05$). Overall mean scores for technology integration demonstrated a positive experience using the online approach.

Keywords:

disaster response, emergency preparedness

Introduction

A survey of US nursing schools validated the fact that the curriculum was lacking in content related to emergency planning and response [1]. In addition, faculty were not prepared to teach this content One of the highest rated requests was for the development of an online curriculum that would meet the competencies as developed by the INCMCE. Beginning development efforts were the result of a think tank of nursing experts in emergency planning and response.

Methods

The modules were developed in conjunction with the multimedia developers from Little Planet Learning, Inc. based in Nashville, TN. Data were not collected until the third case (which was a biological case) was completed. 953 learners were drawn from 33 Medical Reserve units and from six states hosting volunteer nursing registries. The study was a pre and post-test design allowing for data collection in the areas of self-rated confidence of skills (based on defined competencies) and assessment of technology use in delivery of the content (assessed via use of the Flashlight evaluation tool). Demographic data from the users was also collected. During module development, content validity was determined along with an assessment by experts that the design had upheld the principles of "How People Learn" (HPL).

Results

Paired t-tests of pre-course and post-course total confidence scale scores indicated a significant increase in mean ratings ($p < .01$). The first ten items indicated a significant increase in confidence scores ($p < .01$), with the remaining items showing no or limited increases. Given that the total set of modules were not completed by the subjects, these findings are not surprising. The first 10 items are basic competencies, while the remaining 6 are considered more intermediate level skills that require additional content in order to be met After the learning experience, subjects completed a survey that was designed from items using the Flashlight Evaluation Tool comparing this online experience with other non-online experiences. Ratings were based on a five point Likert scale from 1-5 with 5 responses being considered positive. Overall mean scores for the 10 item questionnaire were 4.2, falling between agree and strongly agree.

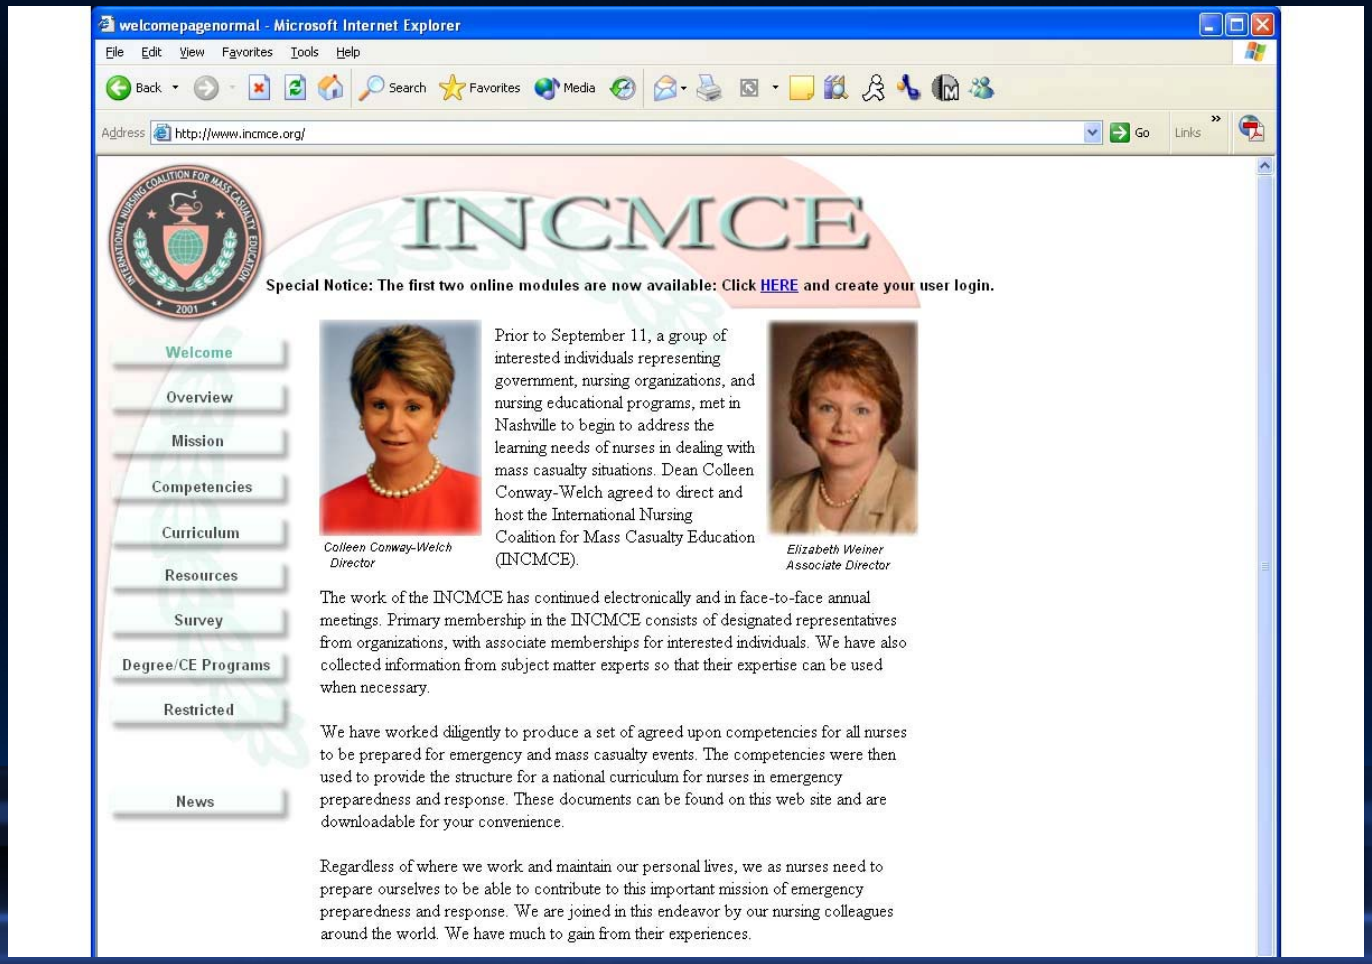
International Nursing Coalition for Mass Casualty Education



Name Change in April 2007

- From International Nursing Coalition for Mass Casualty Education (INCMCE)

- To Nursing Emergency Preparedness Education Coalition (NEPEC)

…committed to emergency preparedness and disaster response education of nurses

www.nepec.net

Mission

- To provide a platform for nurse educators, practice and professional organizations, governmental agencies and others to pool expertise, make recommendations and disseminate best practices about emergency preparedness and disaster response education in the US and worldwide

Specific Aims

- Bring together the best of international expertise to inform the mission
- Identify core competencies
- Create sound curricula
- Develop improved methods of disseminating information
- Strengthen networking
- Inform policy-makers

First Activities

- Agree on Competencies for all nurses in emergency planning and response

- Survey US nursing programs about content taught prior to and post 9/11/2000 that related to emergency planning and response

Online Modules

- Funded by US Agency for Healthcare Research and Quality and US Health Resources and Services Administration Bioterrorism Curriculum and Development Grant
- Designed to meet nursing competencies
- Reflective of national “How People Learn”

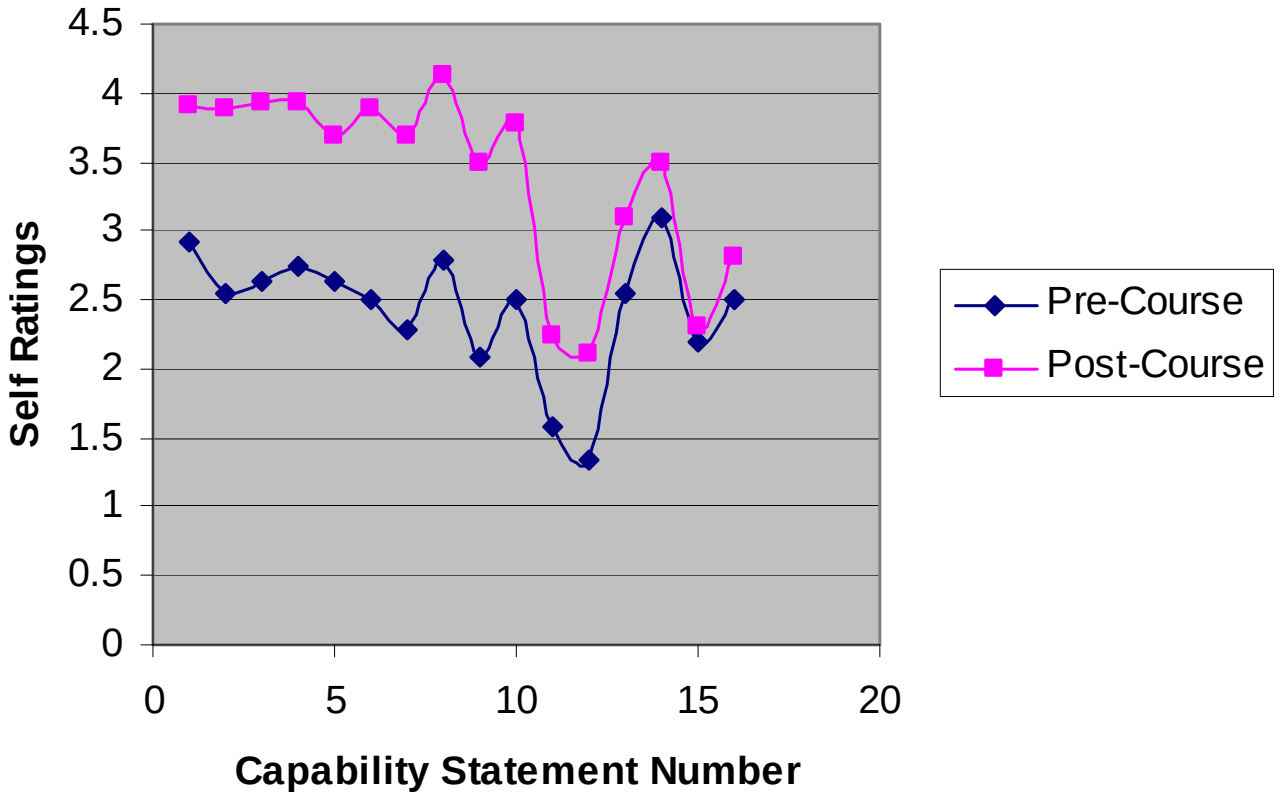
Methods

- 953 nurse learners from 33 Medical Reserve units and 6 states hosting volunteer nursing registries completed first 3 modules
- Pre and post-test design to assess self-rated confidence of skills and assessment of technology use in delivery of the content
- Demographic data and validation of content also completed

Results

- Paired t-tests of pre-course and post-course total confidence scale scores indicated a significant increase in mean ratings ($p<.01$)
- First ten items (basic competencies) accounted for significance

Mean Participant Ratings from Pre-Course and Post-Course Self Evaluations of 16 Capability Statements



Assessment of Technology Use

- Using Flashlight Survey Tool (Teaching, Learning, and Technology Group)
- 5 point Likert scale with 5 being most positive
- Overall mean scores for the 10 item questionnaire were 4.2, falling between agree and strongly agree

Evaluation of Breast Cancer Risk Calculators as Learning Tools

Peggy G. Gregg, Cynthia Phelps

University of Texas at Houston Heath Science Center, School of Health Information Sciences Houston, Texas, USA

Abstract

Many tools are available to teach women about breast cancer risk factors. Breast cancer risk calculators are tools that are available via the Internet to provide information to woman about their breast cancer risk. Women age 35 and older were recruited to participate in a study using online breast cancer risk calculators as learning tools. A total of 45 women participated in the study. A one group pretest post test survey questionnaire design was used to evaluate the impact of the risk calculator websites on women's knowledge and attitudes. The results indicate women identified more breast cancer risk factors after using the calculator, decreased their concern/worry about breast cancer and indicated they would do something with the information to help themselves.

Keywords:

patient education, health status indicators, risk assessment

Introduction

Methods to learn about breast cancer risk factors and risk take on many forms. Leaflets, brochures, TV, magazines, friends, family, personal counseling, group counseling and the Internet all provide information to woman about breast cancer risk factors. Breast cancer risk calculator websites are being used to give women an estimate of their risk for developing breast cancer by asking them questions related to some of the risk factors associated with the disease. The purpose of this study is to assess the learning of risk factors and risk levels using a breast cancer risk calculator, to evaluate changes in perception of risk, and explore behavior modification intent.

Methods

A convenience sample of women age 35 and older was recruited for participation in the study through e-mail invitations and flyers posted in the greater Houston, Texas area. Participants were directed via the e-mail to the informed consent website. If the participant agreed to participate they were directed to an online pretest survey. Once completed, the participant was directed to a public online breast cancer risk calculator. After completing the breast cancer risk calculator the participants clicked on the post test survey link from the e-mail and completed the post test survey. Questions on the surveys consisted of knowledge of risk factors, level of concern about developing breast cancer, and the intended use of the information they received.

Results

Fifty-two women who were aged 35 years old or older responded to the invitation. Of that group 35 completed the study. All of the women in the study indicated they had heard about breast cancer risk factors. The majority of women were Caucasian (86%) between the ages of 41-55 (60%) and had graduated from college (69%). A comparison of the pretest and post test knowledge of 17 breast cancer risk factors[1] showed that participants improved their identification of 9 of them. Interestingly, although 35 percent of the participants were surprised that their risk was higher than they thought, as a whole the participants worry or concern decreased (51%-17% respectively). Based on the information the participants received 80 percent indicated they were going to make changes to the risk factors they could affect. In addition the women indicated they would continue with their current breast cancer screening regimen (71%), begin a screening program (20%), find more information about breast cancer (29%) and talk to their physician (26%). Areas of confusion were the number of risk factors (26%), risk measurements and what they mean (29%), and their risk level in relation to the general population (23%).

Conclusion

The online breast cancer risk calculator appears to be a method that can promote knowledge about breast cancer risk factors and disease risk. However, the topic of risk and how it is communicated via the breast cancer risk calculator needs further investigation to assess ways the information can be presented and understood.

The Practice in Health Information Systems Training

Kaisa Lemmetty, M.Sc, Health Informatics, RN (a)
Eija Häyrinen, M.Sc, Health Informatics Project Manager (b)

[a] *a,b Central Finland Health Care District, Information Management Department, Finland*

Abstract

The health information system implementation is mostly seen as technical project and little research is done evaluating outcomes of organisational learning. There seems to be a gap between teaching new function management and systematically evaluate information system implementation and its effect in healthcare practice. Modern technology like Health Information Systems with computers and new application are implemented. However the training uses traditional educational methods and upholds old-fashioned ways of learning. The pervasiveness of new educational technology has not yet emerged in health information system training

Keywords:

health information system, training, education

Introduction

In Central Finland Health Care district implementation of electronic patient record took place during September 2005 to May 2006. The Health Care district employs approximately 2600 officials: consisting of 282 doctors, 1489 members of nursing personnel, 919 persons in other positions like secretaries and assistants. In this hospital there are approximately 2100 end-users for patient record consisting of doctors, nurses, other healthcare professionals and administrative personnel. Arrangements for implementation included in-house training for users' minimum 3-4 hours. This means 2100 *3 hours that is 6300 hours, which is 777 working days spent in training sessions. For time being there is some knowledge about the influence of training in usage of patient information system.

Training of health information systems

The current awareness in systematic reviews and evidence-informed education within policy and research circles is a part of a general progress towards establishing policies and professional practice on the basis of sound evidence of efficiency. The best practice concept covers those processes, practices or systems, identified in public and private organisations that execute exceptionally well, which are widely recognised as improving an organisation's performance and efficiency in specific areas. Systematic reviews on education can help to collate a range of research types so as to investigate what works and what does not, how things work or why they do not; or to study existing practices, trends, needs or promising areas for development. [1, 2, 3]

Based on a review when instructing health information system previous computer skills or competence were neither explicitly defined nor measured. Even tough in several studies the participants presumably had computer know-how because the system itself presented advanced technology. The learning environment was in most cases the participant's own work surroundings. The knowledge or know-how attained from the training, or the educational impact on information system usage were seldom explored or measured. The review revealed that competence in any level of health informatics contributes to the learning process. The learning environment was seldom created for the educational purpose only. The system training was mainly a part of an introduction course to a new function or changes in the organisation. Teaching methods were interestingly often traditional, including written material and lectures. The innovations in virtual learning are nonetheless proliferating. Different teaching methods were widely used and pedagogical approaches varied from behaviouristic to cognitive and constructive approaches. [1]

Challenges in educational practice

Health information system teaching and learning is going to influence attitudes and future working practices. [4] The health system is expanding its use of information technology to complete evermore demanding tasks within health system. To manage these changes, staff education, personnel attitudes and the management of changes knowledge is required. [5] As main goal for implementing health information system is to manage information so that everyone has right of entry to the information they require to do their jobs effectively and make available better, more competent care.[4] Many healthcare professionals realise they need skills in finding and using information, and in assessing information systems. Yet today's health professionals generally have no formal training in health informatics. [6,7]

It is challenging to asses the impact of training and education on clinical utilisation of health information systems. Objectives for implementation consists of knowing how well do the system work. Then new function management should improve patient care.[1] The goals for training reveal did the training succeed and how clinical utilisation of information system is going on. Evaluation needs to be done in two dimensions taking into consideration both individual and organisational level of learning. Modern technology like Health Information Systems with computers and new application are implemented. However the implementation training uses traditional educational methods, classrooms and supports old-fashioned ways of learning.

The pervasiveness of new educational technology has not yet emerged in health information system training.[1, 6, 7] Learning spaces need to sustain multiple ways of learning. Learning designs should be created around people and learning principles. Learning is more important than the use of technology only, but technology can impede learning. New technology can progress and assist learning in various ways. [8, 9] Best practices in education rise from research, consensus models and benchmarking. Good practice has contact and collaboration, using active learning strategies and respects diverse talent and ways of learning.[2, 10] Within in health care deployment of pedagogies that support high-context, multidimensional, emergent approach and uses asynchronous tools should be apparent.

Discussion

Health information system implementation has effects in learning, both individual and organisational level. Prior to training one should assess competence of trainees. Evaluation of new function management and system usage, training achievements and assessment should be carried out systematically. Publishing findings profits information that is basic for creating Best practice.

The health information system implementation is often seen as technical project and some research is done evaluating outcomes of organisational learning. Hence, there seems to be a gap between teaching new function management and systematically evaluate information system implementation and its effect in healthcare practice.[1]

Learning is enhanced when it is more like a team effort that a private competition. Good learning, like excellent employment, is collaborative and social, not competitive and remote. Functioning with others repeatedly increases contribution in learning. Reflecting, sharing one's own ideas and responding to others' reactions creates meaningful interaction and deepens process oriented learning activity within health care.[9]

Abstract and objective

The purpose of this study was to develop and apply a virtual class for healthy aging education for college students. A class for healthy aging and health management was established based on Network Based Instructional System Design(NBISD), using the following five process: 1) Analysis stage 2) Planning stage 3) Content Framing and development stage 4) Program application stage 5) Evaluation stage. The class homepage consisted of lecture room, discussion, assignment, activities, reference room, question & answer, bulletin board, and announcem

ent. In the application of virtual class, HTML, Javascript, multimedia (image, audio & video, simulation, and game) were utilized. Content and technical validity tests were done by experts. The completed program was applied to college students and showed the positive responses from the target students. Virtual class with multimedia such as simulation and games could be an effective teaching media of aging education for college students in the information age.

Keywords:

virtual, education, aging, multimedia

Introduction

The need to include aging education in curricular for college students has been acknowledged and recommended recently [1]. Rapid increase of old population has prompted an interest in preparing the young generation to better lead the future aged society. Healthy aging education is one method of sensitizing the young generation to the need of aging society [2]. Aging education for college student is one area that could benefit from the use of multimedia interactive virtual class to attract the users who are used to web based teaching environment [3].

Virtual class is one method that can be used to supplement or replace the traditional class room education [4]. Interactive virtual class allows the user to control the computer program, so they may learn at their own pace, provide an interactive learning environment in which materials can be targeted or tailored, and provide a variety of multimedia formats including graphics, video and audio, games, and simulations [5].

The purposes of this study were to develop and apply virtual class of healthy aging education for college students using multimedia simulations and activities.

The specific aims are as follows:

1) to analyze the learning need of the target students, learners' learning and computer related characteristics, and technical and environmental need.
2) to design the information, interaction, motivation, and evaluation mechanisms.
3) to develop the content using multimedia such as graphics, animation, video & audio, games, and simulation.
4) to operate the developed program
5) to evaluate the program

Methods

Virtual aging class was developed in the following five steps. 1) The learning needs of the target students, the learners' general learning and computer related characteristics, and technical and environmental needs were analyzed. 2) The education contents, interaction and motivation method, and evaluation mechanisms were designed using the results from the analysis. 3) The content using multimedia such as graphics, animation, video & audio, games, and simulations were developed. 4) The developed program was demonstrated to the experts and the sample group of students and revised according to their comments. 5) The program was uploaded on the web and operated for 16 weeks. 6) The evaluation was done with the users about learning function, display structure, and system function.

Results

In analysis stage, the topics of virtual class were developed based on a survey about the college students' knowledge and attitudes of aging and literature review. According to the target students' needs for aging education, the following list of contents were determined for aging education: 1) Theory of aging, 2) Aging process, 3) Genetic and environmental effects on aging, 4) Physical and Psychosocial aging, 5) Issues related to the elderly such as elderly abuse, sexuality, alcohol and substance abuse, 6) Successful aging, 7) Nutrition and exercise for

aging, 8) Internet information related to aging and longevity, 9) Social welfare system in Korea and other country, 10) Long-term care system for the elderly. The topics selected were validated with the experts in aging and gerontological area. The education information (cyber lecture, reference room), interface between learner and contents, learner and instructor, learner and learner (question & answer, bulletin board, e-mail, discussion), motivation (game, simulation, video & audio), and evaluation (quiz, test, assignment) were designed with the detailed functions. In development stage, contents frames were constructed based on the order of contents, technical stability, and user interface. Forty five cyber classes, 10 videos, 104 images, 4 simulations, and 4 games based teaching materials were included in the program. Simulations were designed for visual, mobility, and other functional changes during the aging process (Figure 4). Games were designed for brain, family tree, lifeline for student, and lifeline for the elderly (Figure 5). The instructor can check the students' participation using the administrator mode and provide the feedback for each student.

The final program was operated and over 100 students were registered in the aging class as an elective course. The evaluation was done about users' satisfaction of learning function, system function, and screen construction on the web and showed the positive responses from the users using 5 point Likert scale. The students responded that the class helped them to be concentrated and interested in the contents. Also, they gave the high scores on attractive graphics and variety of multimedia. Convenience and speed of the system were scored least and need more improvement. The majority of students reported that this class was very useful and made them feel sympathy for the elderly.

Discussion

This project aims at developing and applying virtual aging class for college students using multimedia simulation and activities. The study results reveal that the virtual aging class with multimedia interaction is an effective learning tool for college students. Students learned the topic more interestingly using the multimedia learning materials. In addition, the class develops positive attitudes about aging.

A majority of subjects indicated a preference for the multimedia instruction of aging. The study results demonstrate that virtual class with multimedia such as games and simulation can be an effective tool for improving comprehension and eliciting interest in the lessons.

Consistent with previous reports[6], the present investigation found that experience with virtual class and multimedia activities was interesting and holding attention of the students in the information age. Multimedia interaction such as video, audio, games, and simulation can clarify instruction by allowing students to visualize and experience the complex and dynamic process of aging.

Conclusion

Based on the findings of this study, further investigation is required to evaluate the effect of the virtual aging class in more detail. Remaining questions to address include the following:

· What aspects of aging process can be effectively simulated for teaching?

· How would virtual only aging class compare with blending virtual and traditional offline learning experience?

· What are the best strategies for incorporating multimedia into aging education?

The ultimate objective of this line of research will be to determine how best to prepare the multimedia such as simulations and games on aging education for successful aging and health promotion for the different age group such as middle age or old age group.

Problem-Based Learning Approach for the On-line Public Health Courses

Young Moon Chae, Seung Hee Ho, Seon Kui Lee, Soo Jin Yoon, Min Kyung Kim, Bernard C. M. Tan Tan[a]

[a] *Graduate School of Public Health, Yonsei University, Korea*

Abstract

In order to develop an online problem-based learning (PBL) method which will fit best into the International Cyber University for Health (ICUH) programs and meet all the learning needs of students in the field of public health, we have first considered the characteristics and nature of each course. Therefore, a modified PBL discussion method was adopted to attain the maximum efficiency for students to learn better from the subjects in the course contents. Although it is still in its initiation stage, the evaluations showed a successful implementation of PBL method with high satisfaction of students. In this article, we will examine the general PBL method, suggest our modification of PBL method for the courses, and finally analyze student's evaluation on PBL method.

Keywords:

problem-based learning (PBL), online education, cyber, discussion approach, public health

Introduction

At the entrance of the 21st century, cyber education offers an environment that enables instruction and learning to become independent of time and space. It opens up learning opportunities to people with physical or other limitations, thus unable to participate in conventional classroom education. The excitement and chance to learn are not limited to a single country, region or group, but extends to global community.

The conventional long distance courses are usually based upon the mere presentation of the didactic materials with an interaction, which is usually limited to question and answer type quizzes. Web conferences and net meetings are not integrated in a comprehensive model of teaching and learning [1]. It was as assumed that one of the main obstacles to meaningful learning is the discipline oriented approach to most of the educational curricula and courses. This is the fundamental reason why many authors claim that problem based learning (PBL) is the most useful way for engaging the students in a learning process based upon realistic situations whereby knowledge from different disciplines are integrated [2].

As a part of the project named, "Development of PBL (Problem-Based Learning) & CDL (Competency-Directed Learning) E-Learning Module for Asia-Pacific Area's Health Professionals," the International Cyber University for Health (ICUH) is currently introducing the public health oriented PBL discussion method into its on-line courses.

The goal of PBL is to motivate students to develop self-learning skills in a small group [3]. The PBL environment is student-centered, students-directed, fosters intrinsic motivation, promotes active learning, encourages peer teaching, involves timely feedback, and inculcate student self- and peer assessment [4]. The students are encouraged to use self-directed learning skills to analyze a given scenario to identify the problem, formulate key-learning objectives and collect whatever additional information required to address those objective [5].

PBL differs from traditional lecture-based curriculums in that it relies on the use of real or simulated problems to develop critical thinking skills. PBL provides a stimulus and a framework for applying problem solving skills, as well as the opportunity to acquire the information needed to understand the mechanisms and solution behind the problem [6].

In order to encourage the student to develop an appreciation for the interrelated nature of the physical, biological, and behavioral mechanisms that must be considered with each health problem, we plan to introduce PBL approach to web-based classes for ICUH.

The purpose of this study was to develop and evaluate the PBL method for graduate students in public health in order to assess the feasibility of an online approach as a PBL modality. In order to develop an online PBL method which will fit best into the ICUH programs and meet all the needs of students in the field of public health, we have first considered the characteristics and nature of each course. Subsequently, a modified PBL discussion method was adopted and implemented to draw the maximum efficiency for students to learn better from the subjects in the course contents. In addition, we also analyzed the student's evaluation on the PBL method employed.

Materials and methods

We introduced PBL discussion learning method to our three courses 2006 Fall semester of the ICUH: Introduction to Health Informatics, Comparative Health Law Seminar, Leadership in Crisis and Communication in Disasters & Health Care.

The students of each course were clustered into small groups of 8-10 students. Through the creation of an online environment, students working in small groups accessed information resources that had been prepared for them in advance. The communications are based on web conferencing, access to web pages, personal contacts, and group meetings.

PBL discussion process

We modified a PBL discussion process to maximize the teaching and learning efficiency for both professors and students. We have considered two factors: (1) characteristics and nature of public health courses and (2) web-based approach.

Three courses (Comparative Health Law Seminar, Leadership in Crisis Communication in Disasters & Health Care and Introduction to Health Informatics) have shown different characteristics and nature in education compared to other similar fields, such asmedicine and nursing. The public health courses often deal with health policy and administration which combines problem-solving with consensus-building and policy-making process. In addition, since this approach is introduced to cyber courses, the whole process should be carried out online, which may require some changes in communication, technology and methodology. After thorough consideration, we have developed the followingPBL process for the public health courses to magnify the learning efficiency for students who participate in online discussions

Table 1 - The modified PBL processof public health

PBL Process	Description
Pre-Discussion Activities – Blackboard Function	
Case (Scenario) Presentation	A case or scenario is posted on the blackboard of online classroom one week prior to the PBL discussion session. The related questions for self-study are also presented.
Private Student Research	Students read the case and begin to find resource materials and other references related to the case.
Intra-Discussion Activities (3~4 groups) – Meeting Room Function	
Case Recitation	A Tutor recites the case to be discussed and confirm if students understand the case correctly.
Fact Finding	A tutor leads students to source the facts, which may become debatable or significant in discussion.
Student Presentation	Each student makes a presentation on the answers for the questions and go on to the crossover discussions amongst the group.
Possible Solution Finding	Students argue and discuss on possible solutions for the posted case study
Consensus Building	Voting process will be carried out to build consensus among students on important matters. (Voting Function)
Decision Making	Students can develop a policy through decision-making process after consensus building.
Post-Discussion Activities – Board Function	
Class Discussion	Using the board function in the online classroom, the discussion results from each discussion group are presented and further discussed among all the students in the class.
Report & Evaluation	Each student submit a separate report as well as an evaluation for each PBL session (Report Function)

Evaluation of the effectiveness of PBL approach

After each PBL session, students evaluated the PBL discussion class for the feedback. We developed a simple 15-question evaluation form with 5-point scale which requires students to write both advantages and disadvantages of online PBL discussion approach. The questionnaire consisted of five sections, learning process, cases & problems, tutor's role, student's role, and learning effectiveness.

We analyzed the relationship among learning process, cases & problem, tutor's role, student's role for the learning effectiveness (Figure 1). This study compared the relative effects of each variable for learning effectiveness in the multivariate model.

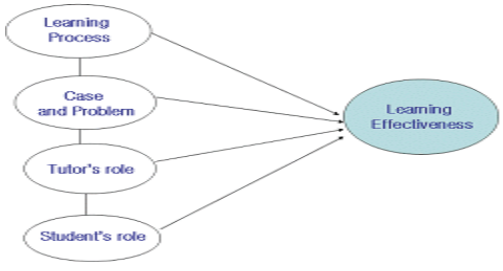

Figure 1 – Framework of the analysis

Kruskal-Wallis test was carried out to examine the statistical significance on the scores among three courses [8]. The

scores of each student were measured by two factors (Agree/ Disagree), and Chi-Square test was used to analyze the association between each factor and learning effectiveness. In addition, Multiple regression analysis was used to analyze the relationship between a single dependent variable and several independent variables.

Results

Students evaluation on online PBL discussion session

The results showed comparatively high scores in most parts. The students enjoyed much freedom to participate in discussions since they were not afraid of making mistakes online compared to traditional classroom environment. Some students pointed out the technical or systematic difficulties in the usage of meeting room function since computer or web access was running as smoothly. The Kruskal-Wallis test showed that the difference in the scores among three courses was statistically significant in learning process (chi-square value = 10.14, p-value = 0.006) and case and problem (chi-square value = 6.73, p-value= 0.034). The detailed results are shown in Table 3.

Association between learning effectiveness and factors type

The changes in learning effectiveness were measured according to the response factors (Agree/Disagree) of each variable. The results show that most variables in learning process, case & problem, tutor's role and student's role except for two variables, Organization of PBL Discussion and Appropriateness of PBL Questions were statistically significant, suggesting the high association between learning effectiveness and factors type as shown in Table 2.

The effect of learning process, case, tutor's and student's role factors on learning effectiveness

The effects of the independent variables to learning effectiveness were tested. Table 4 summarizes the coefficients, t-value, adjusted R2, and significance level of the regression model. In the regression model, the overall model was significant ($F=6.22$, $p<0.001$) and 76 percent of the variance of LDL cholesterol level is explained by independent variables ($R2=0.7567$). The learning process factor had significant influence on learning effectiveness in two variables, organization of PBL discussion and easiness of opinion presentation. The case factor also had significant influence on learning effectiveness in one variable, relevance of PBL case. In addition, the result shows that the case factor was significantly related to learning effectiveness (beta= 0.55622, t-value= 3.21, $p<0.0038$).

Discussion and conclusion

Although it is still in the initiation stage, the evaluations portrayed a successful implementation of PBL method with high satisfaction response from the students. The PBL approach enables students to understand the relevance of underlying knowledge and principles in health care practice [9].

For the PBL process, the web is used as a repository of multimedia documents that can be accessed by the students of the virtual classroom, a source of valuable structured information, and a synchronous communication channel with the capability of recording and marking the sequence of interventions. The use of web-based method appears to be a potentially feasible problem-based learning modality for the graduate public health course. Web-based PBL approach provides a unique opportunity for students worldwide to experience health education challenges that originate in a variety of distinctly different culture. Without any distance constraint, students can collaborate in a common work setting as they pursue solutions to health problems.

Another common setback is staffing time. Efficient PBL learning environment is highly dependent on the function and the participant group. This requires a tutor cum moderator to be well-versed in facilitating the PBL discussion environment, more than simply to be a subject matter expert. Feedbacks provided by students will be used to produce an enhanced PBL approach that will be evaluated further to determine its educational potential as compared to the traditionally assigned reality-based education. The student evaluations provide rich material to be reflected upon in terms of instructional and learning strategy for PBL. The results of the study will be also used to make future design and technology modications to the tutorials as part of an ongoing development process. In our PBL approach, students were given ill-structured problems through which they develop critical thinking and problem-solving skill. The obvious change to a more student-centered focus resulted in students reporting that they were more motivated to learn and that they maximized learning opportunities and became much more focused on their learning needs and responsibilities in the learning process.

Online Problem-Based Learning Approach for Public Health Courses

Presenter: Young Moon Chae

Young Moon Chae, Seung Hee Ho, Soo Jin Yoon, Byung Wha Lee, Seon Kui Lee, Min Kyung Kim, Bernard C. M. Tan,Jee Hee Kim

Yonsei University Graduate School of Public Health, Korea

Introduction

- *International Cyber University for Health* (ICUH)

  - collaborative effort with *Asia Pacific Academic Consortium for Public Health* (APACPH)

  - To provide high quality online public health education in the Asia-Pacific region

  - One of the vision is to offer an environment that enables instruction and learning to become independent of space and time.

  - Since its official inauguration on May 3 2004, ICUH has evolved rapidly to offer PBL based courses, translation services and concurrently run a credit exchange program.

Materials and Methods

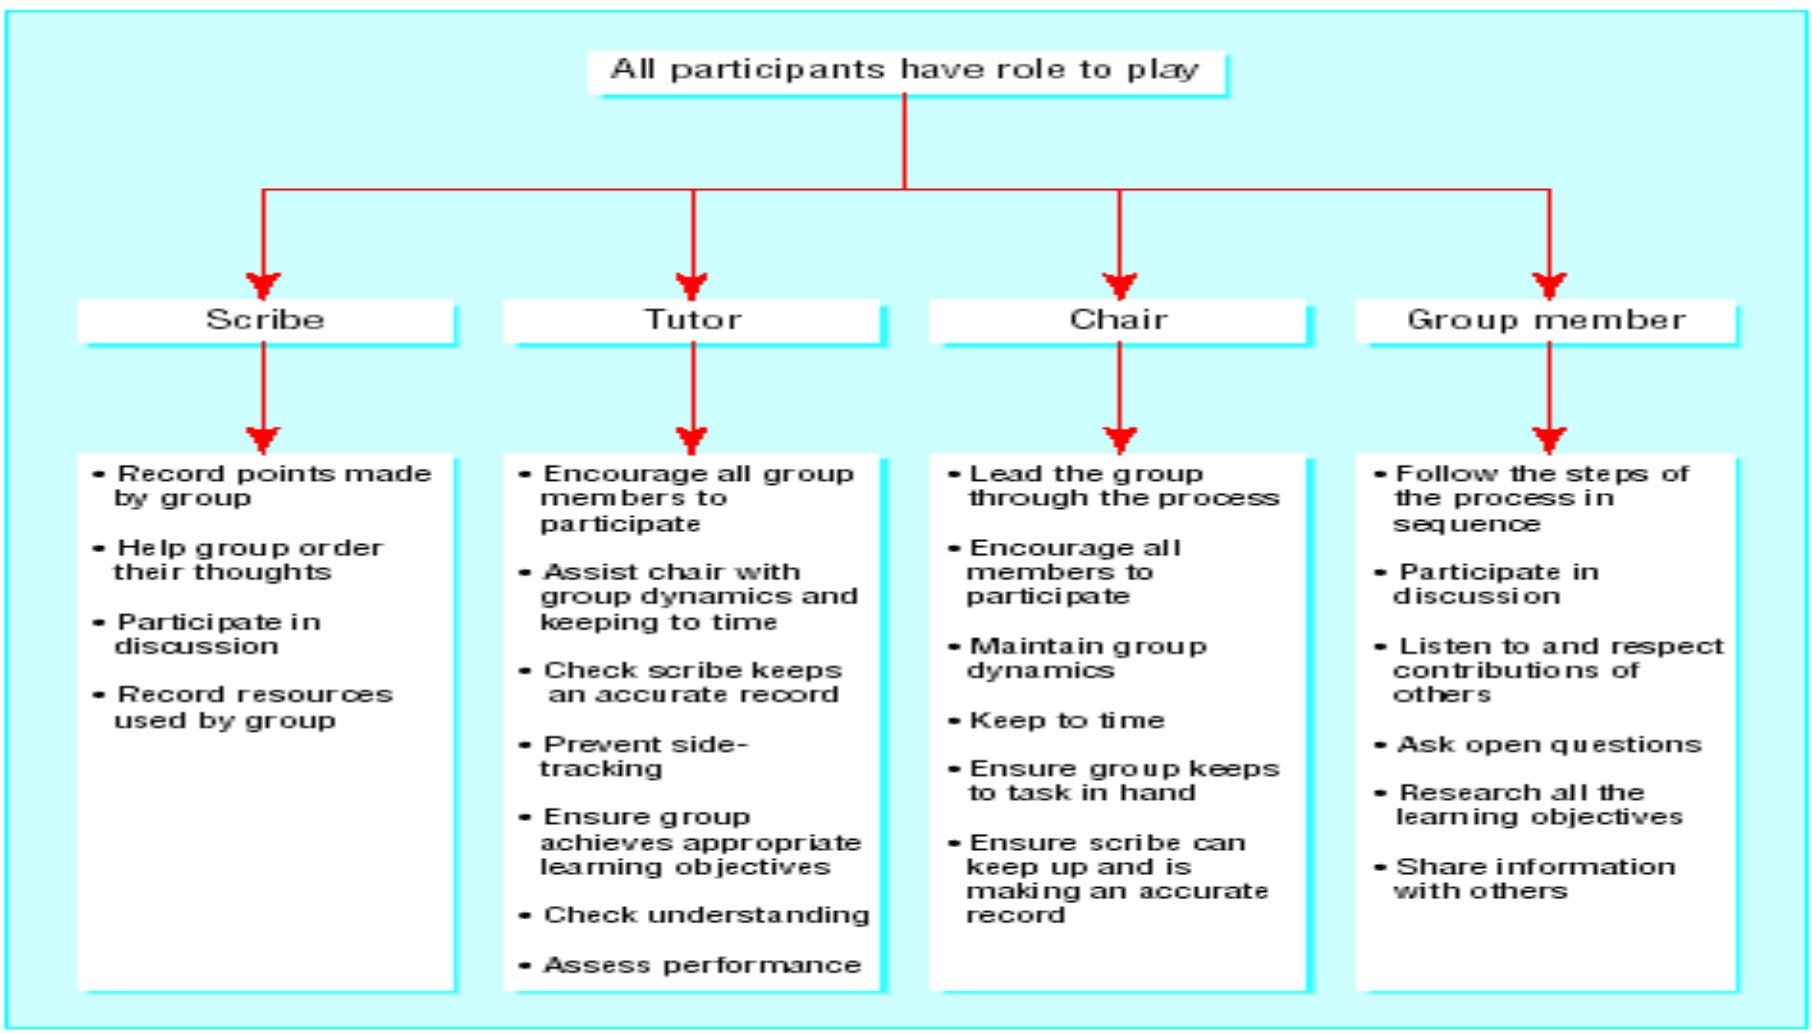
- PBL sessions were implemented in the following courses:
  - 2006 Fall semester：*Introduction to Health Informatics*, *Comparative Health Law Seminar, Leadership in Crisis and Communication in Disasters and Health Care*.
  - 2007 spring semester : *International Child Health, Systems Analysis and Design in Healthcare*

- Small Group discussion (8-10 students)
- Information resources prepared prior to the online discussion sessions
- Communications - Web conferencing, bulletin board

PBL Discussion Process

PBL Process	Description
Pre-Discussion Activities – Blackboard Function	
Case (Scenario) Presentation	A case or scenario is posted on the blackboard of online classroom one week prior to the PBL discussion session. The related questions for self-study are also presented.
Private Student Research	Students read the case and begin to find resource materials and other reference related to the case.
Intra-Discussion Activities (3~4 groups) – Meeting Room Function	
Case Recitation	A Tutor recites the case to be discussed and confirm if students understand the case correctly.
Fact Finding	A tutor leads students to source the facts, which may become debatable or significant in discussion.
Student Presentation	Each student makes a presentation on the answers for the questions and go on to the cross-over discussions amongst the group.
Possible Solution Finding	Students argue and discuss on possible solutions for the posted case study
Consensus Building	Voting process will be carried out to build consensus among students on important matters. (Voting Function)
Decision Making	Students can develop a policy through decision-making process after consensus building.
Post-Discussion Activities – Board Function	
Class Discussion	Using the board function in the online classroom, the discussion results from each discussion group are presented and further discussed among all the students in the class.
Report & Evaluation	Each student submit a separate report as well as an evaluation for each PBL session (Report Function)

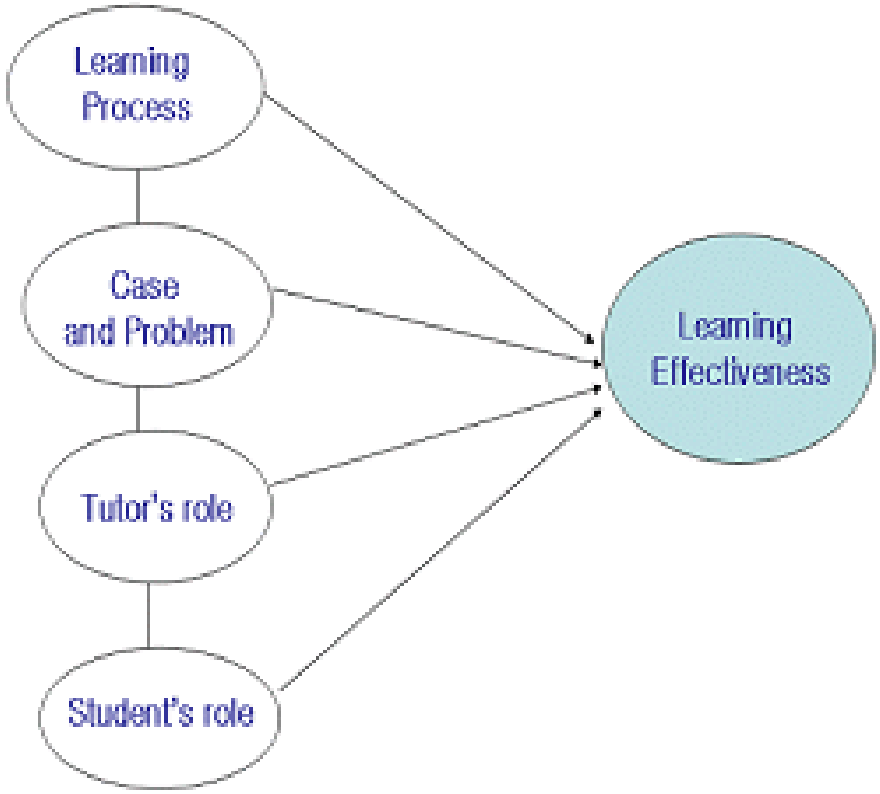
Roles of participants in a PBL tutorial



Evaluation of the effectiveness of PBL Approach

- 15 Question evaluation with a 5 point scale

- Questionnaire consisted of five sections - *Learning process, Cases & Problems, Tutor's role, Student's role, and Learning effectiveness.*



Framework of the Analysis

Results – fall, 2006

			Learning Effectiveness			
			Agree	Disagree	Chi-Square	p-Value
Learning Process	Organization of PBL Discussion	Agree	17(62.96%)	10(37.04%)	0.23	0.63
		Disagree	6(54.55%)	5(45.45%)		
	Easiness of Opinion Presentation	Agree	14(82.35%)	3(17.56%)	6.13	0.013

Model Fitness	F statistic			5.78
	P-value			0.0094
	R square			0.8967

Discussion & Conclusion

- Evaluations portrayed successful implementation of PBL method with high satisfaction response from students.
- The use of web-based method appears to be a potentially feasible problem-based learning modality for the graduate public health course.
- Efficient PBL learning environment is highly dependent on the function and the participant group. The presence of a tutor well versed in facilitating a PBL discussion group than being a subject matter expert is vital.
- The results of the study will be used to make future design and technology medications to the tutorials as part of an ongoing development process.

The Quality Indicators of Delivering E-learning for Dementia Care to Nurses

Zhenyu Zhang [a] , Ping Yu[b]

[ab] *School of Information System & Technology, University of Wollongong, Australia*

Abstract

The inadequate supply of trained professionals to provide quality care for people with dementia is a big problem. E-learning could provide an effective solution to this challenge. Although e-learning is not a new teaching method, a quality framework is lack that can be used to judge the quality of e-learning delivery for working nurses. This gap thus should be overcomed. Therefore, the primary aim of this study is to identify the quality indicator for effective e-learning delivery. Based on these indicators, a quality framework of e-learning packages that teach nurses to deliver dementia care is constructed. The approach taken is systematic literature review. The literature in the fields of e-learning for adult education and nursing continuing education were reviewed. Based on critical analysis of published literature, our quality framework was constructed. It consists of seven components, namely, learner, facilitator, content, delivery mode, technology, service and outcome. Each component covers various issues that need to be further investigated.

Keywords:

e-learning, web-based learning, distance learning, continuing nursing education, e-learning framework, dementia care, adult learner, quality assurance

Introduction

The world's population is aging. Associated with an aging population is a prevalence of dementia. Governments and healthcare consumers are concerned about the inadequate supply of trained professionals to provide quality care for people with dementia. The nurses are the major health care workers that provide quality care to dementia patients. Thus, there is an urgent need to provide training to nurses to ensure that they are qualified and use best practices to provide high quality care to patients with dementia [1]. Nowadays, the advances in Information and Communication Technology (ICT) have made it possible to deliver dementia care information via networked computers. Although a lot of work has been conducted in using e-learning method to deliver health care education to nurses, there is little study about using e-learning method for delivering dementia care education to nurses. To ensure that this e-learning course is effective and efficient, a quality framework should be established as a guideline for its development.

Methods

The approach taken is systematic literature review. Two fields of literature were searched: e-learning for adults and nurse continuing education. The following databases were searched for the literature in the field of e-learning for adults: CINAHL, Medline, ERIC, SpringerLink, the ACM digital library, ScienceDirect, ProQuest 5000, Synergy, A+ Education and IEEE. The keywords used for database search were "nurs*", "e-learning", "online learning", "web-based learning", "adult education", "quality framework", "quality assurance", and "e-learning model". The database searched on the second field include CINAHL, Medline, ScienceDirect and ProQuest 5000. The keywords used for the search were "nurse continuing education", "nurse computer literacy", "nurse information literacy", and "dementia care".

Results

In order to construct an e-learning quality framework, three basic themes need to be considered: learner, teacher, and content. Firstly, the targeted learners are nurses. In order to keep pace with the development in the medical field, technology and policy, they are increasingly engaged in continuous education [2]. The nature of learning and the driving forces for nurses to learn should be considered. Secondly, the teacher's role should always be considered. As both teaching and learning are not happening face-to-face in e-learning environment, 'facilitator' is used to replace the term 'teacher'. Facilitators facilitate the students' learning rather than a dispenser of information, as is sometimes practiced in a traditional learning course. In addition, content are the information to be delivered to satisfy nurses' need for practical dementia care, thus should be carefully designed.

In the online environment, three other themes are worth to be considered, too. They are technology, delivery mode and service. It is obvious that technology is important for the successful delivery of e-learning. Students must be online to learn via computers in Web-based learning delivery. It is critical that learners could interact with other learners, with facilitators, and with content [3]. Moreover, high quality service is the pre-requisite to guarantee the success of an e-learning project, such as, the firewall software problem [4] and password confusion issues have to be solved [5]. In addition, the pedagogical theories which are

suitable to design and deliver knowledge in online learning environment are important for the success of the delivery.

Discussion

A proposed quality framework for an e-learning package that teaches nurses to deliver dementia care is shown in Figure 1. It consists of seven constructs, namely, learner, facilitator, content, delivery mode, technology, service and outcome.

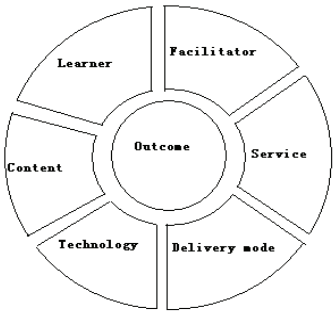

Figure 1 – A proposed quality framework for an e-learning package that teaches nurses to deliver dementia care

1. Learner

Learners of the e-learning course are working dementia care nurses, who have diverse backgrounds and levels of experience. Three issues were emphasized about nurse learners in literature: time limitations, nurses' computer literacy and familiarity with internet technology. It is obvious that lack of time to complete the course is one of the main barriers for nurses to gain a successful e-learning experience [5]. The learners' computer literacy and their familiarity with internet technology are varied. Thus the e-learning designers should understand nurses' levels of computer and information literacy before customizing effective e-learning courses for them.

2. Facilitator

There are two kinds of facilitators that are considered in our framework: knowledge facilitator (online teacher) and technical support facilitator. The knowledge facilitators should create a positive learning experience for each learner and be empathic to individual learner's needs [6]. Technical support is vital to help learners use and access the systems and the learning environment. Both knowledge facilitator and technical support facilitator should be qualified, accessible and responsive [6].

3. Content

The content of e-learning for dementia care package should be interesting, logically organized and flow well [7], comprehensive and authentic [5]. It should be directly relevant to learners' work needs and easy to understand. As the learners are working nurses who already have certain knowledge, what they want to learn via e-learning is new approaches and techniques. The previous researchers [5] suggested that improving understanding about how people suffering with dementia see the world should be an important learning objective; information on the various stages of dementia should be included. The same useful information is about the dementia patient's medications.

4. Delivery mode

In order to achieve high-quality delivery, pedagogical strategies should emphasize the following three issues: *(1)Knowledge base* - learners have different levels of previous knowledge and engagement with dementia. Therefore a variety of levels of information should be included [8]. *(2)Learning pace* - Being able to control their own pace of learning is important for nurse learners. *(3)Delivery format* - a variety of media and communication tools should be used to accommodate different learning styles. It should offer a combination of text, graphics, video and audio.

5 Technology

Technology factors to be considered include usability of website and interactivity. The previous researchers said that usability of Website is comprised of "Format (hyperlinks/buttons for ease of search-ability) and Flexibility (multimedia or plain text of material presentation indicating the utilization of web potential)"[9]. The interface for e-learning material should be carefully designed to ensure usability, which includes ease of navigation, clarity of instructions and so on.

6 Service

Service is defined as accessibility. Access to the entire website should be straightforward. Unconstrained access to services such as libraries, bookstores, and an extensive range of other learning resources should be provided via web links [6]. The course content should be available 24 hours per day, 7 days per week to ensure that the learners could access the course any time, anywhere [7]. It should also provide the learners with the download and printout right from the beginning.

7 Outcome

The outcome in the quality framework is measured by enhancing nurses' competence in two broad aspects, clinical aspect and IT aspect. The e-learning program should facilitate the learners to acquire new and relevant dementia care skills and knowledge. Besides improving nursing knowledge about dementia care, after completing the e-learning course, learners should have better computer skills and be more familiar with Internet technology.

Conclusion

This paper proposed a quality framework of e-learning delivery to teach working nurses dementia care. This framework was build upon the researchers' studies in the fields of e-learning and adult learning. The reliability and validity of this framework is yet to be tested through empirical field studies, which is the direction of our further study.

A Quality Indicators of Delivering E-learning for Dementia Care to Nurses

Zhenyu Zhang, Ping Yu

School of Information System & Technology,
University of Wollongong, Australia

The background

- A big problem: there are not adequate supple of trained professionals to provide quality care for people with dementia.
- E-learning could provide an effective solution to this challenge.
- The aim of this study is to identify indicators of effective e-learning delivery and based on them, to construct a quality framework of e-learning packages that teach nurses to deliver dementia care.

Methods: systematic database search in two fields

- How to deliver e-learning to adults
  - Databases:

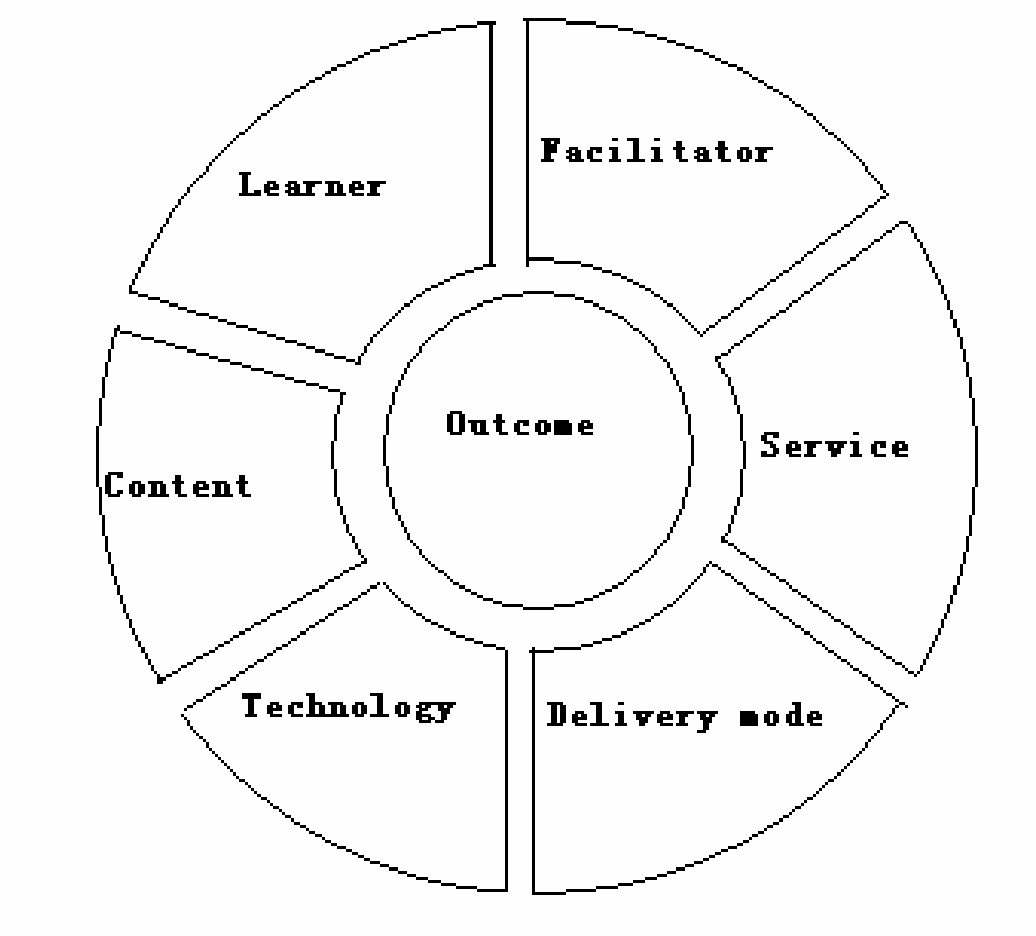
    CINAHL, Medline, ERIC, SpringerLink, the ACM digital library, ScienceDirect, ProQuest 5000, Synergy, A+Education and IEEE.
  - Keywords:

    “nurs*”, “e-learning”, “online learning”, “web-based learning”, “adult education”, “quality framework”, “quality assurance”, and “e-learning model”.
- Nurse continuing education
  - Databases:

    CINAHL, Medline, ScienceDirect, ProQuest 5000
  - Keywords:

    “nurse continuing education”, “nurse computer literacy”, “nurse information literacy”, and “dementia care”.

A proposed quality framework for an e-learning package that teaches nurses to deliver dementia care



Learner

- Learners of the e-learning course are working dementia care nurses, who have diverse backgrounds and levels of experience.
- Two main issues that affected successfully complete the course
  - Nurses' computer literacy and familiarity with Internet technology
  - Time limitations

Facilitator (online teacher)

- Facilitators facilitate the students' learning rather than a dispenser of information, as is sometimes practiced in a traditional learning course.
- The facilitators should create a positive learning experience for each learner and be empathic to individual learner needs[1]
- The facilitators should be
  - Easy to reach
  - Qualified and experienced
  - Responsive

Content

- Features
  - Relevant to clinical practice[1]
  - Logically organized and flow well[2]
  - Interesting and meaningful to learners
  - Comprehensive and authentic[3]
  - Easy to understand
- Useful information on dementia care education suggested by MacDonald and Stodel[3]
  - How people suffering with dementia see the world
  - Information on the various stages of dementia
  - The resident’ medications.

Delivery mode

- In order to achieve the high-quality delivery, pedagogical theories are important. And constructivism seems to be a suitable theory for designing and delivering e-learning course[4,5,6].
- Other issues needed considered:
  - **Knowledge base**: a variety of levels of information should be included to suit different levels of previous knowledge of learners
  - **Learning pace**: self-paced learning
  - **Delivery format**: a variety of media and communication tools should to used to accommodate different learning styles. And it should offer a combination of text, graphics, video and audio, which learner could easily access.

Technology

- Technology includes usability of website, and interactivity.
  - Usability of website comprising ”Format (hyperlinks/buttons for ease of search-ability) and Flexibility (multimedia or plain text of material presentation indication the utilization of web potential”[7].
  - The design of interface should ensure usability, which includes:
    - user friendly
    - ease of navigation
    - clarity of instructions.

Service

- Service is defined as accessibility.
- Access to the entire website should be straightforward.
- Available 24 hours per day, 7 days per week.
- Provide the learners with download and printout right.
- Two issues needed considered: the bandwidth limitations and the time zone issues.

Outcome

- The outcome component in the quality framework means enhancing nurses' competence in two broad aspects:
  - **Clinical aspect**: acquire new and relevant dementia care skills and knowledge
  - **IT aspect**: better computer skills and more familiar with Internet technology

Construction and Evaluation of e-Learning System for Medical Treatment Safety Measures

Tomiaki Morikawa[a], Hiroki Moriguchi[a], Satsuko Suzuki[b]

[a] *Department of Medical Informatics, Tokushima University Hospital, Japan*
[b] *Medical safety management center, Tokushima University Hospital, Japan*

Abstract

To consider effective medical treatment safety measures, various factors that lead to the malpractice should be understood and be analyzed objectively. In The University of Tokushima hospital, the incident report system was constructed. The safety management room is set up in the university hospital. Its system collects information and analyzes many submitted incidents to contribute safe medical treatment. However, there was no mechanism effectively educating though the system that reported on these results to the staff was able to be prepared. Because it is difficult to teach to about 1000 all staff by the set education. Moreover, it is a current state in the staff in the university hospital that in very busy, there is not even so much educated time. Then, it reports in this research because the e-Learning system is developed to do the medical treatment safety education effectively, and it evaluated it to the learners who are staffs in hospital.

Keywords:

e-Learning, medical safety management

Materials and methods

A necessary educational teaching material was made based on the statistical data having been extracted by the incident report system. The composition data of an educational teaching material is the following.

1.Video data used by lecturing on medical treatment safety management. 2.Power Point data made in safety management measure room. 3.Voice data for narration. 4.Test data

System configuration
The system configuration is: Server's OS is FedoraCore3 which is distribution of Linux, Web server is Apache2.0, SMTP server is sendmail8.12.10 , Database engine is PostgreSQL7.4.3 and program language is PHP4.3.4. The flash was used to compose the educated screen that the learner saw easily. When all contents are built in by using the Flash technology, the data capacity downloaded to the client is large. Then, educational Viewer made in the flash, and constructed the function that only contents were able to be downloaded. Thanks to this function, The volume of data that the client downloads is a little. The client downloads only necessary data from the server. Therefore, this system can be used even with the cellular phone whose cost is generated for the amount of the communication of the packet.

Evaluation experiment It experimented for about 50 nurses this time.

Contents Laws to protect personal information took effect on April 1, 2005, banning the public and private sectors from using information on a person other than for its intended purpose and from providing it to a third party without permission. The hospital is not an exception. We made contents for protection of personal information.

Results and conclusion

The nurse's record is made electronic in The University of Tokushima hospital. Then e-Learning was able to be used smoothly in this trial.

Evaluation by nurses Because the nurse was able to access the system from anywhere, it was very convenient. 50 percent of them inspected it outside work. The person who received the lecture was able also to study repeatedly. They could learn repeatedly where they could not understand. They were surprised at the place in which it was able to test by the cellular phone. But move data were not good.

Evaluation by safety management room By the use of only the WWW browser, Safety management person can easily input contents data into the database. With the nurses' usage log of the system, teachers would find their weak points and blind spots at an easier rate than before. The grasp of learner's progress report became possible through the system. Those would be reflected to e-teaching and actual lectures. It encourages interactive education. Once a data is registered, the Safety management person can easily retrieve the slides stored in the database at any time they should give a lecture. In the future, people who work at the university hospital can educate through the system.

This time, the trial was done for 50 nurses. As a result of the trial, it can be said that e-Learning concerning the safety control is a success. There was hardly a convenience of the system. It received high acclaim from the nurses

who was the learner. However, when the number of system users increases, it is necessary to solve the problem on a lot of operation sides like the registration problem etc. of ID. The mechanism of the ASP type is composed of the university hospital and it will expand it to a general hospital in the future.

Construction and evaluation of E-Learning system for medical treatment safety measures

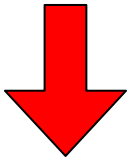
Department of medical informatics,
The Tokushima University Hospital
Japan

徳島大学病院
Tokushima University Hospital

Background

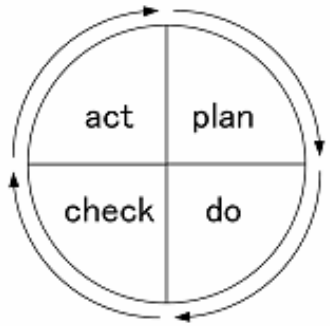
- Health care environment
  - Health care continues to experience dramatic change
  - The rapid explosion of the medical knowledge
  - The medical accidents have happened frequently



- Organization
  - Safety management room

Organization

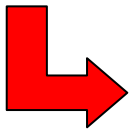
- The Tokushima University Hospital took four measures
  1. Safety management room
  2. Make medical information electronically available
  3. ISO 9001 for quality management
  4. ISO 14001 for environment management



Plan → Do → Check → Action

Safety management room

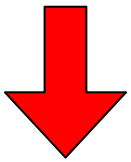
- Submitting: The incident report is submitted through system
- Investigation: The submitted incident is investigated
- Analysis: whether an incident report leads to the malpractice
- Measures: So as not to generate the incident, measures are done.



Education for medical personnel

Purpose

- Face to Face Education: It is the most important method. But all about 3000 staff cannot gather at the same time.
- The educating content is abundant.
- The education effect cannot be measured.



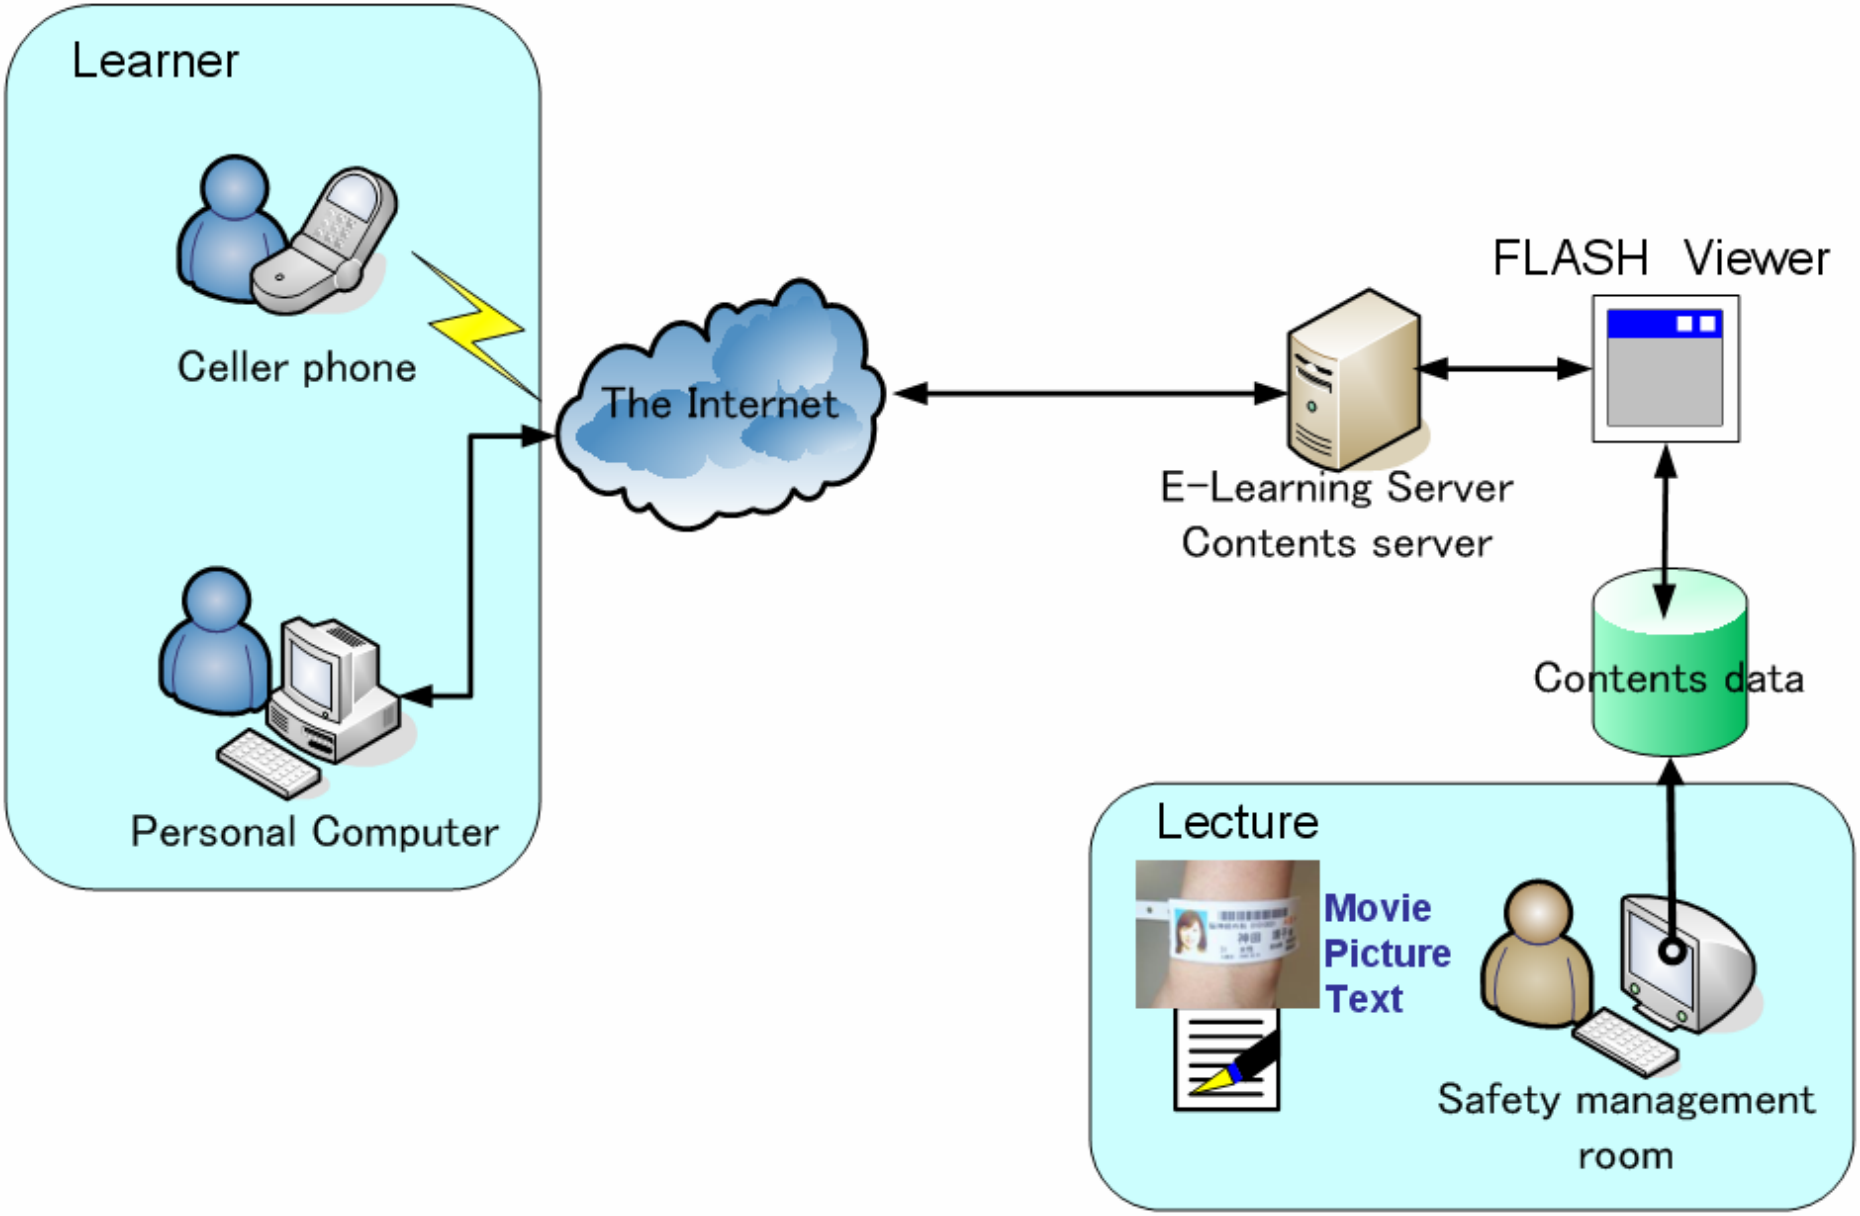
- We constructed E-Learning system for medical treatment safety measures.
  - E-Learning is a tool that supplements Face to Face education.

Method contents

- The necessary educational teaching material was based on the statistical data extracted from the incident report system. The educational teaching material is composed of the following:

1. Video data used for lecturing on medical treatment safety management
2. Power Point data made in safety management room
3. Voice data for narration
4. Test data

Method E-Learning system



VIDEO

Submit

Trial Use & Results

- Trial
  - This experiment involved about 400 nurses.
  - Contents: nursing education programs.
- Evaluation by nurses
  - Because the nurse was able to access the system from anywhere, it was very convenient.
  - 50 percent of them accessed it from outside work.
  - The person who received the lecture was also able to review the information repeatedly.
  - They were surprised at the place in which it was able to test by the cellular phone. But move data were not good.

Trial Use and Results

- Evaluation by safety management room
  - Because the nurses E-learning results are recorded, instructors could find their weak points and blind spots at an easier rate than before.
  - Tracking a learner's progress report became possible through this system.
  - It encourages interactive education.
  - Once data is registered, Safety management personnel can easily retrieve the slides stored in the database at any time they should give a lecture.
  - High appraisal was received as shown above.

Discussion

- Management: In doing the PDCA cycle to a safe medical treatment, the education and the measurement of the education effect are very important.
- Contents: The image and the video data are very important for the medical treatment contents.
- Near future program: The mechanism of the ASP type is now used in the university hospital and will expand to general hospitals in the future.

E-Learning in Ophthalmology: An Approach with High Learner Acceptance

Martin Boeker[a], Silke Biller[b], Hansjürgen Agostini[c], Rüdiger Klar[a], Thomas Reinhard[c], Andreas Stahl[c]

[a] *Department of Medical Informatics, University Hospital Freiburg, Germany*
[b] *Competence Center for Evaluation in Medicine, University Hospital Freiburg, Germany*
[c] *University Eye Hospital, University Hospital Freiburg, Germany*

Abstract

For many clinical departments the assessment of technical and financial implications of e-learning is difficult due to lacking knowledge about effective methods in e-learning.

Here, an approach on the basis of pre-existing lecture material is presented: E-learning contents are generated through extending existing lecture presentations with clinical cases and systematic knowledge as well as further interactive elements. In the summer semester 2006 a series of 13 lecture related e-learning modules was made available for training in the University Eye Hospital Freiburg. In the subsequent evaluation students attested a very high acceptance and contentment regarding the given e-learning modules.

Keywords:

e-learning; ophthalmology; evaluation; multimedia

Introduction

E-learning has a variety of properties leading to an steadily increasing demand for its usage in medical education, e.g. the embedding of high quality multimedia or the re-usage of available learning modules Additionally, several studies have shown that learning outcomes of e-learning are at least at equal with traditional methods [1-3]. Despite these considerable needs for e-learning by students and evident successes in education with it, many clinical departments still hesitate to develop or use e-learning for their training. Possible reasons for this include the difficult assessment of both its technical as well as its financial implications for the medical teachers.

Recently, on-the-fly systems for lecture recording and authoring are available to rapidly generate electronically accessible material with comparable low technical and financial barriers [4, 5]. A problem with this approach in the medical field is the frequent presentations of patients in medical lectures. The need to provide protection of the patients' personal rights can only be met by elaborate post-processing (i.e. "cutting") of the recorded lectures.

Here, an approach is presented which is based on pre-existing lecture materials and which allows for the rapid implementation of e-learning modules by clinical departments with low personal and technical resources. Further, medical learners' requirements for an effective training of extensive contents are met by an easy graphical user interface and the avoidance of unnecessary complexity [6].

Figure 2 – Graphical user interface of the e-learning module Glaukom (in German). Learners are encouraged to interactivly participate in a clinical question-answer dialogue. Source materials are Microsoft PowerPoint presentations which are converted to Adobe Flash Format.

Methods

The e-learning modules were introduced for the first time during the summer semester 2006 accompanying the ophthalmology course at the University Hospital Freiburg. The e-learning modules were aimed for the supplementation and deepening of actual lecture and seminar contents as well as the self-assessment of learners.

The didactic concept involved the presentation of multimedia clinical views on signs, symptoms and diseases in combination with systematic ophthalmologic knowledge. Active participation of students in the learning process was achieved by interactive elements. Therefore, existing high qualitative lecture presentations (Microsoft PowerPoint) were enriched with contents on systematic background knowledge, multimedia clinical cases and interactive ele-

ments like questions and exercises. The learners remember cases they know from their lectures by interactively participating in a clinical question-answer-dialogue.

For security and technical reasons the modules were converted to the Adobe Flash Format (ShockWave Flash) by the Articulate Presenter application. This tool generates a hierarchical navigation tree, thumbnails for previewing and a full text index. Multimedia files in the Adobe Flash Media Format can be inserted in the e-learning modules as well. Distribution with personalized access was served by the Learning Management Systems (LMS) of the University Freiburg (CLIX).

Results and discussion

In the summer semester 2006 a series of 13 ophthalmologic lecture related e-learning modules was made available for a total of 167 medical students. The evaluation was performed at the time of the examination of those students with a return rate of 92% (n=153). 85% percent of the students processed all modules; about 66% of the students worked 30 minutes and longer on each module. An interactive approach to the material was chosen by 68% vs. 32% of the learners who preferred a linear script processing mode. The rting (always on a 4-point Lickert Scale) of texts concerning content was in 100% "rather good" and better. The usability was evaluated in over 82% as being "rather good" and better. Concerning the learning benefits of the e-learning modules, 38% of students found them to be "rather beneficial" and even 56% to be "very beneficial". Over 95% of the students attested to be better prepared for the examination through the e-learning. 92% of learners wanted the e-learning to be further expanded. Of the 153 students in their 2nd or 3rd clinical term, 72% had their first contact with e-learning. The interest in ophthalmology changed from about 64% percent "rather low" and worse to about 90% "rather high" and better during the ophthalmologic education (this effect cannot only be asserted to the e-learning). About 87% percent of students had "rather much fun" or "very much fun" in electronic learning.

The acceptance of the e-learning modules on this large scale was not expected when they were introduced. The clinical curriculum demands a high rate of presence learning after the reformation of medical training in Germany. An average of 8 hour occupation with the e-learning modules is thus a good indicator for the students' very positive attitude towards the e-learning offer.

Medical training is characterized by a high input of systematic and case-based knowledge. Many complex and high interactive e-learning systems are not very well suited to effectively provide high amounts of knowledge. Possibly, the high acceptance by learners is due to the very effective provision of a substantial amount of knowledge necessary to pass the examination. The technical concept and interactive modalities of this e-learning approach are limited compared to some other e-learning systems [7]. However, the learners who are compelled to master large amounts of contents are highly satisfied with this easy and familiar way of learning.

To summarize, a very positive result in students' response to this straightforward and very effective e-learning approach in ophthalmology could be detected. The requirements of medical students for electronic training can be met in many cases with both relatively limited technical and financial resources.

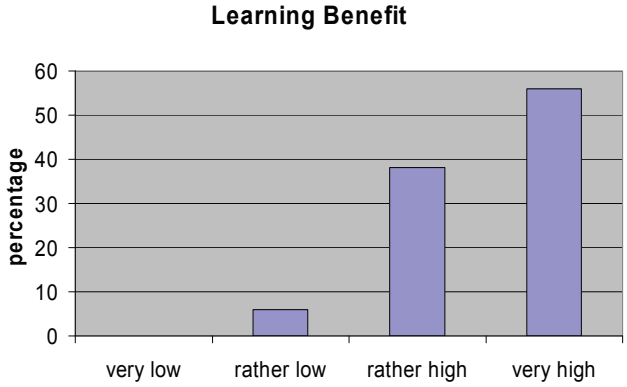

Figure 2 – Self-assessment of the learning benefit due to e-learning (n=152). The overall evaluation results of the e-learning modules were very positive.

Combined Interactive Presentation of Patient Cases and Linear Contents: An Application in Oral and Maxillofacial Surgery.

Martin Boeker[a], Jörg Tchorz[b], Alexander Streicher[a], Rüdiger Klar[a], Ralf Gutwald[b], Rainer Schmelzeisen[b]

[a] *Department of Medical Informatics, University Hospital Freiburg, Germany*
[b] *Division of Oral and Maxillofacial Surgery, University Hospital Freiburg, Germany*

Abstract

Many case-based learning systems are characterized by both time-consuming authoring processes as well as a rigid scheme of interaction with the provided cases. In this paper, an XML-driven e-learning framework is presented which can be generically applied in various medical disciplines. It focuses on the effective development and multimedia-based presentation of patient cases, linear contents and questions. Contents related to each other can be linked and displayed together.

In the Division of Oral and Maxillofacial Surgery at the University Hospital Freiburg this framework was introduced and evaluated through an e-learning system providing a presentation of 41 authentic cases in combination with two standard textbooks. An evaluation showed that learning with the e-learning application resulted in similar learning outcomes than conventional paper based method.

Keywords:

e-learning; oral surgery; maxillofacial surgery; case-based learning; multimedia; XML presentation framework

Introduction

In electronic medical education the interactive multimedia-based presentation of authentic patient cases in combination with systematic background information has shown to be of great value for the acquisition of clinical knowledge. Many sophisticated case-based learning systems with complex user interfaces are available which focus on a problem-oriented learning paradigm [1-4]. They usually require high levels of authoring resources and are sometimes rigid and time intensive in the presentation of material to the learners [5]. Also, learners in today's crowded medical curricula require time-effective methods to learn on authentic case-based materials without the need to follow a certain didactic concept. Furthemore, it is important to support the learners in acquiring, refreshing and combining their systematic knowledge. This is further supported via directly connecting this knowledge to specific cases without the need for any complex search.

In the following, a platform is presented that focuses on both the easy and effective authoring as well as presentation of patient cases and linear contents by employing standard XML tools. The contents can be combined through linking and presenting them together to provide the learner with a unified view on the medical subject of interest.

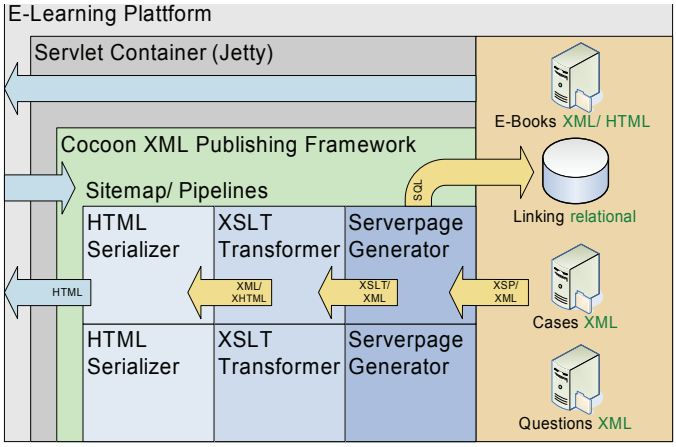

Figure 1 – Generic architecture of the e-learning platform based on the Apache Cocoon XML publishing framework. Cocoons concept of highly modularized "pipelines" enables the rapid development of extensible and reusable software

Methods

A schema driven e-learning platform for the effective presentation of cases and sequential systematic knowledge has been developed, technically based on the Apache Cocoon framework (Figure 1). It can give access to large quantities of cases and linear content with simple hierarchical navigation and search. The sustainable usage of the platform in various medical disciplines is guaranteed by application of extensible schemas and standards.

The case structure is geared towards clinical practice and expressed in a generic RelaxNG XML schema extendible according to specific clinical implementations. The effective authoring and learning has been given special

emphasis by reducing the complexity of the cases to a level that allows for easy access to the cases but is still detailed enough to clarify specific clinical processes.

Linear contents are expressed in the well established DocBook XML standard [6]. Transformation of the DocBook-conformant contents is performed with open-source tools permitting a high flexibility in output design and format. The linkage of patient cases, corresponding background knowledge and associated questions is implemented with common relational database techniques.

Figure 2 – Graphical user interface (in German).On the top-left the main menu appears above a full text search dialogue box. The patient case navigation is shown as a hierarchical tree structure enabling the learners to quickly access the parts of interest. Below the case header a listof links to the relevant systematic contents is opened fordirect access to the associated e-book.

Results and discussion

In the Division of Oral and Maxillofacial Surgery at the University Hospital Freiburg an e-learning system has been developed and evaluated based on the introduced platform providing 41 multimedia-enhanced authentic patient cases and two extensive standard textbooks covering oral and maxillofacial surgery [7, 8]. Navigation between the cases and their corresponding background knowledge has been made possible via two-sided links that are easy to follow from either the case or the e-book.

A controlled cross-over evaluation in the winter semester 2006/07 (n=42) showed e-learning and conventional (paper based) learning to have similar learning outcomes (9.4 vs. 9.5 from a total of 20 point). The assessment of the direct benefits in medical education associated with the particular learning methods is significantly different between e-learning and conventional learning: 4.2 vs. 3.6 on a 5 point Lickert scale (p=0.005). The “fun-factor” while working on the cases differed also significantly: 4.1 vs. 3.2 on a 5 point Lickert scale (p=0.005). In principal, the usability of the e-learning application was evaluated as being good.

The evaluation results further suggest that learners are satisfied with a comparably simple e-learning system which gives them direct access to patient cases and linear contents without the need for any complex interaction. It is highly important for the sustained success of such an e-learning application with only loose user guidance to be integrated in the curriculum in a blended learning approach: medical teachers use e-learning side-by-side with other more conventional means to enrich their lectures.

Further development is directed towards enhanced presentation and navigation of cases and linear contents as well as the extension of the current system to other medical subjects (e.g. general surgery).

An extensible and flexible medical e-learning platform based on XML technologies has been presented enabling the development and presentation of case-based and linear contents. The platform was successfully introduced and evaluated in the field of oral and maxillofacial surgery and is now subject to further extension to general surgery.

E-learning for Occupational Medicine Through an Interactive Guidelines Tool

Silvana Quaglini [b], Ezio Caffi [c], Paolo Ciccarese [b] , Sergio Ghittori [d] , Mazzoleni M.Cristina[a]

[a] *IRCCS Fondazione Maugeri, Clinica del Lavoro e della Riabilitazione, IRCCS, Pavia, Italy*
[b] *Department of Computer Science and Systems, University of Pavia, Italy*
[c] *Biomedical Engineering and Medical Informatics Consortium, CBIM, Italy*
[d] *FSM-ISPEL Laboratory for occupational risk analysis management*

Abstract and objective

We are developing an E-learning system for allowing the occupational medicine physicians to be updated on the most recent guidelines (GLs) in his/her area. The system will be particularly focused on GLs developed within a joint initiative between the "Fondazione Maugeri Clinica del Lavoro e della Riabilitazione IRCCS", involved into occupational medicine since its birth, and the Italian Society of Occupational Medicine and Industrial Hygiene. These guidelines are currently available in textual format (booklets) and, within the project, they will be computerized and used in interactive modality for educational purposes.

Keywords:

e-learning; guidelines; occupational medicine

Introduction

As a consequence of the continuous technological and organizational changes of industrial production activities, occupational medicine increasingly needs a systematic and timely enlarging/updating of its scientific basis and intervention methods. In the near future, occupational medicine physicians will be given supplementary tasks, with respect to the traditional, clinical ones: in addition to medical encounters and healthcare surveillance, they will have the role of consultant for risk evaluation and management, information and education of workers, and the management of burocratic and legal issues.

Within the project "e-learning for the quality of life and the safety in occupational environment", funded by the Ministry of Health, an activity for the continuous education via e-learning has been designed. As first step, an analysis on the educational needs of 300 occupational medicine professionals has been performed through an ad hoc built questionnaire, in order to identify the topics of the learning activities according to the real needs of the potential users. The results, not yet published, pointed out interest as to communication skills, models and strategies for the prevention and control of risks, prevention and surveillance for specific expositions.

Guidelines (GLs) are one of the matters to be administered through the E-learning platform (A-Tutor). In the following sections we explain how GLs may be taught in an interactive way, that we consider more attractive, efficient and effective.

The GL interactive tutorial will be tested on:

- a set of guidelines already available as textbooks, among which: prevention of occupational dermatitis; health surveillance of workers exposed to inorganic lead and other inorganic substances; health surveillance of workers exposed to pesticides; health surveillance of workers exposed to styrene
- a set of rules to implement the risk evaluation and control plan [1]

Methods

The goal of the work is to create a GL repository, that can be browsed and interactively used with real or simulated cases through a portal, that will be the final user interface. Thus, the first step is to represent GLs with a homogeneous computational formalism. GUIDE, a tool developed within our department, will be used to this aim [2].

GUIDE components are organized in a distributed architecture: an editor to formalize guidelines, a repository to store them, an inference engine to implement guidelines instances in a multi-user web environment, and a reporting system storing the guidelines logs in order to be able to completely trace any individual physician guideline-based decision process.

While most traditional systems are limited to display GLs as hypertexts through a web portal, in the proposed architecture, GL-embedded knowledge is represented also as an hyper-flowchart, which allows to:

- represent GL in a synthetic way, as a sequence of tasks and decisional points;
- represent different detail levels without loosing the general view of the GL;
- link to specific sessions of the original GL text, to obtain explanations on a given task;

- suggest the GL-compliant behaviour both in real and simulated cases;
- query the user on cases generated by the system itself (simulated cases) and critically evaluate user's answers

Moreover, if different versions of the GL exist for different users (physician/ nurse/ worker/ etc.), the user will find on the portal the appropriate version according to his role.

Whenever, during a GL running, a user's answer is not GL-compliant, the user is asked for a motivation: may be that answer is due to lack of knowledge, but also it might be due to a reasonable different opinion.

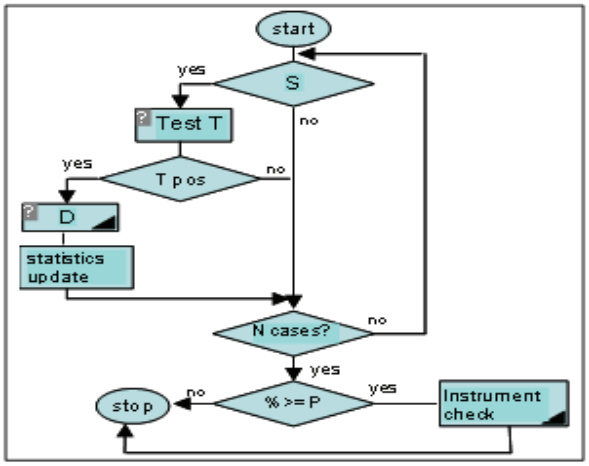

Figure 1 - Formalization of a generic guideline as an hyper-flow chart

Results

To clarify the expected results by a simple example, let suppose to have this GL:

" If the worker is exposed to the potentially dangerous substance S, then he must undergo test T regularly (each 6 months). The test has sensibility equal to k% and specificity equal to h%. If the test result is positive, the individual must be treated with drug D (recommendation supported by scientific evidence reported in L). Administration modality of the drug is the following: begin therapy with a dose d for three days,then shift to dosage d2 for two weeks, then decrease gradually and stop in three months. After having tested N workers, in case the percentage of positive results is above a predefined threshold P%, instrumentation S, present in the farm must be carefully controlled (quality check).The protocol for the quality check is the following: ..."

Its formalization is shown in Figure 1, representing the most general GL level:

Tasks "D" and "Instrument check" show a triangle in their bottom right, meaning these tasks are expandable into more detailed flow diagrams. For example, D task will be expanded in a diagram explaining the drug administration protocol.

Tasks "Test T"and "D" show a question mark in their top left, meaning that it is possible to access an explanation about that recommendation. About test T, the user can see studies on its sensibility, specificity, positive and negative predictive value and accuracy in different testing conditions. From task D, scientific publications about the drug effectiveness, cost and side effects can be found.

System-user interaction

The steps for using the portal are the following:**1.**The user, that must be previously registered, logs-on, allowing the system to retrieve his/her profile (including role)

2. he can browse the GL repository, searching GLs by keywords: for example he can retrieve all the GLs related to the effect of noise in the working environment
3. after choosing the GL, he can simply "study" it, using the hypertext modality
4. then, he can focus the major issues by means of the hyper-flowchart modality, that is more synthetic, modular, and easily allow both general and particular views
5. Then the user may check his performance by two modalities:
    a. "learning by examples": the user provides data for a particular case study and the system show the *solution*, that is the path(s) of the flowchart that represents the GL recommendations for that case
    b. "learning by critiquing": the system generates data of a hypothetical case (simulated case) , the user proposes, step by step, a sequence of actions, and the system advises him if the user-proposed process is not compliant with the GL

Elearning: a comparative study about knowledge acquisition by nurses

Yara Padalino
Nursing Supervisior at HMSL and
Ms Professor at Italo University

Heloisa Helena Peres Cinqueto
Phd Professor at São Paulo University - USP

INTROTUCTION

Organizations have developed several educational strategies to qualify their employees. They have been using eLearning as a tool to disseminate information [1].

São Luiz Hospital and Maternity has been investing in the intellectual capital through the adoption of eLearning in their personnel training process.

The Program, named “Quality Tools”, was implemented on March 1st, 2005, consisting of three steps:

- Introduction and further explanation on the program and definition of the concepts of quality;
- Structure and principles of Quality Enhancing Program and exercises;
- Quality tools: process model, activity flowchart, check-list, brainstorming and exercises.

The objective of this study was to compare the knowledge acquired by each group of nurses – those using eLearning and those receiving face-to-face training.

MATERIAL AND METHODS

The quantitative research methodology followed the experimental method leading to comparison of face-to-face with online training given to the night shift nurses. The control group was formed by nurses attending face-to-face training, while the experimental group comprised the eLearning program trainees.

The population in this study amounted to 60 nurses. Eleven nurses were excluded for different reasons, and the 49 remaining, out of their own free will agreed to participate in the research. The trainees were distributed in each group at random, with restriction and matched treatment populations.

The data collection tools of this study consisted of two questionnaires: one for characterizing the population and the other, called the Pre/Post Test, provided by the eLearning methodology team, consisting of professionals from different areas guided by a pedagogy master. The latter test was applied to the experimental and to the control groups, both before and after the training program, in order to evaluate the trainees´ input.

RESULTS AND DISCUSSIONS

The study population consisted of 49 nurses:

- 46 (94%) were female
- 40 (82%) had been working there for more than three years.
- 23 (47%) were 30 to 39 years
- 18 (37%) were 40 to 49 years
- 41 (84%) had over six years time since graduation
- 44 (90%) had post-graduate degree
- 47 (96%) had some notions for informatics
- 28 (57%) had taken e-learning courses
- 41 (84%) had participated in the first phase of the online course offered by São Luiz Hospital and Maternity.

It can be verified that the group is young and post-graduated, two aspects favoring an early contact with computer science [2].

RESULTS AND DISCUSSIONS

The data have been analyzed with descriptive measures (mean, median, standard deviation, maximum value and minimum value).

The average grades in the different groups and moments of assessment have been compared, and a new model of analysis of variance (ANOVA) has been used, with two factors: assessment moment (pre-course and post-course) and group (face-to-face or Internet): redundant measures were considered in the assessment moment factor.

The data obtained in this research show that, both the face-to-face and the online groups gave a larger number of right answers in the post-course than in the pre-course test.

Table 1 shows the descriptive measures of the grades awarded to the face-to-face and the eLearning groups, at the moment of assessment.

RESULTS AND DISCUSSIONS

Table 1 – Total number of right answers by the face-to-face group population (N=25) and eLearning group population (N=24) in the pre-course and post-course tests - São Paulo, 2006.

Assessement	Face-to-face		E-learning	
	Pre	Post	Pre	Pos
Mean	16.4	17.8	17.8	19.4
Median	19.0	19.0	19.0	20.0
Standard Deviation	4.5	3.2	3.1	1.7
Min.	6.0	11.0	9.0	16.0
Max.	23.0	22.0	21	22

RESULTS AND DISCUSSIONS

The data show that the average grades obtained by both groups are almost equivalent, values being a little higher in the group trained online. This shows that online training is as effective a learning tool as face-to-face training.

The statistical analysis has not shown significant differences between the mean grades of the face-to-face and the online groups. Also there was evidence of an increase in the mean grade after the individuals had undergone training, which means a significant effect of the assessment moment. It has been thus concluded that the mean grade of individuals was significantly higher in the post-course test than in the pre-course test.

RESULTS AND DISCUSSIONS

The comparative results of the two modes of training show that both face-to-face and online learning were efficacious, as the mean grade of trainees was higher in both cases, which indicates acquisition of the contents presented.

Online courses provide an opportunity for instructors or teachers to give better lessons, enabling them to use a series of, not only technical but also pedagogical training tools, instead of the old one-to-many pattern of presentation [3].

Elearning is a strategy adopted by organizations in order to train and qualify professionals and add value to the intellectual assets of the company through knowledge management.

CONCLUSION

The study verifies that the mean number of right answers increased after the training for both groups:

- In the face-to-face group it increased from 16.4 to 17.8
- In the eLearning group it increased from 17.7 to 19.4

These results show acquisition of knowledge by both groups of nurses in an equivalent proportion, thus confirming the efficacy of both methods employed. The research data show that knowledge is acquired, no matter what strategy was used in training – whether it is face-to-face or online.

CONCLUSION

Elearning is an efficacious and efficient method, as it adds several advantages regarding flexibility as well as time and cost saving, which cannot be attained by face-to-face training because of the limitations of the latter.

Elearning, therefore, provides a more customized study, which can be adapted to each trainee's rhythm, overcoming geographical barriers with time flexibility, as the student can choose when and where to undergo his/her training.

In nursing, eLearning provides time optimization and flexibility in training, and it highlights the importance of adopting new teaching tools to suit each individual's learning dynamics; it is a fast and efficient model of professional qualification and training.

CONCLUSION

The implementation of computer science technology in the health sector will equip nurses with an additional instrument to improve the quality of the assistance they render and the knowledge they impart. It will give them the opportunity of being reintegrated in their true functions and enhance their performance in the technical and human care of their patients.

It can be concluded that eLearning permits to change educational behavior and paradigms, and introduces a new learning culture, incorporating technological advances in the formation of nurses.

E-Learning: A Comparative study out Knowledge Acquisition by Nurses

Yara Padalina[a] , Heloisa H. C. Peres[b]

[a] Nursing Supervisor of the "Hospital e Maternidade São Luís – Itaim"
[b] Nurse PhD Professor of the Professional Orientation Department at EEUSP

Abstract

Organizations have been using strategies to enhance human resources, such as computer training. The aim of this study is to compare the knowledge acquired by nurses groups who used computer training and those who had traditional classroom training. The quantitative research methodology follows the experimental method. This study was held at São Luiz Hospital and Maternity. The study population consisted of 60 nurses, divided into two groups. One of them had traditional classroom training, and the other one had computer-assisted training. Participants were evaluated both before and after training. The results show that an equal amount of knowledge was acquired by each group, and the conclusion was that both methods are efficient.

Key words:

distance education - continuing education – comparative study – eLearning

Introduction

Organizations have developed several educational strategies, and among the new technologies developed, those applied to teaching have encouraged the distance learning process [(1)].

To attain a unique position in the market, São Luiz Hospital and Maternity has been investing in the intellectual capital and developing human skills through the adoption of eLearning in their personnel training process.

After a successful initial assessment of eLearning as a teaching tool, the hospital proceeded to invest on the Quality-Oriented Education Program, named "Quality Tools", with three steps: 1.Introduction on the program and definition of the concepts of quality; 2.Structure and principles of Quality Enhancing Program; 3.Quality tools and exercises. At that point, this would be the right moment for this research. The objective of this study was to compare the knowledge acquired by nurses using eLearning and nurses receiving face-to-face training.

Materials and methods

The quantitative research methodology followed the experimental method leading to comparison of face-to-face with online training given to the night shift nurses. The control group was formed by nurses attending face-to-face training, while the experimental group comprised the eLearning program trainees.

The population in this study amounted to 60 nurses. Eleven nurses were excluded for different reasons, and the 49 remaining, out of their own free will agreed to participate in the research. The trainees were distributed in each group at random, with restriction and matched treatment populations.

Face-to face training was given by the researcher in 2 hours through the Power Point software in the hospital training rooms, providing the same content as eLearning. ELearning was given in about 40 minutes in the hospital intranet.

The data collection tools of this study consisted of two questionnaires, one of which was given by the researcher for characterizing the population and the other, called the Pre/Post Test, was provided by the eLearning methodology team consisting of professionals from different areas guided by a pedagogy master. The latter test was applied to both groups, before and after the training program, in order to evaluate the trainee's input.

Results and Discussion

The results and eventual discussions here concern the comparison between both groups of nurses.

The study population consisted of 49 nurses: 46 (94%) were female, 40 (82%) had been employed for over three years, 23 (84%) were 30 to 49 years old, 44 (90%) were post-graduated, 47 (96%) had notions of informatics, 28 (57%) had taken e-learning courses, 41 individuals (84%) had participated in the first phase of the course on line offered by the hospital.

It can be verified that the group is young and post-graduated, two aspects favoring an early contact with computer science.

The computer science is part of the contemporary social context, and drives people to adapt themselves and make use of new technologies in their personal and professional life [(2)].

The data were analyzed with descriptive measures (mean, median, standard deviation, maximum and minimum value).

The average grades in the different groups and moments of assessment were compared, analysis of variance (ANOVA) was used, with two factors: assessment moment (pre-course and post-course) and group (face-to-face or Internet): redundant measures were considered in the assessment moment factor.

The possibility of an interaction effect between factors was assessed. When the interaction effect is not significant, the main effects may be assessed directly, otherwise the behavior of a factor should be assessed according to the levels of the other factor [3].

The data obtained in this research showed that trainees of both methods had a better grade in the post-course test at the moment of assessment (Table 1).

Table 1 – Total number of right answers by the face-to-face group population (N=25) and eLearnning group population (N=4) in pre-course and post-course tests - São Paulo, 2006.

Assessment	Face-to-face		Elearning	
	Pre	Post	Pre	Pos
Mean	16.4	17.8	17.8	19.4
Median	19.0	19.0	19.0	20.0
Standard deviation	4.5	3.2	3.1	1.7
Min.	6.0	11.0	9.0	16.0
Max.	23.0	22.0	21	22

The data showed that as a rule the lowest grades were those of the face-to-face group, not only in the pre-course but also in the post-course tests.

The mean increase obtained in the tests made by e-learning trainees is not significantly different from those attending face-to-face training. The statistical analysis shows that no group effect was verified.

The comparative results of the two modes of training show that both were efficacious, as the mean grade of trainees were higher in both cases, which indicate acquisition of the contents presented.

Online courses provide an opportunity for teachers to give better lessons, enabling them to use a series of, not only technical but also pedagogical training tools, instead of the old one-to-many pattern of presentation[4].

Conclusion

This study has reached its objective, as its results compare the amount of knowledge acquired by both groups.

The study verified that knowledge was acquired, no matter what strategy was used in training. It can be inferred that e-learning is an efficacious and efficient method, as it adds several advantages regarding flexibility as well as time and cost saving, which cannot be attained by face-to-face training because of the limitations of the latter.

E-learning, therefore, provides a more customized study, which can be adapted to each trainee's rhythm, overcoming geographical barriers with time flexibility, as the student can choose when and where to undergo his/her training.

In nursing, the eLearning provides time optimization and flexibility in training, highlighting the importance of adoption of new teaching tools to suit each individual's learning dynamics; it is a fast and efficient model of professional qualification and training,

It can be stated that eLearning allows changes in educational behavior and paradigms, introduces a new learning culture, incorporating technology in the formation of nurses.

Medical Software Usage In a Primary Care Training Program - Are We Training Our Future Doctors To Use the EMR?

Justin Tse[a], Carolyn O'Shea[b], Denise Ho[b], Josh Szental[c]

[a] Clinical Sub-dean, Royal Melbourne Hospital Clinical School, The University of Melbourne
[b] Department of General Practice, The University of Melbourne, [c] Monash Medical School, Monash University

Abstract

The electronic medical record (EMR) is playing an increasingly important role in primary care. This study investigates the current training provided by a primary care training program in the EMR, barriers to training, and an examination of both supervisor and trainee views on technology and training provision. The results indicate acceptance of the EMR in primary care and appropriate basic EMR skills. However, both trainees and supervisors state that there is a lack of formal training. A concern raised through this study was the divergent views between program organisations and supervisors on who should provide this training.

Keywords:

electronic medical record, training, primary care, medical software

Introduction

The usage of computers in Australian primary care has gathered pace over the last decade. Associated with this uptake of computers is the evolution of the electronic medical record (EMR) (1). Given the penetrance of EMR usage in Australian general practice, a number of barriers still exist in Australia for a fully integrated EMR. Liaw et al suggests issues of standards, business costs and training as barriers to usage of medical software (2). This is supported by research that reports that four main areas need to be addressed: environmental, organisational, personal and technical. (3) (4).

John Seely Brown, in his article, "Growing up Digital," suggests two important traits which are present "iPod" generation – their ability to multi-task, and their like for instant information (5). This generation will be the first truly digital generation, with the capacity to use electronic-based work processes such as the EMR. The question lies now in whether we are adequately training our next generation of doctors to succeed in a computerised work setting. As training is important to successful uptake of the EMR, primary care trainees are in the ideal situation to learn, develop and refine their EMR skills (6).

Aims

This study had three goals:

1. To investigate current perceived skills in using computers and EMR functions
2. To investigate what training is currently provided
3. To investigate the views and attitudes of trainees and their supervisors on technology, the EMR, and training provision

Methods

This descriptive study surveyed all GP supervisors (n=74) and community-based trainees (n=273) undertaking a three-year fellowship in an Australian primary care training program. First year trainees were excluded as they were hospital-based, not community-based. Surveys captured quantitative data but also allowed for qualitative descriptive comments. Survey data was entered into a specifically designed Access Database, analysed using frequencies, and a comparison between supervisors and trainees was made using Odds Ratios and Logistical Regression. The qualitative data was independently analysed by three investigators to explore emergent themes, which were subsequently discussed and consensus achieved. This project was reviewed and approved by The University of Melbourne Human Research Ethics Committee.

Results

The survey response rate was 44% from primary care trainees (n=120), and 77% from GP supervisors (n=57) who provide the majority of day to day supervision to the trainee. Seventy-four percent of trainees were female whilst seventy-seven percent of supervisors were male. Mean age of trainees was 32 years old whilst supervisors mean age was 47 years old. Over 90% of trainees and supervisors were trained in Australian universities.

Trainees and supervisors were questioned about their views, knowledge and current skills in medical software. The results are listed in Table 1. On comparison with the two groups studied, skills in using basic EMR processes were equal between groups, with supervisors having superior skills in advanced tasks such as the 75 year-old health assessment (OR 0.31 [0.15-0.62]) and Chronic Disease Management plan (OR 0.20 [0.09-0.47]).

Training issues – trainee views

The majority of trainees had no prior training in the EMR, with only 27% indicating previous training. EMR education in the program for the vast majority of trainees was done on-site with supervisors (78%) in an ad hoc fashion, mainly learn-as-you-go or passively while observing consultations. 58% of trainees reported EMR training that lasted between 30-120 minutes, whilst only a third (35%) received more than 3 hours, and some trainees had none at all.

Trainees were asked about whether they would like further training and if so, when and where training should be undertaken. 53% indicated a desire for formal training with 28% stating no further training was required. There was overwhelming support for formal training to be undertaken before entering community based placements and in particular advanced skills development (81%).

Trainees were asked to describe barriers to the usage of EMR medical software. Common themes emerged regarding lack of time and lack of specific EMR knowledge and are similar to the themes listed in the supervisor views.

Training issues – supervisor views

Over half (53%) of GP supervisors indicated that they had been previously trained in the use of EMR software. However a third (37%) of supervisors indicated a need for further EMR training with a similar number unsure about the need for further training. Supervisors indicated strongly that training for trainees should be undertaken before or at the commencement of their practice based terms (82%).

The supervisors were asked to identify barriers to medical software training in their practices. The responses could be divided into five themes:

1. Generational issues – an assumption that trainees were more IT-savvy and thus no training was required
2. Knowledge – supervisors' lack of medical software skills and knowledge
3. Time – emphasis on pre-placement training
4. Priorities – limited time with clinical issues taking priority
5. Place of training – there were divergent views on the ideal venue for training, between in-house supervisor-run training versus training from dedicated training providers

Discussion

Both trainees and supervisors were positive about the role of medical software, were not intimidated by technology and stated their preference for computers in delivering medical care. Other skills were similar between the two groups.

The results of this study suggest that medical software is not being utilised effectively in the trainee group, yet the trainees are confident in their computer skills. It suggests basic skills are naturally learnt and practised by trainees but higher level functions such as care plans and health assessments are not being utilised for patient care by trainees. This would indicate that training particular in advanced skills is lacking and that direction is required by training supervisors and organisations.

Descriptive comments made by both trainees and supervisors indicating low levels of formal training and previous training in usage of medical software. The comments made by trainees about in-house training are a concern given that the EMR is a legal document and must accurately reflect the patient status. The common assumption that the new generation of doctors will already know how to use EMR software is not only incorrect, but poses a significant barrier towards ensuring that the next generation of general practitioners will be fully proficient in the computerised work environment.

Many barriers listed by the two groups are similar to barriers identified in other published articles. A new barrier to emerge from this study is the divergent viewpoints about which party is responsible for the training. Stakeholders including supervisors, training program organisations and government bodies must provide a consensus agreement in the areas of resources, formal training requirements and competency level evaluations as part of the trainee's learning program.

Conclusion

Primary care training programs will have a crucial role in developing skills in the area medical software usage. Training should be a shared responsibility between both the supervisor and training provider to ensure skill competencies. The future of primary care requires a more computer-literate doctor. Doctors with these attributes will need to be assisted in drawing these skills together.

Table 1 – Training views, knowledge and skills in Medical Software (MS = medical software)

Trainee View (n=120) / Supervisor View (n=57) – listed in combination. Numbers described as %					
Background View	**SA**	**A**	**N**	**D**	**SDA**

Medical software usage in a primary care training program. Are we training our future doctors to use the EMR?

Dr. Justin Tse, Dr. Carolyn O'Shea, Mr. Josh Szental & Ms. Denise Ho

Royal Melbourne Hospital Clinical School
The University of Melbourne

Background:

- Increasing usage of computers in primary care (1)
- Barriers against effective usage: standards, financial costs and training (2,3)
- Digital generation/natives – the “now” generation has the capacity to utilise the EMR for health care (4)
- Primary care trainees are in the ideal situation to learn skills in usage of the EMR (5)

Objectives:

1. To investigate current perceived skills in using computers and EMR functions
2. To investigate what training is currently provided
3. To investigate the views and attitudes of trainees and their supervisors on technology, the EMR, and training provision

Methods:

- Descriptive study of GP supervisors (n=74) and GP trainees (n=273)
- Quantitative and qualitative arm
- Data analysed using frequencies, odds-ratios and logistical regression
- Qualitative study undertaken to complement quantitative data collected

THE UNIVERSITY OF MELBOURNE

Results:

Demographics:

- Trainee response rate – 44%, mean age 32 years old, 74% female
- Supervisor response date – 77%, mean age 47 years old, 77% male

(Male : Female % representative of Australian training cohort)

Training level:

- Trainees – 44% 2nd year/ 56% 3rd year
- Supervisors – 72% 2nd year/ 5% 3rd year/ 13% both 2nd/3rd year training
- >90% trainees and supervisors undertook medical school training in Australia

Skills to use computers in various tasks

Royal Melbourne Hospital Clinical School
The University of Melbourne

Skills/Ability to use computers in various tasks (Numbers as %)		
	Trainees	Supervisors
Writing scripts	97	100
Writing referrals	97	92
Ordering tests	95	96
Performing a patient reminder	91	89
75 year old assessment	47	74
Chronic Disease Management plan	56	86
Past History record update	88	93

Comparisons between trainees and supervisors indicated equal skills except for advanced skills: 75 year old assessments (OR 0.31 [0.15-0.62]) and chronic disease plans where supervisors had better skills (OR 0.20 [0.09-0.47])

Trainee views

- Over 70% had no prior training
- 17% had formal training with their current training provider
- General EMR education was done via GP supervisor (78%) – usually in ad-hoc, in-formal encounters
- Supervisor training – 58% - 30-120 minutes
- 53% would like formal training with most indicating training before commencement of placements
  - Skill areas for training – early survival phase in primary care to advanced EMR skills

Supervisor views

- Nearly 50% had no prior training
- 2% had formal training with their current training provider
- 37% would like up-skilling in usage of EMR
- Supervisors – 82% indicated a need for trainees to have formal training before the start of clinical placements

Results:

Barriers: Five themes

1. Generational issues – an assumption that trainees were more IT-savvy and thus no training was required
2. Knowledge – supervisors' lack of medical software skills and knowledge
3. Time – emphasis on pre-placement training
4. Priorities – limited time with clinical issues taking priority
5. Place of training – there were divergent views on the ideal venue for training, between in-house supervisor-run training versus training from dedicated GP training program providers

Discussion

- Perception that medical software is a useful tool and general confidence in skill levels
- Advanced software functions not utilised by GP trainees which may indicate lack of formal training in these skills – this is confirmed in results which indicate low levels of formal training in supervisors and trainees and that EMR education is ad-hoc, informal and low in training time
- Both trainees and supervisors would like formal training particular before clinical placements however there is discourse on who should provide training; supervisor or GP training organisation
  - This conflict needs to be appropriately addressed for improved EMR software usage
- Barriers to usage are similar to previous studies

Conclusion

- Primary care supervisors and primary care training providers have a key role to play in up-skilling GPs in the usage of the EMR
- Training should be a shared responsibility
- Appropriate use of the EMR by our future primary care doctors will ensure improved patient outcomes

Academic Data Warehouses: Tool for Medical Student Education in Medical Informatics and Population Health

Jason A. Lyman, Robert E. Reynolds

Department of Public Health Sciences, University of Virginia Health System, Charlottesville, VA, USA

Abstract

Academic data warehouses are increasingly being used to support health services research and quality assessment initiatives. A less common use of such systems is in support of medical education. As new requirements for health professional competence in medical informatics emerge, data warehouses are a potentially powerful teaching tool for introducing and reinforcing these concepts. The 2nd report of the AAMC Medical Student Objectives Project describes several learning objectives related to medical informatics and population health. At the University of Virginia, we have a decade of experience with a custom-built academic data warehouse; over the past five years we have explored the educational potential of our system. In this abstract, we describe our vision for how data warehouses like our own might be useful for training in these important areas.

Keywords:

database management systems, academic medical centers, medical informatics, medical education

Academic Data Warehouses and the AAMC Medical School Objectives Project Report II

Academic data warehouses typically include a wide variety of clinical, administrative, and financial patient data. Most commonly, data is integrated within a single healthcare organization, though this is not always the case. These systems often include custom-developed user interfaces allowing users to directly query the database. While curricular demands have broadened to include medical informatics and population health, the information infrastructure to support these requirements has lagged. Data warehouses offer students the ability to gain hands-on experience in interacting with clinical databases, potentially serving as a useful tool in handling these new educational requirements.

In 1998, the American Association of Medical Colleges (AAMC) Medical School Objectives Project (MSOP) Report II focused exclusively on medical informatics and population health, outlining a series of learning objectives for medical students organized into five different roles: Life-Long Learner, Clinician, Educator/Communicator, Researcher, and Manager.

Data warehouses and medical education

Like many of the roles described in the MSOP II, the Life-Long Learner role includes several learning objectives that might be readily addressed by hands-on experience with an academic data warehouse. While this role focuses primarily on accessing knowledge sources, the core areas (including information retrieval skills and the ability to filter, evaluate, and reconcile information) could be appropriately addressed by queries into an academic data warehouse. Using such a system would also potentially allow exploration of medical terminologies and coding systems such as ICD9-CM, SNOMED, and LOINC. The learning objectives associated with the role of Researcher, defined broadly to include a range of skills related to data acquisition, management, and analysis, is perfectly suited to the functionality of a an academic data warehouse. Secondary datasets are key resources for clinical investigators, and students can use data warehouses to learn about their strengths and limitations for this purpose. Finally, learning objectives in the Manager role, with their focus on quality assessment and health care service planning, could be addressed by optimizing these tasks in an academic data warehouse, allowing students to look at benchmarking / performance data for practice groups and discuss the myriad issues related to using existing data for this purpose. Specific details for these examples will be included in the poster presentation.

Conclusion

Information systems in academic medical centers have not been optimized to support new competency requirements in undergraduate medical education. Organizations with data warehouses should strongly consider introducing them into the curriculum as potentially invaluable tools for introducing and reinforcing key concepts related to medical informatics and population health. Many of the key learning objects in the AAMC MSOP II could be very productively addressed by access to these systems.

Evaluation of certifying examination of healthcare information technologists

Member of Healthcare Information Technologist Fostering Task Force-JAMI(**JHIFT**), Japan

Japan Association of Medical Informatics (**JAMI**)

History and Purpose

History

- In 2001, JAMI started the task force to foster healthcare information technologist (HIT), who can understand both information technology and healthcare. And from the year 2003, the certifying examination for HIT have started.
- Tests about **information technology**, **health care**, and **health information system** form the certifying exam. The number of questions of these tests are 40, 40, and 60, respectively.
- From the beginning of this exam many persons applied, and by the end of 2006, 5129 persons have been qualified as the primary HIT.

Number of Applicants each year					Number of Persons Certificated as HIT			
Year	**2003**	**2004**	**2005**	**2006**	**2003**	**2004**	**2005**	**2006**
Male	**2623**	**3036**	**3532**	**2949**	**856**	**1055**	**1391**	**1041**
Female	**898**	**767**	**844**	**786**	**123**	**162**	**257**	**244**
Total	**3521**	**3803**	**4376**	**3735**	**979**	**1217**	**1648**	**1285**

Purpose of this paper

- Evaluate the certifying exam by elucidating whether the desired characteristics has been certified by the exam.

The Desired Characteristics of HIT, seen in the general instructive objectives (GIO) of "Information Technology"

- Basic Knowledge about Computer
  - History, Hardware, Software, Programming, ..
- Network Technology
  - OSI model, Basic knowledge about networking, ..
- Database Technology
  - Architecture, Relational DB, SQL, Transaction, Access control, ..
- System Development
  - Design and System Development, DFD, UML, ..
- Operation and Management
  - Recovery and maintenance, Risk management, ..
- Information Security
  - Security Technology, Secure Operation, ..

The Desired Characteristics of HIT seen in GIO of "Health Care"

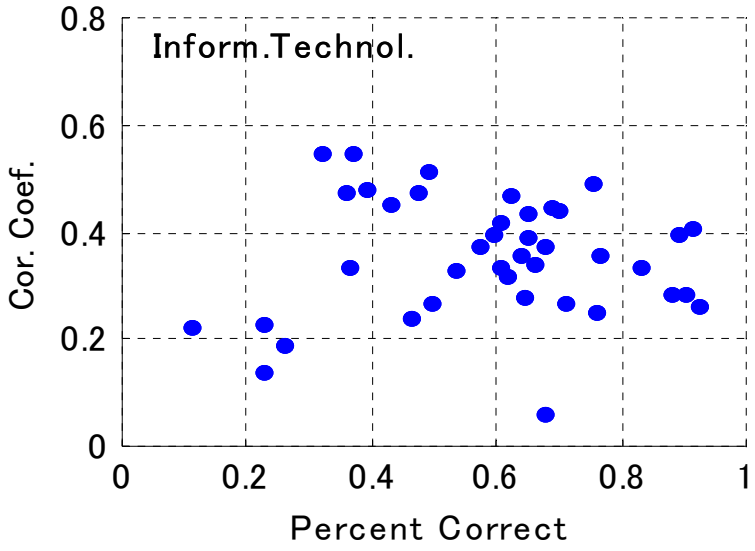
- General Remarks
  - Code of ethics, Informed consent, QOL, ...
- Social System in Medicine
  - Payment system, Insurance, Regulations, ...
- Hospital Management
  - Role of each clinical department, Patient flow, Team medicine, ...
- Social Medicine
  - Systems in public health, ...
- Clinical Medicine
  - Introduction to clinical medicine
- Medical Record
  - POMR, EHR, ...
- Nursing System
  - Nursing chart, ...
- Clinical Examination
  - Blood test, Biochemical test, Blood transfusion, Genetic test, ...
- Safety Management
  - Clinical pass, ...
- Topics
  - Genetic medicine, VR, ..

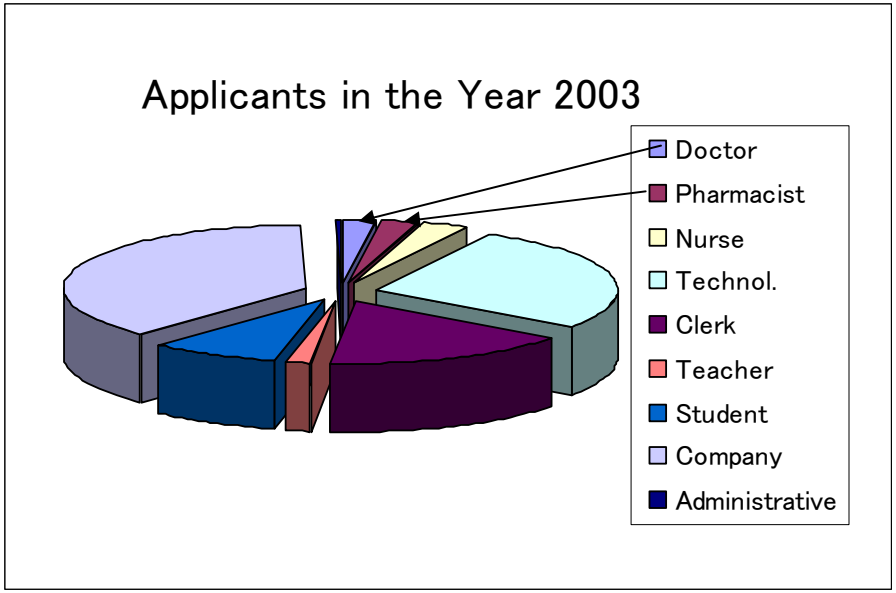
The Desired Characteristics of HIT seen in GIO of "Health Information System"

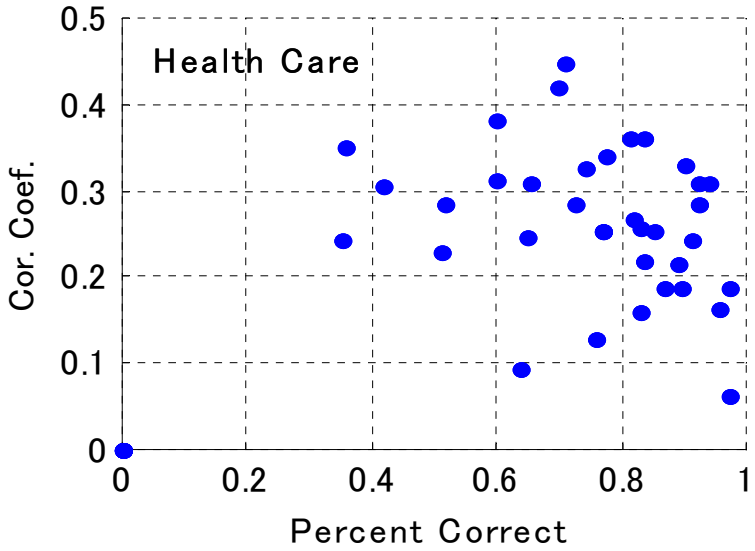
- Characteristics of Health-related Data and System
  - Requirements for health information system, ...
- Issues related to Hospital Information System
  - Explanation of subsystems, ...
  - Design, Development, Install, in practice
  - Practical way in operation, Education, ...
- Wide-area Network in Healthcare
  - Health and welfare system, ...
- Communication, Coordination, Collaboration
  - Role of HIT at the time of system designing, development, negotiation, teaching, daily operations, ...
- Standardization
  - IHE, Security and standardization, ..
- Electronic Health Record
  - Issues related to EHR
- Ethics
  - Code of Ethics, Privacy, ..
- Evaluation of Clinical Data
  - Data mining, Statistics, ...

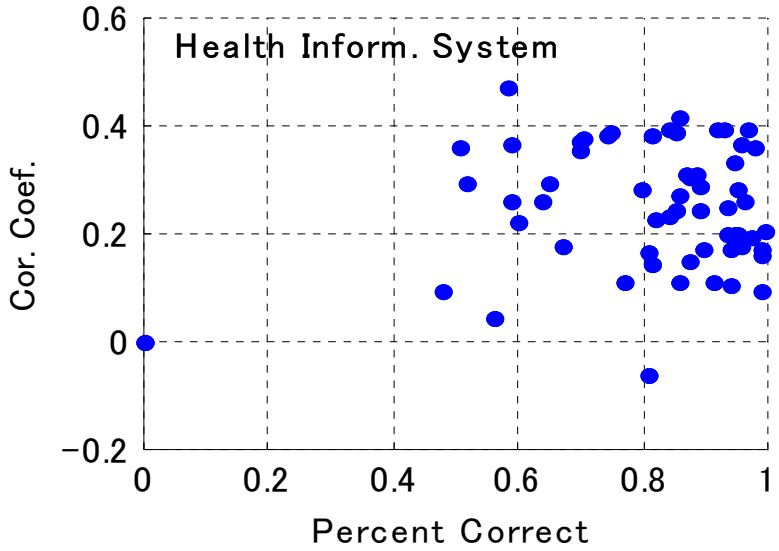
Results of the first certifying exam

As the scores of percent correct of many questions exceed 0.8, it was known that we can ask more to HIT, here Cor. Coef. is the correlation coefficient between the score of each question and the total score of that exam.

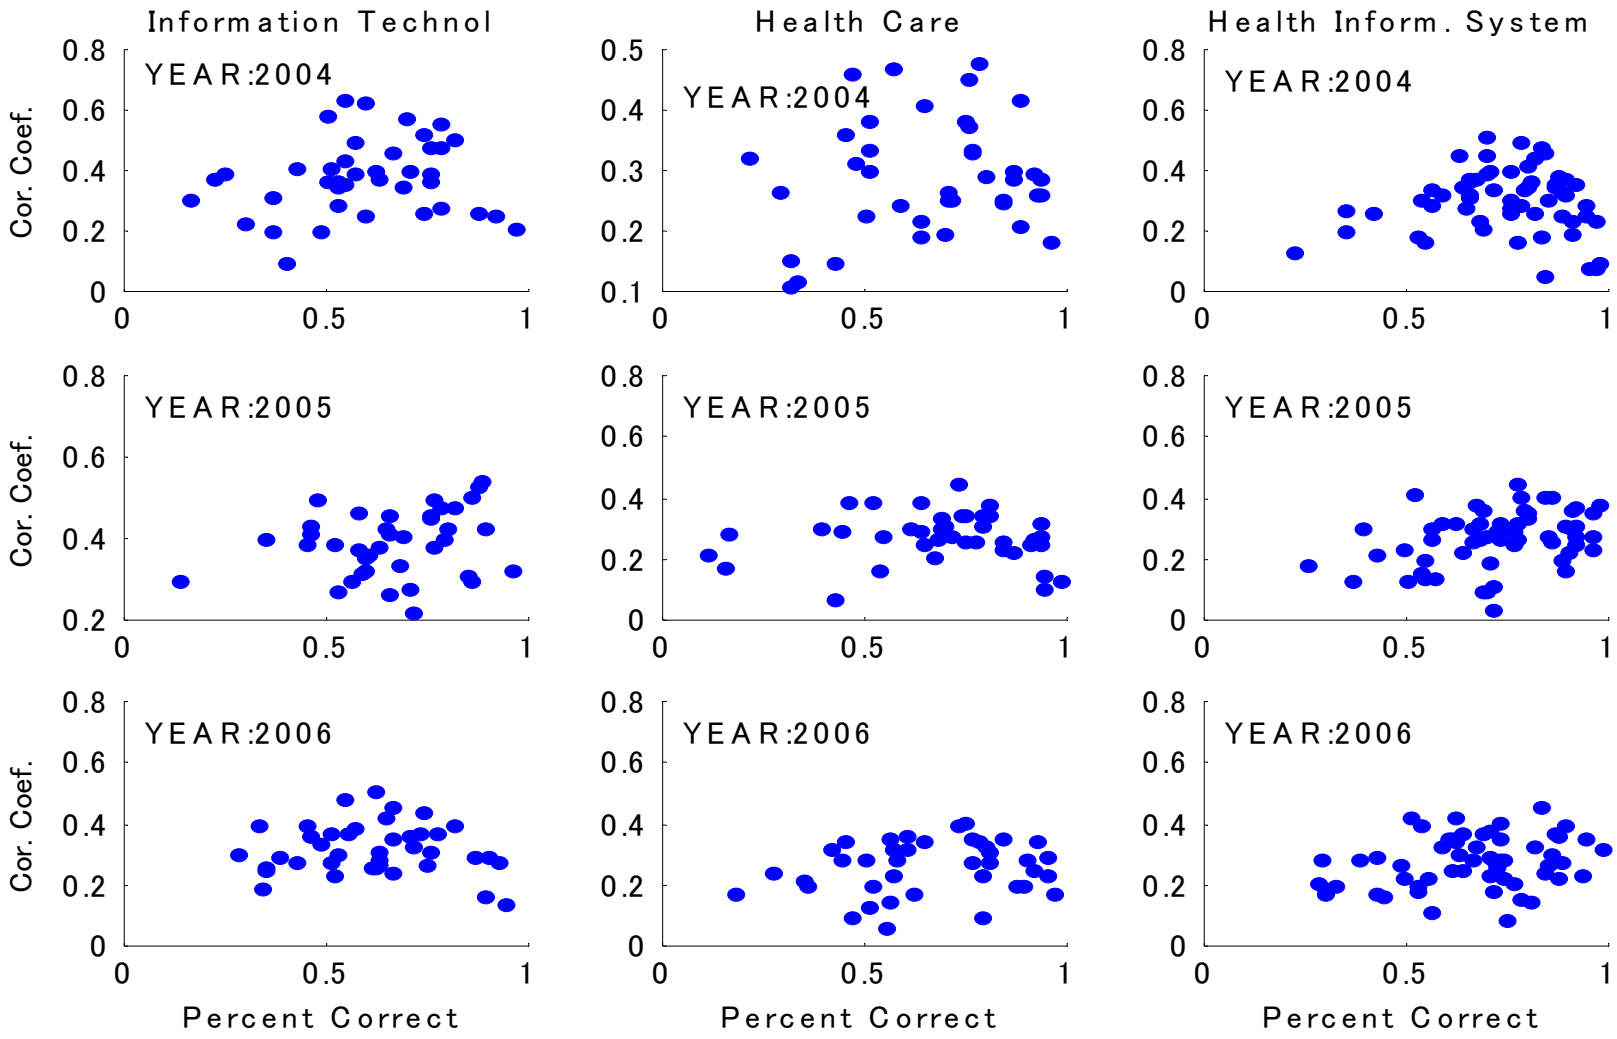








Correlation Coefficient vs. Score of Percent Correct for new Applicants each year



Method and the Categories used in the evaluation

Method

Under GIO, the specific behavioral objectives (SBO) were made. According to SBO, questions were created to measure abilities that HIT should have. As each question always treats one theme, we can categorize the objectives of each question. Seven categories were chosen as listed in the right, and questions were selected in accordance with these categories.

As this is the exam for primary HIT, a few questions are categorized into 5,6 or 7. To avoid distortions caused by the different number of questions we selected at most 3 questions to each category in each test. The selection of these 3 questions is done by the difficulty measure, i.e., average score of each question normalized to the allotted score.

Using the data of the new applicants who first apply the exam, average score of percent correct to each category in each test was evaluated, which are then used to know what category contributes most to the certification of HIT.

Categories

1: **Ability to follow logic**
- **Flow Chart, Binary Mathematics, ...**

2: **Computer Literacy (Knowledge)**
- **Terminology**

3: **Medical Knowledge**
- **Common sense about clinical medicine, ...**

4: **Knowledge about hospital management**
- **Insurance, formulas used in hospital management, …**

5: **Decision with Ethical Mind**
- **Privacy, Security, Code of Ethics, …**

6: **Behavior at the Time of Emergency**
- **Ask best choice or priorities in the time of troubles**

7: **Ability to evaluate/understand Clinical Data**
- **Understand figures or tables describing some clinical status, introductory knowledge about medical statistics**

Results

The percentage of the number of applicants who passed or failed the exam are listed in the "Passed" or "Failed" cell. These percentages were taken to the total number of applicants with the same range of average score.

1:Ability to follow logic

Score	Cases	Passed	Failed
0.00–0.25	3396	14.22	85.78
0.25–0.75	5816	30.38	69.62
0.75–1.00	557	52.06	47.94

2: Computer Literacy (Knowledge)

Score	Cases	Passed	Failed
0.00–0.25	2298	7.57	92.43
0.25–0.75	6135	26.21	73.79
0.75–1.00	1336	56.74	43.26

3:Medical Knowledge

Score	Cases	Passed	Failed
0.00–0.25	1578	16.60	83.40
0.25–0.75	5102	29.18	70.82
0.75–1.00	814	46.93	53.07

4:Knowledge about hospital management

Score	Cases	Passed	Failed
0.00–0.25	2080	14.57	85.43
0.25–0.75	6672	27.01	72.99
0.75–1.00	2612	47.47	52.53

Results (continued)

- 5:Decision with Ethical Mind

Score	Cases	Passed	Failed
0.00–0.25	142	4.23	95.77
0.25–0.75	5122	19.37	80.63
0.75–1.00	6100	38.48	61.52

- 6:Behavior at the Time of Emergency

Score	Cases	Passed	Failed
0.00–0.25	34	0.00	100.00
0.25–0.75	4381	16.91	83.09
0.75–1.00	6935	37.55	62.45

- 7:Ability to evaluate / understand Clinical Data

Score	Cases	Passed	Failed
0.00–0.25	852	10.33	89.67
0.25–0.75	8745	27.11	72.89
0.75–1.00	1767	50.14	49.86

Category	Average	Median	Mode
1	0.32	0.33	0.33
2	0.45	0.39	0.33
3	0.44	0.39	0.33
4	0.55	0.56	0.50
5	0.76	0.80	1.00
6	0.79	0.83	1.00
7	0.58	0.58	0.75

Results (continued) and Discussions

- Logistic regression analysis (dependent variable is the result of exam)

Category	Coef. B ±SE	Wald statistic	estimated odds ratio		
			exp(B)	95% confidence interval	
1	1.48±0.143	107.6	4.40	3.32	5.82
2	2.44±0.148	272.4	11.47	8.58	15.32
3	1.54±0.150	105.5	4.69	3.49	6.30
4	4.58±0.212	465.2	97.75	64.46	148.24
5	3.96±0.261	230.8	52.57	31.53	87.65
6	3.46±0.250	191.4	31.78	19.47	51.87
7	2.59±0.218	141.6	13.36	8.72	20.47

- Discussions
  - The results of logistic regression analysis would mean that the certifying exam will be very sensitive to select persons who have good knowledge about hospital management, having ethical mind, and conduct well at the time of emergency. But the knowledge about clinical medicine may not be so important. All of these characteristics are those we have expected to primary HIT.

Evaluation of Certifying Examination of Healthcare Information Technologists

Koji Yamamoto, Kiyomu Ishikawa, Kunshiku Paku,Katsuya Yahata,Kazuko Yamamoto,Masayuki Irie, Mihoko Okada,Masaki Miyamoto,Michio Naito,Tetsuo Kawamura,Toru Nagasawa, Tsunetaro Sakurai,Yasushi Matsumura, Hiroshi Inada, and Kazunobu Yamauchi

Member of Healthcare Information Technologist Fostering Task Force-JAMI (JHIFT),Japan

Abstract and objective

To improve the healthcare literacy in both of healthcare providers and system vendors, the Japan Association of Medical Informatics started the task force to foster the Healthcare Information Technologists (HIT) in 2001. After two years of preparation, the annual certifying exam for the primary HIT has started. The purpose of this paper is to report the evaluation of this exam by using four year of experiences. It was found that the exam will be sensitive to select persons who have good knowledge about hospital management, having ethical mind, and conduct well at the time of emergency.

Keywords:

healthcare information technologist, certifying examination, education

Introduction

As is stated by Prof. Evelyn J.S. Hovenga, the chair of MEDINFO2007, improvement of health literacy and development of a sound e-health environment that enables us to improve health conditions of individuals by active and effective use of health information among health care team and the individuals will be the keys to reduce the national medical expenditure. To create such the e-health environment, however, the computer system should meet the demands both of users and of the society, i.e., it should support the care process substantially to realize better patient care, it should be cost effective, and all information should be treated in secure and authorized ways. However, the computer systems used in healthcare sectors now in Japan are far behind of these demands. We have not yet succeeded even to prove the value of the computer systems. Moreover, the introduced systems sometimes mismatch the practical patient care, since few computer technologists working at system vendors know the practical health care process. All of these will come from the deficiency of persons who knows both of the health care processes and the computer technology. To solve this problem, the Japan Association of Medical Informatics has launched a project to foster Healthcare Information Technologists (HIT). To grasp the real requirements for HIT and to decide what to certify, 40 specialists gathered in the year 2001. In that assembly we made the general instructional objectives (GIO) and the specific behavioral objectives (SBO) to foster HIT. According to GIO/SBO, we published a series of textbooks. These textbooks have been widely used in schools and companies, and become the first standard textbooks in this area.

From the year 2003, the annual certifying exam for the primary HIT has started. The certifying exam consists of three tests about information technology, health care, and health information system, comprising 40, 40, and 60 questions, respectively. We have created these questions every year in accordance to SBO to measure abilities that HIT should have.

Until 2006, exemption rule existed for the tests of information technology and health care. Applicants having other specified licenses exempted from the test assigned to each license.

From the start of exam, unexpectedly large number of persons applied. Indeed, about 3800 persons have applied the exam each year. By the year 2006, it reaches 15435 persons in total, and 5129 persons have been qualified as the primary HIT.

The persons from system vendors are continuously increasing from 38% to 61% in these 4 years, and the percentages of them who passed the exam improved from 29% to reach 38%. Though the exam is rather difficult for students and for nurses who have little chances either to use healthcare information systems or to see computer programs, the percentage that pass the exam has remarkably improved from 7 to 15% for students, and 7 to 26% for nurses during these 4 years.

There remains a question, however, what characteristics the exam certifies. This paper devotes to answer this question.

Materials and method

In these 4 years, 4037 persons applied the exam more than twice. The percentage to pass the exam after applying it more than twice is 44.1 %, while it is 29.4% to pass the exam at their first challenge. This somewhat large difference may indicate that it will be better to use only the data at the first challenge of each applicant. In this paper, we used the data of the first challenge of the 11398 applicants.

As each question always treats one theme, we can categorize the objectives of each question. As the typical requirements for HIT, we chose seven categories and selected questions in accordance with these categories. The seven categories are: (1) Ability to follow logic. The questions about flowchart, binary mathematics, etc., are in this category. (2) Computer

literacy. Questions of the level of terminology are here. (3) Medical knowledge. Here, the common sense about clinical medicine was asked. (4) Knowledge about hospital management. Questions about formulas used in hospital management, insurance system, etc., are in this category. (5) Ethical mind. Questions about the code of ethics at practical settings are in this category. (6) Behavior at the time of emergency. The questions asking best choice or priorities in the time of troubles are in this category. (7) Ability to evaluate clinical data. Any questions to ask understanding figures or tables describing some clinical status, or introductory knowledge about medical statistics are in this category.

As this is the exam for primary HIT, a few questions are categorized into 5, 6 or 7. To avoid distortions caused by the different number of questions we selected at most 3 questions to each category in each test. The selection of these 3 questions is done by the difficulty measure, i.e., the average score of each question normalized to the allotted score.

After selected the questions, we calculated the averages of the scores of percent correct of questions in each category of each applicant, and performed a logistic regression analysis to know what category contributes most to the certification of HIT. Since some categories, e.g., categories 1 and 2, are taken only from the test results of information technology, values of these categories are missed for such applicants who does not take the information technology test. The number of complete cases was 6028, in which no missing values exist.

Results

To grasp the sensitibity of each category to certification, we first show the distribution of scores in table 1. In this table, percentages of the number of applicants who passed or failed the exam are listed in the "Passed" or "Failed" cell. These percentages were taken to the total number of applicants with the same range of average score.

1: Ability to follow Logic			
Score	Cases	Passed (%)	Failed (%)
0.00-0.25	3396	14.22	85.78
0.25-0.75	5816	30.38	69.62
0.75-1.00	557	52.06	47.94
2: Computer Literacy			
0.00-0.25	2298	7.57	92.43
0.25-0.75	6135	26.21	73.79
0.75-1.00	1336	56.74	43.26
3: Medical Knowledge			
0.00-0.25	1578	16.60	83.40
0.25-0.75	5102	29.18	70.82
0.75-1.00	814	46.93	53.07
4: Knowledge about Hospital Management			
0.00-0.25	2080	14.57	85.43
0.25-0.75	6672	27.01	72.99
0.75-1.00	2612	47.47	52.53
5: Ethical Mind			
0.00-0.25	142	4.23	95.77
0.25-0.75	5122	19.37	80.63
0.75-1.00	6100	38.48	61.52
6: Behavior at the time of emergency			
0.00-0.25	34	0.00	100.00
0.25-0.75	4381	16.91	83.09
0.75-1.00	6935	37.55	62.45
7: Ability to evaluate/understand clinical data			
Score	Cases	Passed (%)	Failed (%)
0.00-0.25	852	10.33	89.67
0.25-0.75	8745	27.11	72.89
0.75-1.00	1767	50.14	49.96

Table 1 - Distribution of Scores

Table 2 shows the simple statistics of each category.

Table 2 - Simple statistics of 7 categories

Category	Average	Median	Mode
1	0.32	0.33	0.33
2	0.45	0.39	0.33
3	0.44	0.39	0.33
4	0.55	0.56	0.50
5	0.76	0.80	1.00
6	0.79	0.83	1.00
7	0.58	0.58	0.75

Table 3 shows the result of logistic regression analysis. The dependent variable is a dichotomous status of the exam.

Table 3 - Result of the logistic regression analysis

Cate-gory	Coef.B ±SE	Wald statistic	estimated odds ratio		
			exp(B)	95% conf. interval	
1	1.48±0.143	107.6	4.40	3.32	5.82
2	2.44±0.148	272.4	11.47	8.58	15.32
3	1.54±0.150	105.5	4.69	3.49	6.30
4	4.58±0.212	465.2	97.75	64.46	148.24
5	3.96±0.261	230.8	52.57	31.53	87.65
6	3.46±0.250	191.4	31.78	19.47	51.87
7	2.59±0.218	141.6	13.36	8.72	20.47

Discussions and concluding remarks

From tables 1 and 2 some characteristics of the exam can be seen. For example, making appropriate decision at the time of emergency is easy for many applicants, but, it is very difficult to pass the exam if one fails to make such decision. The result of logistic regresion analysis would mean that the certifying exam will be very sensitive to select persons who have a good knowledge about hospital management, having ethical mind, and conduct well at the time of emergency. But the knowledge about clinical medicine may not be so important. All of these characteristics are those which we have expected to primary HIT, and this will prove the adequacy of the exam.

To improve the quality of exam, the performance of each question has been evaluated each year, based on the item response theory. GIO/SBO and the textbooks are updated so as to cope with the rapidly changing environment. Training schools are also held annually. Through these activities of JHIFT, HIT has accepted in Japanese society, and the workplaces for HIT have been gradually spreading.

Introduction

The field of biomedical informatics sits at the crossroads of biology science, medical science, computer science, information science, and cognitive science. The convergence of bioinformatics and medical informatics to biomedical informatics will provide a much broader view of the composition of health information soon became the mainstream in these domains. Shortliffe and Cimino pointed the evolution in the field of biomedical informatics in 2006. Our purpose was to study the biomedical informatics research performance based on 7830 documents published in Science Citation Index (SCI)-indexed periodicals between 1991 and 2005. These documents were analyzed and evaluated according to publication distribution and were used to determine the quantitative characteristics of the research.

Methods

Documents used in this study were based on the databases of the *SCI* which was accessed from the ISI *Web of Science*, 'bioinformatics', 'medical informatics' and 'biomedical informatics' were used as keywords to search titles, abstracts, and keywords. Parameters analyzed included type of document, page count, authorship, journal, author keywords and country of publication.

Results

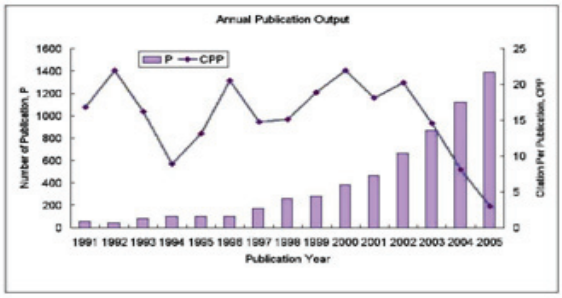

Figure 1 - Annual publication output

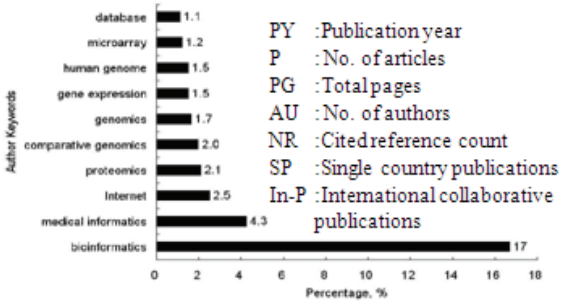

Figure 2 - Ten most used author keywords

Sweden	90	1.8	37	3.8	127	2.1

Conclusions

- The results show an increasing number of articles since 1997 and author numbers, article pages and cited reference count numbers indicate a continuous growth of biomedical informatics community.
- The five most author used keywords were bioinformatics, medical informatics, internet, proteomics and comparative genomics.
- Fifteen document types were found in the total of 7830 documents. 78 percent of all documents are articles.
- The USA was the leader and dominated the most publications followed by UK, Germany, Japan, France ,Canada.
- The production came from many countries, denoted the devotion to this research in different area around the world.

The Convergence of Bioinformatics and Medical Informatics : Bibliometric analysis of health informatics research, 1991-2005

Conclusion (1/2)

- The results show an increasing number of articles since 1997 and author numbers, article pages and cited reference count numbers indicate a continuous growth of biomedical informatics community.
- The five most author used keywords were bioinformatics, medical informatics, internet, proteomics and comparative genomics.
- Fifteen document types were found in the total of 7830 documents. Seventy-eight percent of all documents are articles.

Conclusion (2/2)

- The production came from many countries, denoted the devotion to this research in different area around the world.
- A step farther….
  - Based on our concurrent leading status, Taiwan can devote more to this new field.
  - The keywords analysis provide us a hint for the future research.

The survey of computer literacy among students of Mazandaran University of Medical Sciences 2005-2006

Siamian, Hasan, MSc (PhD student), Dean of the Medical Records Department, Faculty Member
Mazandaran University of Medical Sciences, Iran
Babaee, Heidar, Medical record student at Mazandaran University of Medical Sciences, Iran
Naderi Rad, Esmaeel, Medical record student at Mazandaran University of Medical Sciences, Iran

Abstract

Information technology (IT) has radically changed the way that many people work and think. Computers are integral to medical practice, education, and research. As computer literacy has given way to information literacy, knowing how to manage and utilize the information that technology brings is essential for students of the future Computers are becoming ubiquitous in health and education, and it is expected that nurses from undergraduate nursing programs are computer literate when they enter the workforce. The call for medical students to become literate in the uses of information technology has become a familiar refrain. Every student needs a basic understanding of information processing. It is not necessary that every student be a programmer. Students should develop and demonstrate proficiency in the use of computers, learning to use applications such as word processing, spreadsheets, database management programs, electronic mail, and packages and applications specific to their field of study. The purpose of this study was to examine the level of computer literacy among Mazandaran University of Medical Sciences in Iran. This article describes a cross-sectional survey research study. This study has done among students of Mazandaran university of Medical sciences include 45% male and 55% female. Data collection was semi- structured and standard questionnaire contains 34 closed questions and 4 open questions that are classified in three divisions include using of the computer, basic knowledge of computer and IT skills. More than 50% of students had a sufficient knowledge about IT. Most of them reported that they learn IT by themselves and got more knowledge and skill in the university. We studied the relationship between the special computer course passing and IT skills in 108 students includes 54 passed and 54 hadn't this unit. 36 persons with special computer course were familiar to IT skills but 18 persons of them were not. Versus them in the persons who hadn't the special unit (computer course) 24 persons were familiar to IT and 30 persons were not.

Why teach computer security to medical students?

Introduction

- Electronic Medical Records
  - integrate heterogeneous patient information
  - support healthcare practice

- Barriers
  - information security

Need for young doctors to better understand and use security

Objective

- To investigate attitudes and awareness of 1st year Medical students towards EPR security

- Do medical informatics' lectures help?
- Do they influence their attitudes?
- How can they be improved?

Methods

- Anonym questionnaire applied before and after the lectures in the academic year of 2003/2004
- The questionnaires introduced security scenarios for the students to comment
- 4 questions were answered

Results (1)

The first scenario described a breach of patient privacy to an EPR by one of the students' colleagues

Q1.A – Is the described scenario a security breach?

	Before the lectures % (n)	After the lectures % (n)
Answered questionnaires	***(238)***	***(222)***
Valid answers	*98 (232)*	*98 (217)*
Yes	**100 (232)**	**100 (217)**

Results (2)

Q1.B – What would you do if you found out about this security breach?

	Before the lectures % (n)	After the lectures % (n)
Valid answers	*61 (144)*	*60 (132)*
Reason with the colleague	**54 (77)**	**44 (58)**
Inform responsible authorities	**40 (58)**	**50 (66)**
Others	**6 (9)**	**6 (8)**

Results (3)

Q2 – Would you change your attitude if you found out that the colleague shared his password with a friend and that friend breached patient confidentiality?

	Before the lectures % (n)	After the lectures % (n)
Valid answers	*62 (148)*	*62 (138)*
No	**74 (109)**	**83 (115)**
Yes	**26 (39)**	**17 (23)**

U.PORTO
FMUP FACULDADE DE MEDICINA UNIVERSIDADE DO PORTO
BIOSTATISTICS AND MEDICAL INFORMATICS DEPARTMENT
CINTESIS
CENTER FOR RESEARCH IN HEALTH INFORMATION SYSTEMS AND TECHNOLOGIES

Results (4)

Q3 – Do you think that more sensitive information (HIV, Cancer) requires stronger security measures than other types of information?

	Before the lectures % (n)	After the lectures % (n)
Valid answers	*43 (103)*	*91 (204)*
No	**44 (91)**	**38 (77)**
Yes	**55 (112)**	**52 (127)**

Discussion

- After Security and Ethics' lectures, students:
  - feel more conscientious to report privacy breaches to responsible parties (Q1.B)
  - understand better what computer security is and how to behave in order to protect confidentiality of electronic information
  - consider indirect disclosure of sensitive information, such as with another person's password, a serious fault (Q2)
  - become more aware for the need of different protection levels of security depending on how sensitive information can be (Q3)

Conclusion

- We believe that the introduction of Information Security and Ethics early in the degree of the Medical course influences the awareness and attitudes of first year medical students towards computer security and EMR

- This can greatly influence the success of EMR integration whilst improving and fastening healthcare treatment

Abstract

The introduction of Electronic Medical Records (EMR) within the healthcare practice can be beneficial in order to integrate and centralize heterogeneous patient information. However, there are still some problems that hinder the successful use of EMR. The concern for patient privacy is one of them. The aim of this paper is to present the results of a study that assesses attitudes of 1st year medical students towards computer security and the EMR. An anonym questionnaire was given to the students at the beginning and at the end of the academic year of 2003/ 2004 for them to comment on several security related scenarios. 238 questionnaires were answered at the beginning of the year whilst 222 were answered at the end of the year. The students feel, at the end of the year, that they understand better what computer security is and how to protect patient privacy information. This shows that teaching computer security to medical students, the future users of EMR, can greatly influence the success of EMR integration and therefore improve and fasten healthcare treatment.

Keywords:

computer security; education, medical, undergraduate

Introduction

The introduction of Electronic Medical Records (EMR) within the healthcare practice allows for the integration of heterogeneous information that are usually scattered over different locations [1] [2]. However, there are some barriers that impede its successful integration in most healthcare practices [3] [4].

One specific barrier relates with the privacy and security of patient information [5]. The use of new information systems within healthcare stresses the need for young doctors to comprehend them from their conception so that they can be used in a beneficial way and support their future daily work. As such, all the feedback provided during their training into the medical profession is essential for the enhancement of those systems [6], moreover in terms of computer security.

The Biostatistics and Medical Informatics Department of Porto Faculty of Medicine teaches Ethics and Medical Informatics to 1st year medical students [7]. The later subject includes theoretical and practical lectures about Electronic Medical Records (EMR) and computer security.

This study aims to assess the opinions, attitudes and awareness of 1st year medical students towards computer security issues relating to EMR, and how these can affect the successful integration of EMR within the healthcare practice.

Methods

An anonym questionnaire was given to the students both at the beginning and again at the end of the academic year of 2003/2004. It was applied two times so that we could compare their attitudes before and after they had attended the Ethics and Medical Informatics' subjects.

The questionnaires introduced 3 scenarios for the students to comment. The first scenario described a breach of patient privacy to an EMR by one of their colleagues. There were two questions relating with this scenario:

- Q1.A – Is the described scenario a security breach?
- Q1.B – What would you do if you found out about this breach?
- The second scenario included additional information to the first scenario. It explained that the colleague in question had shared his password with a friend and that friend was the one to access patient private information, without him knowing it. The question related with this scenario was:
- Q2 – Would you change your attitude if you found out this new piece of information?

The third scenario introduced the issue of more sensitive information (e.g. HIV, Cancer results or even VIP related) and how this information must be protected. The question presented within the questionnaire was the following:

- Q3 – Do you think this kind of information requires stronger security measures than other types of information?

The answers to these questions were inserted into SPSS® and analysed separately.

Results

A total of 460 questionnaires were filled by the students. 52% (238) were answered before the lectures started whilst 48% (222) after the lectures finished. Table 1 shows the results obtained from the applied questionnaires.

Table 1 – Results obtained from the questionnaires

		Before the lectures % (n)	After the lectures % (n)
Answered questionnaires		*(238)*	*(222)*
Q1.A	*Valid answers*	*98 (232)*	*98 (217)*
	Yes	100 (232)	100 (217)
Q1.B	*Valid answers*	*61 (144)*	*60 (132)*
	Reason with	54 (77)	44 (58)
	Inform	40 (58)	50 (66)
	Others	6 (9)	6 (8)
Q2	*Valid answers*	*62 (148)*	*62 (138)*
	No	74 (109)	83 (115)
	Yes	26 (39)	17 (23)
Q3	*Valid answers*	*43 (103)*	*91 (204)*
	No	44 (91)	38 (77)
	Yes	55 (112)	62 (127)

For Q3, the main reason given by the students that felt no extra security measures were needed to access more sensitive information is that all security measures must be effective for all cases, independently of the patient or healthcare performed. The majority of the students that thought extra security measures were necessary agreed that this would provide for the protection of certain social groups from discrimination.

Conclusion

According to this study's results, after Medical Informatics and Ethics' lectures, students feel more conscientious to report privacy breaches to responsible parties (Q1.B). They understand better what computer security is and how to behave in order to protect confidentiality of electronic information. They consider indirect disclosure of sensitive information, such as with another person's password, a serious fault (Q2). Further, at the end of the year, students become more aware for the need of different protection levels of security depending on how sensitive information can be (Q3).

We believe that the introduction of Medical Informatics and Ethics early in the degree of the Medical course has an influence in the awareness and attitudes of first year medical students towards computer security and EMR. This can greatly influence the success of EMR integration whilst improving and fastening healthcare treatment.

An e-Learning Experience in a Biomedical Research and Public Health Institute

Ángeles Villarrubia-Enseñat, Oscar García-Hernández, Isabel Hermosilla-Gimeno, Verónica Hurtado-Linares, Fernando Martin-Sánchez.

Medical Bioinformatics Department, Institute of Health "Carlos III"

Abstract

This paper evaluates the current state of educational activities in biomedical informatics, bioinformatics and convergent technologies from the Department of Medical Bioinformatics of the National Institute of Health "Carlos III". It raises the possibility of designing several didactic virtual activities. It establishes the key elements that define the structure and educational methodology necessary for the success of a virtual course. They highlight the importance of collaborative work, the need of the implementation of new methods of communication and the design of new learning activities and new evaluation criteria. It also establishes the need of an e-learning platform for distance on-line learning. The implementation of e-learning in the Institute of Health "Carlos III" has opened the possibility of adapting diverse courses traditionally taught face-to-face to be taught on line. Also new courses have been designed. Health management, research methodology, biosecurity, studies of epidemiological outbreaks, bioinformatics or biomedical informatics are some examples of the wide range of topics offered.

Keywords:

education, e-Learning, medical bioinformatics

Introduction

The Area of Biomedical Informatics (BIOTIC) was founded in 1998, as an answer to the increasing need of the Institute of Health Carlos III (ISCIII) to establish an expert team, with the mission of developing and researching new informatics tools to facilitate the use and understanding of new approaches to genomic based medicine. The ISCIII is a National Public Research Institution that provides scientific support to all the National Health System of Spain. One of its appointed tasks is to promote research in biomedicine and health sciences, being its main goal to develop and provide scientific and technical services to the National Health System and to society in general. In this respect, the BIOTIC team which is composed of biologists, chemists, pharmacists, informatics experts, statisticians and experts in education and e-learning is entrusted with the research and development of informatics tools that aid in the understanding and use of new approaches to genomics based medicine[1]. This multidisciplinary group also facilitates the knowledge of new technologies such as Nanotechnologies, Biotechnologies, Information Technologies and Cognitive Sciences (NBIC) and their convergence for the treatment of biomedical information and their application in research, clinical practice and public health [2].

The relevant role that BIOTIC plays in the research areas mentioned above has made it possible to develop and carry out an important educational and training activity. These programs address the training needs of different collectives such as personnel in hospitals, public health schools, research centers, scientific societies, universities, associations of health professionals, technological centers and national centers. Some of this activity is done through BIOTIC's participation in the Education Node of the National Institute of Bioinformatics (INB). This initiative funded by Genoma España, has as its main objective the training of bioinformaticians for their integration in genomics and proteomics research groups.

Methods

Researchers in the area of BIOTIC regularly attend courses and congresses related with bioinformatics, microarrays, genomics and health, biomedical informatics and convergent technologies to be up to date on their areas of specialty.

Courses developed by BIOTIC have been traditionally taught face-to-face. The teaching methodology implemented focuses on the analysis of the learning needs and the profile of the students and it depends on the characteristics of the program to be taught. Once the needs have been identified, the next steps are to design the learning contents and to define the criteria for performance as well as to prepare and/or adapt available resources (technical, human and material) to adequately carry out the specific educational program.

The instructional methods are mainly of two types: exposition of the information and exercises or practical activities with feedback. Practical activities apply theoretical concepts, which are determined by the learning objectives of the education program. The area of BIOTIC bases its work in three main axes:

- Technology and innovation: the new technologies are revolutionizing the research and education fields.
- Sustainability: trying to make new technologies to become part of the student's everyday work.
- Promote an enterprising scientific nature.

The key elements that define the teaching methodology carried out are based on the transfer of knowledge through [3]:

- Planning and design of the teaching program based on curricular models validated through scientific research.
- Evaluation of the students' previous knowledge and their expectations about the course.
- Use of the didactic methods that are most adequate for the objectives of each program.
- Application, through the available materials and tools, of the knowledge and skills obtained.
- Evaluation activities are carried out to see if the students have learnt the concepts.
- Evaluation of the teachers and the quality of the course.

In general, the lack of specialists and experts that can lead these processes, together with the lack of an economic, didactic, technical and management plan, can drive any program to its failure. With the objective of implementing this educational model, the ISCIII acquired a tele-educational platform (WebCT). At the same time the National School of Public Health of the Institute created the e-learning commission, of which BIOTIC is a member.[4]

The tele-education platform WebCT (Web Course Tools) has all the basic characteristics required for distance learning systems through networks. The WebCT enables knowledge management directed towards teaching online through the Internet and requires some minimum technical requirements, basically the same that are needed to connect to the Internet. The WebCT permits to establish interaction spaces through the communication tools that it offers (e-mail, chat, forum, shared blackboard, etc...). It also permits to define different roles and functions to the participants (teacher, student, technical administrator, etc.), the publication of learning contents, building of glossaries, evaluation tests or exams, design of individual and group activities, links to databases and digital libraries, among other resources.

Implementing virtual education demands previous training of the future on-line teachers both at the technological and didactic level. In response to this increasing interest, the area of Biomedical Informatics suggested and developed and now teaches a course for training online teachers. This is an alternative educational solution that also meets the strict scientific and academic requirements necessary to respond to the training needs of the professionals of the ISCIII. It was thought that it was important that the whole course be taught through the WebCT platform so that students (future online teachers) would experience themselves the advantages and disadvantages of e-learning. This way they could get the skills and abilities specifically needed for teaching online which include technological, didactic and curricular training. It was essential for the students to apply the acquired knowledge by designing an online course in their professional field based on a curricular perspective.

The teaching in virtual environments has to be established under pedagogical models that promote education processes through the implementation of communication techniques, creating spaces that make possible active, creative and critical participation of the agents involved.

Results

The results of the evaluation of the courses taught by the Area have been highly positive. The circle of centers and universities in which the researchers in BIOTIC teach is getting wider and some of these courses have been awarded with a "Mention of Quality".

One of the main achievements of the course recently taught by the Area of Biomedical Informatics about online training for the professionals of the ISCIII is the development of several courses or Masters related to the professional specialty of the students [5]. Most of the students worked in groups of 2 or 4 members.

Discussion and conclusion

It is important to approach e-learning education with an open mind for virtual environments and not with a face to face teaching mentality. Online teachers have to be familiar with both Information and Communication Technologies (ICT) and pedagogic strategies for virtual environments. They should be aware of the possibilities and limitations of these technologies in virtual environments. They should have knowledge of group work techniques adapted to the virtual environment and knowledge of the different learning theories applicable to virtual surroundings. It is important not to confuse means with the ends: the technology should be at the service of education and not the other way around.

Medical Bioinformatics Department, Institute of Health "Carlos III"

An e-Learning Experience in a Biomedical Research an Public Health Institute

Introduction

- The National Institute of Health Carlos III (ISCIII) provides scientific support to all the National Health System of Spain.
- The Area of Biomedical Informatics (BIOTIC) aims to develop new computational approaches for facilitating genomic based medicine.
- Research lines are: Biomedical Informatics, Bioinformatics and Microarrays and Convergent Technologies (NBIC) in health applications.
- BIOTIC carries out an intense teaching activity in its areas of specialization and it is involved in the e-learning program of the National School of Public Health of Spain.
- BIOTIC has developed and it is now teaching a virtual course on methodological and technological aspects of e-learning (the scientists of the BIOTIC Department had previously taken this course).
- They develop and teach virtual courses in their field of knowledge and specialization both at the national and the international level.

An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods

- BIOTIC participates in educational programs of several national and international institutions, both public and private.
- The area is involved in the National Institute of Bioinformatics (INB), funded by "Genome Spain Foundation" through the Horizontal Training Node".
- The main objective of the INB is to contribute and to apply bioinformatics solutions to the development of projects in the fields of genomics and proteomics.
- BIOTIC has developed several courses to disseminate and train health professionals in Bioinformatics and other applications of Information Technologies in the Biomedical field (Figure 1). Traditionally these courses were taught "face to face".
- Nowadays BIOTIC is a member of the e-learning commission of the ISCIII.

An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods

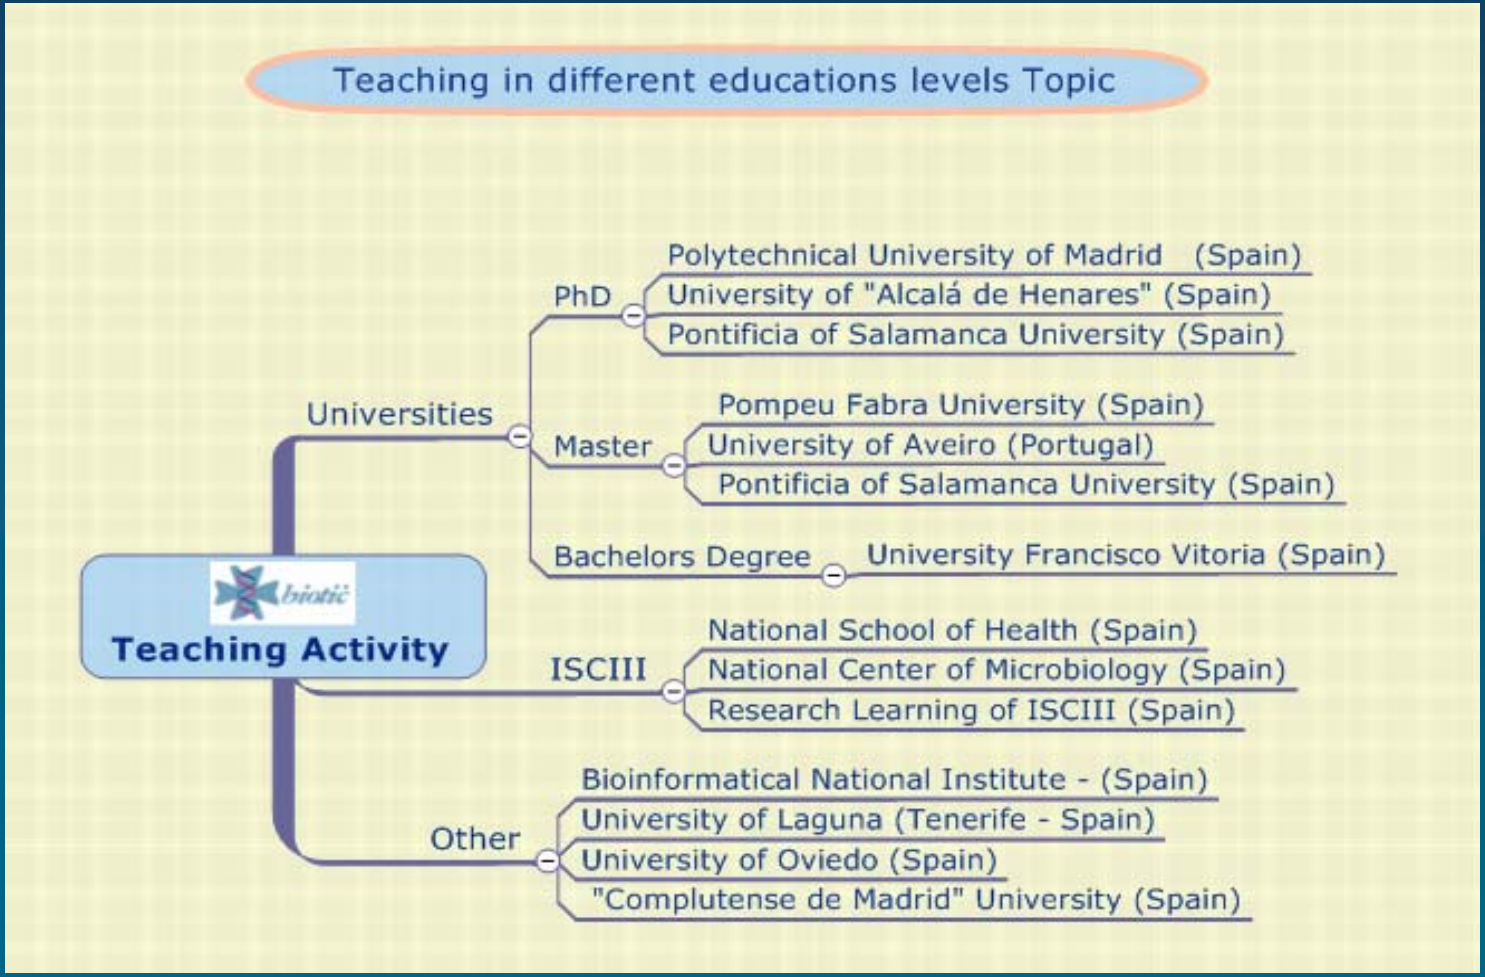

Figure 1

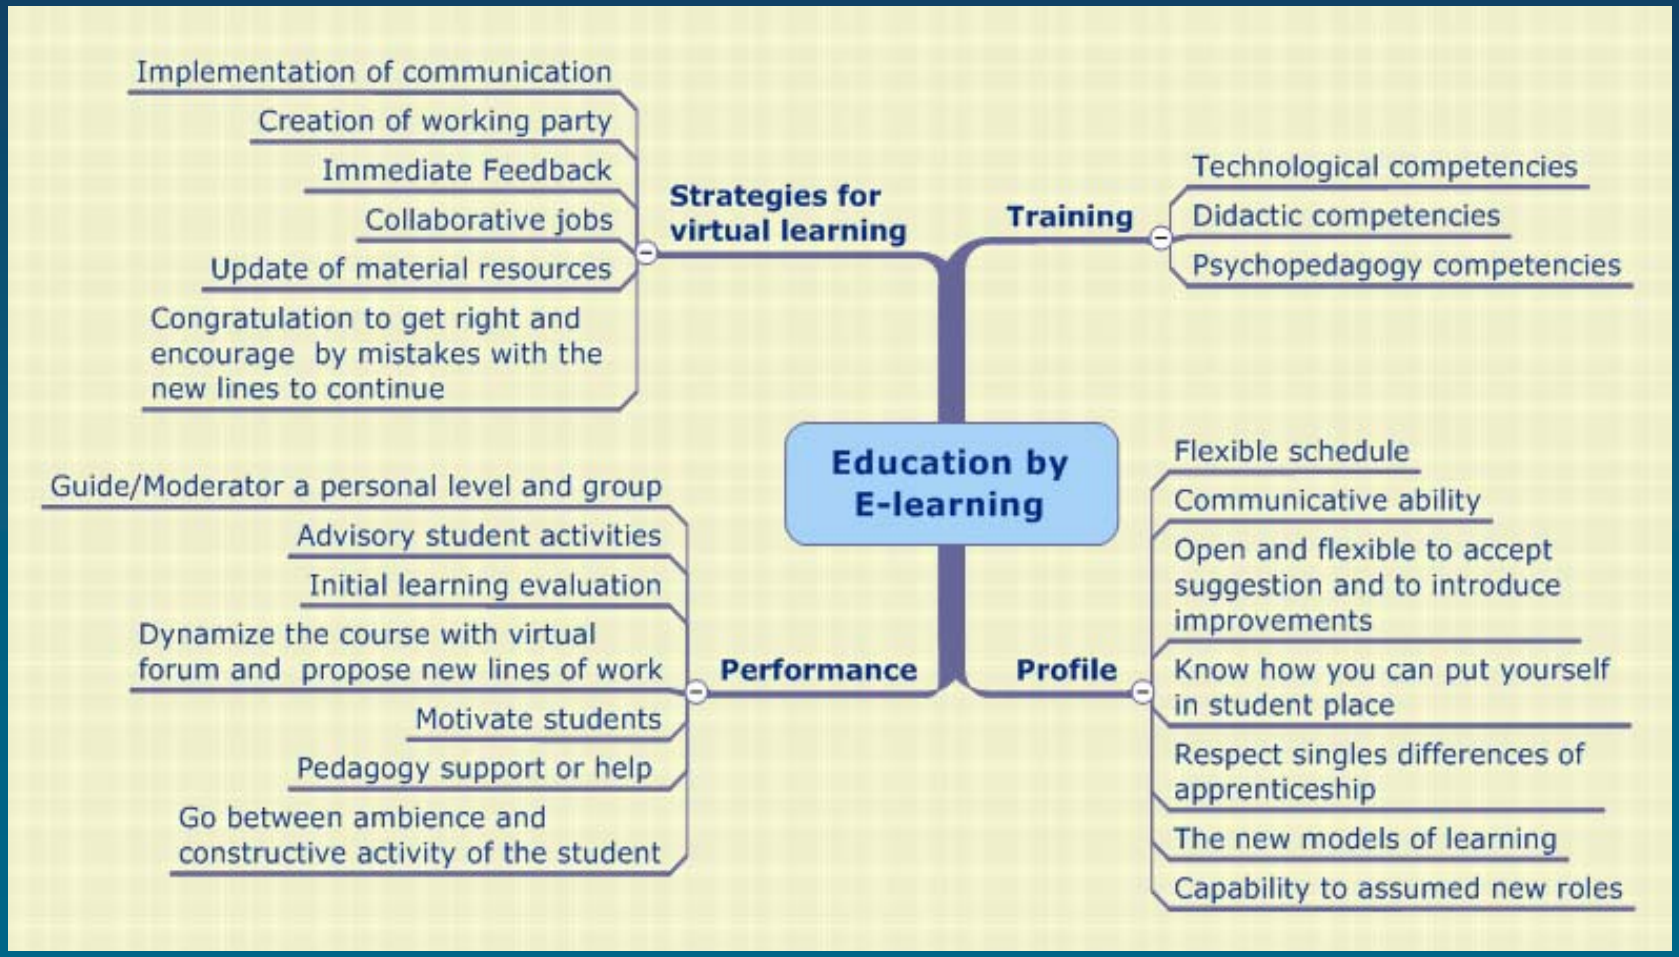
An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods: Teaching Methodology

- The teaching methodology implemented has several steps:
  - analysis of the learning needs and the profile of the students,
  - design of the contents and definition of the evaluation criteria
  - preparation and/or adaptation of the available resources (technical, human and material).
- After careful assessment of pros and cons the ISCIII acquired a tele-educational platform (WebCT). There is a need to train future online teachers both at the technological, didactic and curricular level.
- BIOTIC developed a virtual course for training online teachers through the WebCT platform. The objectives were:
  - experience themselves the advantages and disadvantages of e-learning
  - learn how to use the WebCT tool
  - development of abilities, knowledge, an attitudes that online teachers should have
  - Application of the acquired knowledge by designing an online course in their professional field based on a curricular perspective (Figure 2).

An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods: Knowledge in e-learning education



An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods: Teaching Methodology

◇ Elements that define the teaching methodology online:

- The teaching experience of the teachers, as well as their knowledge of the subject they teach.
- Models validated through scientific research: analysis of the educational needs in the field of knowledge, the instructional resources and the method of teaching (face-to-face, virtual or mixed).
- The evaluation of the students' previous knowledge and their expectations about the course.
- Activities that encourage students to actively participate should be designed with the conviction that the student is the first agent of its own learning.
- Continuous update of the learning contents.

An e-Learning Experience in a Biomedical Research an Public Health Institute

Materials and Methods: Teaching Methodology

◇ Elements that define the teaching methodology online (cont):

- The practical activities are carried out through computers connected in a network.
- In some cases students go the microarray laboratory to acquire their knowledge "in situ".
- Evaluation activities such as exams and/or practical exercises are carried out to check that the students have learnt the concepts.
- Evaluation of the teachers and in general of the quality of the course

An e-Learning Experience in a Biomedical Research an Public Health Institute

Results

- The results of the evaluation of the courses taught by BIOTIC have been highly positive
- The circle of centers and universities in which researchers at BIOTIC teach is getting wider and some of these courses have been awarded with a "Mention of Quality"
- One of the achievements of the course online taught by BIOTIC is the development and or adaptation to the WebCT platform of several courses or Masters´ modules related to the professional specialty of the students :
  - Master in Health Administration (MASe) (semi-online)
  - Expert in Health Research Methodology (online)
  - Operation of the Level 3 (P3) Biosecurity Installations in the National Center for Microbiology (semi-online)
  - Field Epidemiology: Study of outbreaks (online)

An e-Learning Experience in a Biomedical Research an Public Health Institute

Results

◇ Researchers in BIOTIC have designed the following courses:

- Integration of Protein Classical Biochemistry with New Technologies (online)
- Introduction to Bioinformatics and Proteins and Nucleic Acids Sequence Analysis (online)
- Introduction to Biostatistics in Biomedical Informatics (online)

An e-Learning Experience in a Biomedical Research an Public Health Institute

Conclusions

- It is important to approach e-learning with an open mind
- Online teachers have to be familiar with both Information and Communication Technologies (ICT) and pedagogic strategies for virtual environments
- Be aware of the possibilities and limitations of virtual environments
- Knowledge of the different learning theories
- Knowledge of group work technique adapted to the virtual environment
- Its important not to confuse means with the ends. Technology should be at the service of education

Medical Bioinformatics Department, Institute of Health "Carlos III"

Abstract

This paper evaluates the current state of educational activities in biomedical informatics, bioinformatics and convergent technologies from the Department of Medical Bioinformatics of the National Institute of Health "Carlos III". It raises the possibility of designing several didactic virtual activities. It establishes the key elements that define the structure and educational methodology necessary for the success of a virtual course. They highlight the importance of collaborative work, the need of the implementation of new methods of communication and the design of new learning activities and new evaluation criteria. It also establishes the need of an e-learning platform for distance on-line learning. The implementation of e-learning in the Institute of Health "Carlos III" has opened the possibility of adapting diverse courses traditionally taught face-to-face to be taught on line. Also new courses have been designed. Health management, research methodology, biosecurity, studies of epidemiological outbreaks, bioinformatics or biomedical informatics are some examples of the wide range of topics offered.

Keywords:

education, e-Learning, medical bioinformatics

Introduction

The Area of Biomedical Informatics (BIOTIC) was founded in 1998, as an answer to the increasing need of the Institute of Health Carlos III (ISCIII) to establish an expert team, with the mission of developing and researching new informatics tools to facilitate the use and understanding of new approaches to genomic based medicine. The ISCIII is a National Public Research Institution that provides scientific support to all the National Health System of Spain. One of its appointed tasks is to promote research in biomedicine and health sciences, being its main goal to develop and provide scientific and technical services to the National Health System and to society in general. In this respect, the BIOTIC team which is composed of biologists, chemists, pharmacists, informatics experts, statisticians and experts in education and e-learning is entrusted with the research and development of informatics tools that aid in the understanding and use of new approaches to genomics based medicine[1]. This multidisciplinary group also facilitates the knowledge of new technologies such as Nanotechnologies, Biotechnologies, Information Technologies and Cognitive Sciences (NBIC) and their convergence for the treatment of biomedical information and their application in research, clinical practice and public health [2].

The relevant role that BIOTIC plays in the research areas mentioned above has made it possible to develop and carry out an important educational and training activity. These programs address the training needs of different collectives such as personnel in hospitals, public health schools, research centers, scientific societies, universities, associations of health professionals, technological centers and national centers. Some of this activity is done through BIOTIC's participation in the Education Node of the National Institute of Bioinformatics (INB). This initiative funded by Genoma España, has as its main objective the training of bioinformaticians for their integration in genomics and proteomics research groups.

Methods

Researchers in the area of BIOTIC regularly attend courses and congresses related with bioinformatics, microarrays, genomics and health, biomedical informatics and convergent technologies to be up to date on their areas of specialty.

Courses developed by BIOTIC have been traditionally taught face-to-face. The teaching methodology implemented focuses on the analysis of the learning needs and the profile of the students and it depends on the characteristics of the program to be taught. Once the needs have been identified, the next steps are to design the learning contents and to define the criteria for performance as well as to prepare and/or adapt available resources (technical, human and material) to adequately carry out the specific educational program.

The instructional methods are mainly of two types: exposition of the information and exercises or practical activities with feedback. Practical activities apply theoretical concepts, which are determined by the learning objectives of the education program. The area of BIOTIC bases its work in three main axes:

- Technology and innovation: the new technologies are revolutionizing the research and education fields.
- Sustainability: trying to make new technologies to become part of the student's everyday work.
- Promote an enterprising scientific nature.

The key elements that define the teaching methodology carried out are based on the transfer of knowledge through [3]:

- Planning and design of the teaching program based on curricular models validated through scientific research.
- Evaluation of the students' previous knowledge and their expectations about the course.
- Use of the didactic methods that are most adequate for the objectives of each program.
- Application, through the available materials and tools, of the knowledge and skills obtained.
- Evaluation activities are carried out to see if the students have learnt the concepts.
- Evaluation of the teachers and the quality of the course.

In general, the lack of specialists and experts that can lead these processes, together with the lack of an economic, didactic, technical and management plan, can drive any program to its failure. With the objective of implementing this educational model, the ISCIII acquired a tele-educational platform (WebCT). At the same time the National School of Public Health of the Institute created the e-learning commission, of which BIOTIC is a member.[4]

The tele-education platform WebCT (Web Course Tools) has all the basic characteristics required for distance learning systems through networks. The WebCT enables knowledge management directed towards teaching online through the Internet and requires some minimum technical requirements, basically the same that are needed to connect to the Internet. The WebCT permits to establish interaction spaces through the communication tools that it offers (e-mail, chat, forum, shared blackboard, etc...). It also permits to define different roles and functions to the participants (teacher, student, technical administrator, etc.), the publication of learning contents, building of glossaries, evaluation tests or exams, design of individual and group activities, links to databases and digital libraries, among other resources.

Implementing virtual education demands previous training of the future on-line teachers both at the technological and didactic level. In response to this increasing interest, the area of Biomedical Informatics suggested and developed and now teaches a course for training online teachers. This is an alternative educational solution that also meets the strict scientific and academic requirements necessary to respond to the training needs of the professionals of the ISCIII. It was thought that it was important that the whole course be taught through the WebCT platform so that students (future online teachers) would experience themselves the advantages and disadvantages of e-learning. This way they could get the skills and abilities specifically needed for teaching online which include technological, didactic and curricular training. It was essential for the students to apply the acquired knowledge by designing an online course in their professional field based on a curricular perspective.

The teaching in virtual environments has to be established under pedagogical models that promote education processes through the implementation of communication techniques, creating spaces that make possible active, creative and critical participation of the agents involved.

Results

The results of the evaluation of the courses taught by the Area have been highly positive. The circle of centers and universities in which the researchers in BIOTIC teach is getting wider and some of these courses have been awarded with a "Mention of Quality".

One of the main achievements of the course recently taught by the Area of Biomedical Informatics about online training for the professionals of the ISCIII is the development of several courses or Masters related to the professional specialty of the students [5]. Most of the students worked in groups of 2 or 4 members.

Discussion and conclusion

It is important to approach e-learning education with an open mind for virtual environments and not with a face to face teaching mentality. Online teachers have to be familiar with both Information and Communication Technologies (ICT) and pedagogic strategies for virtual environments. They should be aware of the possibilities and limitations of these technologies in virtual environments. They should have knowledge of group work techniques adapted to the virtual environment and knowledge of the different learning theories applicable to virtual surroundings. It is important not to confuse means with the ends: the technology should be at the service of education and not the other way around.

[b]*School of Medicine and Health Sciences, Nagoya University, Japan*
[c]*School of Nursing, Osaka Prefecture University, Japan*
[d]*Division of Nursing Sciences Faculty of Health Sciences, Tokyo Metropolitan University, Japan*
[e]*Nagano College of Nursing, Japan*
[f]*School of Engineering, The University of Tokyo, Japan*

Abstract

In order to reorganize Japanese textbooks for nursing informatics, we compared the contents in three recent Japanese textbooks for students of nursing, nurse managers and healthcare information technologists with those in the latest American textbook. The American textbook had twenty or seventy times as many items as corresponding contents to the Japanese textbooks. The results indicated the necessity of a considerable improvement in Japanese textbooks of nursing informatics for nursing managers.

Keywords:

nursing informatics, textbook, education

Introduction

The Japanese government expects that national healthcare costs will rise dramatically in the future. New strategy in 2006 recommended that maximizing IT structural reform capabilities will be essential in resolving these issues. The Ministry of Health, Labour and Welfare actively promoted comprehensive and effective computerization throughout the medical, healthcare, nursing and social welfare fields. There was no certification program for informatics nurses in Japan. However reorganization of Japanese textbooks for nursing informatics is necessary to train Japanese nurse informatists as soon as possible.

Methods

We used three Japanese textbooks published in 2004 for this comparison.

The first one was the fourth edition of an introduction to nursing informatics for students (TBI).

The second one dealt with health information management for nurse managers (TBM).

The third one showed the way to implement and update clinical information systems for healthcare ITs (TBH).

Some nurses applied to take the certification examination for healthcare information technologists, and our previous

study proved that the certification requirements for healthcare ITs were similar to those for informatics nurses.

We regarded the American textbook, Saba's fourth edition[1] (TBS), as the latest standard work, because it was revised in 2006. We compared the index of each textbook with that of the American textbook.

Results

All Japanese textbooks had an English index. TBS had over 2000 items in the index. However, the Japanese textbook had few English items. In the Japanese index, a total of 492 items were found in TBI, and 347 in TBM. There were 662 items in TBH (Figure 1). All Japanese textbooks were found to have fewer contents.

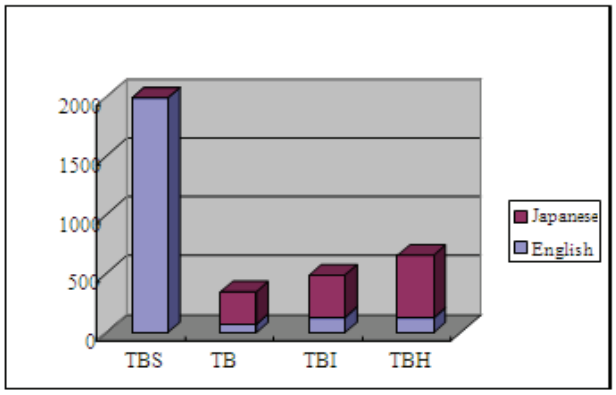

Figure 1- Total items in index

113 items in TBM were the same as those in TBS, while TBI had thirty four corresponding items and TBH had twenty nine items (Figure 2). TBM had more corresponding items than the other Japanese textbook surveyed

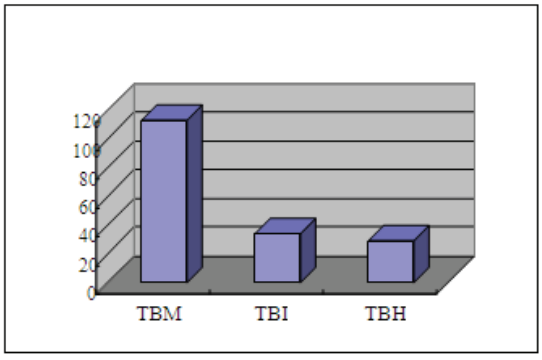

Figure 2- Items corresponding with TBS

Fifty two items in TBI and in TBH were the same as those in TBM (Figure 3). TBM had more corresponding items with other Japanese textbooks than TBS.

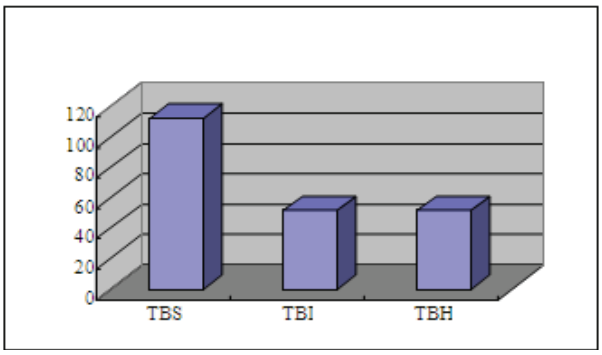

Figure 3- Items corresponding with TBM

Items found in only one textbook were prominent. Sixty seven items were found in only two textbooks, and thirty items were found in only three textbooks.

Only 16 items were common to all Japanese textbooks, and could be classified into two groups: 9 items were related to data sharing and standardization, and 7 items were related to electronic health records (Table 1).

Table 1- Items found in all Japanese textbooks

Group 1
Data sharing, ICNP, ICN, HL7, ISO, NIC, SNOMED, EBM, Standard Privacy Policies
Group 2
EHR, Nursing record, Specifications, Informed consent, Information, Security, Data warehouse

Discussion

Japanese textbooks were not standardized. Each textbook had many independent items.

Using Saba's textbook as a reference, all Japanese textbooks were found to have fewer corresponding contents. Most of the contents in Japanese textbook did not correspond with those in the American certification examination for informatics nurses.

The Ministry of Health, Labour and Welfare is promoting the implementation of electronic health recode in every hospital. However no educational program for nursing informatics specialists existed in Japan. Many nursing managers are confronted with issues related to the effective use of electronic health records. The finding that TBM had more corresponding items with TBS than with the other Japanese textbooks surveyed illustrated the need for increased information and knowledge in nursing informatics among Japanese nursing managers.

Conclusion

Japanese textbooks should be standardized and the content for nursing managers should be improved.

New IT Reform Strategy in Japan

Priority Policy Program 2006

July 26, 2006

IT Strategic Headquarters

1. The Pursuit of IT Structural Reform Capabilities

1.1 Structural reform of healthcare through IT
— Full online processing of all medical insurance claims and lifetime self healthcare management —

<Basic Aspects>

Since the adoption of the e-Japan Strategy II, priority measures have been taken for the computerization of healthcare as one of seven leading areas, but computerization remains at low levels. With estimations showing the rapid increase in national healthcare expenditure resulting from our aging society in the future and so on, it is with urgency that we must: prevent illnesses, improve medical quality and increase medical efficiency, streamline healthcare costs and rectify healthcare disparity by utilizing IT's structural reform capabilities to its fullest.

First, we must effectively utilize the health information collected and accumulated from medical records, health check results, and medical insurance claim data, etc. with computerization, to prevent illnesses and raise the quality and efficiency of medical care. Possible policies would be lifetime self healthcare management, nationwide statistical and epidemiological analysis with personal information protection such as ensuring anonymity of health information, and medical cooperation among institutions by utilizing IT. We must actively work toward realizing these measures by developing a standard for computerization, reducing costs to implement medical information systems, and creating incentives to encourage medical cooperation using IT.

Secondly, there is a need to streamline healthcare costs, by cutting healthcare insurance administration costs through promoting medical computerization. For example, complex medical fee calculations and processing of medical insurance claims mostly on paper lead to higher costs for healthcare insurance administration. Therefore, we have paved the way, in principle, to oblige online processing of medical insurance claims from medical institutions to

Building Health Informatics Capacity - Educating the Workforce

Marianne Sørensen [a], Christian Nøhr [a, b]

[a] *Virtual Centre for Health Informatics, Aalborg University, Denmark*
[b] *Department of Development and Planning, Aalborg University, Denmark*

Abstract

The master program in health informatics at Aalborg University in Denmark has existed in more than 10 years and more than 140 students have graduated from the program at the time of the survey. A questionnaire survey was conducted to get an overview of the student's motives for entering the program, and get their opinion about being a student in the program, and what subjects they felt contributed to their further career. The survey also formed a basis for drawing job profiles. The majority of the graduates changed job once or more after graduation, but they stayed within health informatics. The survey has contributed substantially to the revision of the curriculum.

Keywords:

medical informatics, education, employment, career mobility

Introduction

The health informatics master's program at Aalborg University was started in 1994 and the first masters earned their degree in 1998. The main goal of the program is to enable the students to bridge the gap between health professionals and IT professionals.

To be admitted in the program the student must hold a masters degree or a B.Sc. in a health science and after three years of study the student has earned 90 ECTS points and will receive a Master's Degree in Health Informatics. The program consist of 26 ECTS of traditional course work and 64 ECTS of problem-based project work. The subjects in the courses are organized in four tracks: 1. Database theory, network theory and decision support. 2. System and context, demand/system specifications, user interaction. 3. Project management, assessment/ evaluation, and organizational change. 4. Methodologies for data acquisition, quantitative/qualitative analysis. The students gather four times a year at weekend workshops for intensive lectures, laboratory exercises and oral discussions. The rest of the time the backbone of communication is a conference system which runs on a server at the university [1,2].

In order to evaluate how the students contribute to the health informatics capacity, and to monitor how the program is able to prepare the students for their future job we have investigated the student's job situation after graduation. The survey was done in 2004 where 147 students had graduated from the program.

Method

A cover letter pointing to a web-based questionnaire containing 45 questions was sent to the 147 students who had graduated from the program. The questionnaires were analyzed anonymously. Descriptive statistics were applied to the standardized answers. There were very few free text answers which were summarized by the authors.

Results

The response rate was 69%. 80% of the students had more than 10 years of work experience when they entered the program. 70% of the students indicated that one of the reasons for entering the program was a desire for personal development. 58 % further indicated that they wanted to achieve a new job profile and 38% saw an opportunity to advance their career. 51% also indicated that they wanted to gain insight in the use of IT systems. Only 17% indicated that higher salary was a driving factor for entering the program.

Table 1 - Employment before and after graduation

Employment	Before	After	Migration
Hospital - clinic/laboratory	36	16	-20
Nursing school	11	11	0
Regional institution/administration	5	10	5
Hospital - administration	11	9	-2
University or research institution	3	8	5
Hardware/software industry	3	8	5
Hospital IT-department	10	7	-3

* = Development/purchase of systems for ….

All the masters were employed or had set up their own business at the time of the survey. The raise in income after the job they had during their studies was significant.

At the question: "If you were in the situation to day when you entered the program would you then choose to study health informatics in this program again?" 77% responded yes, 7% says no and 16% were not quite settled in their view.

Discussion

Much has been written about various university graduate programs in health informatics, but only little has been written about the outcomes for the graduates of the programs. [3-6].

The dominant motivation for entering the program was the desire to achieve personal development. It is naturally very difficult to evaluate such an outcome, but comparing the very high satisfaction with the program in general, we assume that this goal has been achieved by the graduates. The second most common motivation was to achieve a new job profile. 58% of the graduates indicated this, and as 50 % had changed job one, two or three times since they graduated it is very likely that they achieved new job profiles. This is supported by the results regarding job migration.

In the contrary to the programs at Heidelberg University and University of Utah the majority (76%) of the graduates from Aalborg University work with health informatics after graduation and 92% remain within the health care sector. An immediate explanation is that nearly all the students at the point of entering the program already have a job in health care.

At Heidelberg University more than half of the graduates worked outside of medical informatics, which in their opinion underlined the quality of the informatics oriented part of education, because the medical informatics graduate can compete with those from general computer science. We find it rather supporting for the quality of our program that the graduates are able to find jobs within health informatics – the area in which they are specialized to function in and that they can contribute with high level knowledge about very complex problems.

Conclusion

The majority of the graduates from the master program in health informatics at Aalborg University participated in the survey of their background and motivation for entering the program, and which activities had contributed to their further career.

The majority of the students enter the program with a Bachelor degree in Nursing or Medical Laboratory Technology. They change their job once or more after graduation they migrate from employment in clinical settings to job in the administration, universities or research institutions and industry. None are unemployed, and they stay within health informatics working with implementation of it-systems, education, and project management. They were practically all very satisfied or very satisfied with their education, and they would choose the same program if they were in that situation to day.

The survey has been essential to the revision of the curriculum.

AALBORG UNIVERSITY

Building health informatics capacity - educating the workforce

Marianne Sørensen, Christian Nøhr
Virtual Centre for Health Informatics
Aalborg University
Denmark

Master programme in Health Informatics at Aalborg University

- Started in 1994
- 3 year programme – 30 ECTS / year (part time study)
- 243 masters have earned their degree
- 35 students admitted every year
- Drop out < 20% mainly during 1. year
- 100 active students at any time
- 53% Nurses, 13% Lab techn., 11% MD, 23% other Bachelor degrees
- Age of the students 28 – 50 years
- Recruiting from all Scandinavia

4 key characteristics of the program

- Problem based
  (interdisciplinary)
- Project organised
  50% project work
  50% course work
- Team work
- Distance and
  face to face learning

Problem-based project work

Each year focus on health informatics from different perspectives:

1. year: an analytical perspective
2. year: a design perspective
3. year: a scientific research perspective

The project work can be divided into 4 phases

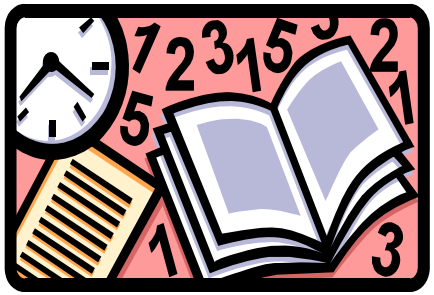
1. Formulation of the problem
2. Investigation research
3. Production writing/editing process
4. Evaluation process

Students bring their own problems – faculty does not suggest problems

Coursework

A course is a systematic representation of a discipline

The purpose is to provide the student with sufficient disciplinary knowledge to cope with interdisciplinary problems



Courses are introduced at the weekend seminars and the students guided on a conference system (FirstClass)

Organization of the courses

The courses are organized in four tracks, and within each track there is a learning progression through the three years

	From data to decision	System and context	Technology change	Methods for data collection and analysis
3.Yr	Systems for decision support	User interaction with health information systems	Technical and organizational change	Quantitative and qualitative analytical methods
2.Yr	Advanced health information management	Health information system modeling	Technology assessment and evaluation of	Descriptive quantitative and qualitative methods
1.Yr	Basic data collection, -transport, -storage and decision making	Health information system's requirements	Organizations and project management	Methodology for project work and basic literature search

Evaluating the capacity build

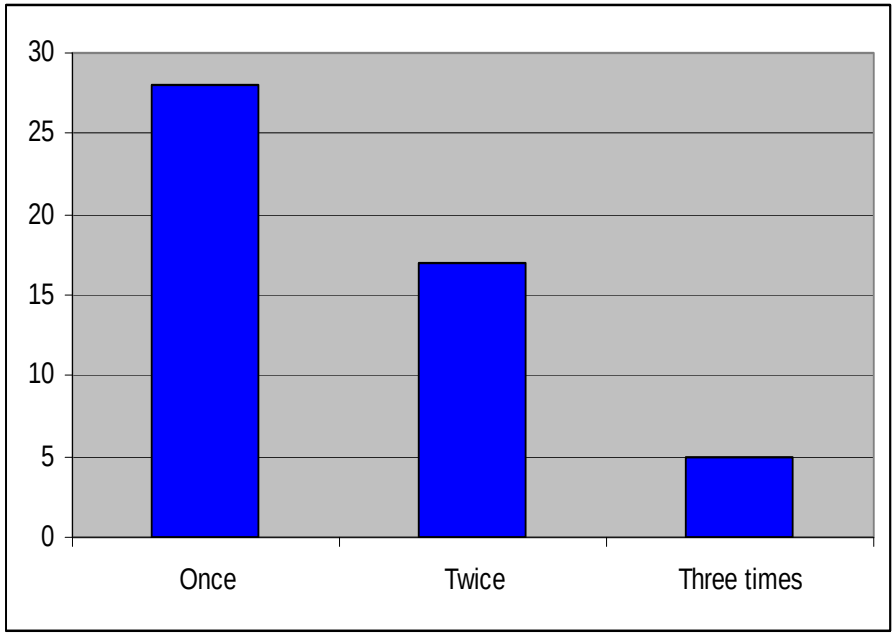
In order to evaluate how the students contribute to the health informatics capacity, and to monitor how the program is able to prepare the students for their future job we have investigated the student's job situation after graduation. The survey was done in 2004.

A cover letter pointing to a web-based questionnaire containing 45 questions was sent to the 147 students who had graduated from the program. 69% responded. The questionnaires were analyzed anonymously. Descriptive statistics were applied to the standardized answers.

Results: Change of jobs

76% of the graduates are working within health informatics. 8% are working with IT outside the health area, mainly IT- or pharmaceutical industry. 15% do not work with IT at all, the majority is either working in clinical positions (nurse or physician) or in managerial positions within the hospital.

Half of the students change job after graduation. The figure shows how many students have changed their job once, twice or three times since they graduated.



Results: Employment before and after graduation

The students were asked where they were employed before they entered the program and where they were employed three month or more after graduation.

Employment	Before	After	Migration
Hospital - clinic/laboratory	36	16	-20
Nursing school	11	11	0
Regional institution/administration	5	10	5
Hospital - administration	11	9	-2
University or research institution	3	8	5
Hardware/software industry	3	8	5
Hospital IT-department	10	7	-3
Other	7	6	-1
Ministry or government institution	1	4	3
Municipal institution	3	4	1
Other public institution	2	3	1
Other health informatics industry	0	2	2
Consultancy	1	2	1
Homecare	4	1	-3
Pharmaceutical industry	0	1	1
Own company	1	0	-1
Missing	3	9	6
total	101	101	

Results: Work function

Work function	
Implementation of it-systems	57
Education	47
Project management	45
Quality assurance	40
Consultancy	35
* for hospitals	33
Management/organisation	29
General administrative tasks	20
* for primary care	13
Decision support	13
Multimedia, internet, intranet	13
* for municipality health care/administration	12
Telemedicin	10
Research and development	8
* for education	7
Medical image analysis	4
* for public health	3
Pervasive computing	3

There are many different work tasks fulfilled by the masters, and the majority fulfills more than one task in their job. The masters were asked to check as many as necessary to describe their current work function on which they spend more than 10% of their time, and the result is shown in the table.

* = Development/purchase of systems for ….

Discussion

In the contrary to the programs at Heidelberg University [3] and University of Utah [5] the majority (76%) of the graduates from Aalborg University work with health informatics after graduation and 92% remain within the health care sector. An immediate explanation is that nearly all the students at the point of entering the program already have a job in health care.

At Heidelberg University more than half of the graduates worked outside of medical informatics, which in their opinion underlined the quality of the informatics oriented part of education, because the medical informatics graduate can compete with those from general computer science [3]. We find it rather supporting for the quality of our program that the graduates are able to find jobs within health informatics – the area in which they are specialized to function in and that they can contribute with high level knowledge about very complex problems.

The survey has been essential to further development of the curriculum.

Readiness and Necessity for Self-directed Learning Among Nursing Students in Japan

Mika Tomita[a], Mariko Iwasawa[b], Yoichi Nakamura[c], Nobuyuki Midorikawa[b], Katsuhiko Takabayashi[d]

[a] *Department of Nursing, Ibaraki Prefectural University of Health Sciences, Japan*
[b] *Department of Library, Information, and Media Studies, University of Tsukuba, Japan*
[c] *Center for humanities and Sciences, Ibaraki Prefectual University of Health Sciences, Japan*
[d] *Division of Medical Informatics and Management, Chiba University, Japan*

Abstract and objective

In nursing education, self-directed learning is important for both nursing students and nurses [1]. The objective of this study was to understand information-related learning behaviors in order to establish a self-directed learning curriculum for nurses. In addition, the information-use environment for clinical nurses was also considered. Nursing students were surveyed using a questionnaire, and a clinical nurse was interviewed. More than half of the nursing students were dissatisfied with regard to document retrieval. Difficulties between the conformability of the search terms and the search results were a concern. Regarding the information-use environment and information-seeking behaviors, many students requested that the library service be attended. Some suggested that training for performing scholarly information searches specializing in the nursing field and for evaluating search results would be useful.

Keywords:

students, nursing; education, nursing; education, professional; curriculum; information storage and retrieval

Methods

Survey for nursing students

Forty-nine students completed a questionnaire survey regarding information retrieval and the information needs of nursing students.

Interview with a clinical nurse

We interviewed a nurse with more than 20 years of clinical nursing experience. The interview included questions regarding her information needs and the information-use environment in clinical settings. The results were analyzed using a qualitative method.

Results

Survey for nursing students

More than half of the nursing students were dissatisfied with the information-use environment and the information retrieval process. Specifically, they found the selection of keywords for document retrieval to be difficult and the system to be unadaptable.

Interview with a clinical nurse

Information-use environment

The nurse used Internet search engines, e-mail, and the university library at her office and at home and was proactive with regard to seeking information. However, she reported that her colleagues had various difficulties.

Information needs in clinical settings

Information regarding medicine was the most frequent topic of her information searches. Original documents were the most difficult items to obtain.

Conclusion

Nursing students and clinical nurses are rather uncertain with regard to how they should seek needed information. Their difficulties were exacerbated by the diversity of their information needs, time restrictions, and the information-use environment. We think that the creation of a self-directed learning curriculum for nursing students is needed in Japan.

Backgound

- In nursing education, self-directed learning is important for both nursing students and nurses [1].

Objective

- The objective of this study was to understand information-related learning behaviors in order to establish a self-directed learning curriculum for nurses.
- In addition, the information-use environment for clinical nurses was also considered.

Method(1)

- Survey for nursing students
  - Forty-nine students completed a questionnaire survey regarding information retrieval and the information needs of nursing students.

Method(2)

- Interview with a clinical nurse
  - We interviewed a nurse with more than 20 years of clinical nursing experience.
  - The interview included questions regarding her information needs and the information-use environment in clinical settings.
  - The results were analyzed using a qualitative method.

Result(1)

- Survey for nursing students
  - More than half of the nursing students were dissatisfied with the information-use environment and the information retrieval process.
  - Specifically, they found the selection of keywords for document retrieval to be difficult and the system to be unadaptable.

Result(2-1)

- Interview with a clinical nurse
  - Information-use environment
    - The nurse used Internet search engines, e-mail, and the university library at her office and at home and was proactive with regard to seeking information.
    - However, she reported that her colleagues had various difficulties.

Result(2-2)

- Interview with a clinical nurse
  - Information needs in clinical settings
    - Information regarding medicine was the most frequent topic of her information searches.
    - Original documents were the most difficult items to obtain.

Conclusion(1)

- Nursing students and clinical nurses are rather uncertain with regard to how they should seek needed information.
- Their difficulties were exacerbated by the diversity of their information needs, time restrictions, and the information-use environment.

Conclusion(2)

- We think that the creation of a self-directed learning curriculum for nursing students is needed in Japan.

A Web-based Data Management System for Ubiquitous Bio-signal Data Monitoring

Sooyoung Yoo, Jinwook Choi, Jaepil Kim

Department of Biomedical Engineering, College of Medicine, Seoul National University, South Korea

Abstract

For the successful ubiquitous healthcare, the biological signal data should be easily assessed and properly maintained. This paper describes a system for the web-based data management. It consists of a device interface, an HL7 gateway, a data upload control, a central repository, and a web server. We use MFER standard for encoding medical waveforms and HL7 for transferring data. For the easy assessment and management of data, the user-specific web services were designed.

Keywords:

computer systems, system integration, internet, MFER

Introduction

Recent advances in the ubiquitous computing technology make it possible to measure bio-signal data anywhere, anytime. For the early diagnosis, treatment, and prevention, the measured data should be easily accessed and properly maintained. This paper demonstrates a web-based data management system which encodes the bio-signal data using MFER standard, wraps them in HL7 messages, transfer the messages, and stores them in the central database.

The Ubiquitous House (U-house) Project is a long-term project funded by Korean Science and Engineering Foundation. The goal of the project is to develop ubiquitous telemonitoring systems, bio-sensors, and a central database system. All of the bio–signals such as EKG and EEG are supposed to be monitored unconsciously during the daily life in the U-house. In order to collect the measured data from the U-house regardless of various monitoring devices, we have developed a web-based data management system.

Methods

Currently six types of biological signal data (ECG, blood pressure, glucose, temperature, weight) are monitored and collected from the U-house. The web-based data management system consists of the five components.

Device interface: For the communication of the waveform data (ECG, EEG etc.), we use the MFER[1] (Medical waveform description Format Encoding Rule) standard specialized in encoding medical waveforms. We developed MFER DLLs to support fast and easy implement for other developers.

HL7 gateway: After receiving waveform data, the HL7 gateway automatically generates HL7 (Health Level 7) messages. An HL7 message contains the patient information and the metadata for the waveform. HL7 gateway sends the messages to the central repository.

Data upload control: The role of the web-based data upload control is to provide a robust method for uploading waveform data. We designed a client-side ActiveX control which consists of the three key components: an MFER parser, a file compressor, and a transfer module. The MFER parser gets the header information of the encoded files. Then it hands over the information to the file compressor and the transfer module. Files are compressed by the file compressor. Finally the transfer module uploads files to the repository.

Central repository: The central repository contains the integrated biological signal data. For MFER files, we only stored header information (e.g., the number of channels, sampling rate, etc) and file pointers in the database.

Web server: Three kinds of web services were designed for three different user groups (doctors, patients, and system administrators). Doctors can review all of the measured data of his/her patients. Patients (subjects) can review their own bio-signal data and add new data. System administrators can check file transfer errors and establish new connections between the new devices and the waveform device interface.

Results and discussion

The first generation of the data management system was developed in 2003. For the second generation of the data management system, we have designed a more robust data upload module. We used Microsoft Internet Information Server 5.0 as a web server, and Active Server Page (ASP) and scripting languages. Microsoft SQL Server 2000 is used as the database management system of the central repository.

1 Available at: http://ecg.heart.or.jp/Jp/Index.htm

We expect that the proposed system can be a promising model for the ubiquitous health care environment.

Acknowledgments

This work was supported in part by the Advanced Biomedical Research Center (ABRC) funded by KOSEF, and in part by the MIC (Ministry of Information and Communication), Korea, under the ITRC (Information Technology Research Center) support program supervised by the IITA (Institute of Information Technology Advancement) (IITA-2006-(C1090-0620-0002)).

A Web-based Data Management System for Ubiquitous Bio-signal Data Monitoring

Department of Biomedical Engineering,
College of Medicine, Seoul National University,
South Korea

Research Purpose

- **Development of ubiquitous bio-signal telemonitoring system**
  - **Using standard exchange format**
  - **Using efficient web technologies**

Motivations

- Necessity of medical information standardization
  - To reduce medical error
- Convenient practical use of medical information
  - Dynamic manufacturing and administration of patient information and measuring information of medical devices
- Application and development of standardization technology
  - HL7 : A standard for the exchange of electronic data used in medical environments
  - MFER : A JAHIS (Japanese Association Health Information System Industry) standard for waveform data

Open Source Network Infrastructure for Health Information Systems

Paulo B. Paiva, Rafael V.D. Giusti, Marco A.G. Ribeiro, Meide S. Anção, Daniel Sigulem

Health Informatics Department, Federal University of São Paulo, Brazil

Abstract and objective

This paper describes a network infrastructure based on Open Source software implanted in an academic hospital and medical school at the Federal University of São Paulo (UNIFESP). The UNIFESP network serves more than 3,300 workstations spread in a metropolitan campus. The network was planned in order to connect multi-platform workstations based on the IP protocol, using distributed servers and a decentralized administration. All network services provided by a pool of low-cost central servers and low-end departmental servers, 90% of the peripheral servers are base on free software. Free/Libre/Open-Source Software, or FLOSS, is a term for software that is liberally licensed in order to grant users the right to redistribute, change and improve its original source code. The use of Open-Source Software for the network infrastructure allowed building with scarce resources an always up-to-date system managed by in-house trained staff.

Keywords:

internet, free software, computer networks

Methods

The main concern when building an Open Source network infrastructure was the administration and implementation of network services. The main administrative tasks are facilitated by in-house developed scripts. User administration, network device administration, backups, user directory services, web-page deployment and generation of dynamic web content. Core service administration is performed by a small staff who also train administrators of departmental servers. User accounts are maintained in a central corporative directory based on the Lightweight Directory Access Protocol (LDAP). The use of a centralized directory enables the aggregation of different users rights into a unique structure, facilitating the management of resources available for users.

The network is composed by several class C subnetworks, mainly used for servers and academic workstations, and 4 class B subnetworks, for internal use. Firewalls are implemented using free software at the routers. The policies in the firewalls are based on the denial of all services by default, connections to well known services are allowed selectively. Address translation, which allows workstations with internal addresses to access Internet services is implemented using NAT (Network Address Translation). Segmentation is done by low-end computers, avoiding the propagation of network broadcasts commonly originated by Windows based workstations.

Network management in a large heterogeneous environment presents several pitfalls ranging from the control of new networks and workstations to monitoring traffic. These tasks are performed by the core administrative staff supported by several open source software and in-house developed applications. A device database keeps track of all equipment which is used for network monitoring. Network traffic is monitored using open source software that were tailored to fit specific idiosyncrasies of the university and hospital network. Off-site monitoring, e-mail and pager alerts were implemented.

Results

A network infrastructure based on the IP protocol for heterogeneous workstations of a university and 7 colligated hospitals, was built based upon low-cost servers using Open Source Software for core services. More than 3,300 workstations based on different operating platforms (MS-Windows, Macintosh, SunOS, IRIX , Linux, FreeBSD), and 7,000 users.

Conclusion

A decentralized administration and extensive training of network management staff were of central importance in order to use and maintain the network. Although there are no software license costs, the total cost of ownership (TCO) could be higher than using proprietary software. The network administration was decentralized in order to propagate knowledge between the core administration staff and the rest of the administrative personnel.

Open Source Network Infrastructure for Health Information Systems

Emergency and Disaster Recovery System Extensions to caBIG™

Martin E. Cryer[a] and Lewis Frey[a]

[a] *Biomedical Informatics Department, University of Utah, USA*

Abstract and objective

The proposed system, ca!, considers the requirement for medical resource planning as the result of a wide scale disaster. For the purposes of this scenario a Radiological Dispersal Device (RDD) explosion was considered as the event. In order to provide data for planning input for first responders and healthcare workers, combined radiation intensity, type and location (GPS) sensors need to be co-located with such service providers, providing reliable environmental data streams in the potential absence of electrical utility power and Internet, wireless or cellular connectivity. Information should be available in real time for multiple recipient organizations to perform analysis at the local and national level. This proposed low cost solution is comprised of wireless sensors and access points based upon equipment currently provisioned with the emergency services relayed to a caBIG™ style processing node on a grid computing network. Sensors are low power devices designed to run from automotive batteries.

Keywords:

disaster planning, grid computing, caBIG™, explosive agents, radiation, fault tolerant, wireless, RDD

Introduction

Subsequent to the 9/11 terrorist attack on the World Trade Center in New York, there has been an increased public and government awareness for potential terrorist attacks on U.S. soil and overseas assets [1]. Prevention or warning against such acts, are, by their very nature difficult to predict or prevent. Whilst prevention is the most desirable outcome of any counter terrorism activity [2], there has to be the distinct possibility that terrorists, domestic or foreign, will eventually succeed in any case. Therefore, systems designed for monitoring, containment and handling phases of disaster management must be available in a timely and cost effective manner [3]. Monitoring and detection systems are the initial building blocks upon which the containing and handling or treatment phases of intervention are based; the proposed system is a monitoring phase system.

Due to the large potential target list for a Radiological Dispersal Device (RDD) [4], providing an effective monitoring system with adequate geographical coverage in the same manner that one could provide, say, with airport security scanners could be an extremely expensive proposition. Additionally, RDD detonations being only effective for large conventional explosive triggers [5] will likely result in some level of disruption to both power and public wireless or cellular communications infrastructure, complicating existing monitoring device operations [2].

With the first responder, public safety and hospital clinical workers, there is a degree of health risk due to the direct and indirect contamination resulting from a Radiological Dispersal Device [6-8]. By equipping first responder vehicles and medical facility fixed assets (hospitals, morgues and clinics) with sensor devices we can obtain an informed judgment as to the likely levels and nature of exposure for critical health care workers, from both the environment and the triaged patients they come into contact with.

In this project, we propose that by the use of low cost, first responder vehicle mounted, publicly available wireless networking and computing resources, we can provide an effective sensor network for monitoring RDDs. In order to deliver captured sensor data to points of interest in a portable and understandable manner, we propose utilizing the existing caBIG™ Grid network [9-12].

Methods

The initial project is for a laboratory bench simulation providing a proof of concept. The mobile network conjoining all the sensor devices would be simulated using laptop computers, as mounted in law enforcement or first responder vehicles. The initial proof of concept and subsequent simulations will be performed using a cellular based network. Further simulations will be performed using a self-healing mesh network, as the reliability of a cellular network for sensor connectivity or data collection and filtering cannot be guaranteed. Network therefore will consist of wireless sensor devices, collection systems and a network infrastructure built upon ad-hoc wireless networks using laptop computers.

To enable distribution of the data collected by this mesh network, the network will be connected to one or more Grid computing nodes, as part of the caBIG™ computing environment. The use of the caBIG™ Grid computing network allows data to be extracted from the sensor network to a specified vocabulary and with a common data abstraction. Additionally, the data may be accessed from a variety of client nodes, at high speed, in a secure and reliable manner. The data may therefore be viewed both by local and

national government agencies, as well as by regional and distributed cancer centers, allowing for wide area participation in treatment and risk minimization planning.

Results

It is envision that the simulations will show that it is possible to build and operate a low cost, minimally invasive system for monitoring the important environmental concerns regarding a major disaster in an urban environment. Additionally, such a system can be expanded to cover a wider variety of health care relevant indicators to allow for intelligent victim to facility routing and transport. Health care facilities and emergency workers can also provide more effective decontamination site location and secondary radiation sources can be tracked in an automated fashion.

The system will enable improved interpretation of bio-hazard risk for first responders, as well as providing applications to process sensor information in a distributed and tiered manner for clinical and law enforcement purposes. Further analysis by applications developed for regional and federal agencies, especially for the scenario of handling multiple simultaneous events, is a straightforward extension due to the underlying caGRID architecture. Using existing a low cost and proven infrastructure at all application tiers should reduce barriers to entry for public agencies, from both cost and risk perspectives.

Discussion

Our goal is to demonstrate the feasibility of constructing an effective sensor information network for use in public emergencies such as an RDD detonation event. Such a system will be shown to be effective by considering aspects of availability, data coverage, spatial resolution and temporal granularity. For the future, achievement of the specific aims specified here will enable us to work towards delivering a working prototype of the overall system, covering sensor detection, data acquisition and analysis and a hierarchical medically useful set system of analysis applications.

Sensor data as received by an analysis application can be viewed as raw sensor data or aggregated and filtered data, each with a variety of temporal parameters. All sensor data, aggregation and filter services, as well as temporal parameters are represented by metadata within the caBIG™ Cancer Data Standards Repository (caDSR) [13].

Conclusion

Core to the system will be a universal data model allowing for rapid low cost applications software development. In order to provide aggregated sensor data to a distributed set of analysis applications, there must be an abstraction of the acquired sensor data via an agreed protocol and messaging format, tied to a vocabulary. Additionally, provision of a reliable and secure networking framework is assumed, as well as generated application programming interface (API) in order to provide rapid development of low cost analysis application services. The use of the caBIG™ Grid assists in these development goals.

martin.cryer@hsc.utah.edu

The University of Utah

Biomedical Informatics

ca! - The Overall Project

Is it feasible to construct a highly available, low cost, environmental sensor data collection and analysis system for use in emergency situations, by utilizing existing emergency response system infrastructure, for data acquisition, and a distributed computing grid (caBIG™) [3-5] for an applications development and execution environment?

ca! Components

The conceptual model is comprised of three components:

- A sensor data acquisition component
- A sensor data aggregation and storage component
- An applications development and execution environment (caBIG™)

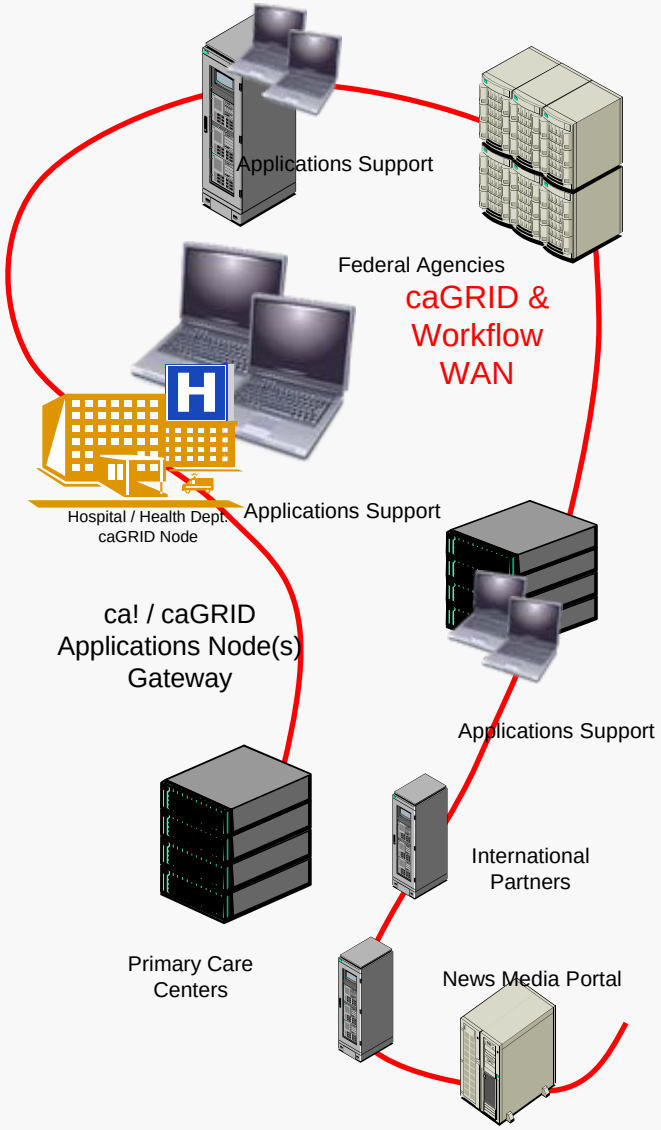
ca! - Sensor Component Criteria

- Sensors operate with no VAC, all 12DC
- Two node types, static and mobile
- Use existing equipment, laptops, in first responder vehicles
- Simple sensors, data recovered using sensor embedded web servers
- Data recovered in raw form, processed at the GRID node I/F
- Very low cost technology, small delta over existing expenditure
- Sensors connected via WI-FI and Peer to Peer networking (reliable network)

caBIG™ Architecture Background

Why Use caBIG™?:

- caBIG™ [3-5], a WAN distributed series of functional cancer research nodes accessible in a manner analogous to plugging into the power *grid* (caGRID [5]) - plug and play…
- Each node may be a single system, a cluster or a parallel system



caBIG™ Functions

- caBIG™ provides a network resource for handling desired cancer research tasks in a standardized manner
- caBIG™ provides the ability to execute tasks in a coarse grained parallel or distributed manner, caGRID / Workflow
- caBIG™ allows for data portability, both at functional and semantic levels, including vocabulary, common data elements, message passing formats and APIs
- Emphasis on cancer research, but extensible

caBIG™ Platform

- caBIG™ uses the Globus Toolkit Version 4 (GT4) [7] for underlying transport
- caBIG™ is a form of GRID computing at the broadest form of the definition, caGRID
- caBIG™ provides an SDK for developers (Cancer Applications) within the caCORE component
- GRID aware applications platform, caGRID
- caGRID provides for security and supports Workflow capabilities

caBIG™ Platform…

- What do we get with caBIG™?
  - Distributed Applications, caGrid
  - Security
  - Service Directory
  - Semantic Services, Vocabulary, Ontology
  - Resource Manager
  - Standard Query Language and Interface
  - Data Integration and Standardization
  - Software Development Environment
  - Standards and Certification

ca! - Sensor Network

Our Task:

- Extend caBIG™ to support a dynamic mobile sensor network
- Provide a sensor abstraction to the caBIG™ GRID via the Cancer Data Standards Repository (caDSR) [6]
- Allow sensor network and processed sensor data to be visible by any authorized node on GRID
- Accommodate Three Aspects to Sensors:
  - Raw Data
  - Aggregated Data
  - Temporal Parameters

ca! - Applications Layer

- Data is visible to any authorized caBIG™ client on the GRID
- Adheres to caBIG™ standards for vocabulary and data formats, messaging and APIs
- Exploits caBIG™ security controls for sensitive information access
- Allows for remote processing of data
- Distributed data archiving
- Supports layered applications:
  - First Responder
  - State or Area Level
  - Federal or National Level

ca! - Architecture

Secure Remote Access for Web Based Clinical Information System Using Policy Control of PCs and Healthcare PKI Authentication

Katsuya Tanaka[a], Mayumi Yoshida[b], Ryuichi Yamamoto[b]

[a] *Department of Planning, Information and Management, The University of Tokyo Hospital*
[b] *Interfaculty Initiative in Information Studies, Graduate School of The University of Tokyo*

Abstract and objective

This paper describes a robust method of secure remote access for Web based clinical information system using Healthcare PKI authentication. It enables medical staffs to refer the medical data using his own PCs from their home or their mobile phones over the Internet. This system contributes to reduce strain of medical staffs especially in such institutes where intensive care is carried ***uninterruptedly.*** *For this purpose, it must permit the remote access to the hospital information system from PCs in various conditions, it is necessary to establish a secure connection using VPN or SSL, and control the policy of client PCs for the prevention of computer virus effect etc., and at the last, confirm user authentication with strict identification using Healthcare PKI (HPKI).*

Keywords:

Healthcare PKI, Clinical Information System, Secure Remote Access Control, VPN

Introduction

In Japan, healthcare ICT is promoted by Japanese government and in 2006, the government made "New IT Reform Strategy" and "The Action Plan 2006". It emphasizes the reengineering in the healthcare field using ICT. It includes some actual plan such as constructing secure and reliable network for regional and inter-regional cooperation and development of Healthcare PKI (HPKI) which is based on ISO 17090. Actually we started to use HPKI in 2004, as a demonstration experimental system in the University of Tokyo Hospital for secure remote access to the medical data. HPKI was used in this system for authentication purpose, with verification the attributes of the national licenses of healthcare professionals, such as medical doctors, registered nurse, etc. By using this system, a physician can access the medical data of his patients with his own PCs even in his home or his mobile phones.

Methods

In our hospital, medical staffs are able to access to medical records using web based system in addition to special client PCs. The overview of the developed system is shown in Fig.1. Mainly based on the web interface, the following parts were developed.

1. Certification Authority (CA)
For the convenience of user registration operation, All CA function was implemented in a note PC. It is also used for registering HPKI certificate to USB token. The CA function was implemented on a virtual Linux machine in that note PC using OpenSSL library, and the host OS of the PC was Microsoft Windows 2000 with a capability of handling HPKI certificates (i.e. getting a certificate via web interface of the virtual machine, and storing it to the USB token).

2. VPN gateway
The connection between the hospital network and a client PC is established using IPSec. We picked a VPN gateway, Cisco Systems/VPN 3005.

3. Policy Control System
At the establishment of VPN connection, the server side policy is downloaded to the client PC, and during the connection, client PC is under the predefined policy which force PC to evoke only modules essential to brows our server and stop working other unnecessary modules. We picked Check Point (Zone lab)/Integrity.

4. USB Token for HPKI
At the insertion of this USB token, HPKI certificate is copied to the certain repository in Windows, and on the removable of token, the repository is cleared.

5. Reverse Proxy Server
For the verification of the HPKI certificate, especially hcRole attribute, user access is only allowed via this SSL reverse proxy server. At the connection to an internal web server in hospital, the user certificate in client PC is pushed and verified. This proxy server was developed by adding a capability of handling HPKI certificates to Fujitsu Co. Ltd./Interstage Security Director

6. Mobile Access System
For the mobile access over the Internet not using HPKI, we developed CHTML converter gateway. The identification number of each mobile phone is stored at the registration in server side, and the access of unknown device is prohibited. The overview of the system is shown in Fig. 2.

In each case, the user needs to access the SSL gateway first of all, and then log onto the web-based hospital information system using his account (id/password), choose a patient, refer to the patient information.

Results

In this experiment, 30 doctors for the PC client access system and 20 doctors for the mobile phone access system participated and the developed systems are now in use. This system is effective to check the results of emergency laboratory tests, or radiological images on PACS system from remote place.

We also carried out a questionnaire for the participants, and the following points were pointed out.

1. Identity Verification

At the registration, the hospital ID card and the driver's license card with a picture were checked. The participants say it is reasonable enough for the user verification.

2. Client Software

This system requires various client software modules, such as IPSec client software, USB token driver and policy control client, so it is difficult to manage for the user to install or operation.

The software environment of PC clients quite differs from one to another depending on the user's usual system usage or his work. It sometimes caused troubles at the installation or the operation. We had some difficult problems to support users against these various PCs.

3. Connection Environment

For the access from the user's home, the client PC is not always directly connected to the Internet. Especially when the access needs to be established through a NAT router, some users had a difficulty to realize an IPsec VPN connection.

For the mobile-phone access system, no claims were pointed out.

Discussion

Our developed system aims to realize a secure access over the Internet to the web-based clinical information systems in the hospital. Main issues are,

1. Secure Connection

SSL connection over IPsec VPN was used. It is safe enough to protect the clinical information from snooping or other risks for the access over the Internet.

2. Policy Control of client PCs

For the restriction of running dangerous .exe/.dll programs, we need to gather the environment information of various client PCs. It is easy to restrict the access depending on browser type or its version, but it is very difficult to judge whether other installed programs or libraries are safe or not. Our policy control method which allows only essential modules to work is an effective solution in such situation.

3. Authentication using HPKI certificate

In this experimental system, we restricted access to the user whose certificate includes an hcRole attribute of "Medical Doctor". The account itself has the attribute information of the user's job title. The requirement of this feature has lower priority.

We are now discussing for the improvement of this system, taking in recently available technologies such as smart card for the HPKI token, SSL-VPN technology for an easy management of client PCs. Concerning secure data access, it is better to use virtual machine environment on the client PC side working with a SSL-VPN gateway.

Conclusion

Our developed secure remote access system is described. It was implemented based on proxy gateway adding no special reconstruction to our hospital information system. In the experimental results, several improvement factors for the software installation or operation issue were pointed out. For the achievement of higher user-friendliness, it is necessary to apply other easy-to-use methods, such as SSL-VPN with virtual client environment.

The Web-based Learning Environments Affect the Learning Outcomes: Website Design for the International Journal of Medicine

Lin Guo[a]

Centre for Adult and Paediatric Gastroenterology, Institute of Cell and Molecular Science, Queen Mary's School of Medicine and Dentistry, Barts and The London, Queen Mary, University of London, UK.

Abstract

This project is to describe the development and preliminary evaluation of a website design for the International Journal of Medicine (IJM), and to evaluate if the attitude and learning experience of using information technology would be more positive in the web-based learning environment. The International Journal of Medicine (IJM) is a peer-reviewed, refereed Journal with distribution in more than 200 countries and territories. The journal website was designed to help healthcare professionals and students in their daily practice, lifelong learning and career development. Consequently, there would be a website in a designed learning environment with special learning and communication tools when using the Internet for medical education and practice purposes. Information technology (IT) is there to be used and website and electronic communication provide competitive advantage. Properly planned, designed and implemented website should pay for itself and providing a return on investment. Website provides convenience to the healthcare professionals and students and offers them the ability to communicate more effectively in medical practice and education.

Keywords:

web-based learning, healthcare professionals, medical student, information technology, website design

Introduction

To describe the development and preliminary evaluation of a website design for the International Journal of Medicine (IJM), which can be used by all healthcare professionals and medical students in the field of medical practice and education worldwide to access healthcare information to enhance evidence-based patient care and personal professional development and to evaluate if the attitude and learning experience of using information technology would be more positive in the web-based learning environment, in which the healthcare professionals and medical students could use information technology based learning tools.

Design and methods

The International Journal of Medicine (IJM) is a peer-reviewed, refereed Journal with distribution in more than 200 countries and territories. The journal website was designed to help healthcare professionals and students in their daily practice, lifelong learning and career development. In addition, it seeks to be at the forefront of the international debate on health. The Journal website was designed by the Editor in Chief, Professor Comfort Osonnaya in collaboration of the Editorial and Production Team of the Journal and in collaboration with the various organisations linked to the Journal. These include: the Association of Health Care Professionals (AHCP), the owners of the Journal, the International Medical Publishing Group (IMPG), the publisher of the Journal, the Lowcost Services Group (LSG), the typesetting, production, distribution, administrative and website coordinating Managers of the Journal.

All production, editing, review, commissioning, legal and ethical issues, details of Editorial Board Members and other relevant information and links were included in the website.

Infotex Internet Providers of Sussex, UK were commissioned to host the website and members of the Editorial and Production Team have been working closely with them on the website design.

It was agreed that a complete book, which contains all the information on the website will be published by the Journal Publishers, in order to act as a reference for the production. It was also agreed that the website would have a link to the AHCP, IMPG, PHCJ and other related websites, which are also being updated. The timescale agreed for the IJM and other linked website to go live is between September to December 2006.

The website design team agreed that the initial designed website would be tested and first evaluated by the Editorial and Production Team, together with a small sample of other potential users of the website (healthcare professionals and members of the public). The manuscript of the website book would also be available at the IJM Editorial Board Meeting for further comments from the Editorial

Board Members. The summary of the results of the initial evaluation of the website are stated below.

Results:

The web-based learning environments affect the learning outcomes differently according to the pedagogy (traditional instruction versus constructive), the design of website (linear versus hypertext), and the interaction possibilities provided by the learning platforms (interaction only with the learning materials versus interaction with peer review and the instructor). Consequently, there would be a website in a designed learning environment with special learning and communication tools when using the Internet for medical education and practice purposes. The majority of the respondents indicated that the website met the users' requirements to a very good extent and the website promotes efficient information delivery to the healthcare professionals and students in research, medical practice and education.

Discussion:

The study had a pre-/post-text control group design. The different learning styles for healthcare professionals and medical students can be generated in the following:

- a didactic style where texts and tutorials were offered in a structured way
- a problem-solving style, where the material was presented in the context of the case and the computer asked appropriate questions in a series of multiple-choice tests,
- a free text style, which allowed the user to respond to open-ended questions by typing in natural language responses.

The website environment was designed for healthcare professionals and medical students in two different forms:

- Journal materials offered through conventional www-technology and by engaging in an e-mail discussion with an instructor for a non-interactive web-based learning, and
- Journal materials offered using the web-based learning for self-direct learning as well as interactive forums with an instructor and peer review for a shared learning process.

The advantages of the website include[1-3]:

- being available 24 hours a day, seven days a week
- it is convenient to browse the website and check the information whenever they want
- the website can also allow students and healthcare professionals to collect information and allows them to sign up and order journals and related products and services
- the need for administration is reduced
- an on-line website which is quick, easy and inexpensive to modify
- providing answers to frequently asked questions thus saving staff time
- improved communication by email which is professional and convenient
- it is significantly better than leaving messages on answering machines

Conclusion:

The more interactive computer-learning environment improved learning outcomes. Information technology (IT) is there to be used and website and electronic communication provide competitive advantage. Properly planned, designed and implemented website should pay for itself and providing a return on investment. Website provides convenience to the healthcare professionals and students and offers them the ability to communicate more effectively in medical practice and education.

THE WEB-BASED LEARNING ENVIRONMENTS AFFET THE LEARNING OUTCOMES: WEBSITE DESIGN FOR THE INTERNATIONAL JOURNAL OF MEDICINE

Lin Guo

Centre for Adult and Paediatric Gastroenterology, Queen Mary's School of Medicine and Dentistry, Barts and the London, Queen Mary, University of London, London E1

Aims and Objectives

- To describe the development and preliminary evaluation of a website design for the International Journal of Medicine (IJM)
- To access healthcare information to enhance evidence-based patient care and personal professional development
- To evaluate if the attitude and learning experience of using information technology would be more positive in the web-based learning environment

Design

- The Journal website was designed by the Editor in Chief, Professor Comfort Osonnaya in collaboration of the Editorial and Production Team of the Journal and in collaboration with the various organisations linked to the Journal.

- All production, editing, review, commissioning, legal and ethical issues, details of Editorial Board Members and other relevant information and links were included in the website

Methods

- The initial designed website would be tested and first evaluated by the Editorial and Production Team, together with a small sample of other potential users of the website (healthcare professionals and members of the public).

- The manuscript of the website book would also be available at the IJM Editorial Board Meeting for further comments from the Editorial Board Members.

Results (1)

- The web-based learning environments affect the learning outcomes differently according to the pedagogy (traditional instruction versus constructive), the design of website (linear versus hypertext), and the interaction possibilities provided by the learning platforms (interaction only with the learning materials versus interaction with peer review and the instructor).

Results (2)

- There would be a website in a designed learning environment with special learning and communication tools when using the Internet for medical education and practice purposes.

- The majority of the respondents indicated that the website met the users' requirements to a very good extent and the website promotes efficient information delivery to the healthcare professionals and students in research, medical practice and education.

Advantages

- being available 24 hours a day, seven days a week
- it is convenient to browse the website and check the information whenever they want [1]
- the website can also allow students and healthcare professionals to collect information and allows them to sign up and order journals and related products and services
- the need for administration is reduced [2]
- an on-line website which is quick, easy and inexpensive to modify [3]
- providing answers to frequently asked questions thus saving staff time
- improved communication by email which is professional and convenient [2]
- it is significantly better than leaving messages on answering machines [1]

Discussion (1)

- The study had a pre-/post-text control group design. The different learning styles for healthcare professionals and medical students can be generated in the following:
  - a didactic style where texts and tutorials were offered in a structured way
  - a problem-solving style, where the material was presented in the context of the case and the computer asked appropriate questions in a series of multiple-choice tests,
  - a free text style, which allowed the user to respond to open-ended questions by typing in natural language responses.

Discussion (2)

- The website environment was designed for healthcare professionals and medical students in two different forms:
  - Journal materials offered through conventional www-technology and by engaging in an e-mail discussion with an instructor for a non-interactive web-based learning, and
  - Journal materials offered using the web-based learning for self-direct learning as well as interactive forums with an instructor and peer review for a shared learning process.

Conclusions

- The more interactive computer-learning environment improved learning outcomes.
- Information technology (IT) is there to be used and website and electronic communication provide competitive advantage.
- Properly planned, designed and implemented website should pay for itself and providing a return on investment. Website provides convenience to the healthcare.

Utility of Search Strategies Used by Nurses Seeking Internet-Based Health Information

Susan K. Newbold[a]

[a] *Vanderbilt University School of Nursing, Nashville, Tennessee, USA*

Abstract

Understanding the search mechanisms associated with using the Internet to locate health information is essential to improve health care information seeking behaviors of both nurses and their patients.

An observational descriptive cross-sectional study design was used to evaluate the strategies nurses use to search for health-related information on the Internet. There was little variability in the sample.

Keywords:

information seeking, internet, health information, nurse

Introduction

The objective of this study was to determine the utility of clinical nurses' search strategies to obtain healthcare information on the Internet. The aim was to establish if there are successful patterns that can be documented and taught to others.

Methods

An observational descriptive cross-sectional study design was used to evaluate the strategies nurses use to search for health-related information on the Internet at one major east coast school of nursing in the Fall of 2005. The convenience sample of 216 subjects searched for data surrounding a specific healthcare related scenario, then reported their satisfaction with the results of their search and answered some disease specific questions using a questionnaire. Data about search strategies used was collected automatically using Spector Corporate Network Edition (Spector CNE) software. Descriptive statistics and linear and logistical regressions were used to examine the hypotheses.

Results

The number of links used by the participants was significantly related to the search time (more time used more links). The group with less effective scored searches tended to use more links than those with effective searches. Low computer experience tended to predict the number of links used.

Discussion

There are many implications for nurses in clinical practice, education, research, and administration.

- Clinical Nurses need to know most efficient and effective ways to search for healthcare information on the www.
- Will access to online information provide a better quality of patient care?
- Do nurses need access to the www whilst at work?
- CE courses should be conducted to enhance information seeking skills.
- Journal clubs can be created to stimulate the integration of Evidence-based practice.
- Learning styles
- Nurses need skills for searching for and judging the quality of online information sources.
- Basic computer skills and computer literacy is needed by all nurses.

Conclusions

More investigation is needed in order to be able to determine the utility of clinical nurses' search strategies to obtain healthcare information on the Internet. The study conclusions offer suggestions for future study.

The Evaluation of Nursing Cart In Inpatient Medication and Documentations

Wen-chih Chen MD[a] , Yu-Yin Kuo MD[a], Li-Ping Fang BSN[b], Huoy-in Liou BSN[b]

[a]*Li Shin Hospital, Department of Medical Informatics, Taiwan (R.O.C.)*
[b]*Li Shin Hospital, Nursing Department , Taiwan (R.O.C.)*

Abstract

In the hospital, there are many tools or technology to help the care givers to do their jobs. From the doctor writing orders, to the pharmacist to dispend the drugs, and the nurse give the medication to the patient. Many tools can help them to do these things correct and quickly. The CPOE (Computerized Physician Order Entry) can help the doctors descript the medication, to reduce the wrong spell or it can check the contraindication. The pharmacist can use the robots to fill the prescriptions. They double check the package, and sent the medication to the nurses. On the nursing side, however, they do not have a good tool to help them. Moreover, they need to do much duplicate paper work. It is hard to check the medication by a human brain, and complete the medication in the right time. We also consider the implementation of barcode medication in the feature. Therefore, we want to take a useful tool for nurse to complete their work effective and correct.

Keywords :

nursing cart, cost effective

Methods

In the previous study, we interviewed 98 nurses (about 51% fellows) for what kind of nursing cart they would like. More than 70% nurses accepted to take the mobile tools with the nursing cart together. So, we find out some solutions, such as, Tablet PC, Laptop, PDA, Panel PC and Desktop. With considering the battery life and the screen size, we eliminated the Desktop and the PDA. The Tablet PC, however, is too heavy for a female in Taiwan to take in hand for a long time. At last, we take laptop and panel PC for the final choice for nurses.

We built two kind of nursing cart. One is Panel PC (see Figure 1), and another one is laptop (see Figure 2). In order to make the laptop monitor become touchable. We added a touch screen kit in front of laptop screen.

We take these two nursing cart to the nursing station for 3 weeks. And ask the leader and fellows to use both carts. We designed the questionnaire based on the usability and feasibility. The final vision included 23 five-scale items.

Figure 1- The panel PC

Figure 2 - The laptop

In our information system, there are many buttons, check box, or radio buttons. So, the touchable screen is great useful. We designed an Excel VBA program to simulate our HIS, and asked users to finish one scenario. We supposed that if one take more time to finish a scenario, the tools would be useless. Besides, we also do the qualitative research. We asked them for the advantages, disadvantages and suggestion for both carts.

Results

Of all the 23 items, there are 9items meaning in statistics ($p<0.05$). Most of fellows thought the Panel PC would be more useful than laptop with touch screen. In the time test, the nurses spent more 44 seconds when they use laptop with touch screen averagely to finish a scenario.

The results of qualitative research showed that the work space for nurses was much bigger in the Panel PC. However, the laptop with touchable screen was light and handy.

Conclusion

The result showed that the nursing cart with Panel PC would be better option. But we still need to consider some factors, such as, the price, the maintain cost. In the feature, we want to improve the faults of both nursing carts. Besides, we will bundle the barcode medication and the NIS (Nurse Information System) together. Based on these changes, in the further research we hope we can find out the useful and effective nursing cart for the nurses to do their daily works. With these “smart” nursing carts, we will bring the care givers more time to take care of the patient and do the medication effectively and correctly.

The Mobile Phone and Health – Results from a Literature Survey

Günter Schreier

Austrian Research Centers GmbH – ARC, Biomedical Engineering, eHealth systems, Graz, Austria

Abstract

Due to its ubiquitous availability and rapid technological advancement the mobile phone (MP) has been considered and evaluated for many applications beneficial to health. On the other hand, MP use has raised concerns related to possible adverse health effects like interference with and exposure to electromagnetic fields or distraction during driving. The aim of the present study has been to elucidate and quantify the relationship between research on potentially beneficial and adverse effects of MPs on health by means of a literature survey. Results show that relevant publications increased steadily since the 1990's, initially dealing mostly with potentially adverse effects. Publications on beneficial effects started to increase since the late 1990's and amount to approximately 20% of all publications since 2004. Upcoming technologies and still rapidly increasing numbers of MP users are likely to further increase research within the full spectrum of supposedly beneficial and adverse health effects of MP use.

Keywords:

mobile phone, eHealth, telemedicine, health risk

Introduction

Patient empowerment is one of the top priorities among the many hopes and chances the eHealth era is expected to bring for future healthcare [1]. Placing patients in the center of the healthcare system and providing them with tools and knowledge to manage their health and health related data is considered to be essential in facilitating prevention and improving the outcome of treatment.

Due to its ubiquitous availability and rapid technological advancement the MP is poised to be the universal information and communication toolbox for a steadily increasing portion of the worlds population, both in the developed and the developing parts of the world. MPs have, therefore, the potential to serve as a universal eHealth terminal.

As a consequence, MPs have been used and evaluated for health applications by numerous authors. Likewise, we demonstrated the benefits of MP use for the management of patients with chronic diseases [2] and cardiological teleconsultations [3] together with clinical partners.

On the other hand, MP technologies have also raised concerns related to possible adverse health effects. Initial research occurring during the early 1990's assessed health risks in the following categories:

1. distraction during using and handling MPs, e.g. traffic accidents,
2. the impact of electromagnetic fields on medical devices, i.e. electromagnetic interference (EMI),
3. exposure of humans to electromagnetic fields associated with MPs.

A systematic comparison of both, adverse and beneficial effects of MP technology, however, is lacking. The aim of the present study has been to elucidate and quantify the relationship between research on potentially beneficial and potentially adverse effects of MPs on health by means of a literature survey.

Methods

The impact of MPs with respect to health related issues was assessed by querying the PubMed database [4Eysenbach G. What is e-health? J Med Internet Res 2001: 3(2): e20.with the following search phrase:

"(mobile [ti] OR cellular [ti] OR cell [ti]) AND (phone [ti] OR phones [ti] OR telephone [ti] OR telephones [ti])" so as to find any citation containing at least one of the various expressions for "mobile phone" in the title string.

The received citations were classified based on the title and - if necessary and available - the abstract as belonging to one of the following main categories:

1. **Adverse:** article clearly deals with potentially adverse effects of MPs on health
2. **Beneficial:** article clearly deals with potentially beneficial applications of MPs to improve health
3. **Other:** Undefined (title and abstract are inconclusive), Irrelevant (article not specifically associated with health), and Duplicate (article relates to a preceding article which had already been classified)

Results

A total of 814 citations have been obtained and examined (last PubMed access update on Nov. 28th, 2006).

The evolutions of the frequencies of articles over time are depicted as histograms for citations on adverse and beneficial effects in Figure 1 - Annual numbers of citations

dealing with adverse (lower and light part of the bars) and beneficial effects (upper and dark part of the bars) of MPs on health1.

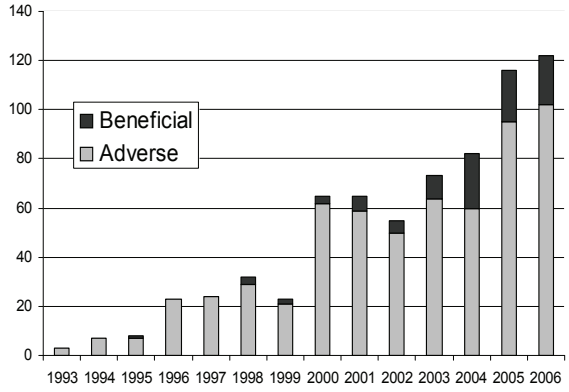

Figure 1 - Annual numbers of citations dealing with adverse (lower and light part of the bars) and beneficial effects (upper and dark part of the bars) of MPs on health

Discussion

Figure 1 - Annual numbers of citations dealing with adverse (lower and light part of the bars) and beneficial effects (upper and dark part of the bars) of MPs on health1 indicates that Publications on the health impact of MPs actually started in the early 1990's and increased in a more or less linear way during the subsequent years. Initially, there were mostly publications on potentially adverse effects. Consistent publication activities on beneficial effects started in the late 1990's, increased until 2003 moderately and leaped to higher levels beginning with 2004. In recent years such publications amount to approximately 20% of all publications considered by this survey.

The presented survey includes only articles listed on PubMed. There are – of course – additional articles dealing with this issue, e.g. articles being associated with the author [3], including articles that would actually have satisfied the search phrase but are not listed on PubMed [5]. Hence, the list is far from being complete and no conclusions can be drawn in terms of absolute numbers.

Since the survey was concluded at the end of November 2006, the numbers for the year 2006 do not yet include December and are therefore underrepresented.

It has to be emphasized that this survey did not attempt to assess details of the outcome of the many articles, neither with respect to adverse nor beneficial effects. Other than a review, this survey did not intend to answer questions like "what is the odds ratio of using MPs with respect to a certain cancer?" or "does MP based home monitoring reduce the frequency of hospital admissions in heart failure patients?". Since for many – in particular older – articles only the title is available on PubMed, a detailed analysis with respect to the outcome would require an additional (probably enormous) effort.

This survey specifically aimed at assessing the interest of the scientific community in all health related effects of MP usage, not only in a particular class or sub-class of effects. To the author's best knowledge such a survey has not yet been performed. This notion is supported by the fact, that in the present sample, no article has been found which covered both, adverse and beneficial aspects of MP use.

Conclusions

Today's MPs provide a large portion of the world's population with an ever more powerful communication tool. With respect to health, MPs were already shown to have both adverse and beneficial aspects – as can be expected from any kind of effective technology. After initial research focused mainly on the risk aspects of MP use, during the last years an increasing number of investigations concentrated on potential benefits.

Upcoming technologies and capabilities and a still rapidly increasing number of MP users will warrant continued and new research within the full spectrum of possible risks and benefits of MP use with respect to health.

Localization Of Health Agents And Resources By Mobile Devices

Romeu Meirelles, Mauricio Amaral de Almeida, Marcia Ito

Information Technology Application Centre, "Paula Souza" State Technology Education Centre, Sao Paulo, Brazil

Abstract and objective

This poster reports the research being carried on the following: Initially, some health care situations where low resolution positioning is effectively usable are identified. Despite their limited processing capacity, due to its popularity, mobile devices are a natural choice to implement location awareness. Software can be used to turn regular cell phones and connected PDA's into low resolution positioning devices, without the subscription of expensive Telco's services. Remote computing is used to overcome the processing capacity restraint and improve the performance of the solution. Then, remote Artificial Intelligence techniques are used to improve the geographical resolution and to perform user problem's solution search. Finally, the need of articulated integration with other emerging technologies like Evidence Based Medicine (EBS), Body Area Network (BAN), Portable Patient Record (PPR) is pointed.

Keywords:

telemedicine, health services accessibility, mobile localization, location aware, ubiquitous computing

Introduction

In large cities like Sao Paulo, Brazil, there are several situations when geographical information can affect the health care result. Due to cellular phones and other mobile devices popularity and increasing processing capacity, they are a natural choice to location aware computing implementation. Though their majority don't currently offer built in geo positioning technologies, software solutions can be implemented to supply these capabilities.

Methods

Geographic low resolution health related problems

The importance of geography is intuitive whenever a triggering event, in an unfamiliar place, requires a quick decision of where to go as soon as possible in order to get proper health care. Every connected mobile device knows the fixed antennas they are talking to. Once their coverage area is around 3 km, the worst case resolution is known. Including the low resolution restraint, one possible statement to this rule can be: mobile connected devices software supplied positioning is useful whenever someone has to decide something related to the health care, satisfying geographical restraints with accuracy of at least 3 km. This definition excludes time restraints in order to consider situations as when a patient has to select a specialized doctor which fee can be refunded by his medical insurance system, who has free agenda matching to his schedule and who can be reached inside his 1 hour drive distance geographical area. This is a typical Artificial Intelligence (AI) problem.

Mobile device technologies independence

There are basically 4 technologies to connect mobile devices: Satelite, GSM, CDMA and WIFI and the subgroups and evolutions of these 4. The mathematical solution for positioning in each one of them is different, and the same happens with the resolution. This plurality produces additional complication once the devices often switch from one network to another.

Results

Limited processing capacity

Mobile devices cannot handle AI yet. It demands the transference of the processing is to a remote server. Java technology is used to handle the diversity of mobile device's models. Once it doesn't load the device, additional data processing is used to increase the geographical resolution, offer clues and to build graphical maps to be downloaded into the device.

Conclusion

Integration with other emerging mobile technologies

The presented technology can be easily integrated with EBS, PPR, and BAN mobile solutions through a future platform standard. This can help to supply the location aware part of the ubiquitous computing paradigm in medical informatics.

Low cost solution

Once this approach doesn't use the Telco's positioning expensive services, it can be usable to solve localization problems that require geographical information for a huge number of people that could not afford it otherwise, several years prior to mobile equipment evolution and substitution.

Informatics Support for Decompression Sickness on Space Missions

Tyler N. Carruth, MPAS-C[a,b], M. Sriram Iyengar[a] PhD[a]

[a] *The University of Texas Health Science Center School of Health Information Sciences at Houston, Houston, Texas.*
[b] *Wyle Life Sciences, Houston, TX*

Abstract

Text-based checklists (paper and electronic) together with telecommunications links to Earth-based physicians are currently used to diagnose and treat medical conditions during space travel. GuideView, an application that augments text by presenting clinical guidelines in a structured, interactive, multi-modal format, presents clinical instructions simultaneously in voice, text, pictures video or animations. In this paper we describe a Decompression Sickness (DCS) guideline implemented in GuideView for the diagnosis and treatment during space flight

missions

Keywords:

space flight, decompression sickness, practice guidelines, multimedia

Introduction

During low earth orbit missions aboard the International Space Station (ISS) and the Space Shuttle, text-based clinical guidelines and checklists (paper and electronic) augment the assistance provided by ground-based medical support staff, including flight surgeons, to assist the crew in the diagnosis and treatment of a host of medical conditions. Astronauts can communicate with and be advised by their ground medical support via audio and/or video telecommunications links as well as downlink images for review. Due to possible telecommunication delay or loss of signal during low earth orbit missions, however, this contact with the earth-based medical support can be interrupted or intermittent. This may force the astronauts to rely on the text based procedures to navigate through complex medical tasks to respond to an emergency if one would arise.

Numerous drawbacks and limitations exist with text-based medical checklists, especially for non-physician astronaut users, whose medical experience and knowledge base may be minimal.

Through this project, we present a means of informatics support to create a "procedure assistant" using GuideView to assist in medical event response. In GuideView, procedural steps and information needed by the user to complete a task is externalized; the text is accompanied by video, audio, and images that augment the users ability to perform a task without relying on his or her memory of the system.

Guide view

GuideView technology was originally developed at NASA Johnson Space Center to provide an interactive, electronic means of guiding a user through a series of complex tasks during space exploration missions or in settings where physician availability may be low such as rural areas or remote environments. GuideView consist of two components; the GuideView Author is used to develop the guidelines in the GuideView format, and the GuideView Viewer, used to execute and display these guidelines. Guidelines developed and saved in the GuideView format are called GuideViews.

GuideViews are compatible with multiple platforms including the internet, stand-alone Windows computers, PocketPC-based PDAs, and Windows Mobile cell phones such as T-Mobile SDA and Cingular 3125. This compatibility adds to the versatility of the application in various environments.

Demonstrating GuideView

To showcase the GuideView technology, complex clinical guidelines currently used aboard the International Space Station (ISS) to evaluate Decompression Sickness (DCS) were developed using GuideView. DCS was chosen due to the complexity and number of procedures involved in the required response and treatment.

DCS, otherwise known as "the bends", is a condition astronauts may be susceptible to. In DCS, inert gas present in the bloodstream can come out of solution forming bubbles. These bubbles can embolize various tissues of the body including joints, lungs and brain causing significant pain, musculoskeletal and/or neurological impairment.

Astronauts performing space walks from the ISS may be at increased risk for this injury due to the difference in gas pressure within space suits and the interior of the Space Station[1]. When the human body is exposed to this sudden significant decrease in ambient pressure, or if a suit leak were to occur, DCS may result.

Since DCS can cause substantial impairment, response must expeditious. Because the response to such an event involves many different systems in addition to the medical component, procedures are located in multiple documents including the ISS DCS System Handbook[2,3] and the ISS Medical Checklist.[4]

Creating the DCS GuideView

In the first phase of this project, the procedures related to the recognition and treatment of DCS was reviewed by clinician subject matter advisors. These documents, developed by NASA Flight Surgeons, were used to create structured procedures that could guide an astronaut through the necessary actions of DCS treatment.

The GuideView Author, an authoring program special to this application, enabled the creation of the GuideView interface content through encoding of guideline structure and embedding of text and multi-modal content[4]. Using the GuideView Viewer, the procedural steps are presented using text, voice, still pictures, video, or animation, simultaneously.

Results

Using GuideViews, DCS guidelines were presented through a rich content delivery environment by incorporation of video and images detailing the required tasks to be preformed. Users are able to navigate through the procedure by mouse clicks directing them to the next treatment step based on information from their findings. The development of the DCS GuideView is ongoing and will involve incorporation of additional media and tangential procedures.

Voice command is a feature currently available when GuideView is run on Windows desktops and laptops and allows the user to proceed through the procedure by voice triggers such as “next” and “stop,” and “repeat last” enabling hands-free patient interaction while interacting with GuideView. This feature will be eventually incorporated into the DCS GuideView.

Conclusion

Due to telecommunication delays, real-time earth-based medical support may be difficult during long duration space missions. Text-based medical checklists have significant limitations, especially for non-physician astronauts. Instead, a more informative methodology is needed to provide informatics support such as that provided by the GuideView technology.

Abstract

- Text-based checklists (paper and electronic) together with telecommunications links to Earth-based physicians are currently used to diagnose and treat medical conditions during space travel.
- GuideView is an application that augments text by presenting clinical guidelines in a structured, interactive, multi-modal format
- GuideViews present clinical instructions simultaneously in voice, text, pictures video or animations
- This project incorporated a Decompression Sickness (DCS) guideline used for the diagnosis and treatment during space flight missions into GuideView.

Background

- For each ISS Expedition, at least one crewmember is designated a Crew Medical Officer (CMO) and tasked with assisting in the health maintenance of his or her fellow crewmembers.
- Although there are a few astronaut physicians, the majority does not have a formal medical background and will have received only limited medical training as part of mission preparation.

Background

Crews aboard the International Space Station rely on telecommunications support to assist them in providing medical care during a mission.

Crews communicate with their ground medical support via audio and/or video telecommunications links as well as downlink images for review.

Text-based clinical guidelines and checklists (paper and electronic) are available too assist the in the diagnosis and treatment of a host of medical conditions.

GuideView

- GuideView technology was originally developed at NASA Johnson Space Center to provide an interactive, electronic means of guiding a user through a series of complex tasks during space exploration missions
- Information and task steps are externalized and presented via text and multimedia
- The cognitive load of the user is decreased.

GuideViews

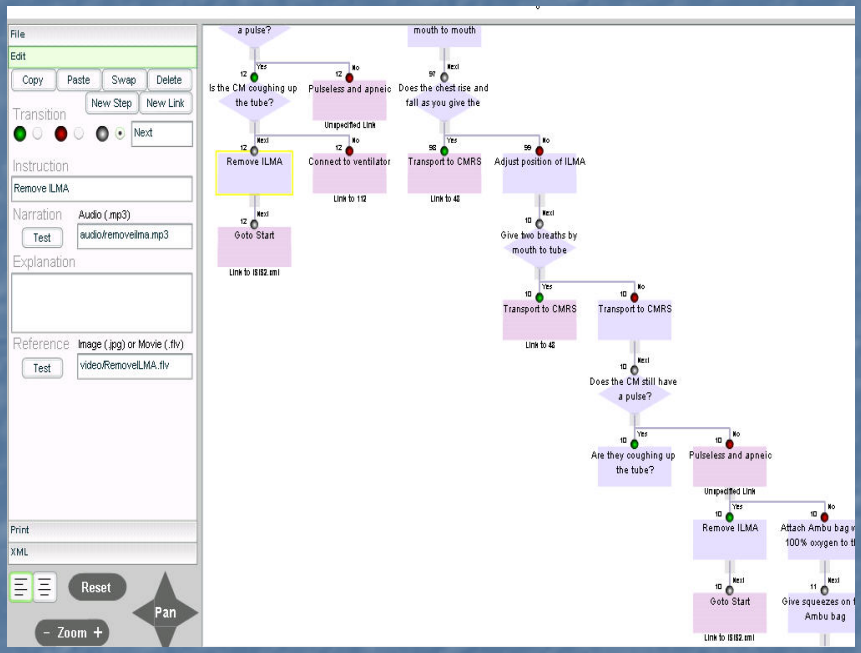
- GuideView consist of two components
  1. GuideView Author - used to develop the guidelines in the GuideView format
  2. GuideView Viewer - used to execute and display these guidelines
- Guidelines developed and saved in the GuideView format are called *GuideViews*.

GuideView Author screen

Enables:

- development of the guidelines in the GuideView format
- insertion of the Visual content (images and/or video)

**The images and video inserted into the program were obtained from NASA archives or produced de novo.*

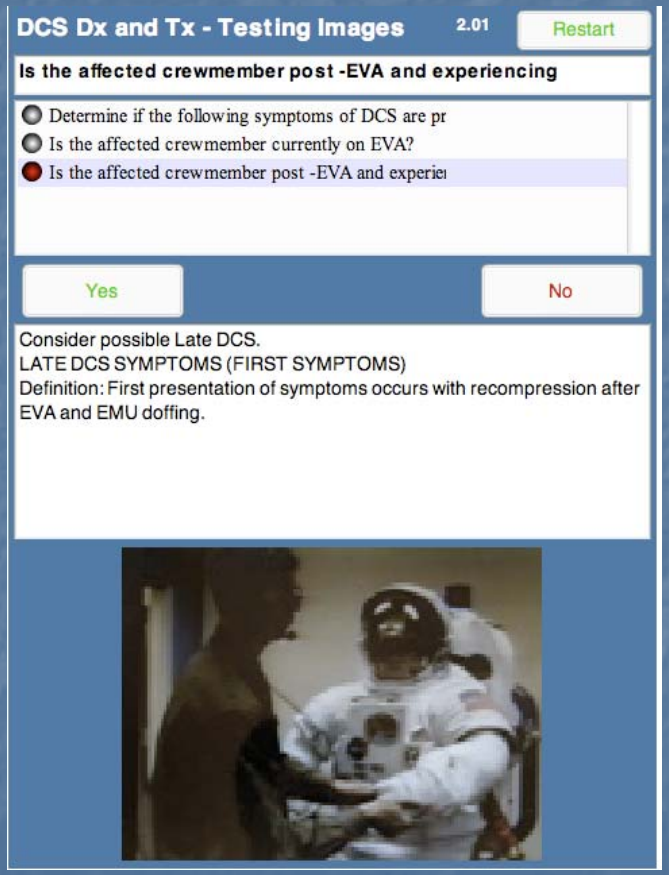


GuideView Author screen

GuideView Viewer

Enables:

- used to execute and display the guidelines in the GuideView format
- Users are able to navigate through the program using mouse clicks



GuideView Viewer screen

Creating the DCS GuideView

- Procedures related to the recognition and treatment of DCS was reviewed by clinician subject matter advisors.
- These documents, developed by NASA Flight Surgeons, were used to create structured procedures that could guide an astronaut through the necessary actions of DCS treatment.
- GuideView Author was used to encode the guideline structure and embedding of text and multi-modal content to create the interface.

GuideView versatility

GuideViews are compatible with multiple platforms including:

- Internet
- stand-alone Windows computers
- PocketPC-based PDAs
- Windows Mobile cell phones
  - T-Mobile SDA and Cingular 3125

This compatibility adds to the versatility of the application in various environments

Conclusion

- Due to telecommunication delays, real-time earth-based medical support may be difficult during long duration space missions.
- Text-based medical checklists have significant limitations, especially for non-physician astronauts.
- A more informative methodology is needed to provide informatics support such as that provided by the GuideView technology.

Drugs Trading in the Hospital Pharmacies Through a Multi-Agent Electronic Market

Andreia Malucelli[a], Luciane Malucelli Fadel[b], Eugénio Oliveira[c]

[a] *Pontifical Catholic University of Paraná (PUCPR), Master Program of Health Technology, Curitiba - PR, Brazil*
[b] *Regional University of Blumenau (FURB), Department of Medicine, Blumenal - SC, Brazil*
[c] *Faculty of Engineering, University of Porto (FEUP), Porto, Portugal*

Abstract

Several challenges involved in the reduction of hospital drugs expenditures are difficult to be solved, at least nowadays, but it is important to look for possible ways to undertake or reduce the problem. In this paper we propose an electronic market as a possible solution to reduce costs and time for the hospital pharmacies while increasing flexibility and access to new possibilities of negotiation. This electronic market is based on a Distributed Multi-Agent System which has a multi-criteria negotiation and uses ontology-based services to solve the interoperability problems. The potential solutions obtained through the electronic market interactions will compete with the solutions found by the hospital pharmacy own system. We believe that using our system architecture and services is a step forward in achieving the cooperation between hospital pharmacies and pharmaceutical drug manufacturers around the world. However, we are also aware of challenges and problems that might arise from using this approach.

hospital pharmacy, pharmaceutical medicine manufacturer, electronic market, multi-agent system, negotiation, ontology

Introduction

United States perspectives database were used in a study to evaluate trends in hospital drug expenditures [1]. The study presents these data consisted of drug purchasing information for 5230 hospitals in 2003. The hospital drug expenditures were approximately $23 billion in 2003, representing a 6.3% increase in drug expenditures compared with 2002. Authors identify that some of the factors affecting the trend in hospital drug expenditures included drug prices (2.3%), volume and therapeutic mix (2.1%), and new drugs (1.6%). They projected for 2005 a 10-12% increase in drug expenditures in outpatient settings, a 12-15% increase in clinics, and a 6-9% increase in hospitals. Authors conclude that "Pharmacy managers must remain vigilant in monitoring drug costs in their health system and take a proactive role in pursuing efficient drug utilization" [1]. Several barriers and challenges involved in the reduction of drugs expenditures are difficult to be solved, at least nowadays, but it is important to look for possible ways to undertake or reduce the problem.

One way would be to find the supplier (pharmaceutical drugs manufacturer) with the best price for each one of the needed drugs and also be able to negotiate based on hospital pharmacies (HP) preferences.

Nowadays, most of the HPs around the world buy drugs by contacting each pharmaceutical drugs manufacturer (PDM) that may provide the respective drug. There are several PDMs that may provide the same drug with different commercial names, prices, quality and delivery time. As an example, the HP could need antibiotic drugs, and in this case they could buy "Amoxil" developed by Glaxo-Smithkline, "Novocilin" developed by "Aché", Velamox developed by "Sigma Pharma", just to name a few. The HP could also buy the generic drug (amoxicillin) developed by Abbott, Eurofarma, Sanval, or Medley. It is not an easy task for the hospital pharmacy responsible looks for the best supplier around the world, for each needed drug.

An electronic market (TEM) for trading drugs could reduce costs and time for the HP that needs a specific drug, while increasing flexibility and access to new possibilities of negotiation. Moreover, the PDM would have more chances to sell its drugs.

Electronic marketplaces are enabling new kinds of services and interactions between suppliers and customers [2]. It is an application domain where thousands of heterogeneous companies, acting both as suppliers and customers and using different names to represent the traded products and different currencies to represent the prices, may be involved. Moreover, different companies tend to use knowledge representations (ontologies) that differ significantly either syntactically or semantically. This heterogeneity in the representation of the commercial products is a critical impediment to an efficient business information exchange and to the automation of the business-to-business (B2B) transactions. Furthermore, in a decentralized and distributed approach, companies may negotiate with other companies geographically distributed. The companies negotiate using their own product descriptions as well as their local currency. If each company uses

local currency, and they differ from the ones used by other companies then an interoperability problem occurs. The interoperability problems make the negotiation process more difficult and consequently make hard a final agreement.

We are proposing an EM based on multi-agent system (MAS) paradigm, where each HP and PDM will be represented by an agent. For helping to solve the interoperability problems (problems caused by the use of distinct terminology; and problems generated by the lack of standardization) the ontology-based services [3] are integrated in the EM proposed. In this context, ontologies play an important role since they provide the vocabularies used by the agents. Whereas, in homogeneous MAS, the adoption of a common ontology guarantees the intelligibility of the communication between agents, in open MAS, where the agents are intrinsically heterogeneous and have different private ontologies, the interagent communication is affected by unknown and, thus, incomprehensible terminology, as well as, by the *ad-hoc* use of disparate currencies to represent the price of products.

We believe our proposal is a step forward in achieving the cooperation between hospital pharmacies and pharmaceutical drug manufacturers decreasing time and price, while increasing the number of negotiation with different PDM around the world.

Electronic market solutions

Many electronic markets (EMs) or online pharmacies have been proposed, but they are mainly related with business-to-consumer (B2C) domain, as for example 101Pharmacy[1] and Acme Fresh Market[2]. To the best of our knowledge, this is the first proposal for an EM applied to this specific domain.

The EM proposed here is a permanently open virtual marketplace where registered PDM and HP (represented both by agents) can meet each other through the Web to purchase services according to established norms and rules.

Drugs trading electronic market architecture

Due to the fast growth of B2B e-commerce, the demand for agents is growing because agents are able to, on behalf of their owners, locate and retrieve information and make reasonable decisions based on the owner's profile. Agents negotiate with multiple suppliers, monitor multiple auctions, and use intelligent strategies to find the best deal for the users. Agents can also represent companies/organizations in a B2C and B2B context. This shows not only how agents can collaborate with one another to achieve a common goal, but also how an agent selects the best partners through negotiation [4]. A central point of the agent's paradigm of software development is that communities of agents are much more powerful than any individual agent, which immediately raises the necessity for interoperable agent systems.

In our multi-agent approach we will have at least five types of agents: (i) Facilitator Agent (FAg), (ii) the Customer Agent (CAg), (iii) the Supplier Agent (SAg), (iv) the Ontology-based Services Agent (OSAg), and (v) the External Agent (EAg). The FAg, CAg and SAg are cooperating through a website with the objective of providing or getting drugs, in collaboration, but keeping their own preferences and objectives. The OSAg supports the negotiation process in case the SAg has not understood the content of a message, and it helps in the calculation of prices (that may be necessary when dealing with different currencies).

The agents are deliberative, autonomous, intelligent entities that use different ontologies and apply goal driven reasoning to achieve their objectives. Agents have an inference engine which derives the recommendations from the knowledge base (ontologies) and problem-specific data in instances. In our scenario, the CAg (representing the HP) and the SAg (representing the HP) have the same objective: they want to trade products in the same application domain and still use their own private ontologies (the PDM and HP will not waste time and money converting their drugs catalogues, changing the drug names and involved knowledge). Due to this common objective, we provide an e-commerce ontology that defines an e-commerce vocabulary just for the trading, *i.e.,* a negotiation protocol. This vocabulary contains terms which are used during the negotiation process. Thus, we ensure that all agents will uniformly interpret the negotiation messages exchanged. This does not imply identifying correctly the specific content of the messages, *i.e.*, the requested drugs, since each agent interprets this information based on its own private domain ontology. A user interface allows the interaction between the users and the agents [3].

When a request for a drug is made by some of the registered CAg (HP), the FAg will look for the registered SAg (PDM) that may provide the respective drug. The OSAg enables appropriate conversations and makes possible to reach agreements between agents representing different HP and PDM. In order to avoid the EM indicating a drug that will satisfy the customer needs but will have later some special constraints, the FAg requests to the EAg the validation of the request.

These five types of agents play the following roles:

(i) **FAg** is the entity that matches the right agents and supports the negotiation process.

1 101Pharmacy.org, http://www.101pharmacy.org, November, 2006.

2 Acme Fresh Market, http://www.acmestores.com/pharmacy/pharmacy.html, November, 2006.

(ii) **CAg** represents HP interested in buying drugs. Several suppliers in the world may sell these drugs with different prices and conditions. The user representing the registered HP inserts the information an agent needs in order to ask for a drug and their negotiation preferences. This includes the attributes: drug name, quantity, and currency, with the respective HP negotiation preferences. The currency chosen will be the currency in which the CAg wishes to receive a proposal, *e.g.* Dollar (USD). If the SAg wants to make a proposal, but the drug is priced in another currency, *e.g.* Euro (EUR), the SEAg requests to the OSAg the currency conversion service.

(iii) **SAg** represents pharmaceutical medicine manufacturers interested in providing drugs. Whenever a drug is needed, the FAg conveys this announcement to all registered interested SAg (PDM). The SAg makes an offer if the announced drug is currently in stock and if it understands what the CAg is asking for (the drug name). At least one SAg has to be present in the platform so that communication can be established.

(iv) **OSAg** is responsible for providing the services that support the negotiation among agents. This approach is compliant with the Foundation for Intelligent Physical Agents (FIPA) [5] proposal of creating a specialized Ontology Agent (OA) [6] for open MAS platforms. The idea is to support the interoperability between agents with different individual ontologies by means of a dedicated agent. Our implementation of the ontology agent is named OSAg and follows the FIPA recommendation. It is responsible for providing services to the customer and supplier agents that help solving the interoperability problems. Its task consists of applying different methodologies to detect lexical and semantic similarities between two terms (in this case, between drugs), as well as providing currency conversion services. The OSAg is an autonomous server-side agent that does not require any direct user interaction. The user interface only controls the tasks performed by the OSAg responsible for providing services to other agents to enable them to effectively negotiate together.

(v) **EAg** represents drugs and healthcare products regulatory agencies responsible for enhancing and safeguarding the health of the public by ensuring that drugs and medical devices work and are acceptably safe.

Negotiation Protocol

Java Agent DEvelopment Framework (JADE) [7] is the agent development platform used to build our system. The main reason for choosing JADE lays on the fact that JADE implements the FIPA standards. JADE encloses implementations of the FIPA library of behaviours and interaction protocols. All agents in our platform communicate by exchanging FIPA Agent Communication Language (FIPA-ACL) messages. A FIPA-ACL message contains a set of one or more message parameters, *e.g.*, type of communicative act (performative verb), participants in communication, content of message, description of content, and control of conversation. The communication follows the FIPA Contract Net Interaction Protocol (FIPA-CNP) [8]. The type of communicative act, defined by the performative parameter, is a required parameter of all FIPA-ACL messages. The participants consist of sender and receiver.

The implementation of our negotiation round combines the FIPA-CNP with an additional protocol called ontology interaction protocol (OIP). The former represents the general scenario of agents trading goods or services proposed by FIPA. Alike other interaction protocols, it structures complex tasks as aggregations of simpler ones. The latter implements the message flow necessary for solving the problems of interoperability, including the interaction of customer and supplier agents with the OSAg.

In our context, the CAg plays the role of the initiator while the SAg is the participant during the FIPA-CNP. The initiator wishes to have some task performed and further wants to optimise a function that characterises the task. In this context, the CAg announces in the market the need for a specific drug. For a given task, the participants (SAg) may respond with a proposal or a refusal to negotiate (sell drugs). Negotiations then continue only with the SAg that offered proposals. The CAg (representing the HP) selects, among all proposals received, the best offer based on its own cost-benefit criteria and replies to all SAg (representing the PDM) that made offers with an acceptance or rejection message, depending on the case.

In the former case, once the SAg has completed the task, it sends a message to the CAg in the form of an inform-done performative or, using a more explanatory version, in the form of an inform-result performative. However, if the participant fails to complete the task, a failure message is sent. Three different situations may occur when a SAg receives a CFP (Call-for-Proposal) message: (i) the SAg refuses the CFP, (ii) the SAg accepts the CFP or (iii) the SAg contacts the OSAg because it is unable to fully understand the CFP.

In the first case, the SAg answers with a refuse performative. In the second case, the SAg responds with a propose

performative based on a multi-criteria negotiation (explained later) stating its conditions to sell the drug. The SAg's conditions should be compatible with the conditions originally contained in the CFP. In the last case, after having received a CFP and not being able to interpret the requested item, the SAg sends a message with the performative not-understood to the OSAg, identifying both the sender of the CFP (CAg) and the name of the unknown drug. The OSAg generates and sends a query-ref message to the CAg inquiring about the unknown drug.

- The CEAg analyses the request and answers with an inform performative containing all the information about the required drug. The price is taken from its pricelist.
- After receiving all the information about the item under negotiation the OSAg applies the similarity detection methods [9] trying to find the correspondent drug in the SAg ontology. These similarity detection methods aim at detecting syntactic and semantic similarities between terms. Every candidate term (SAg drug) is compared with the requested term (CAg drug).
- The OSAg informs the SAg of the outcome of the process, *i.e.*, sends the name of the best match or informs that it was unable to find any corresponding item. If necessary, the CAg requests the unit conversion service.
- The SAg is then able to respond to the CAg CFP, either with a proposal (based on the multi-criteria negotiation) or with a refuse performative according to the FIPA-CNP.

Multi-criteria negotiation

The CAg (PH) is responsible for selecting among a set of SAg (PDM) the subset that will provide the needed drugs. As already explained, the CAg negotiates with several SAg to select among them the ones that are the most promising, at the moment, to satisfy its actual need. The negotiation results in a process of multiple rounds.

The negotiation is a kind of decision making where two or more parties jointly search a space of solutions with the goal of reaching a consensus [10]. This search usually is a single dimension process (usually the price) where the different agents, involved in the negotiation process, mutually adapt their price offers in order to reach their goals (to sell or to buy a good). However, this process is inflexible and often unrealistic because more than one single issue has to be negotiated in order to find out an adequate agreement [11]. The first step is to translate the human preferences in attributes that can be analysed, communicated and negotiated by agents.

Each CAg (PH) has some negotiation preferences based on attributes as price, delivery time, or specific PDMs, which have to be taken into consideration during the negotiation round. These preferences mean the PH cost-benefit criteria.

The CAg request describes the needed drug, represented in a private ontology and describes also the CAg preferences, which are codified in the relative order by which attribute are defined in the product structure definition: $Product_x=\{Atb_{x1}, Atb_{x2}, Atb_{x3}\}$ with $Atb_{x1} >_{imp} Atb_{x2} >_{imp} Atb_{x3}$, where $>_{imp}$ means "more important than". In this case it means that Atb_{x1} is more important than Atb_{x2}, and Atb_{x2} is more important than Atb_{x3}. This order is relevant for the negotiation process. Each attribute has also dependencies associated with the different attribute's values (Dep_i). These dependencies may be of three types: time, event and value. $Dep_i=\{\{Dept_i\}, \{Depe_i\}, \{Depv_i\}\}$, where time dependencies constrains the attribute's values in specified time intervals, event dependencies constrains the attribute's values when some specified event happen, and the value dependencies constrains the attribute's values to other attributes' values of other components. During the negotiation process, the SAg formulates proposals in an adaptive way, learning with qualitative feedbacks formulated by the CAg in previous negotiation rounds [12].

The selection of the SAg (PDMs), which will provide the requested drugs, is done through a negotiation algorithm called Q-Negotiation. The Q-Negotiation algorithm uses a reinforcement learning strategy based in Q-learning [Rocha and Oliveira, 2001] for the formulation of new proposals.

In particular, Q-learning enables on-line learning, which is an important capability for B2B negotiations where agents may effectively learn in a continuous way during all the negotiation process, with information extracted from each negotiation round, and not only in the end of the negotiation. The adaptation of the Q-learning algorithm to our scenario, leads to the inclusion of two important features (the reward value calculation and the decrement of the exploration space) detailed in [13].

The distributed dependencies satisfaction algorithm, besides reaching the optimal solution, keeps agent's information as much as possible private. Each agent involved in the distributed dependent problem resolution should know all possible values for its own dependent attributes. Agents will then exchange among them alternative values for the dependent attributes, in order to approach an agreement. As in any iterative negotiation process, agents start the negotiation by proposing its optimal solution and, in the next rounds start trying to reach a consensus. A more detailed description of this algorithm may be found in [13].

Conclusions and future work

An electronic market, including ontology-based services, to solve the trading drugs problem between hospital phar-

macies and pharmaceutical drugs manufacturers has been proposed.

We have implemented a prototype with one agent representing a hospital pharmacy and several agents representing pharmaceutical drugs manufacturers cooperating through a website. To support the negotiation of products, we provide an e-commerce ontology which is shared by all agents and defines a domain-independent business vocabulary. This ontology ensures a meaningful e-commerce communication since all agents will uniformly interpret the intention of the messages exchanged and the generic business terms used. Besides this e-commerce ontology, each agent has its own private drugs domain ontology. Since in a real-world business context, the companies will use different ontologies and adopt diverse ontology representation formalisms, our approach also envisages this possibility: the ontologies may be developed by any ontology development tool and stored in any standard format.

A facilitator agent and an ontology-based services agent were integrated in order to monitor and support the negotiation process. The agents representing the external agencies were not integrated in this phase.

We have implemented a multi-criteria negotiation where CAg may order their preference for using during the selection of the best SAg.

An important requirement in this process, is that information must be kept private to individual companies, since they are competitive by nature and do not want to reveal their market strategy to others. The Q-Negotiation algorithm has the ability to maintain information private and, at the same time, it includes the capability to evaluate multi-attribute proposals, to guide learning during the negotiation process, and to resolve attributes' mutual interdependencies.

Regarding the trading of drugs, things are not so linear, hospital internal rules and country specific rules, just to mention a few, and they have to be taken into account when approach this subject. Our proposed EM already deals with these subjects, in an elementary way, but there is still space to make several improvements. Others issues like communication between different information systems, security, privacy and authorization, are also problems that we will have to address in our proposed EM as well as specific EM subjects like contracts.

We know that it is a hard job but we believe that, after solving all the questions related with the previous mentioned subjects, our proposed EM might be a profitable one for hospitals as well as for pharmaceutical drugs manufacturers that might be created just specialized in supplying solutions to these problems.

Agent-Based Secure Aggregation of Distributed Health Data

Zim Chan[a,b], Peter Croll[a], Anthony Maeder[b], David Hansen[b]

[a] *Faculty of Information Technology, Queensland University of Technology, Australia*
[b] *CSIRO E-Health Research Centre, Australia*

Abstract

A common problem in the health sector is in balancing the need for patient health information against the risks posed by releasing such private information. The idea of Secure Multi-party Computation (SMC) provides potential ways in which this can be mitigated, by allowing for analysis of data distributed amongst multiple parties to take place without the need to disclose it. This paper presents a two-party SMC protocol which can be used to calculate some basic aggregate functions. In addition, we discuss a rationale for using an agent-based framework to utilize SMC techniques in order to support privacy-preserving access to health information.

Keywords:

data linkage, patient data privacy, data security, secure multi-party computation

Introduction

Consider two separate databases, Diagnoses and Prescription, containing pre-linked patient information about illnesses and drug prescriptions respectively. Suppose that as part of a study into drug adverse effects, a researcher wishes to find a count of people who were diagnosed with cancer less than 3 years after being prescribed with drug X.

Normally, this would require the release of potentially sensitive information – for instance, it would be necessary to release the cancer diagnosis date and drug prescription date in order to be able to perform some meaningful comparison.

This paper presents a two-party SMC protocol for computing a scalar product on *privately selected* elements of private vectors, while ensuring that:

- no party discovers which elements in the vector are used for the aggregation
- no party discovers the values of any individual data, or the partial aggregates at each database

Such a protocol can be used to calculate basic aggregates such as counts and weighted/un-weighted sums. In addition, we discuss how this protocol could be extended towards the calculation of other statistics such as average, standard deviation and covariance in a true (i.e., >2 participants) multi-party scenario.

Finally, we discuss the rationale for an agent-oriented framework to support SMC operations for providing aggregate processing of distributed health information.

Method

The protocol, shown in Algorithm 1, is based on using a series of SMC primitives, whereby the output of each step is fed into the input of the next phase. Standard cryptographic notions of secret-sharing and encryption ensure that while these intermediate values can be used in their successive stages, they do not leak information.

Step 1 of the protocol makes use of general SMC theory, which states that *any* function which can be represented as a combinatorial circuit can be evaluated securely [1]. What prevents the execution of the entire protocol in this manner is that the circuit size is polynomial with respect to input size and complexity. In the case of Step 1, the function is expected to be a relatively simple computation. For the example, it is necessary to reduce the following predicate to circuit form:

(has_cancer == TRUE & uses_drug_x == TRUE & diagnosis_date > prescription_date & (diagnosis_date + 365*3) < prescription_date).

While SMC remains mainly in the theoretical domain, implementations such as Fairplay [2] exist that allow such high level expressions to be compiled and executed.
In Step 2, Alice and Bob engage in a 1-2 Oblivious Transfer protocol using their secret shares obtained in Step 1 for the input. An Oblivious Transfer ensures that Alice cannot determine which message Bob has received. As it is encrypted, Bob is similarly unable to determine which message is received.
The messages are aggregated in Step 3 – By exploiting the properties of a homomorphic public-key cryptosystem, Bob performs a blindfold evaluation of the scalar product in the same manner as used in [3]. Note that, if the predicate P evaluated to 0 (or false), then the value received by Bob, $c_{i,b_i} = E(0,r)$, and Bob is essentially multiplying a zero payload.

Private Input: Databases DbA, DbB owned by Alice and Bob respectively, where DbA_i, DbB_i is the data corresponding to patient i, $|DbA| = |DbB| = N$, and $DbA_i.attr$ refers to the attribute *attr* in DbA.

Public Input: Predicate function $P(DbA_i, DbB_i) \rightarrow \{0,1\}$

Private Outputs: Selective scalar product as secret shares

$$S_A + S_B = \sum_{i=0}^{N} DbA_i.x \cdot DbB_i.y \cdot P(DbA_i, DbB_i)$$

0. Setup. Alice generates a public/private keypair (E, D) for a homomorphic cryptosystem

1. Selection. For each $i \in \{1 \ldots N\}$ Alice and Bob evaluate $P(DataA_i, DataB_i)$ via circuit-based SMC evaluation. Alice obtains $a_i \in \{0,1\}$ and Bob obtains $b_i \in \{0,1\}$ such that $a_i \oplus b_i = P(DbA_i, DbB_i)$

2. Vector Transfer: For each $i \in \{1 \ldots N\}$:

a. Alice sets $c_{i,1-a_i} = E(DbA_i.x, r)$ and $c_{i,a_i} = E(0, r)$ for some random r

b. Alice and Bob execute a 1-2 Oblivious Transfer whereby Alice sends the pair ($c_{i,0}, c_{i,1}$) and Bob selects c_{i,b_i}.

3. Multiplication: Bob sets $w = \prod_{i=1}^{N} c_{i,b_i}^{DbB_i.y}$

Algorithm 1 – Private Selective Scalar Product

Finally, Bob blinds the final product with a random, before returning it to Alice, who can decrypt it. At this stage, both parties hold secret shares of the final output.

In its simplest form, Alice and Bob can set $x, y = 1$ to obtain secret shares of the count of elements.

Extensions

As the output of the protocol is a series of secret shares, it lends itself to a number of natural extensions. Principally, the idea is that the protocol can be run a number of times with x values, and the outputs of each run can then be combined via general SMC circuit evaluation. This has two major implications:

- It can easily be extended to a *true* multi-party scenario with greater than two participants, for instance, in the case where the data is further distributed horizontally (e.g. a scalar product over 3 vectors) or vertically (if a vector is partitioned amongst two parties), or a hybrid mix.
- Based on basic primitives, the protocol can be used to calculate other aggregates such as average (count, sum), standard deviation(sum of squares, average), and covariance (scalar product, average).

An agent-based framework

It is proposed to use software agents – autonomous, proactive, social software entities – towards realising a privacy-preserving framework utilizing SMC techniques on behalf of researchers and database custodians.

The use and execution of SMC protocols is a non-trivial task. They are interactive in nature, requiring databases to become active participants in the information gathering process. Agents are a natural paradigm for an environment involving distributed, complex interactions with multiple points of control [4].

Agents could provide the following functionality:

- Decomposition of researcher queries into SMC primitives
- Dynamic formation of coalitions for query answering, and role fulfillment
- Execution of SMC protocols
- Adapting to intermediate computation results.

Conclusion

Secure multi-party computation protocols, such as the one presented, offer potential ways in which private health data can be analysed without requiring its disclosure. An agent-based framework offers promising ways in which they can be effectively applied. Currently, such a framework is undergoing implementation in the Java Agent Development Framework (JADE) [5].

GELLO – A Practical Implementation through the Application of Real World Examples

Peter R. Tattam [a], Andrew McIntyre [b]

[a] *Medical-Objects Pty Ltd, Hobart, Tasmania, Australia,*
[b] *Medical-Objects Pty Ltd, Buderim, Queensland, Australia*

Abstract and objective

The computing language GELLO has been designed by the HL7 community as a standardized way of expressing complex clinical data queries, yet few implementations exist publicly to explore the practical aspects of such a language and its application towards real clinical information systems. We present a GELLO language implementation and detail the challenges and obstacles encountered without a reference implementation of the language or many suitable real examples of GELLO usage available. The compiler was developed as a component in a GLIF guideline for the treatment of Lymphoma. We conclude that GELLO is a language worthy of use by the medical information community and that effective development of the language through the active implementation of practical examples will allow it to achieve its full potential.

Keywords:
GELLO, GLIF, ARDEN, vEMR, USAM, CDS

Introduction

As part of a project to build advanced decision support and registry reporting tools for the treatment of Lymphoma a decision was made to use GELLO encoded logic. It was originally envisaged that Arden would be the vehicle, however further investigation suggested that GELLO would be a better candidate to evaluate the clinical data to assist relevant decisions, in particular its rich querying facilities. We set about to implement what we believe to be one of the first practical implementations of GELLO worldwide.

Methods

For our compiler tools, we used a standard LALR(1) parser embedded within an existing HL7 V2 framework written in the Delphi programming language. A vEMR (Virtual Electronic Medical Record) interface to the existing data was written as part of the project. The lack of any available implementations of GELLO to refer to required us to work directly from the latest GELLO and HL7 specifications. As GELLO is a work in progress, some changes were required to aspects of the formal grammar. Since GELLO is based on OCLv2 we referred back to the OCLv2 specifications to clarify some of the finer points. We made cosmetic changes to the lexical rules of the grammar, allowing for either " or ' as a string delimiter, and allowing tokens to be case-insensitive. Other changes made comprised of minor syntactic changes to the language. The LET statement and other similar constructs were extended to make the type of the variable optional since in most cases the type of the expression can be inferred. The grammar was reworked to resolve ambiguities in the IF-THEN-ELSE-ENDIF constructs of the original GELLO grammar by introducing a Block construct comprising of a list of Declaratives followed by a final GELLO expression, and also reworking the IF statement to contain a Block rather than a Statement. Other minor extensions included allowing for the final GELLO expression to be optional, and fleshing out several incomplete syntactic structures in the original GELLO specification. We have also progressed with further extensions to the GELLO grammar such as class and type definitions to facilitate building standard GELLO libraries, however these are subject to further research and fall outside the scope of the current GELLO project. The accompanying GELLO grammar as implemented provides a concise record of our current implementation.

Conclusion

GELLO is a powerful decision support tool capable of supporting highly complex querying of medical data in a very concise but readable manner. Its application to decision support is highly productive and with the relevant necessary extensions for practical use, we believe that is entirely suitable to the purpose for which it is designed.

This project has received funding of $185,000 by the Australian Government through the Information Technology Online (ITOL) Program of the Department of Communications, Information Technology and the Arts.

GELLO, A Practical Implementation through the Application of Real World Examples

Peter R. Tattam, B.Sc.
Andrew McIntyre, M.B.B.S. (Hons) F.R.A.C.P.
http://www.medical-objects.com.au
peter.tattam@medical-objects.com.au

Choice of GELLO for decision support

- Project to build advanced decision support and registry reporting tools for the treatment of Lymphoma.
- GLIF was vehicle for Guidelines.
- Decision was made to use GELLO encoded logic.
- Originally envisaged that Arden would be the vehicle, however further investigation suggested that GELLO would be a better candidate to evaluate the clinical data to assist relevant decisions.
- GELLO features
  - Rich querying facilities.
  - Object oriented
  - Integrates well with HL7
- Implemented what we believe to be one of the first practical implementations of GELLO worldwide.

Working with GELLO specifications

- GELLO is a work in progress
- Developed in coordination with HL7 Decision Support Group
- Based on OCL 2.0
- Started in Dec 2003
- Most recent draft of specification dated May 2005
- Mailing list started Dec 2006 with active discussion
- Implementation raised many issues with specifications

Limitations with GELLO Language and Grammar

- Typographical errors
- Incomplete language elements
- Incorrect language elements
- Ambiguous constructs
- Discrepancies between grammar and examples used
- Semantic limitations of the language
- Typically formal grammar and actual grammar differ in practice due to implementation details
- Even so, formal grammar in specification is incorrect, incomplete and does not even parse the examples in the specification

Minor Corrections

- Had to cut & paste grammar from HTML document
- Built a tool to process the BNF into a useful form
- Found syntax errors in the BNF and corrected.
  - Misspellings
    - Fixed by inferring correct names.
  - Undefined and unused symbols using reachability analysis
    - Symbols “GELLOType”, “ReferenceToClass” undefined
      - Fixed by changing “GELLOTypes” to “GelloType”, and adding “ReferenceToClass” to point to “ReferenceToInstance”
    - Symbols <IMPLIES>, <NEW>, <ENDCONTEXT> unused
      - Fixed by including <IMPLIES> in “ConditionalExpression”, and omitting <NEW> and <ENDCONTEXT>
  - Syntax errors in terminal regular expressions
    - Fixed
  - Fixed errors in some of the terminal regular expressions
    - <DECIMAL_LITERAL> only generated numbers without digit “0”!!
    - <REAL_LITERAL> is ambiguous with <INTEGER_LITERAL>
    - <NUMBER> was removed by simplifying grammar.

Completing the Language

- Various Elements in language appear to be stubs
- Referred back to OCL to figure out what elements should look like
- Elements fleshed out
  - "CollectionLiteral" defined

    CollectionLiteral::= CollectionType "{" (CollectionLiteralElement ("," CollectionLiteralElement)*)? "}"

    CollectionLiteralElement::= Expression (".." Expression)?
  - "TupleLiteral" defined

    TupleLiteral::= <TUPLE> "{" TupleLiteralElement ("," TupleLiteralElement)* "}"

    TupleLiteralElement::= <ID> ":" GELLOType "=" Expression
  - "EnumerationType" extended

    EnumerationType::= <ENUM> "(" <ID> ("," <ID>)* ")"
  - "CollectionType" extended

    GELLOType::= BasicType
    | CollectionType "(" GELLOType ")"
    | TupleType
    | EnumerationType

Trivial Extensions to language

- Added comments
  - // A comment to end of line.
  - /* A comment which is
    more than one line.
    */
- Allow “ to be used synonymously with ‘ for strings
- Generalized parameters to standard functions to be “Expression”s rather than specific typed literals.
- Allow identifiers to be case insensitive.

Significant Enhancements to Language

- Many of the examples refer to lists of Statements rather than a single GELLO Expression or Statement.
- Based on implementation experience and recent discussions on the mailing list, a significant extension to allow for multiple declarative statements to be specified.
- These issues were resolved by the following constructs:
  - Introduction of "Block" construct.

```
GELLOExpression::=     Block
Block::=               Declarative* ExpressionNP
Declarative::=         LetStatement
                     | ContextNavigationStatement
```

  - Redefining "IfStatement" and "ComparisonExpression" and introducing "IfExpression"

```
IfStatement::=     <IF> Expression <THEN> Block <ELSE> Block <ENDIF>
ComparisonExpression::=                              IfExpression (<EQUAL> IfExpression |
                        <NEQ> IfExpression | <LT> IfExpression  |
                        <LEQ> IfExpression | <GT>  IfExpression  |
                        <GEQ> IfExpression)*
IfExpression::=          AddExpression
                       | IfStatement
```

- Resolution of no statement separator
  - The introduction of multiple statements introduced a difficulty in the grammar in that statements do not have a terminator or separator (e.g. ";").
  - Problem occurs when two GELLO expressions appear next to each other within the language.
  - Resolved by restricted form of Expression in the grammar
- Included the [and] operators to index into collections.
  - By reference to OCL V2.0
  - Shorthand method for the ElemAt() collection operator

Unambiguous Grammar Constructs

- Many of the constructs as defined in the original specification result in a highly ambiguous grammar.
- Constructs which look superficially correct for descriptive purposes end up generating an ambiguous grammar.
- The importance of an unambiguous grammar is two-fold
  - Being able to specify the language in a portable way to a wide range of users and implementers
  - Being able to generate practical parsers for the language
- A great deal of time was spent trying to resolve the ambiguous nature of the GELLO language as specified by the original grammar.
- The general nature of the ambiguities fell into several categories
  - Places where one construct overloaded another.
    - E.g. when a “Name” and an <ID> were derivable in the same place.
  - Places where one construct next to another resulted in an ambiguity i.e. when an “Expression” appeared next to another “Expression”. These two examples are identical syntactically but have different meaning
    - Example 1.

      Let A: Integer = C + D

      (A * 20)
    - Example 2.

      Let A: Integer = C + D(A *20)
- The changes to resolve the ambiguities were many and varied. The more significant of these are
  - A restricted form of “Expression”, “ExpressionNP” which does not start with “(“, “+” or “-”.
  - Introducing the “Operand” construct from which variable references, attribute references, method operators and collection operators are formed.

Rich HL7 infrastructure

- The GELLO and GLIF modules have been built to operate over a Rich HL7 infrastructure developed over many years by Medical-Objects
- HL7 version 3 Data Model (RIM) is incorporated into GELLO
  - Observation
  - Patient
  - Medication
- Model data and GELLO results visible from IDE
- Can dynamically bind Model data to GELLO infrastructure
- Uses Windows COM to manage data ownership.
- Also includes SNOMED engine access.
- Supports concept of Medical Logic Modules (MLM) as in Arden

Embedded GELLO

- The GELLO as implemented by MO-GELLO has been developed as an embedded component within a GLIF and Archetypes framework.
- It was developed using a LALR(1) parser framework in conjunction with a Delphi Object Pascal HL7 framework.
- It is interpretive in nature.
- Gello expressions are compiled at run time and stored as an internal object oriented expression tree.
- Execution speed is facilitated by the use of object oriented techniques.
- There is no “byte code” to execute, all calls are made natively to the HL7 framework.
- GELLO expressions can be implemented using an embedded IDE called “Mowgli”.
- Library facilities have been developed whereby frequently used GELLO expressions can be run indirectly from within another GELLO expression

Scheduling for Complex Dynamic Distributed Environments

Problems with current systems [6] :

- Do not react well to dynamic environments
- Do not react well to time
- Leave difficult scheduling decisions up to the user of the system
- Are expressively limited – not good for modelling complex system requirements

A complex scheduling environment is one which has a large number of variables, a large number of constraints between them, and multiple, often conflicting, scheduling goals

E-HEALTH RESEARCH CENTRE

Distributed Constraint Satisfaction [DisCSP]

DisCSPs offer an excellent framework for modelling and solving complex distributed problems

A DisCSP [14] consists of :

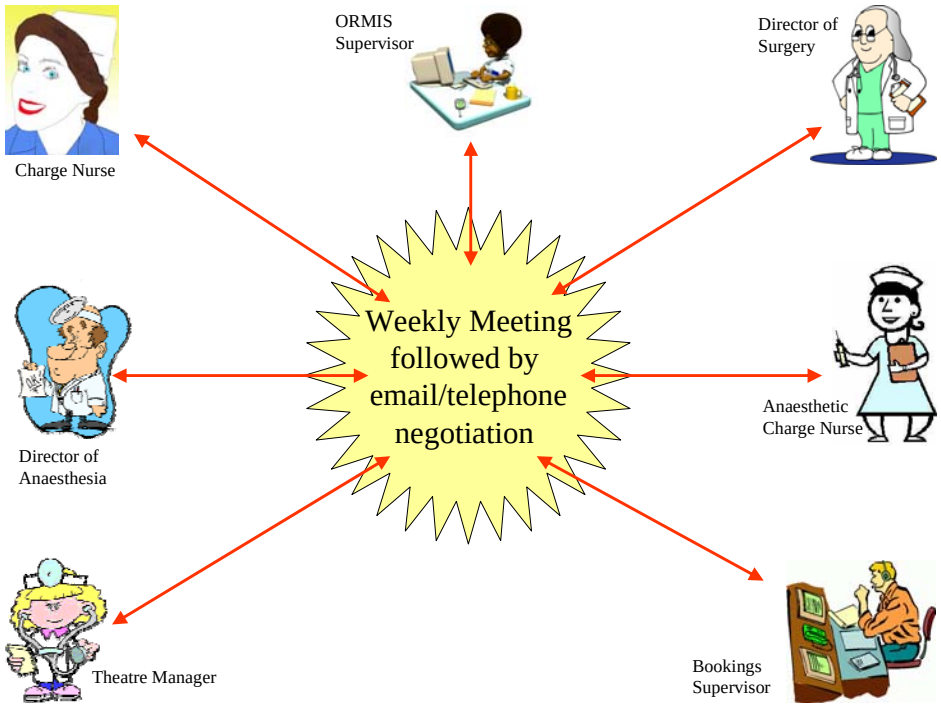
- A finite ordered set of Agents A = {A1,A2,A3,…,An | n∈Z+}
- For each Agent there exists :
  - A finite ordered set of variables V = {V1,V2,V3,...,Vn | n∈Z+}
  - A finite and discrete domain set D = {D1,D2,D3,...,Dn}
  - An intra-agent constraint set C = {C1,C2,...,Cm}, m∈Z+
  - An inter-agent constraint set IC={IC1,IC2,...,Icm}, m∈Z+
  - An ordered solution set S = {v1,v2,v3,..., vn | vi∈Di,∀i ∈ [1,m]}
- The solution set of the DisCSP is the set of solution sets of each agent

Most current DisCSP efforts at modelling real world complexity however suffer from several limitations

Case Study … PA Hospital, Brisbane

Scheduling Elective Surgery at the PA Hospital

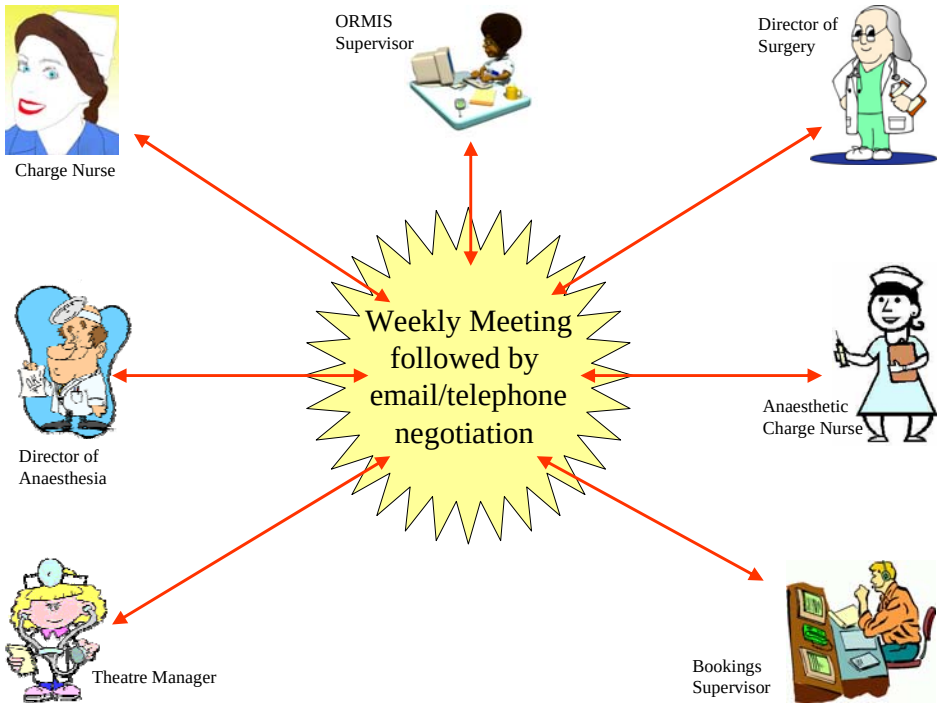
- There are 21 theatres dedicated to Elective Surgery at the PA Hospital
- The Bookings department books patients into the ORMIS system after discussions with surgical teams
- The updated Theatre schedule is posted online everyday at 3pm
- Each Department schedules its own staff/resources while maintaining the requirements of the Theatre schedule
- Every Thursday, the heads of the various departments get together to discuss and coordinate their schedules for the coming week



Case Study … PA Hospital, Brisbane

Scheduling Elective Surgery at the PA Hospital

- During the scheduling meeting, conflicts between schedules are manually resolved. At this point, the theatre bookings list is typically 70%~80% complete
- After Thursday, all readjustments and conflicts are resolved on a case-by-case basis using email, phone or in-person communication
- If a conflict cannot be resolved in time, it may lead to the creation of a bad or compromised schedule
- Temporary absence of the domain expert from the scheduling process may also lead to a bad or compromised schedule



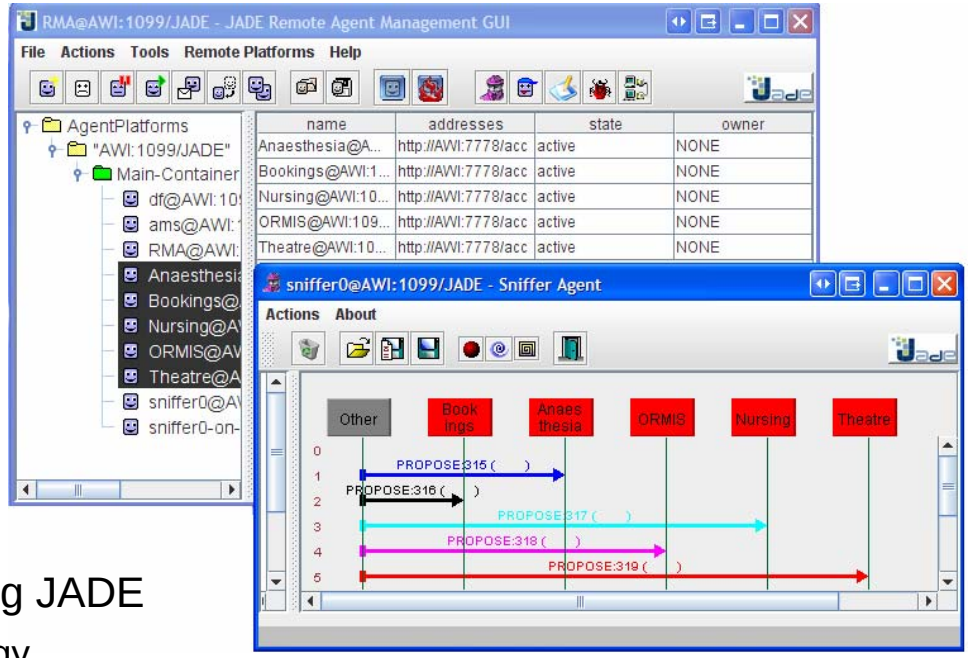
Griffith UNIVERSITY

E-HEALTH RESEARCH CENTRE

Current State of the Project

We are currently developing a methodology that can :

- Handle the inherent complexity
- Incorporate complex negotiation
- Select the solver based on problem characteristics
- Incorporate intelligent decision making
- Learn from user feedback & the decision making process



We are also building a prototype system using JADE

- **To Demonstrate :** The developed methodology
- **To Evaluate :** Performance of the methodology
- **To Establish :** Benchmarks that aid future research

[b] e-Health Research Centre / CSIRO ICT Centre, Australia.

Abstract

The complexity and changeability of interacting factors affecting scheduling in a distributed environment demands a very flexible and dynamic solution, in order to achieve a high level of utilisation and cater for many different competing priorities. A typical example of the problem domain can be found in elective surgery scheduling where efficient scheduling is critical to ensure optimum utilisation of the public health system. Current approaches have however failed to offer an efficient solution. The task of making complex resource allocation decisions is still left up to the operators of the system.

We propose a multi-agent approach to modelling distributed environments that employs distributed constraint satisfaction for intelligent scheduling. The proposed model is based on a case study of elective surgery scheduling at the Princess Alexandra Hospital in Brisbane, Australia.

Keywords:

allocation of resources, distributed systems

Introduction

Scheduling in a complex, dynamic environment is an open research problem. The problem is compounded further in the case of a distributed environment where each unit is working at optimising its own resources. In this situation, several units, and thus several schedules, need to be optimised simultaneously to ensure proper utilisation of resources.

While scheduling has been a long studied problem in Artificial Intelligence, no concrete intelligent solutions exist for real-world complex scheduling problems. The core of the problem lies in the inability of current systems to effectively model the inherent distributed structure and distributed decision-making of real-world scheduling environments. What is needed is an intelligent flexible methodology that can adapt itself to the problem at hand, instead of modifying or scaling down the problem to suit its structure. What is also needed is a series of real-world benchmarks to aid proper experimental analysis of current and future methods [1][2].

The hospital elective surgery scheduling problem is chosen as the foundation for building this study as it is an inherently distributed and complex real world problem and begs for an urgent solution. As at 1 January 2007, 35,058 Queenslanders were waiting for elective surgery. Of these, 29% had waited longer than a clinically desirable time [3].

Elective surgery at the PA Hospital

The Princess Alexandra hospital in Brisbane offers 21 operating theaters that can be utilised by various departments for emergency and elective surgery. For the process of scheduling, the theatre schedule is divided into AM and PM slots of 3.5 hours each. These slots are allocated to various doctors, departments, trauma or emergency.

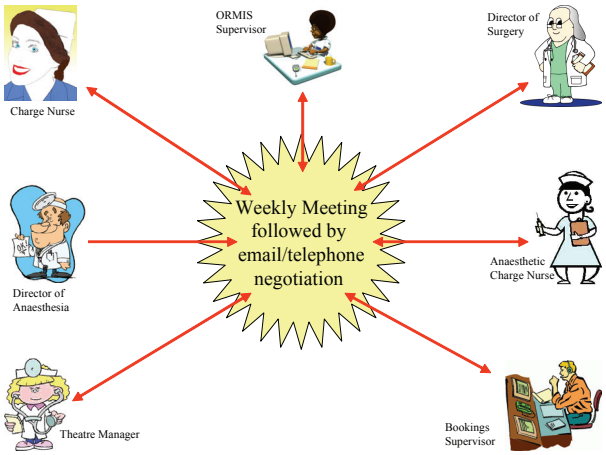

Figure 1- Current scheduling model at PA Hospital

Each department connected with the surgery (i.e. allocating staff or other resources to the surgery) carries out their individual scheduling activity. As elective procedures are booked into the ORMIS[1] (Operating Room Management Information System) system by the bookings department, they become visible to each of the other departments and any rescheduling required because of the nature or demand of the booking is carried out.

Every Thursday, the managers of the different departments meet and review bookings for the week ahead. Each session is discussed and if any of the managers has a problem, they bring it to everyone's notice and a solution is worked out by negotiation. Unexpected emergencies, variation in patients' health state, sudden perturbations in staffing and surgeon availability etc. lead to further changes being

1 http://www.isoftplc.com/corporate/products/2593.asp

required often. However, all changes made to the system after this meeting are dealt with individually by the departments, and resolved on a case-by-case basis using conventional communication such as telephone and emails, or even by face-to-face meetings. In keeping with the dynamics of the domain, the schedule needs to be updated quickly and efficiently. This is often not possible, because of the delays in communicating with the different departments to make the change, and leads to the adoption of an easy but inefficient solution resulting in a bad or compromised schedule.

Methods

Recent advances in the fields of Distributed Constraint Satisfaction (DisCSP) [4] and Multi Agent Technology offer powerful tools including autonomous, intelligent agents for solving complex distributed problems efficiently. "Autonomous agents are computational systems that inhabit some complex dynamic environment, sense and act autonomously in this environment, and by doing so realize a set of goals or tasks for which they are designed" [5]. An intelligent agent also possesses the capability to act without explicit user intervention and to learn and self correct itself. Given the decentralized and highly dynamic nature of hospital decision making, an intelligent agent based approach is a promising paradigm for modelling the environment. Using the DisCSP formalism further provides promising structured and reusable techniques to model complex and distributed problem domains efficiently and to handle the dynamics of the environment.

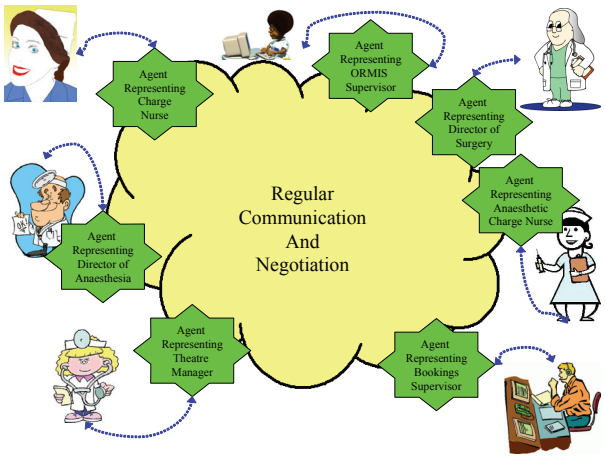

Figure 2- Proposed scheduling model

We are currently developing a methodology where intelligent agents trained with the medical constraints, preferences, priorities etc. of the administrators would carry out scheduling for their respective departments. They would also collaborate with each other to resolve conflicts and align themselves. As changes affect the system, the agents would automatically negotiate to realign themselves. It is proposed that the methodology will allow each unit(agent) to solve their local problem using independent algorithms and then negotiate with each other to maintain global requirements. By translating negotiation requests and strategies to constraints, it will also allow multiple negotiation strategies to be applied within the framework. The system as a whole would be intelligent – learning and self-correcting from user feedback.

We are also building a prototype application using JADE[2] (Java Agent DEvelopment Framework) as a proof of concept and to perform an experimental evaluation of the proposed methodology and its component algorithms. Scheduling process information and data from the case study is being used to construct problems for analysis. These problems, along with the performance data collected, will be used to create suitable benchmarks to further assist evaluation and aid future research.

Conclusion

An approach to intelligent scheduling in complex distributed environments is presented. The proposed method effectively models the distributed domain and uses DisCSP techniques to solve the scheduling problem. We are currently designing efficient scheduling algorithms and an implementation of the concept based on this case study in scheduling elective surgery.

Development of Team Competence and IT Projects at Hospital

Tokiharu Miyahara [a], Hiroyuki Ohtsuka [a], Kiyohiro Ishii [a], Kenji Kato [a], Naoko Nagai [a] Shigefumi Morioka [a]

[a] *Department of Medical Informatics, Kobe City Medical Center General Hospital, Japan*

Abstract

So-called "upper process", that is from the process of System Requirements to External design, is very important for developing good performed Health Information System (HIS). But there are few who understand both information technology (IT) and medical field. We trained some medical staff for understanding IT at our hospital. So that, more than 30 staff have been certified as Healthcare Information Technologists, given to capable persons who understand both IT and medical field by Japan Association of Medical Informatics (JAMI), so far. An IT project team was formed officially with these staffs and given some short courses of Unified Modeling Language (UML) and the method of modern project management (PMBOK) for HIS innovation project. Our team achieved successfully writing documents of System Requirements of our new HIS consists of more than 30 subsystems within ca.2 months at our hospital.

Keywords:

system requirements, UML, project management, PMBOK, healthcare information technologist

Introduction

It is widely known that so-called "upper process" is very important for developing good performed HIS. JAMI began to certify Healthcare Information Technologist (HIT) in 2003, for bringing up a capable person who understand both IT and medical field. We trained some medical staffs for understanding IT at our hospital, and more than 30 members have been certified as Healthcare Information Technologists. After training of some short courses of Unified Modeling Language (UML) and learning the method of modern project management (PMBOK), HITs are thrown into IT project of HIS innovation of our new hospital which will be built 4 years later.

Methods

IT Project Team and competence development

Our IT project team is constructed by 30 members (5 medical doctors, 6 medical lab technologists, 5 radiological Technologists, 4 nurses, 4 pharmacists, 1 clinical engineering technologist, 1 Physical Therapist, 4 medical secretaries). All members are certified as HIT by JAMI. The team is organized officially in our hospital, so that it enable us to use several resources of the hospital, and to make up environment for studying and/or practicing IT technology.

Every members select one of 3 Special Interest Groups in our team; network technology, information security, database technique, to develop their own competence for achieving various services in each field. Members have been given some short courses of Unified Modeling Language (UML) and Project Management (PMBOK) for developing their competence.

Results

To innovate our hospital HIS, we organized IT project team and developed our team competence in advance. Our team achieved successfully to writing documents of System Requirements for new HIS, which is made up more than 30 subsystems, within ca. 2 months.

Smart House Infrastructure for Chronic Disease Management

Neil W. Bergmann, Stephen Wilson

School of Information Technology and Electrical Engineering., The University of Queensland, Australia

Abstract and objective

Information and Communication Technologies are enablers for next generation home healthcare. This poster describes a proposed ICT-based home care system for chronic disease management. Key characteristics are patient-centred data ownership, broadband Internet connectivity, self-configuring networked instruments for measurement and treatment, individualized treatment rules and regimes, and automatically cascading levels of alarms and interventions.

Keywords:

chronic disease management, internet, home care services

Introduction

Over the next 50 years, Australia can expect to see an increasingly aging population. A particular problem, most pronounced in the aged, is appropriate care and management of chronic conditions, whilst maintaining quality of life and opportunity for independent living.

The most common 10 chronic diseases (illness which has lasted longer than 6 months) accounted for 43% of the total disease burden in Australia in 2002-3. In that time, more than 17% of hospital admissions were for management of chronic disease which cost $11 billion from the total health budget of $60 billion. These ten diseases were: Coronary Artery Disease; Lung Cancer; Cerebrovascular Disease; Dementia; Chronic Obstructive Pulmonary Disease (COPD); Diabetes; Depression; Colorectal Cancer; Asthma; Osteoarthritis.[1]

A model of health care delivery whereby the diagnosis, treatment and ongoing management of chronic conditions occurs in total or in part, remote from a hospital is clearly of benefit. Hospital-based care of chronic conditions is expensive, and an inefficient use of hospital resources. The benefit in terms of psycho-social wellbeing of the individual, the family and community is an additional bonus if care can be migrated to the home setting.

Many health home-monitoring projects have aimed to provide very low-cost, low-bandwidth solutions, using technologies such as modems and phone-lines, and these continue to be an area of active interest amongst many groups. However, the more widespread availability and adoption of broadband Internet, home computers, mobile phones and wireless technologies suggests better solutions are possible.

Methods

This paper presents our initial system design, based on analysis of existing telemedicine solutions for diagnostics and health-care management, combined with insights regarding the changing population demographics and societal attitudes to healthcare.

The results presented below include both our analysis of the relevant aspects of current western healthcare systems, plus our predictions of how to better address the requirements of such systems.

Results

Assertive, well-educated and politically astute baby boomers are now taking a major role in caring for their parents, and will soon start to enter old-age themselves. There is already a move away from professionally-centred patient care models (where doctors take primary responsibility for health care decisions) to patient-centred care models where patients (and their families and friends) take an increasingly dominant role in health care management, with professional staff assuming more the roles of consultants and advisors.

With an increasingly aging population and increasingly costly health-care, future health care models for health management in the aging will necessarily depend on a distributed community of volunteer carers. Jointly with the move to patient-centred care regimes, and with the desire to maintain independent living well into old age, this all suggests a substantial shift in models of care for the chronically ill will occur in the coming decades.

Current practitioner-centred medical records systems and health monitoring systems are inadequate to deal with these forthcoming significant changes in models of care. There will be an increasing emphasis on the role that modern Information and Communications Technology (ICT) can play in enabling and supporting these new models of care. Our project investigates new models of care, and the Smart House technologies that will assist in implementing them.

1 Australian Institute of Health & Welfare Report. 2002-3.

In terms of diagnosis, ICT technologies can extend the range of scenarios and locations where extended diagnostic testing can be done. For example, in Obstructive Sleep Apnoea, first level diagnostic filtering can be done with low-cost Pulse Oximetry in general hospital wards, or even at home rather than in specialized sleep-medicine wards, with just the diagnostic information (not the patient!) being relayed to the sleep specialist. However, detailed information needs to recorded and validated before meaningful remote diagnosis can be done.

In terms of long-term home-based care, ICT technologies can assist in patient-centred record keeping, in recording care regimes (diet, exercise, drugs), in implementing those regimes (eg. automatic monitoring of drugs taken, physiological monitoring), in remote communications with other volunteer carers such as friends and relations, and also with health professionals, and in automated alerts of atypical behaviour (perhaps indicating a fall or a chronic episode).

Incorporating Smart Home technology into new housing developments might differentiate such developments by making Smart Home technology an agency for improved health outcomes, not just improved convenience and entertainment. The same technologies might be applied to residential aged care facilities, particularly those with independent and semi-independent living units.

Such new models of patient care need input from clinicial researchers who would design, implement, trial and evaluate the health care regimes. There appears ample scope for significant clinical research outcomes from such a program.

The electronics of an ICT-based home health-care support system centres on a secure home healthcare portal device, basically an inexpensive embedded computer, which provides local data storage, a broadband Internet connection, a secure web-server for remote access and data analysis, and a wireless networking capability to connect to instruments.

Measurements can be analysed and filtered on the basis of required level of care. Basic measures of body attitude, activity and daily weight can be progressively augmented with electrocardiographs, pulse oximetry and blood glucose levels for example. Instrumentation can be ambulatory for some sensing modalities. Wireless is the preferred means of communication from sensor to the portal. Therapeutic devices (such as automated medication dispensers) are similarly connected.

The software of the system (running on the portal) consists of a home healthcare monitoring executive, whose particular characteristics are customized for the disease and the patient. Reminders for measurements to be taken, and medications to be taken can be scheduled into the executive. Customization of care regimes occurs at three levels. Firstly, dosing can be customized to the individual patient. Secondly, dosing can be adjusted (within approved limits) in response to measurements. Thirdly, a remote practitioner can review and manually change either of these first two regimes.

The system can also initiate cascading levels of alarms in response to events. Lack of user input might trigger a notification to a nurse, unexpected measurements might trigger notification to a doctor, a panic button might trigger an ambulance.

Discussion

Clinical/Systematic research issues include:

- How can new patient-centred care regimes be designed so as to put more control into the hands of the patient, and what should the role of the health care professional be?
- What sorts of technological assistance might be required to implement such care regimes, which are not adequately addressed by current mechanisms?
- How are patient outcomes measured, and what improvements can be made to patient outcomes by such technologically-enabled patient-centred care regimes?
- What are the cost/benefit tradeoffs of such home-based, technology-enabled care regimes?
- How can such benefits be realised within the constraints of the current health funding systems? – Who would pay for such models to be developed and implemented?

Computer systems research is needed to investigate appropriate devices, communications, networking and database technologies that are needed to implement such a system in a cost-effective manner

Human Computer Interaction (HCI) research is needed to investigate appropriate interaction methodologies between patients and the Smart Home technology.

Trials are needed to validate the potential of such an ICT system to better facilitate patient-centred healthcare. Figure 1 shows the change in data-management.

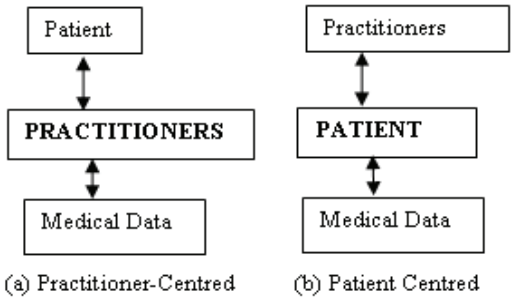

Figure 1 - (a) Current and (b) proposed models of medical data ownership and control

Conclusion

If patient-centred healthcare is to become a reality, with an emphasis on keeping the aged and chronically ill out of hospitals and nursing homes, then the ICT support for the management of patient care also needs to be devolved to the Smart Home under the control of the patient. This requires new ways of thinking about ICT support for healthcare, based on patient-centred, semi-autonomous, widely-distributed and highly networked patient information systems.

Experiences in Implementation of a Statewide Telemedicine System at a Medical College with Multi-speciality Hospital in Kerala

Nabeel.M.K, Hariharan.S.

Academy of Medical Sciences, Pariyaram, Kerala INDIA

Abstract

This is an extended abstract of a paper which narrates the authors' experiences in implementing a telemedicine system in their institution in the southern Indian state of Kerala, as a part of a state-wide telemedicine network. The focus was to achieve the maximum with the limited resources available. Though the project is running smoothly as outlined in the initial phase, scaling up to more rural centres only will make it a cost-effective and sustainable solution.

Keywords:

telemedicine, telehealth, low-resource setting, developing country

Introduction

Academy of Medical Sciences, Pariyaram is one of the new generation medical colleges in the southern Indian state of Kerala. It has been chosen as one of the specialist nodal centres under the Kerala Government's Tele-Medicine project connecting various Medical Colleges in the state with District Head Quarters Hospitals in the first phase and later to be extended to the Primary Health Centres.

The Project

The project is partly funded by the Indian Space Research Organization (ISRO) and is christened as the Kerala Tele-Health & Medical Education Project. An IP based system, working on satellite technology, it has got its own merits and a few demerits as well. This paper discusses the issues faced by the authors and their fellow officers in implementing this project statewide. Though ISRO has been providing such connectivity elsewhere in the country it is the first time where it has been declared to be used for educational activities as well.

Figure 1- Map of India showing Kerala in the South

Figure 2 – Map of Kerala showing Pariyaram

Currently we are getting consultations from district hospitals and at times from other specialist centres as well. Similarly we can seek expert opinion from other specialist centres as well. There is customized software for using this, which helps in transmitting electronic medical

records and imaging data from a tele-nodal centre to a tele-specialist centre like ours. (Store and forward method) Based on the patient record, an appointment is fixed for videoconferencing between the consultant at the specialist centre and the treating doctor at the nodal centre (Real time method). But the above software does not support consultations between the tele-specialist centres - this is a major drawback to be worked upon - for which videoconferencing alone has to be used.

The connectivity is extended from the main tele-medicine room to the operation theatre complex, one lecture theatre and a small seminar hall. The connectivity for operation theatre is being used both for seeking expert advice as well as to conduct Tele-Education programmes on surgical techniques. The connectivity with the lecture theatre and seminar hall again is intended for scaling up the continuing education activities. In the next phase of the project, apart from extending the connectivity to more centres, plans are put forward for using the connectivity for sharing electronic resources and also to use it for enhancing surveillance and epidemiological research.

Conclusion

Here we have tried to give just an overview of this large scale eHealth programme. A detailed account of the project from its planning stage to the implementation stage has to be narrated in order to derive lessons and best practice guidelines, which shall be dealt with in the full paper. Finally the paper will compare with other institutions within our community and from outside and shall highlight the best practices. Definitely there is a lot to be learnt from the Kerala State Tele-Health & Medical Education Project.

Videophonic System for Cancerous Patients Receiving Chemotherapy at Home

Mona Laila[a], Vincent Rialle[a,b], Lydie Nicolas[c] , Catherine Duguay[c], Alain Franco[a,c]

[a] Laboratoire TIMC-IMAG UMR CNRS 5525e, Université Joseph Fourier, Grenoble, France
[b] Département d'informatique Médicale, Centre Hospitalier Universitaire de Grenoble, Grenoble, France
[c] Pôle de Médicine Aiguë et Communautaire, Centre Hospitalier Universitaire de Grenoble, Grenoble, France

Abstract

Videophonic systems have been used for several homecare applications in various medical specialties including oncology. The purpose of this poster is to describe the methodology and the materials of a controlled non randomized study; concerning the evaluation of the feasibility and the utility of a videophonic system used for following-up cancerous patients receiving chemotherapy at home. The study aims to show the patient and patient's family acceptability of videophony and their satisfaction, the clinical effects of using videophone on the patients' physical, functional and mental state, on their quality of life, and on the quality of healthcare provided at home. We use standard measurements (SF36, ADL index, index of Karnofisky, POS) and personal questionnaires (for the acceptability and satisfaction) prepared in the Medical Home care (MHC) service at the Grenoble university hospital.

Keywords:

videophone, satisfaction, acceptability, home healthcare, oncology, chemotherapy

Introduction

With the increase of social, medical and economic needs of dependent people (old, sick, disabled), and with the growth of health resources consumption, the Telemedicine Applications (telemonitoring, telesupport, teleconsultation) favor a medicalized maintenance at home. This one allows: preserving the patients and patients' carers quality of life, saving patient and hospital staff time, and eventually reducing health costs [1- 3]. Several studies evaluated the feasibility, the utility and the effectiveness of technology for providing and sharing various and necessary oncological expertises. However, no study evaluated the use of videophony for the delivery of home healthcare in oncology. The goal of our study is to evaluate the feasibility and the utility of a videophonic system used for following-up cancerous patients receiving chemotherapy at home. This study is carried out in the MHC service at the Grenoble university hospital. It is one of the MCC* (Medical Care Continuity) project clinical experimentations.

Materials and methods

Population:

The study concerns adult cancerous patients hospitalized at home * http://www.eten-mcc.org. The patients are selected according to the following criteria: having cancer and receiving chemotherapy, older than 18 years, life expectancy more than 12 weeks, stable vital state (vital parameters), specialized medical care provided at home, patient and general practitioner consent.

Videophonic system:

A videophonic system (Fig. 1) is used to link the patient at home with the hospital staff. The communication is established between tow stations: one is installed at the hospital/ call centre (central station) and the other one is installed at the patient's home (patient station). Each station is equipped with a videophonic kit composed of a Personal Computer, remotely operated camera, modem, microphone, loudspeaker, and keyboard. The central station enables to remotely control some elements of the patient station: the camera (move, rotation, zooms), the sound heard by the patient. The patient uses a remote control with unique button, having three functions: receiving a call, sending a call, and finishing a communication. The phone works independently of the videophonic apparatus so in case of problem with the videophone, the phone is still working.

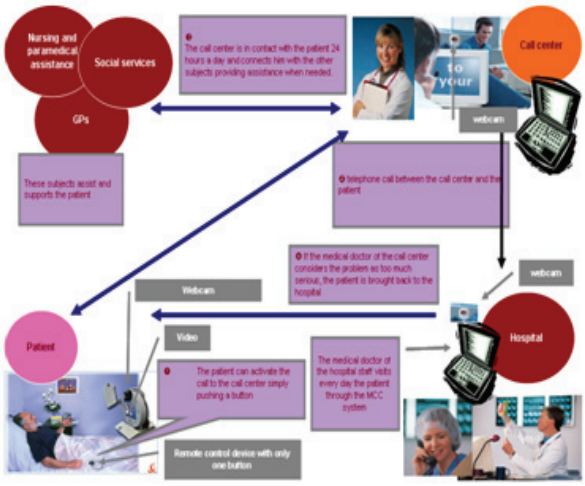

*Figure 1 - MCC videophonic system**

Clinical evaluation

Specific tools are used to evaluate each of the following items:

- Patient and patient's family satisfaction and acceptability of videophone: evaluated using three questionnaires for the patient and three others for the family. These questionnaires wear prepared for the study, by the healthcare team of MHC service at the Grenoble University Hospital.
- Patient functional state evaluated using functional
- capacity index of KARNOFSKY[4].
- Patient independence in daily activities evaluated using
- the index of KATZ ADL (Activity Daily Living)[5].
- Patient's anxiety and depression evaluated by the Hospital Anxiety and Depression Scale (HAD) [6].
- Patient quality of life evaluated using the SF36 scale [7].
- Life and care qualities evaluated using the POS
- (Palliative patient Outcome Scale)[8].

A controlled non-randomized method is used in the clinical evaluation. The comparison is realized between two groups of patients receiving home healthcare: the first one is the telemedicine group which benefit from the videophonic equipment, and the second one is the control group which does not have a videophonic system at home. The same evaluation tools are used for the two groups, except the evaluation of patient and patient's family acceptability and satisfaction; which are evaluated only in the telemedicine group. The Questionnaires and the scales are filled in three times during the study, every 4 - 6 weeks (at the beginning, at the middle and at the end).

Discussion

The use of telemedicine in usual practice at health institutions is still very limited. Following reasons can justify this limitation: patients and healthcare providers reject of telemedicine, non covering of telemedicine activities costs by health insurance systems, and lack of relevant research methodologies which provide proof of its efficiency and its utility [9]. To get a valuable and efficient telemedicine evaluation, it is necessary to consider the following items: diagnostic test reliability, clinical effects, patient and healthcare provider satisfaction, patient quality of life and economic analysis [10]. Until now the studies related to the videophonic application in oncology were interested in: radiotherapy, teleconsultation, multidisciplinary meeting, e-learning, and professional update [11 -15]. Few studies considered the clinical effects of using technology on cancerous patient quality of life and on their physical and mental state. No experience has been done to evaluate the videophone utility for following-up patients receiving a chemotherapy treatment at home. This study evaluates patient acceptability and satisfaction, videophone effects on the patient functional state and quality of life, and quality of healthcare provided at home. It is in progressing so there are no results yet.

Conclusion

Videophone applications favour medicalized maintenance at home, but there is still a lack of proofs which confirm the benefits of using technology to provide homecare for cancerous patients. Therefore, new clinical researches, like this study, are still necessary in this field.

Introduction

- Nowdays progression of various medical phenomena:
  - ✓**Increase of social, medical and economic needs of dependent people(old, sick, disabled).**
  - ✓ **Progression of nosocomial infections specially in cancerous patients.**
  - ✓**Growth of health resources consumption and healthcare expenditure.**

  ⇨ Increase of medicalized home care request
- Telemedecine applications (telemonitoring, telesupport, teleconsultation) favor a medicalized maintenance at home
- Medicalized maintenance at home represents an interesting alternative to the placement/stay at health institutions (1-2).

Introduction

Goal of study

- Evaluation of the feasibility and utility of videophonic system used to provide healthcare for patients having cancer and receiving chemotherapy at home.
- The study is carried out in HMC(Home Medical Care) service at the Grenoble University Hospital, in the framework of MCC*(Medical Care Continuity) Project

* http:// www.eten-mcc.org

Materials and methods

- Controlled non randomized study:
  - Telemedicine group: patients receiveing home healthcare and beneficiary from videophonic system.
  - Control groupe: patients receiveing home healthcare and non having videophonic system at home.
- Population:

Adult cancerous patients receiving chemotherapy treatment at home.

Materials and methods

- Inclusion criteria

✓ Having cancer and receiving chemotherapy.
✓ Older than 18 years.
✓ Life expectancy more than 12 weeks.
✓ Stable vital State (vital parameters).
✓ Specialized medical care provided at home.
✓ Patient and general practitioner consent
✓ Logistic feasibility

Materials and methods

- Videophonic system (figure 1) links patient at home to hospital staff and consists of:
  - ✓ **Central station (central station) installed at HMC unit.**
  - ✓ **Mobile station (patient station) installed at patient's home.**

- Each station (patient and central), is equipped with a videophonic kit: personnel computer, digital camera, modem, Microphone, loudspeaker, keyboard.
- Remote control with unique button, allows the patient to receive, send, and finish a call.
- Functions availables at central station: piloting of camera at patient home , control of sound heard by the patient.
- Communication established by HMC staff ⇒ directe contact with the patient at home.
- Communication established by the patient ⇒ call centre ⇒ HMC staff or urgency service

Materials and methods

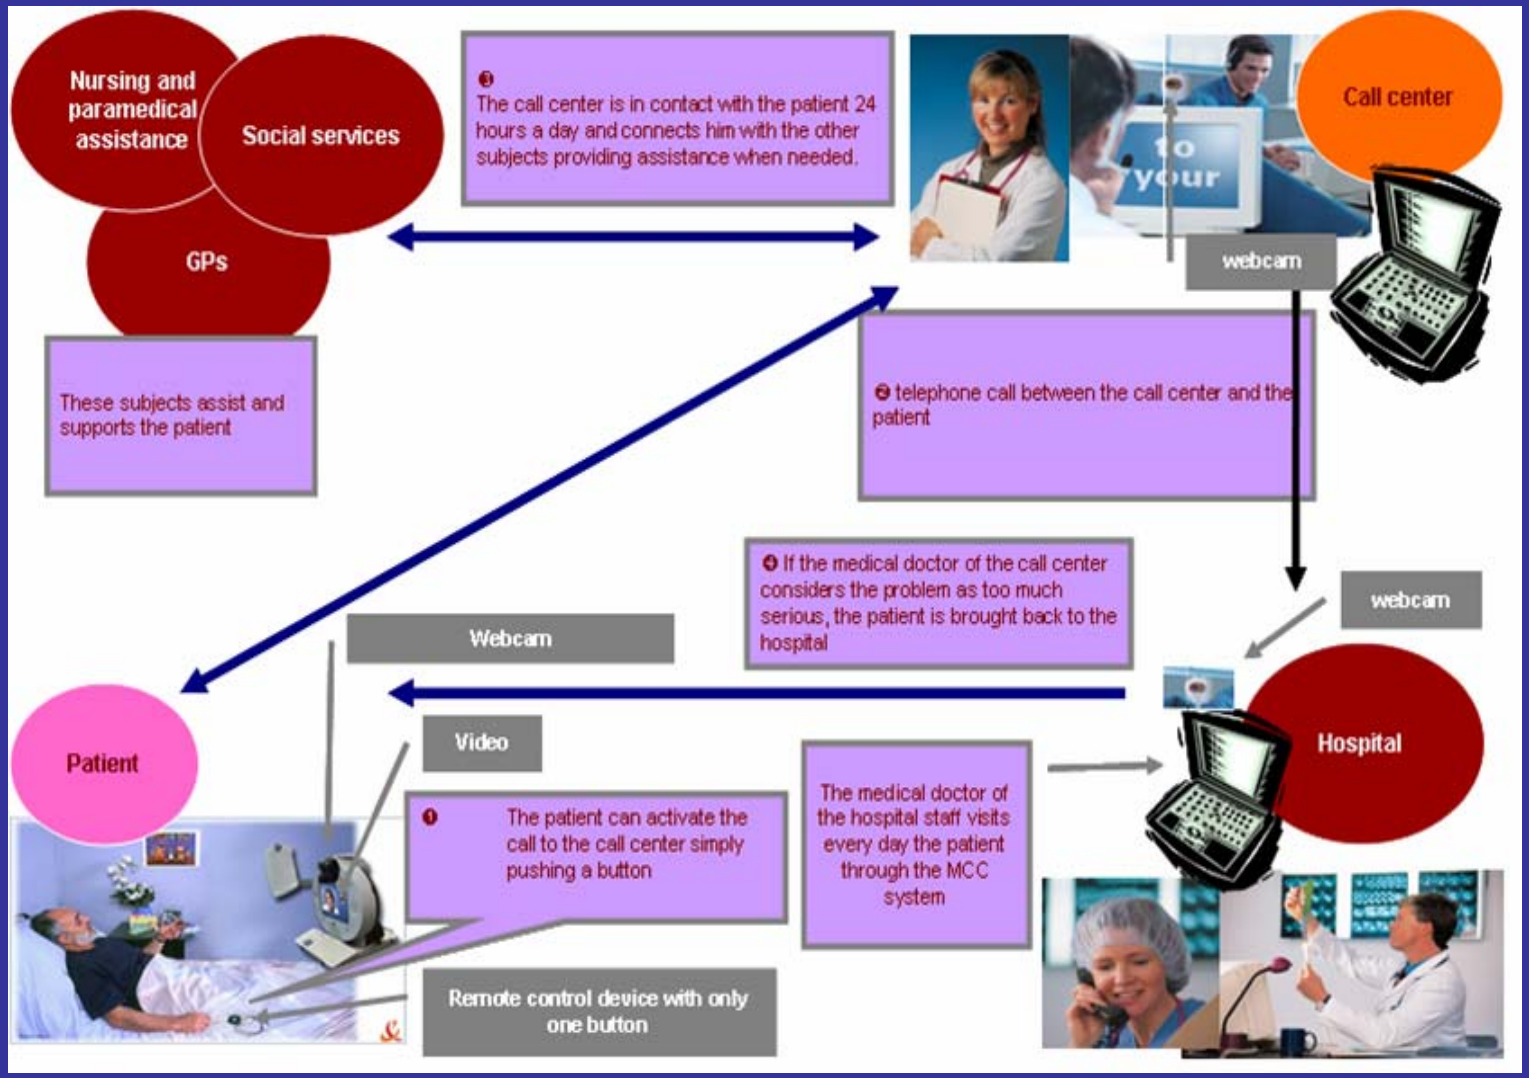

Figure1: Videophonic system for medical care continuity

Materials and methods

- Clinical evaluation
  - ✓**Patient and patient's family satisfaction and acceptability of videophone (questionnaires prepared at the HMC unit for this study).**
  - ✓**Patient functional state (functional capacity index of KARNOFSKY)[3] .**
  - ✓**Patient independence in the daily living activities (index of KATZ ADL)[4] .**
  - ✓**Patient's anxiety and depression(Hospital Anxiety and Depression: Scale HAD)[5].**
  - ✓**Patient quality of life and healthcare quality (SF36 scale and POS scale)[6,7].**

Materials and methods

- The same evaluation tools are used in the two groups, except the patient and patient's family acceptability and satisfaction which are evaluated only in the telemedicine group.
- For each patient:
  - ✓Inclusion duration for 3 months
  - ✓3 clinical evaluations carried out during the study (at the begining, at the midle and et the end).

Discussion

- In spite of the large developement achived in telemedicine field, its use in usual practice at health institutions is still limited(8):
  - ✓ **Patient and careprovider reject (not enough familiar in the socio-medical milieu).**
  - ✓ **Lack of pertinent studies about its utility and effectiveness.**
  - ✓ **Telemedicine activities not covered by health insurance systems.**
- Following items are necessary for telemedicine evaluation :diagnostic test reliability, clinical effects, patient and care provider satisfaction, patient's life quality and economic analysis[9].
- Experience related to using videophony in oncology concerned radiotherapy, teleconsultation, multidisciplinary meeting, e-learning, and professional update[10,11,12]. No one evaluated the delivery of home healthcare.

conclusion

- Telemedicine applications favor a medicalized patient maintenance at home.
- There is a lack of proofs showing the benefits of using technology to provide home healthcare for cancerous patients.
- New clinical researches, like this study, are still necessary in this field.

Hierarchical Expansion for Concept-Based Search

Roee Sa'adon[a], Robert Moskovitch[a] and Yuval Shahar[a]

[a] *Medical Informatics Research Center, Ben-Gurion University, Beer Sheva, Israel*

Abstract

Although many digital libraries are indexed using a hierarchical conceptual structure, improving the performance of traditional free text search is not trivial. We present a preliminary evaluation of a novel method of a hierarchical concept based search, as implemented in the Vaidurya search engine, with the innovation of using automated query mapping. Using MetaMap, textual query is mapped into MeSH concepts, which are later abstracted. Preliminary encouraging evaluation results on the TREC Genomics 2004 test collection are presented.

Keywords:

information storage and retrieval, concept based search

Introduction

While the idea of concept based search is researched for several decades, not too many studies shown that it outperforms traditional free text search. Recently we introduced Vaidurya, a search and retrieval tool developed originally within the DeGeL library, which in a rigorous evaluation a significant improvement was observed when concept based search was used. In this study we propose a novel approach, in which the user has to enter only a textual search phrase, which is converted into a concepts using *MetaMap*.

Vaidurya

Vaidurya implements a free text search (FTS) and concept based search (CBS). For the FTS, documents are represented and indexed using the *vector space model* introduced by Salton. The CBS in Vaidurya uses the logical operators *conjunction* (AND) and *disjunction* (OR) at two step of retrieval, called *inner-op* and *outer-op.* All the documents classified along a queried concept and its descendent are retrieved. Based on the *inner* the documents sets are intersected of unified to represent each tree, which then processed similarly based on the *outer* operator.

Methods

Based on the previous evaluation, we concluded that adding a query for concepts at the top levels will enhance FTS results, since the relevant documents commonly share abstract concepts. Our goal was to avoid the need in specifying explicitly the concepts, thus, enabling querying using a normal textual query, while exploiting the CBS. Given a set of *query terms*, a set of concepts at *varying* levels of the hierarchy is extracted using *MetaMap*. Then, the concepts are abstracted to their ancestors at a required level *k*, by climbing up through the MeSH hierarchy. In order to evaluate our method we used the TREC 2004 Genomics Track test collection, which offers 50 queries, and in which the documents are classified along MeSH concepts. As evaluation measures we refer to the precision measured at the top *5, 10 and 100* retrieved documents, and mean average precision (MAP). We report the preliminary evaluation of three important variables: (1) *CBS method (2) abstraction level (3) CBS weight.*

Results

Table 1 shows some of the best runs compared to the baseline. Results for runs which are higher than the baseline are bolded.

Table 1 – The best results compared to the baseline, the algorithm is specified by inner^{op}-outer^{op}/level/weight

Algorithm	MAP	P@5	P@10	P@200
OR-OR/3/0.2	0.228	**0.508**	**0.486**	0.196
AND-AND/2/0.2	0.226	**0.508**	**0.490**	**0.199**
OR-AND/4/0.2	0.222	**0.512**	**0.496**	0.193
Free Text Baseline	*0.231*	*0.488*	*0.480*	*0.198*

The improvement noticed at P@5 for run OR-AND/4/0.2 was significant with p=0.067 and for P@10 with p=0.079.

Discussion

We introduced an extension of Vaidurya which enables CBS through an automatic conversion of textual to conceptual queries using MetaMap. The evaluation done with the TREC-G showed a slight improvement. In the 10 and 15 queries, having the worst FTS performance, a significant relative improvement was observed. These are encouraging results for further development of the method**.**

Virtual Reality Assessment of Checking Symptoms in Patients with Obsessive Compulsive Disorder

Kyung Ryeol Cha [a], Chan-Hyung Kim [a], Junyoung Park [a], Sun Il Kim [b], Kwang Wook Kim [b]

[a] *Department of Psychiatry, Yonsei University College of Medicine, South Korea*
[b] *Department of Biomedical Engineering, Hanyang University, South Korea*

Abstract

Virtual reality(VR) is being used in many field of psychiatry and psychology. However, there are few cases of its application to ob-sessive compulsive disorder(OCD). We developed virtual reality system for OCD. The aim of this study is to assess the checking symptoms in patients with OCD using Severance virtual reality system for OCD(SeVROS).

Keywords:

virtual reality, obsessive-compulsive disorder, assessments

Methods

The sample population comprised the checking-type OCD group (n=11), non checking-type OCD group (n=10), and a control group of matched healthy volunteers (n=14). The virtual environment was designed to induce checking behavior. Two virtual environment was implemented: a home environment with a gas burner, a gas valve, a water tap, a window, a light switch, a door, and a lock to a gate; an office with a heater, a computer, a cabinet, a light switch, a door, and a lock to a gate. After leaning and distracting tasks, participants were given a mission that checks whole things in the environment. During ckecking session, response time, behavioral response (object operation, gazing, and trajectory) and checking urge were measured by computer. We also used Yale-Brown Obsessive-Compulsive Scale(Y-BOCS) for severity of symptoms.

Results

There was no significant difference in accomplishment of task between patients and matched healthy controls (age, gender, education, VR experience and intelligence matched controls). There was significant difference in checking time in checking-type OCD group as compared to that of other groups.

Conclusion

Virtual reality is useful in assessment of symptoms in patients with obsessive compulsive disorder. Furthermore it can give us more profound data of attention and visuospatial function in OCD patients. Further study for cognitive and behavioral treatment of OCD patients using SeVROS is being executed.

The aim of this study is to assess the checking symptoms in patients with OCD using Severance virtual reality system for OCD(SeVROS). the primary or first author.

- Obsessive-compulsive disorder (OCD) is a clinically heterogeneous disorder.
- Two main types of compulsions in OCD : Checking and Cleaning.

Jenike et al., 1990

Causes of checking compulsion in OCD

Impairment of memory

1. More nonverbal memory deficits
2. Less verbal memory impairments

Moritz et al., 2005

Low confidence of memory

1. Doubt of one's ability to recall
2. Whether correctly completed

Rachman and Hodgson, 1980

Limitations of previous studies

- Paper and pencil test or 2-D computerized test for assessment of visuospatial memory
- Self-report measures for confidence

Aim of this study

To find behavioral factors related to checking compulsion in patient with OCD using virtual environment.

ECHOLOGICAL STUDY

Methods

Twenty five patients with OCD and 14 normal controls volunteered for this study. The SeVROS-checking-type is Head Mounted Device(HMD) based VR system and has two virtual environment; office version and home version. Each virtual environment has 5 checking items with 5 distracting items. We used complete MINI(Mini International Neuropsychiatric Interview) for psychiatric evaluation. Other scales for assessment of OCD, depression, anxiety, quality of life, and feeling of presence were used. Intellectual function was also assessed.

Results

We classified the patients into 3 sub-group; checking-type, contamination-type, and symetric-type. The patients have more checking behavior than normal controls. The checking type patients have more checking behavior than other type patients. Two patients show low function of working memory. The SeVROS cuased anxiety to patients only.

		Checking type OCD	Non-checking type OCD	Control group	p-value

Delivering Structured, Multi-modal Clinical Guidelines via Cell Phones

Jose F. Florez-Arango[a,b], M. Sriram Iyengar[a]

[a]*School of Health Information Sciences, University of Texas Health Science Center at Houston*
[b]*School of Medicine, Universidad de Antioquia, Medellin - Colombia*

Abstract

The widespread penetration of cellular (mobile) telephones worldwide, along with their increasing power and sophistication as computing devices, makes them an attractive telehealth platform. Cellphone-GuideView is a technology designed to deliver multi-modal clinical guidelines on cell phones. The system is intended to assist non-physician healthcare providers by presenting diagnosis and treatment advice in a simple discourse structure. The advice is augmented simultaneously by images, animations/video, text, and voice instructions. The contents of the guideline are stored primarily on the cell phone. If the guideline determines that a medical situation requires expert advice, the system automatically calls a remote physician or treatment facility. Cellphone-GuideView represents a model of telehealth in which synchronous assistance of experts is requested only when needed, thus decreasing costs and enhancing productivity.

Keywords:

practice guidelines, cellular phone, multimedia, telemedicine

Introduction

Low physician density is endemic in developing countries, as well as in rural/remote areas of developed nations[1]. In these situations, non-physician care providers (NPCPs) are often the primary providers of medical care to a large segment of the population. Such individuals typically have uneven levels of clinical training and thus the care they provide often falls short of medical standards. While strict adherence to clinical guidelines can help alleviate the problem, clinical guidelines are typically designed for physicians and presented in text form (see www.guidelines.gov, and are often beyond the understanding of NPCPs..

GuideView was designed to overcome these issues and enforce standardization of care. It has two main components: GuideView Author and GuideView Viewer. GuideView Viewer delivers the guidelines in a rich and easy-to-use multi-modal format that includes voiced instructions, text, images, video and animations simultaneously. Each mode compliments the other, resulting in a rich content delivery environment.

GuideView Author enables development of GuideView-compatible guidelines (referred to as *GuideViews*) using a GUI-based authoring environment.. Typically, a team consisting of clinicians and subject-matter experts develops GuideViews. The architecture of the GuideView system enforces clear separation between presentation and content. A benefit of this approach is that content can be integrated in multiple languages. The GuideView Viewer is agnostic to such content variations.

Further details of GuideView can be found in [2],[3]. In the remainder of this paper, we describe the implementation of GuideView on mobile phones.

Mobile phones and healthcare

Currently, worldwide adoption of cellular phones is without precedent in the history of technology. While the number of cellular phone users in developed countries in Western Europe is estimated to be close to 380 million, it is the growth in cell phone usage in developing countries in Latin America, Asia, and Africa that is the most stunning [4]. Growth in the cellular phone market in this regions is around 17%. In India, it is estimated that there are currently (October 2006) 100 million to 125 million cellular phone users and new subscribers sign up at the rate of 3 to 5 million every month [5]. Media reports have documented the innovative ways in which rural and economically disadvantaged populations utilize cellular phones to improve their daily lives [6]. Previous research have noted that digital media tends to benefit already privileged users, but that cell phones can help to close the gap[7]. In Colombia people with income levels below the country's mean represent 72% of those with cellular phones [8]. The number of cellular phone subscribers worldwide is estimated at 2 Billion (32.2% of world population). These subscribers give access to mobile telephony to more than 5 billion people (80.6% of world population) [4].

Competition among cell phone manufacturers and service providers results in constant introduction of new cell phone models with increasingly powerful processors, higher data storage capacities, and higher display resolutions. Cell phones have gone from being purely a communications device, to becoming a sophisticated, powerful, mobile communications-computing device.

A strong motivation for exploring the use of cell phones in health care is that in developing countries care providers are mobile, traveling from village to village. This is due to limited resources in the general population and poor transportation infrastructure. Thus, portability and availability of medical information at the point of care is highly desirable. These are some reasons why cellular phones can potentially contribute to telehealth and health care delivery in general.[9]

Cellular phones have been used to monitor cardiac function for occurrences of arrhythmias that are then transmitted to medical experts[10]; short messages services for data exchange between nurses and patients [11]; traditional on-demand direct voice connection between caregivers and patients [9].

While there is worldwide interest in exploring the use of mobile phones in health care, it appears that delivery of multi-modal clinical guidelines on cell phones, as in C-GuideView, is novel.

Methods

In this paper we present a technology called *C-GuideView* (CGV) that enables delivery of clinical guidelines using cellular phones. While the use of cell phones for data gathering and communications with specialists has been investigated [9-11], to the best of our knowledge, delivering clinical guidelines via cell phones is novel.

Our interest, based on previous work with the GuideView system [2], is to support decision-making and treatment by non-physician care providers (NPCPs) using clinical guidelines presented in an effective, easy-to-use format.

We evaluate different cellular phones platforms and selected one based on price and back compatibility with standard versions of GuideView.

Results

Recently (4th quarter of 2006), several cellular phones based on Windows Mobile, such as the Cingular 3125 and T-Mobile SDA have appeared. These models have the same form-factor as conventional phones and are also significantly cheaper.

CGV targets such cell phones and has been tested on the Cingular 3125. Challenges that had to be overcome were related to the small (albeit high resolution) screen size and the necessity to develop a new navigation paradigm using the cell-phone keypad and soft-keys. Quality of voice, image display, and video playback were found to be comparable from that on PDAs or lap/desktop machines.

As in the case of GuideView, target users of CGV are NPCPs. A notable feature of CGV is that these guidelines are kept locally on the cell phone itself. However, when the guideline determines that the NPCP needs expert help, it automatically dials the pre-stored phone number of a physician, a specialist, or to other expert facility. In contrast to other forms of telehealth that typically require the physician to participate in a voice or video-conferencing session, CGV initiates such synchronous communication only when needed. This feature enables better utilization of all care providers, ensuring that routine care is handled in an appropriate and standardized form locally by the NPCP. Expert assistance from physicians and specialists is called upon only if and when necessary.

Conclusions and future work

Due to their ubiquity and increasing sophistication, even in less developed areas of the world, cell phones have great potential as a powerful medium for Telehealth. The goal of Cell-GuideView is to help realize this potential. The technology is being improved in several directions such as improving screen formatting, voice commands, data compression, documentation of care in a simple EMR, porting to Symbian OS, and others. Usability and field testing studies are also being planned currently.

MEDInfo 2007

Abstract

The University of Texas
Health Science Center at Houston

- Cellular (mobile) telephones are powerful computing and communications devices potentially useful for Telehealth
- Cell phones are cheap and ubiquitous world wide, including in developing countries
- GuideView is a technology designed to deliver structured, interactive multi-modal clinical guidelines to assist non-physician care providers (NPCPs)
- Cellphone-GuideView (C-GV) is an implementation of GuideView on mobile phones
- Cellphone-GuideView supports a model of telehealth in which synchronous assistance of experts is requested only when needed, thus decreasing costs and enhancing productivity.

MEDinfo 2007

Introduction

THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON

- In many areas of the word health care is typically provided by non physician care providers (NPCPs)[1]
  - Includes developing countries such as India, Colombia
  - Also remote and rural areas of developed countries
- These individuals often end up providing non-standard care due to uneven quality of training
- Clinical guidelines, if adhered to strictly, can alleviate this problem and improve quality of care
- However, clinical guidelines are complex and many NPCPs find them difficult to understand and implement

Introduction - 2

- GuideView was designed to overcome these issues and enforce standardization of care.
- GuideView has two main components:
  - GuideView Author
  - GuideView Viewer
- GuideView system enforces clear separation between presentation and content. A benefit of this approach is that content can be integrated in multiple languages.
- GuideView delivers the presents guidelines in a rich and easy-to-use multi-modal format that includes voiced instructions, text, images, video and animations simultaneously. [2,3]

Mobile Phones Worldwide

THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON

- Worldwide adoption of cellular phones is without precedent in the history of technology.
- In Western Europe there are 380 million.[4]
- Cellular phone usage in developing countries in Latin America, Asia, and Africa is growing around 17% per year. [5]
- Media reports have documented the innovative ways in which rural and economically disadvantaged populations utilize cellular phones to improve their daily lives.[6]
- It has been observed that digital media tends to benefit already privileged users, but that cell phones can help to close the gap.[7]
- The mobile phone is rapidly becoming a ubiquitous and portable computing device, in addition to communications capabilities
- For example: In Colombia people with income levels below the country's mean represent 72% of those with cellular phones[8]

MEDinfo 2007

Mobile Phones and Healthcare

THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON

- The number of cellular phone subscribers worldwide is estimated at 2 Billion (32.2% of world population). These subscribers give access to mobile telephony to to more than 5 billion people (80.6% of world population)
- Cellular phones can potentially contribute to telehealth and health care delivery in general:[9]
  - In many countries healthcare providers often travel and approach the needy
    - This happens even in developed countries where NPCPs visit elderly populations in their homes
  - Healthcare is community based.
- Portability, easy communications with specialists, and availability of medical information at the point of care is highly desirable.

MEDInfo 2007

Use of Mobile Phones in Healthcare

THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON

- In healthcare, mobile phones have been used for
  - Data transmission
    - Example: monitor cardiac function for occurrences of arrhythmias that are then transmitted to medical experts.[10]
  - Communication of small snippets of information
    - short messages services for data exchange between nurses and patients.[11]
  - Synchronous voice communication
    - on-demand direct voice connection between caregivers and patients.[9]
- However, the use of cell phones to deliver clinical guidelines appears to be novel.

[g] *Nursing Research Group of Madeira, Portugal*

Abstract

The plethora of emerging technologies provide the impetus to consider a future vision of nursing that maximizes the benefits of technology supported health care for consumers. An international group of nurse informatics leaders at the International Medical Informatics Association – Nursing Informatics Working Group (IMIA-NIWG) Post Congress considered the potential trends in health informatics, with particular regard to technology and health care for the future, looking forward to 2020. The focus is on how technology could be used to provide health care in tomorrow's world and the impact this might have for nursing. Technology use will increase, be everywhere and part of everyday life – technology will be ubiquitous. This will impact significantly on nursing practice and we propose that ubiquitous nursing (u-nursing) will be the future trend.

Keywords:

nursing practice; diffusion of innovation

Introduction

This poster is a representation of the deliberations of an international group of nurses who were charged with contemplating the potential trends in health informatics. Due to the rapid developments in technology and the myriad of possibilities, the group looked forward to the year 2020. We predict that technology use will be ubiquitous and this will impact significantly on nursing practice and the future role of nurses.

Scenario for healthcare in 2020

A consumer with diabetes is discharged from the Clinical Care Facility after bypass surgery with personal sensors in a wristwatch and as most others, they live in a 'smart house'. The wristwatch has near infrared spectroscopy sensors (NIRS) monitoring blood glucose, peripheral arterial oxygen saturation and carbon dioxide, pH, electrolytes, ECG, BP and peripheral temperature. Sensors in chest and leg dressings send messages to the nurse when it is time to change them. The radio frequency identification (RFID) medication cabinet monitors prescribed medication use and need for supplies. The consumer's exercise program and diet for the day is scheduled and appears on screen and the consumer can log onto a chronic disease support / post operative education group Sensor data is forwarded to U-Health Center, processed and any values outside the range are returned to consumer with correctional suggestions. The consumer is supported by a communication system (voice activated - video phone) between home and the nurse at the community-based U-Health Center.

U-Nursing

Extending the current understanding of nursing to u-nursing in 2020 the authors decided on the following definition of U-nursing: "Provision of nursing for anyone or any organization, anytime, anywhere, through any networks and any devices". Further discussion identified many challenges and issues, as well as opportunities for nursing the future.

Nursing in 2020

The nurse of the future will have a key role as info-mediator to facilitate the consumers' use of technology. It is recognized that nursing education as it is currently provided will not adequately prepare the nurse we envisage for the future. Patients are redefined as consumers, as users and partners in health care. We are united in emphasizing that the focus should be on consumers and not the technology. Rather the consumers and health priorities should drive technology development. International trends of the aging population and the increase in chronic diseases indicate that the consumers of the future are likely to be older and many may have chronic diseases. Health services will be

needed to support these consumers. However, an additional important focus will be on health promotion and maintenance to reduce the burden on the health services.

Use of emerging technologies in healthcare: A future vision for u-nursing

Elvio Jesus, *Nursing Research Group of Madeira, Portugal*

Background

- Authors - an international group of nurse informatics leaders at the International Medical Informatics Association – Nursing Informatics Working Group (IMIA-NIWG) Post Congress held in Korea 2006.
- Considered the potential trends in health informatics, with particular regard to technology and health care for the future (2020).
- Focus on how technology could be used to provide health care in tomorrow's world and the impact this might have for nursing.

Our assumptions for 2020

- Technology use will increase, be everywhere and part of everyday life – technology will be ubiquitous.
- This will impact significantly on nursing practice and we propose that ubiquitous nursing (u-nursing) will be the future trend.

U-Nursing

Definition

"Provision of nursing for anyone or any organization, anytime, anywhere, through any networks and any devices".

Trends

- International trends of the aging population and the increase in chronic diseases indicate that the consumers of the future are likely to be older and many may have chronic diseases.
- An additional focus will be on health promotion and maintenance to reduce the burden on the health services.

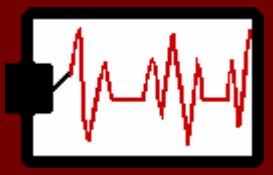
Nursing in 2020

- Patients are redefined as consumers
  - users and partners in health care.

- Nurse as info-mediator
  - facilitates the consumers' use of technology.

Scenario for healthcare in 2020

- A consumer with diabetes is discharged from the Clinical Care Facility after bypass surgery with personal sensors in a wristwatch to their ‘smart house’.
- The wristwatch monitors blood glucose, pH, ECG, BP, peripheral arterial oxygen saturation, carbon dioxide, electrolytes, and peripheral temperature.
- The radio frequency identification (RFID) medication cabinet monitors prescribed medication use and need for supplies.



Community based U-Health Centre

- Sensors in chest and leg dressings send messages to the nurse when it is time to change them.
- Sensor data is processed and any values outside the range are returned to consumer with correctional suggestions.
- Nurse can see data and is sent alerts.

Supported in their ‘smart house’

- Consumer’s daily exercise program and diet appears on screen.
- The consumer can log onto a chronic disease support / post operative education group.
- Consumer supported by a communication system (voice activated - video phone) between home and nurse at U-Health Center.

Issues

- Current nursing education will not adequately prepare the nurse we envisage for the future.
- Focus should be on consumers and not the technology.
- Consumers and health priorities should drive technology development.

Application of Wireless and Mobile Computing Technologies to Improve the Efficiency of Patient Care and Education: The Role of Medical Engineering and Information Technology

Lin Guo[a]

Centre for Adult and Paediatric Gastroenterology, Institute of Cell and Molecular Science, Queen Mary's School of Medicine and Dentistry Barts and The London, , Queen Mary, University of London, UK.

Abstract

This study explored the potential of the application of wireless and mobile computing technologies to be used in improving the efficiency of patient care and education and future developments in information and communication technologies to support healthcare professionals and medical students in healthcare research, medical education and training. The design used for this study was a systematic review of published materials obtained from EMBASE and MEDLINE online databases, and the Cochrane Library database, including personal observations. Today, more than 50% of healthcare professionals and medical students are using Personal Digital Assistant with expected growth of more than 75% by year-end 2007. In addition, wireless and mobile computing technologies allows Personal Digital Assistant to connect directly to networks or the Internet. Studies relating to processes of patient care and should evaluate mobile computing technologies as a potential timesaving tool. Wireless and mobile computing technologies is only beginning to take its first step in improving patient care and education. They have shown a positive impact on patient safety, health care efficiency, and ultimately patient satisfaction.

Keywords:

wireless and mobile computing technologies, patient care and education, efficiency, personal digital assistant

Introduction

Wireless is a term used to describe telecommunications in which electromagnetic waves (rather than some form of wire) carry the signal over part or all of the communication path.[1] Mobile Computing is a generic term describing your ability to use technology 'untethered', that is not physically connected, or in remote or mobile (non static) environments.[2] The term of wireless and mobile computing technologies is evolved in modern usage such that it requires that the mobile computing activity be connected wirelessly to/through the application of internet or to/through a private network. This connection ties the mobile device to centrally located information and/or application software through the use of battery powered, portable, and wireless computing and communication devices.[1, 2] This includes devices like laptops with wireless LAN or wireless WAN technology, smart mobile phones, wearable computers and Personal Digital Assistants (PDAs) with Bluetooth or IRDA interfaces.

This study explored the potential of the application of wireless and mobile computing technologies to be used in improving the efficiency of patient care and education and future developments in information and communication technologies to support healthcare professionals and medical students in healthcare research, medical education and training.

Design and methods

The design used for this study was a systematic review of published materials obtained from EMBASE and MEDLINE online databases, and the *Cochrane Library* database, including personal observations. Materials that match the set criteria on the application of wireless and mobile computing technologies in medical engineering and information technology research for healthcare professionals and medical students to improve the efficiency of patient care and education were selected and analysed following the United Kingdom National Health Service Centre for Reviews and Dissemination Guidelines. A variety of data collection approaches were developed to ensure data were collected on the various aspects.

Results

Wireless and mobile computing technologies is seen to be convenient to get in touch, compact, fast and portable, but problems are attached to the levels of security, confidentiality and scalability of the hardware. It is also apparent that most commonly used wireless and mobile computing technologies within the health contexts is the Personal Digital Assistant. Today, more than 50% of healthcare professionals and medical students are using Personal Digital Assistant with expected growth of more than 75% by year-end 2007.[3] Not only can the healthcare professionals and medical students use the tool on the Personal Digital Assistant as a quick look-up resource at the bedside, but

can also flag a topic for further research when back in the office. Changes in treatment guidelines, concerns about patient safety, efforts to contain costs, time limitations, and better informed patients make it critical to have clinical reference information at the point of patient care and education.[4] In addition, wireless and mobile computing technologies allows Personal Digital Assistant to connect directly to networks or the Internet.

Discussion

According to the results of this systematic review of this study, wireless and mobile computing technologies has become a valuable resource for both healthcare professionals and medical students over the past decade. This has enabled new perspectives to be developed on the interface between hardware, software and education and training processes for those involved in delivering healthcare research. Studies relating to processes of patient care and should evaluate wireless and mobile computing technologies as a potential timesaving tool, as they can be synchronised with hospital information systems to facilitate retrieval of patient information. The findings also indicate that the healthcare professionals and medical students would benefit from some technologies that they can easily use to search for such sources as database, E-journals and the Internet. At a theoretical level, wireless and mobile computing technologies such as Personal Digital Assistant is ideal for meeting these needs. Further study on processes of patient care and education should also explore wireless and mobile computing technologies as vehicles for disseminating evidence-based guideline recommendations.

Conclusion

Wireless and mobile computing technologies is only beginning to take its first step in improving patient care and education. They have shown a positive impact on patient safety, health care efficiency, and ultimately patient satisfaction. The integration of the Internet and wireless and mobile solutions will transform the use of information and communication technologies in patient care and education and take it in the role of medical engineering and information technology. The potential of wireless and mobile computing technologies is vast and its principles, application and practices are seen as a choice for healthcare professionals and medical students to be in the right place at the right time. In the future we will see more valuable resources in improving patient care and by developing wireless and mobile computing technologies.

Evaluation of Wireless Teleradiology System for Emergency Care with Mobile Network

Keon Ho Yang[a,c], Bong Mun Jang[a,c], Sun K. Yoo[a,b,c]

[a]Brain Korea 21 Project for Medical Science, Yonsei University College of Medicine, Korea
[b]Dept. of Medical Engineering, Yonsei University College of Medicine, Korea
[c]Development Center of Emergency Medical Informatics (CEMI), Yonsei University, Korea

Abstract and objective

The wireless mobile service with a high bit rate using CDMA-1X EVDO is now widely used in Korea. Mobile devices are also increasingly being used as the conventional communication mechanism. In this study, we have developed JPEG 2000 compression module. We have also developed a web-based mobile system that communicates patient images using CDMA-1X EVDO for emergency care. A wireless mobile emergency patient imaging communication system is developed by using Microsoft Visual Studio.NET, and JPEG 2000 ActiveX control for PDA phone was developed by using the Microsoft Embedded Visual C++. Also, the CDMA-1X EVDO is used for connections between mobile web server and the PDA phone, and between ambulance car and hospital. In particular, images were compressed into a JPEG2000 format and transmitted from the hospital to the radiologist using a PDA phone located outside of the hospital. We successfully demonstrated this system for moving using an RW-6100 PDA phone used in the Yonsei university medical center in Korea.

Keywords :

PDA phone, JPEG2000, CDMA-1x EVDO, emergency care

Methods

A system development environment

The develop environment for mobile imaging communication system was composed a mobile web application system by using a Microsoft Window 2003 server, and internet information service and it is developed by using the Microsoft Visual Studio.NET, and the JPEG 2000 ActiveX control for a PDA phone was developed by using Microsoft Embedded Visual C++. In this study, we used a CDMA-1X EVDO service provided by the KTF communication firm in Korea. The CDMA-1X EVDO transmits data by using a maximum forward bandwidth of 2.46 Mbps and this is used for connection between a mobile web server and a PDA phone.

Composition of the whole system

Considering three spaces of the ambulance car, the hospital to where the emergency patient will be evacuated, and outside, we composed the whole system layout. Emergency patient images which are acquired using the portable imaging acquisition modality are sent in advance to the hospital where the emergency patient will be taken so the emergency doctor in the hospital can quickly receive and confirm transmitted information. CDMA-1X EVDO is also used for mobile communication. Also, it will be possible to refer to received information in the hospital where the emergency patient is taken, using a PDA phone anytime, anywhere.

System evaluation properties

In this study, we evaluated two items using wireless mobile imaging communication system. First, when we refer to JPEG 2000 images using a PDA phone, display time is measured. Second, PSNR values are measured by peak signal-to-noise ratio (PSNR) measurement function in order to compare image quality between the original image and the JPEG 2000 compressed image. In order to evaluate two items, various brain CT images (530KB, 512x512, 16bit) are used. And, PSNR values are measured in proportion to the increase of the JPEG 2000 compression ratio.

Results

The compression of 10:1 is a clinically reasonable maximum compression ratio for emergency care according PSNR measurement in this study. Also, JPEG2000 images of 10:1 compression ratio are transmitted approximately 0.08s from hospital to PDA Phone for moving using CDMA-1X EVDO.

Ratio	File Size	Theoretical Trans. Time (s)	Actual Trans. Time (s)
Original	543kB	1.78s (at 2.4Mbps)	5.43±1.22s
5:1	36.4kB	0.11s (at 2.4Mbps)	1.93±0.22s
10:1	24.1kB	0.08s (at 2.4Mbps)	0.65±0.07s
30:1	12.9kB	0.04s (at 2.4Mbps)	0.44±0.03s
40:1	9.87kB	0.03s (at 2.4Mbps)	0.22±0.02s
50:1	7.59kB	0.02s (at 2.4Mbps)	0.19±0.02s
100:1	4.45kB	0.01s (at 2.4Mbps)	0.14±0.02s

Table 1 - The result of average transmission time of various compression ratios from hospital to portable mobile device – brain CT image (attempt number = 30)

Conclusion

The results of this study are expected to play an interface role between the mobile emergency medical system and ubiquitous healthcare.

MedInfo 2007

Introduction

❖ Background

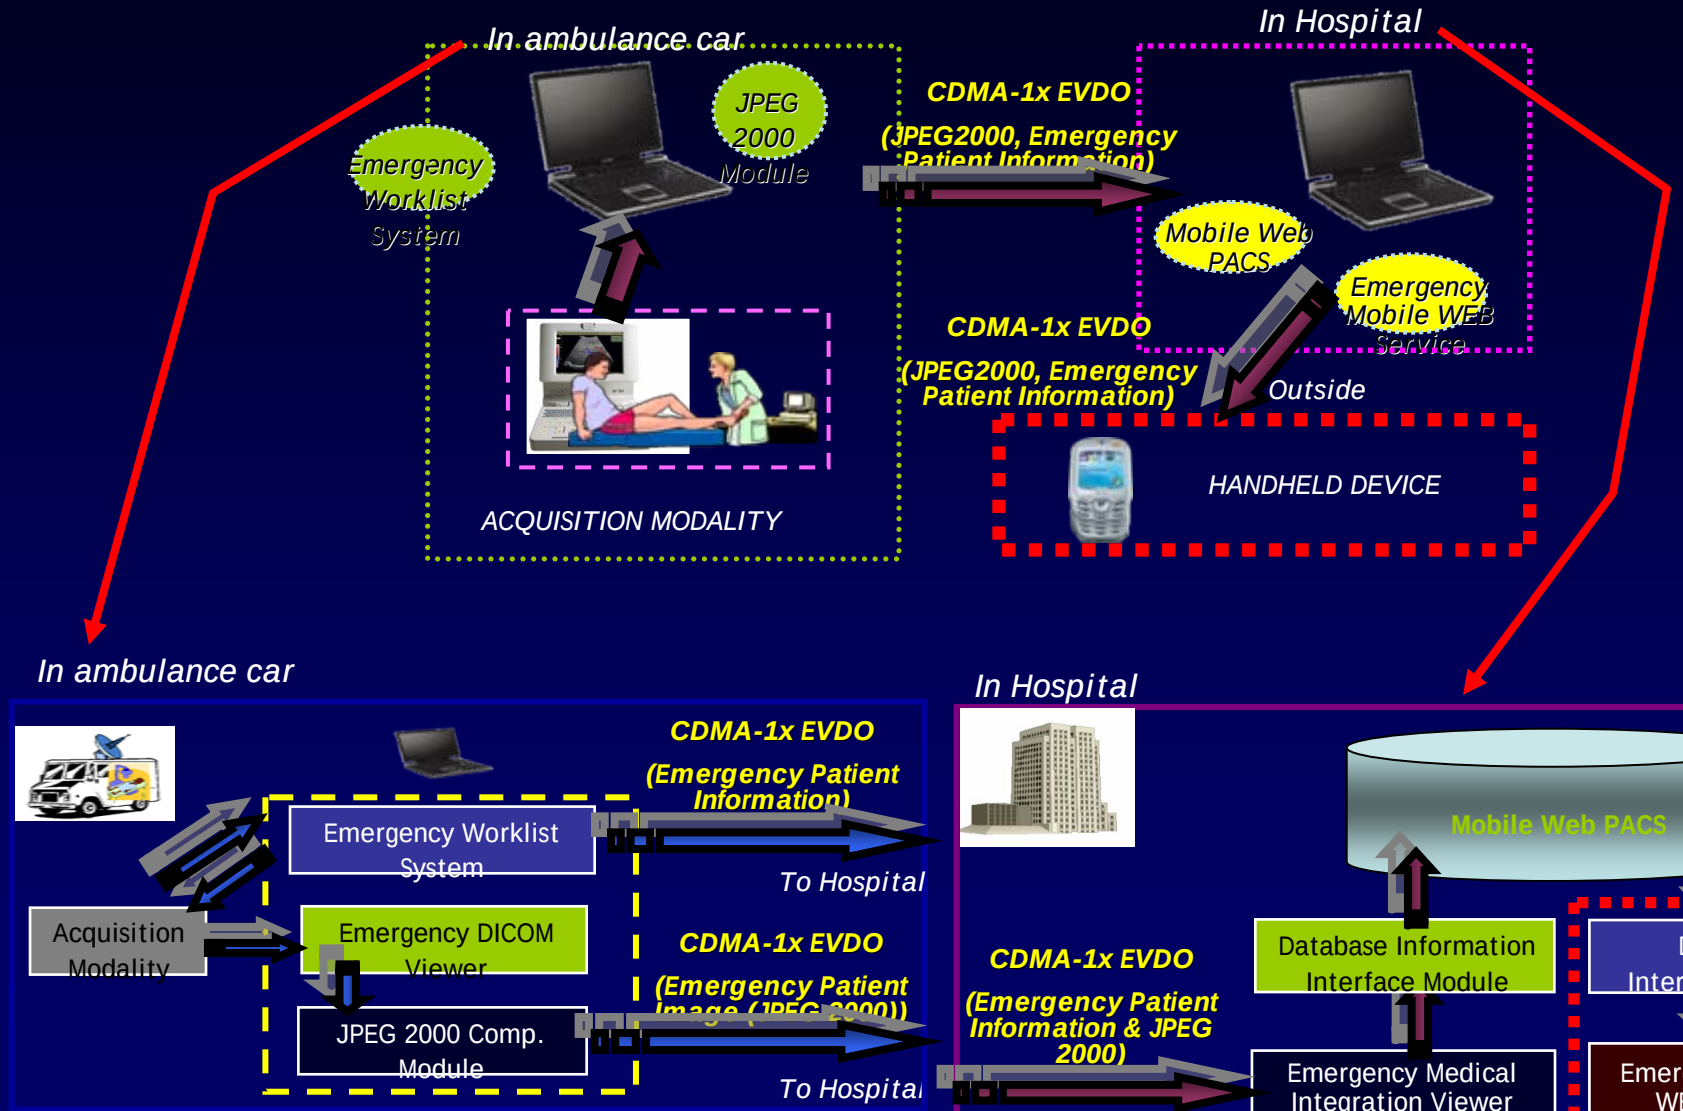
- Recently, study about Emergency Medical Information System is actively in progress to improve quality of Emergency Medical diagnosis.
- Study about Installation of Portable acquisition modality in ambulance car is also in progress.
- Although, the exact and rapid consultation from medical specialist is necessary to further treatment… especially for emergency surgery..
- If the specialist is in outside of hospital in that time, → Can not perform next treatment process!!
- If using wireless LAN based PDA, it is impossible to read the images where access point (AP) is not exist.
- Recently, the technique and infrastructure of commercial wireless network such as CDMA-1x EVDO have been dramatically promoted.

❖ Objective

- In this study, we designed a wireless mobile emergency patient information and imaging communication system using CDMA-1x EVDO service based personal digital assistant (PDA) phone for emergency care.
- And we evaluated the performance of this system which is a Wireless Teleradiology System for Emergency Care with Mobile Network

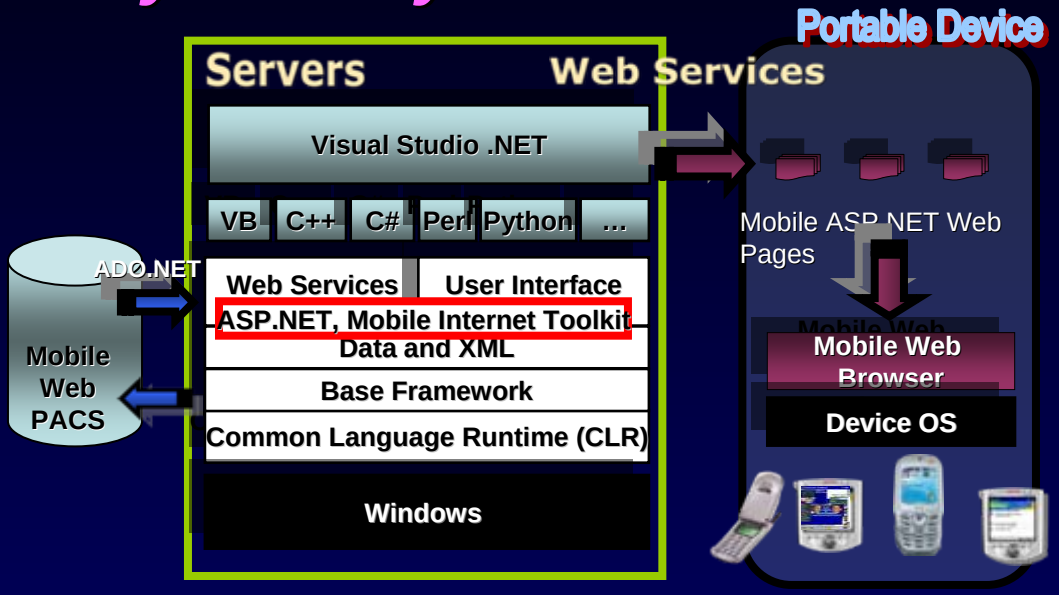
Materials and Methods

❖ System Layout



Materials and Methods

❖ System Layout



❖ Material

❖ Development Environment

Emergency Worklist System
- ❖ *Microsoft Visual C++ 6.0 (Microsoft, USA)*

JPEG2000 Compression Module & Emergency Info. Viewer :
- ❖ *Microsoft Visual C++ 6.0 (Microsoft, USA)*
- ❖ *Lead tool JPEG2000 SDK (Lead tool Corporation, USA)*

Mobile Web PACS:
- ❖ *Microsoft Access 2003 (Microsoft, USA)*

Mobile Web Service Module:
- ❖ *Microsoft Visual Studio .NET 2003 (Microsoft, USA)*
- ❖ *Embedded Visual C++ 4.0 (Microsoft, USA)*
- ❖ *Microsoft Window 2003 Server (Microsoft, USA)*

RW6100, LG Electronics, Korea
- *Intel Bulverde PXA270 520 MHz Processor*
- *Windows Mobile 2003 SE (Second Edition)*
- *128M Intel State Flash ROM*
- *240 x 320 pixels*

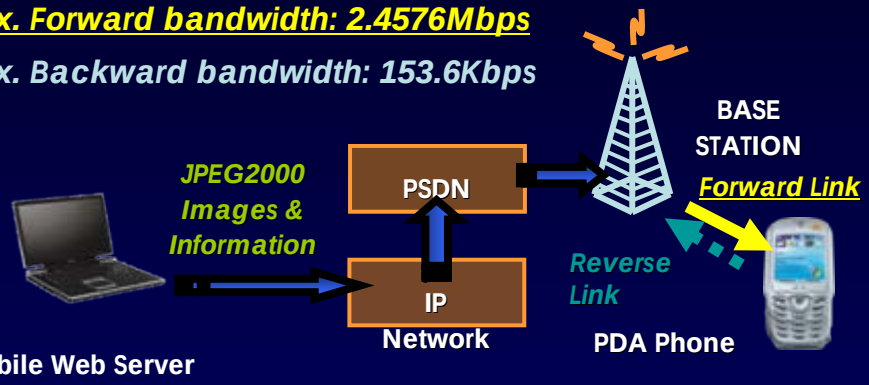
- *Support both Wireless local area network (WLAN) and CDMA 1x EVDO service*

Materials and Methods

❖ Forward Link vs. Reverse Link

CDMA2000 1x EVDO has asymmetric data rate structure.

- ***Max. Forward bandwidth: 2.4576Mbps***
- *Max. Backward bandwidth: 153.6Kbps*



❖ System Evaluation

Transmission Time Measurement

- *for evaluation about medical image application in the Mobile Network*
- *from emergency car and hospital*
- *from hospital and outside*
- *using X-Note Express LW20-EV3MK (CDMA -1x EVDO Support)*

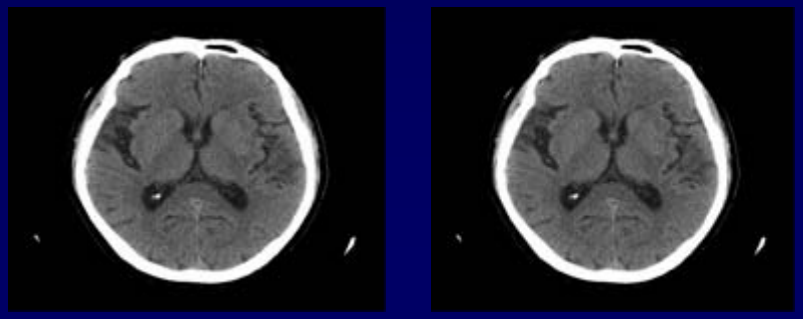
❖ System Evaluation

- *Transmission time of JPEG 2000 image on the PDA phone was measured using our system outside hospital.*
- *PSNR measurement according to JPEG2000 Compression Ratio of Medical image Compression*
- *Evaluation of Medical Image Compression*

❖ System Evaluation

PSNR (Peak Signal to Noise Rate)

- *for evaluation image usability according to compression ratio using mathematical factor*
- *Using PSNR measurement function which is included in Aware Image Compression Factor Measurement System*



Original image : JPEG2000 Image

Materials and Methods

❖ System Evaluation

Test Images were selected..

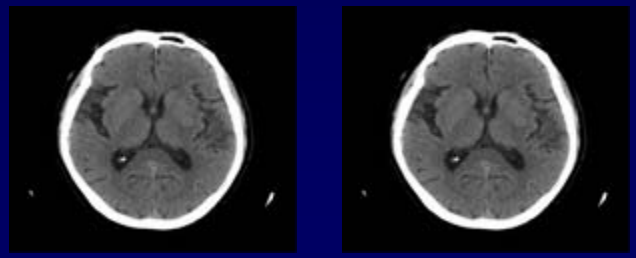
- *For measurement of PSNR*
- *brain axial and sagital CT Images (512x512 -16bit)*

Compression Ratio was.. (for each image)

- *5:1, 10:1, 15:1, 20:1, 25:1, 30:1, 35:1, 40:1, 45:1, 50:1 and 100:1*

Evaluation of Medical Image Compression

- *using both DICOM image and JPEG2000 image (according to Compression Ratio)*
- *brain CT image (512x512, 16bit) – 12 case study(360 images)*
- *Desktop Environment vs UMPC, PDA Phone*



Original image : JPEG2000 Image

❖ System Evaluation

Evaluation Method of Medical Image Compression

- *Implementation Alberta Stroke Program Early CT Score (ASPECT) Test to evaluate medical image diagnosis possibility (Random)*
- *One radiologist*
- *Wilcoxon signed rank test – Statistic Process Method*

Evaluation of Medical Image Compression

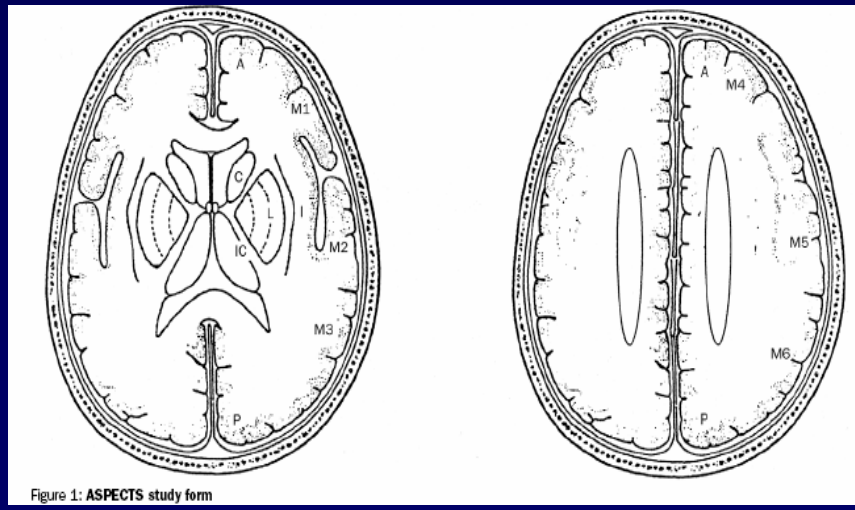


Figure 1: **ASPECTS** study form

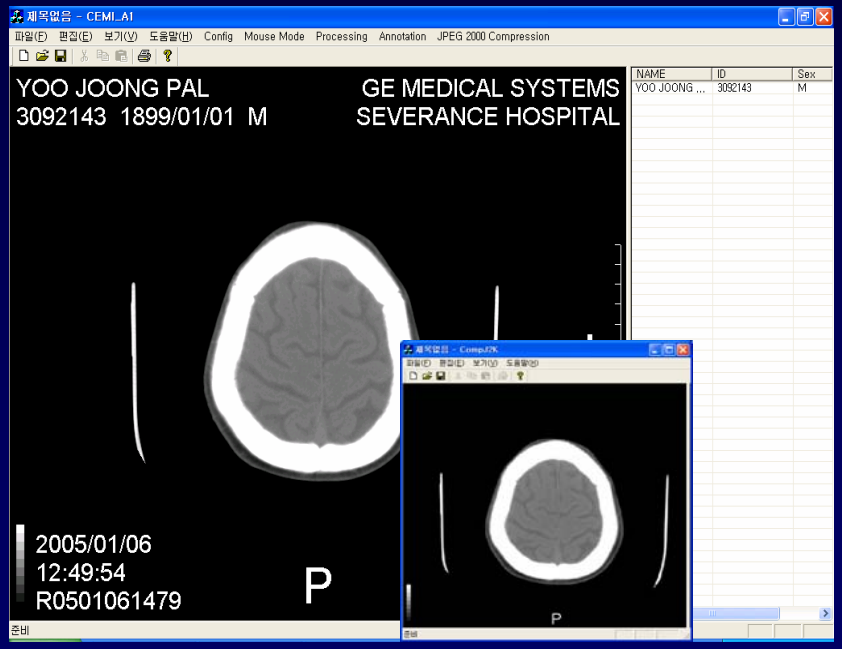
Results

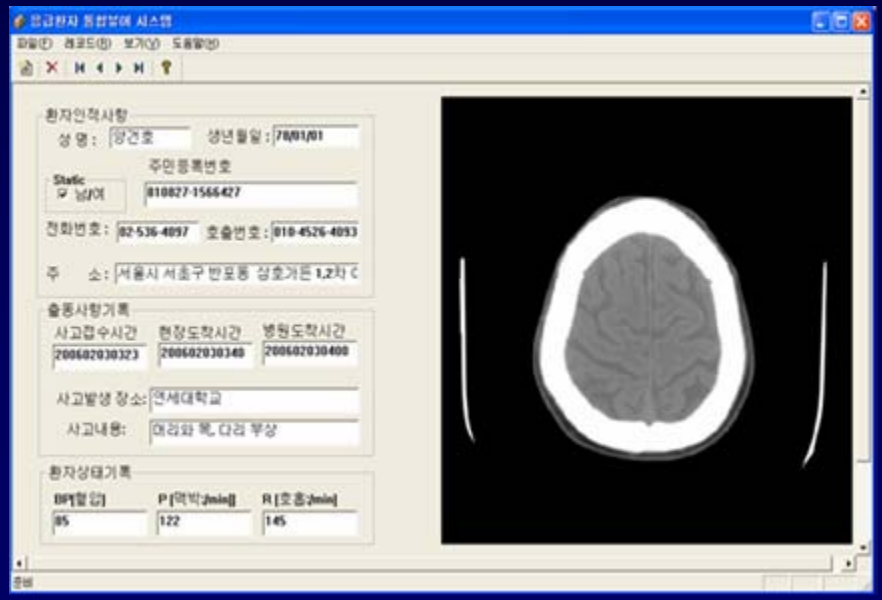
❖ JPEG2000 Transmission Module

- Compress DICOM images from acquisition modality to JPEG2000 files and Send JPEG 2000 Image to the hospital



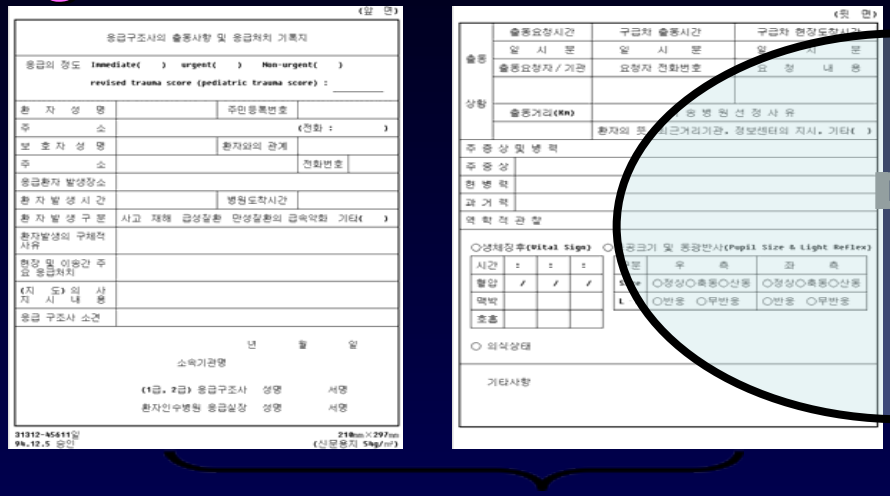
❖ Emergency Medical Integration Viewer

- View Emergency Patient Information and JPEG 2000 Image
- Storing Emergency Patient Information & JPEG 2000 image to Mobile Web PACS of the hospital

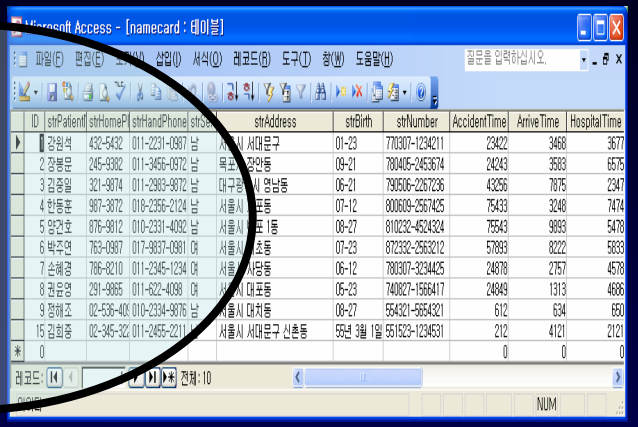


Results

❖ Design of Mobile Web PACS

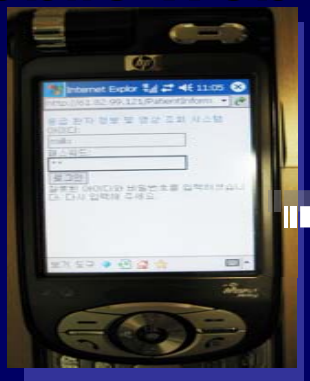


Structure of Emergency Patient Information



Design of Database using Access

❖ EM Mobile Web Service using PDA Phone



Login Process

The ASPECT test result of 10:1 compression image

Discussion

- *In this study, we evaluated two items using wireless mobile imaging communication system. First, when we refer to JPEG 2000 images using a PDA phone, display time is measured. Second, PSNR values are measured by peak signal-to-noise ratio (PSNR) measurement function in order to compare image quality between the original image and the JPEG 2000 compressed image. In order to evaluate two items, various brain CT images (530KB, 512x512, 16bit) are used. And, PSNR values are measured in proportion to the increase of the JPEG 2000 compression ratio.*

- *The compression of 10:1 is a clinically reasonable maximum compression ratio for emergency care according PSNR measurement in this study. Also, JPEG2000 images of 10:1 compression ratio are transmitted approximately 0.65s from hospital to PDA Phone for moving using CDMA-1X EVDO.*

Conclusion

- *The results of this study are expected to play an interface role between the mobile emergency medical system and ubiquitous healthcare.*

Abstract and objective

In order to monitor the variation of body temperature from multi-patient in real-time in the hospital room based on body sensor network (BSN), a miniaturized wireless telemetry module based on PAN was designed and implemented in this paper. The transmitting part of telemetry system consists of a temperature sensor, a miniaturized UHF transmitter with a transmitting antenna, a microprocessor for data encoding, and a battery. The diameter and thickness of implemented transmitter are 20 mm and 3 mm respectively. The receiving part consists of a receiving antenna, a RF receiver, and a processor for data decoding, and the decoded data was transformed to RS232C format to be transferred to computer. From the experimental result in the simulation environment that resembles a hospital room, the implemented telemetry module was verified to operate well with sufficient reliability.

Keywords[1]:
telemedicine, physiologic monitoring, medical electronic

Introduction

The wireless sensor network is becoming a significant enabling technology for a wide variety of applications. The rationale behind the distributed sensor network is for detecting, identifying, localizing, monitoring, or tracking one or more subjects of interest. One of its potential deployments is in the form of body sensor network (BSN) for measuring physiological parameters. The aim of having a ubiquitous monitoring environment for wearable sensors is to provide continuous management of patients under their natural physiological states so that transient but life threatening abnormalities can be detected and predicted.

The wireless telemetry system at the environment of wearable computing system must be small and have sufficient bandwidth for transmission of various biomedical signals. In this paper, a miniaturized telemetry module was designed and implemented based on personal area network, which uses a wireless RF transmission at ultra high frequency.

Methods

The wireless communication system for wearable computing needs miniaturized device size and wide band width that is possible to transmit various bio signals. In this paper, the UHF (ultra high frequency) bio signal telemetry module which based on the PAN (personal area network) is designed and implemented.

The designed system consists of a signal pre-processor which includes an A/D convertor, digital encoder which prevents a noise and divides a communication channel, a RF transmitter, an antenna, and a crystal oscillator. The designed receiving system includes a receiving antenna, a RF amplifier, signal post-processor which consists of the decoder and demodulator, and an interface circuit. The biomedical signal which is divided with each channel and restored to original data, is changed to the RS-232 format and transmitted to the computer.

The μ-processor C8051F330 (Silicon Labs, USA) was used as the pre-processor for A/D converting and encoding of analog data. This μ-processor consists of a 10-bit ADC, several digital I/O ports, and a high speed control core. The control core supports the CPU, flash memory, SRAM, and interrupt controller. The speed of CPU is 25 MIPS at the 25MHz clock, and the power consumption is 6 mA at the range from 2.7 to 3.6 volt.

The biomedical signal pre-processed in analog part is converted to the suitable stream for digital transmission in the digital I/O part, and the transmission rate is controlled by the controller core. All data steam was converted to 100 kbps because the maximum transmission bandwidth of implemented transmitter was 100 kbps.

In this paper, the target signal for wireless transmission was the variation of body temperature. The temperature data are accumulated to the register in the u-controller without a parity and garbage bit. 12 bit temperature data is accumulated to the register during 10 times. It is added to 4 bit address data, so whole stream for transmission at a time is 124 bit. If the various signals or many patients' data

1 * This work was supported by the grant No. RTI04-01-01 from the Regional Technology Innovation Program of the Ministry of Commerce, Industry and Energy(MOICE).

has to be transmitted simultaneously, each of signals can be distinguished by the address, which can be extended by simple programming. The sleep mode guarantees the lower power consumption of whole system, and this sleep time can be controlled by programming.

The whole data stream is encoded by the Manchester encoding method, which has the clock information, so the synchronization of transmitted data in the receiver is easy to be implemented. The RF transmitter consist of a MAX7044 (Maxim, USA), a crystal oscillator, and some passive elements. The MAX7044, which is a crystal-referenced phase-locked-loop (PLL) VHF/UHF transmitter, is designed to transmit OOK/ASK data in the frequency range from 300 to 450 MHz. The transmitter circuit was consisted to support the transmission rate of 100 kbps, with was designed in considerations of channel extension and increasing resolution. The RF transmission power was set up to minimize and distance guarantee is 5 m radius.

The receiver was designed and implemented using a MAX1473 (Maxim, USA). The minimum sensitivity of receiver was 109.3 dB at the 433.92 MHz. The block diagram of implemented receiver is illustrated in figure 5. The RF signal which is received in the antenna is amplified and controlled by low noise amplifier (LNA) and auto gain control (AGC). The amplified signal is mixed with the signal from the local oscillator. The mixed signal is changed to the digital data by a data slice circuit, and the sliced data is sampled with over sampling method by μ-controller. Then, the μ-controller decodes the Manchester-encoded data and distinguishes it to the address and temperature data. The decoded data is transmitted to PC using the RS-232 cable.

Results

From the designed circuits and algorithms for signal processing, a miniaturized transmitter which can be attached to human skin and a portable receiver was implemented respectively. The whole elements were placed on a top layer because the bottom side of the PCB was stock to the human skin. The diameter and thickness of implemented transmitter was 20 mm and 4 mm respectively. The implemented receiver using a Max1473 chip was illustrated in Figure 7, and the width, height, and thickness was 20 mm, 25 mm, and 12 mm respectively.

The wireless communication experiments were performed using the implemented system in laboratory environment, where has the same conditions as a hospital room. In the experiments, the transmitted temperature signal from the miniaturized transmitter was received in the RF receiver and restored to original data. This data was transmitted to PC using RS-232c interface and displayed on the monitor. The experiments for verification of implemented system were performed as following methods respectively;

(a)Leaving alone the transmitter module for wireless measurement of room temperature.
(b)Gripping the transmitter module on the hand for measurement of hand temperature.
(c)Blowing breath to the transmitter module for measuring the steam of breath.

From all experimental result in the environment that resembles a hospital room, the implemented telemetry system was verified to operate well with sufficient reliability. The system response of temperature variation was in real-time and the displayed waveform reflected well the variation of temperature.

Results

A miniaturized telemetry system that can simultaneously measure the variation of patients' body temperature was designed and implemented. The miniaturized transmitter and receiver were implemented respectively and the stable operation was confirmed from all experiments, which was performed in the environment similar to the hospital room. The implemented telemetry is expected to be useful solution for the ubiquitous technology in the field of non-intrusive measuring from the human body.

Abstract

Ubiquitous communication technologies are transforming medical practice. In these technologies, especially RFID or small sensor networks can provide information about medical practices and patient status in real time and therefore improve the quality of medical care. We developed a new system named "smart stretcher" which is continuously monitoring patient's vital signs during transfers within the hospital. This system consists of a small air-mat type pressure sensor measuring both heart and respiration rate and a wireless network transmitting these vital data as well as patient ID to the alert system to notify patient's emergency. Also we added function of location detection to the smart stretcher by using a wireless sensor network. We conducted experiments in the clinical settings. It was found that this system showed reliable performances in continuous respiration monitoring and detection of apnea during patient's transfer on this stretcher, suggesting its high feasibility for real clinical usage.

Keywords:

medical errors, safety of medical care, wireless network

Introduction

Ubiquitous communication technologies are transforming medical practice. Conventional hospital information systems have not been yet been able to make use of all information that can be collected with simple sensors. RFID or small sensor networks can provide information about medical practices and patient status and therefore improve the quality of medical care. As an example of this application, we developed a new system named "smart stretcher" which continuously monitors patient's vital signs during transfers within the hospital. This monitoring system consists of air-mat type supersensitive pressure sensor measuring heart rates and respiration rates and an ad hoc wireless communication network ZigBee that transmits these vital data to the hospital LAN and to an alert system to notify patient's emergency immediately when it happens. Patient ID read from the RFID wristband is transmitted to prevent misidentification of the patients. Also we addedÅ@a function of location detection to the smart stretcher by using a wireless sensor network.

We conducted experiments to estimate the feasibility of this wireless monitoring system in real clinical situation to examine whether it can detect apnea of the patient reliably during patient's transfer within the hospital.

Methods

To realize the smart stretcher, we equipped three kinds of measurement devices with the stretcher: one is the measurement system for the vital signs such as heart rates and respiration rates, the second is the system for automatic patient ID recognition and the last is the detection system for patient location within the hospital.

These kinds of information are transmitted by ZigBee wireless network.

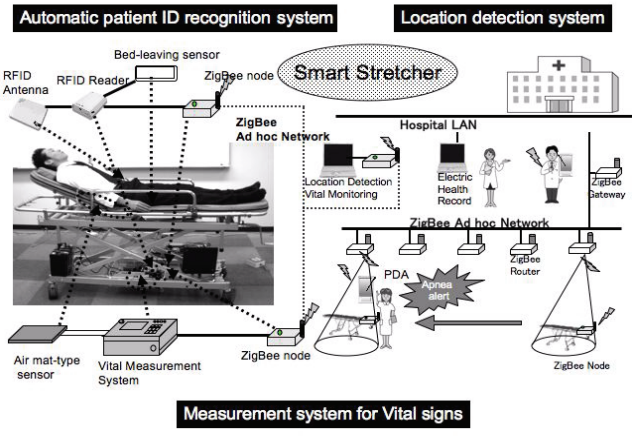

Figure 1- Smart stretcher system

These measurement systems work together to monitor the patient physiological status and give a warning against patient emergency such as apnea and transmit this

emergency information to the alert system in the ward (Fig. 1).

We conducted the feasibility experiment of the smart stretcher in the real clinical setting. In the experiment, three experimental subjects, two males and one female, were taking the role of the patients transferred on the stretcher who wore the RFID wristband on their left hands and were asked to stop respiration for 7 seconds during their transfer in the hospital.

First, the readability of wristband patient ID was examined. The readable distance in which patient wristband ID can be recognized by the RFID reader equipped on the left side surface of stretcher was measured. Secondly, the experimental subject was transported on the stretcher for fifteen meters in one minute, and was asked to stop breathing intentionally in the mean time to investigate whether the monitoring system would detect the apnea in spite of the stretcher movement and emitting the warning signal. This experiment was repeated with three subjects.

Results

Readability of patient ID

In almost all cases, the RFID was recognized within 15 seconds after the reader started reading and patient ID was displayed on the monitoring screen in real time. Readable distances were increased in proportion to the size of a tag. The difference of readable distance between the patient postures of a face-up position and a semi-sitting position was not found. In the case we set the RFID reader antenna under the stretcher mat, RFID was difficult to read, whereas in the case an antenna is setting in left side, RFID was able to well read. RFID was most reliably to read, when the patient's hand wearing RFID wristband is straight along with the edge line of the stretcher, whereas RFID was rather difficult to read if the direction of the hand is other direction.

Measurement of vital signs and detection of apnea

The three subjects were reliably measured for their respiration rate during their transfer. Figure 2 shows an example of experimental results of respiration waveforms. We can see from this figure that apnea was detected for about 10 seconds. Apnea was detected in all subjects. In contrary to the respiration rate, it was difficult to reliably detect the heart rate during the movement of the stretcher. Through the ZigBee wireless network, the patient's name, respiration rates and heart rates were correctly displayed on the PDA screen. The apnea warning alert and the warning screen in PDA were displayed mostly in real time. As the conclusion it was found that the aimed functions of the smart stretcher work in good performance.

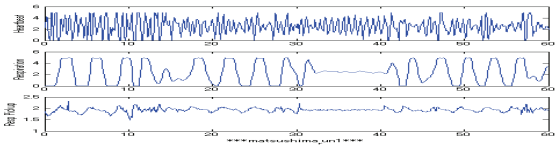

Figure 2 – Result of respiration waveform

Location detection of the Smart Stretcher

We detected the location of the smart stretcher within the hospital by location detection system using ZigBee ad hoc network. For the experimental settings, we installed five ZigBee routers and one gateway configured at even intervals onto the ceiling of the hospital corridor. Two members of hospital staffs carried the experimental subject on the smart stretcher in the hospital corridor for eighty meters. We monitored the patient location in the display by floor map in the terminal connected to the ZigBee network. The location detection system showed good performance providing the correct location in real time (Shown in fig.3). Serious errors and delays in the display of the detected location were not observed in this location detection experiment.

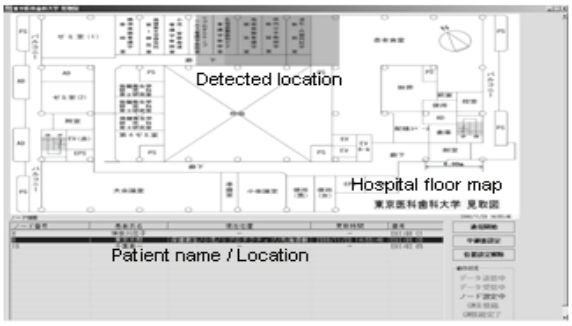

Figure 3 –The floor map of detecting Location

Discussion

From these primary results, the patients' vital signs, patient IDs and locations could be obtained in real time during a patient's transfer on the smart stretcher. By utilizing of the three kinds of information, the smart stretcher may be able to contribute to medical safety in the clinical settings.

However, the measurement precision in this system is sometimes sensitive to the various environmental factors. We should investigate the factors that influence the precision of the measurements in details to improve precision in recognition of RFID and in monitoring of vital signs. A further direction of this study will be to apply these basic technologies for medical use in a wheel chair or bedside care in home health environments.

Conclusion

This system was able to show the feasibility of the medical malpractice preventive measures by ubiquitous technology. This study is another step towards the ultimate goal to realize a smart medical space with security and safety.

Abstract

Since pressure ulcers remain a major health issue in individuals with spinal cord injuries, a new medical device is being developed. Based on the principle of sensory substitution, it aims at compensating the sensory deprivation in the buttock area by the tactile sensory modality in the tongue area. This paper concisely describes the last homemade medical device and reports the first methodological steps of a sustainability study: an open pilot prospective clinical study in 10 healthy seated subjects with 92% success in 100 performed tests; a current open randomized prospective controlled clinical trial with the methodology used.

Keywords:

medical device, evaluation studies, sensory substitution, paraplegia, deprivation

Introduction

The prevalence of pressure ulcers ranges from 23% to 39% in adults with spinal cord injuries and remains high in this population. Pressure ulcers are recognized as the main cause of rehospitalization for adults with paraplegia. Their treatment is always long difficult and expensive. This pathology appears thus to be a major health issue for this population.

The concept of sensory substitution has its origins in the works of P. Bach-y-Rita for blind people. To demonstrate his statement "we do not see with the eyes but with the brain" - the visual image does not go beyond the retina, but is turned into patterns of pulses along nerves and is carried to the brain - a human-machine interface, the Tongue Display Unit (TDU), was developed. It consists in an array of electrodes put in contact with the tongue surface. Visual information is then transmitted from the digitalized signal of a TV camera to this array of electrical stimulator which transmits information to the brain. Evidential results were obtained, as, for instance, the capacity of executing complex "eye-hand" coordination tasks.

Our research aims at particularizing works of P. Bach-Y-Rita for blind people to paraplegics by compensating the sensory deprivation in the buttock area through the tactile sensory modality in the tongue area. This compensation would indeed enable paraplegics to feel again "information" arising from the buttock area, from which they could adopt suitable movement in order to prevent the formation of pressure ulcer in this area.

Materials and method

A new medical device has been developed to compensate for sensory loss in paraplegics in the buttock area. It consists of three components: a ***pressure mapping system***, the **T**ongue **D**isplay **U**nit (***TDU***), and a ***laptop***.

The ***pressure mapping system***, built by the Vista Medical® Company, connected with the laptop, enables the real-time acquisition of the pressure applied on the seat/skin interface. The **TDU**, initially developed by P. Bach-y-Rita and colleagues, has been improved and miniaturized by the Coronis-Systems® Company to put the whole human-machine interface into an orthodontic retainer with real-time reliable wireless transmission from the laptop to the TDU. The ***laptop***, which enables communication between the pressure mapping system and the homemade TDU, has been programmed to send electro-stimulations to the tongue. According to the detection of pressure maximum applied at the seat/skin interface during one minute, the best direction of chest movement that the paraplegic has to adopt to correct this detected pressure maximum (and thus to prevent the tissue suffering) is then sent.

Two first steps have been performed to study the potential sustainability of this new approach to prevent the formation of pressure ulcers in paraplegics. The first one is a pilot open prospective clinical study in 10 healthy subjects. In this study, each subject has to move his chest according to an electro-stimulated direction. The detection of an adapted resulting movement is established by the adequacy between the electro-stimulatory information and the recorded pressure changes induced by the chest move-

ment. The second one, performed in paraplegics, is a randomized double-blind prospective controlled biomedical study. The primary outcome is to evaluate the possibility of improving, in a determinist way, the spatio-temporal distribution of the pressure applied at the seat/skin interface in order to avoid tissue suffering. The secondary outcomes are related to the quantitative and qualitative evaluations by paraplegics of the tongue calibration step which is required because of the personal spatial anisotropy of the tongue sensibility, and of the potential acceptability by paraplegics of this new medical device in everyday life.

Results

With 92% success in 100 performed tests, the first study in healthy subjects demonstrates three main points: first, the healthy subjects have a strong perception of the electro-stimulated information on the tongue; second, this information is both meaningful and correctly interpreted; and third, the action resulting from the interpreted information is adapted, with changes in pressure, to the electro-stimulatory information.

The second study is currently performed according to the French biomedical research law. This clinical study takes place in the Grenoble Clinical Investigation Centre (GCIC) in collaboration with the Grenoble Technological Innovation Centre (GTIC). Two arms (with and without electro-stimulation) have been planed in the clinical trial (cf. figure 1) to evaluate the potential impact of the electro-stimulation on the spatio-temporal distribution of the pressure. The statistical unit is the difference, by subject, of the results adapted with changes in pressure. The statistical analysis will compare means (medians) between the two groups. The statistical tests will be performed after verifying the conditions of use. The secondary outcomes will be principally analyzed in a descriptive way.

Discussion

To our knowledge, there has been no study to date that uses sensory substitution via the tongue in order to prevent the formation of pressure ulcers in paraplegics.

One of the main difficulties of using sensory substitution reported by P. Bach-y-Rita was the development of a practicable user-friendly human-machine interface. As this device has to be wholly accepted by paraplegics, we built a new cosmetically acceptable interface into an orthodontic retainer, with RF transmission of the signals from the laptop connected to the pressure mapping system to the tongue device unit for relay to the brain.

The first study showed that communication from the organ of sensory substitution “towards” the region of sensory loss is achieved (pressure changes adapted to the electro-stimulatory information). The reverse communication from the buttock area to the tongue is currently evaluated in the randomized prospective controlled clinical trial. If this reverse communication is confirmed, it would then enable the simulation of the whole conscious or subconscious loop defined in the healthy subject by ***perception*** of a stimulus coming from the buttock area (alert), ***analysis*** of this signal and ***action*** adapted to the signal in order to correct the cause of this alert.

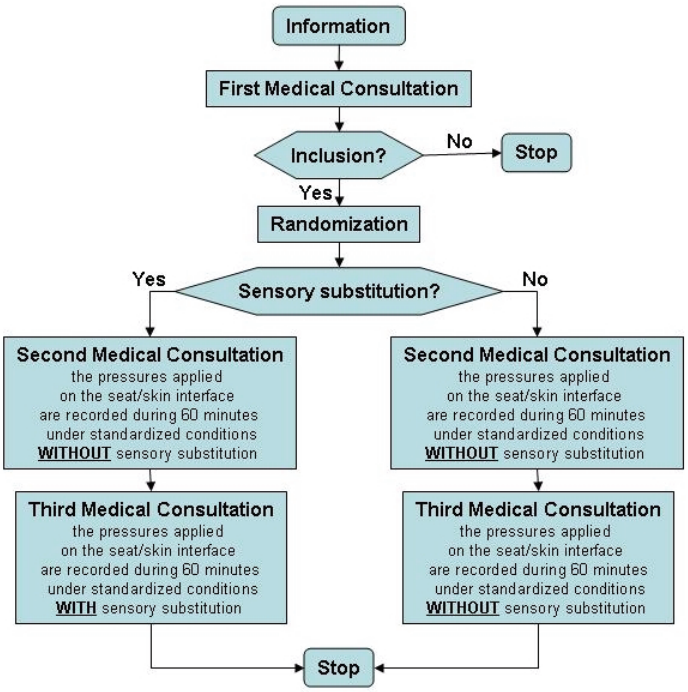

Figure 1 – An open randomized prospective controlled biomedical research

Further research has to be performed to determine the type of information that will be applied through tongue electro-stimulation as well as the electro-stimulation scheme. For instance, in the first case, should low-level information (pressure) be used with the subject having to interpret this “raw” information? Or should high-level information be used, such as an optimal direction of movement computed in an automated way from pressure maps?

The sustainability evaluation of new medical innovative devices is always difficult because of the complexity of the different components that have to be taken into account. Our studies are made easier by the Grenoble Technological Innovation Centre, a French structure which is playing a real interface part between the three essential actors of the innovation: the University, the Hospital and the Companies.

To determine the real sustainability of this new medical device, future evaluations would have to be as exhaustive as possible, from a clinical relevance point of view to a public health point of view, as, for instance, by taking into account the economic point of view (cost-effectiveness analysis).

Conclusion

Because pressure ulcers are still a major health issue for individuals with spinal cord injuries, a new health strategy to address this problem is developed. This paper reports the principles of a new approach using computer and sensory substitution via the tongue and the first steps performed in a sustainability study.

Pressure Ulcer Formation Prevention in Paraplegics using Computer and Sensory Substitution via the Tongue

First Steps in a Sustainability Study

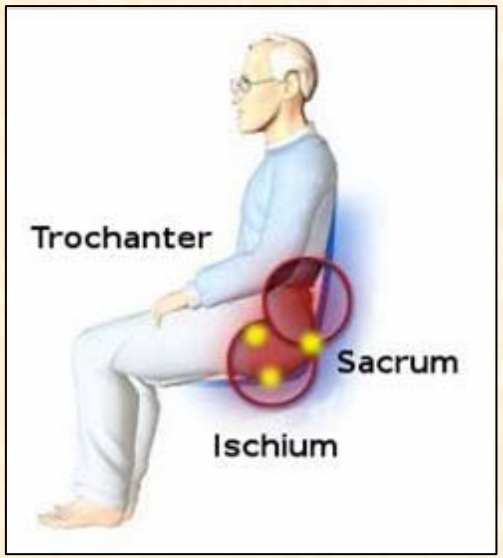
WHAT IS A PRESSURE ULCER?

Pressure Ulcer

- « Working definition *(EPUAP)* : a pressure ulcer is an area of localized damage to the skin and underlying tissue caused by pressure, shear, friction and or a combination of these. »

Most Common Sites

- Ischium
- Sacrum
- Trochanter



Consequences

- Main cause of rehospitalization for patients with paraplegia
- a - Aggravation of existing pathologies ***(septicemia)***
- b - Functional, psychological and social outcome
- c - Increase in health care costs.

A NEW APPROACH

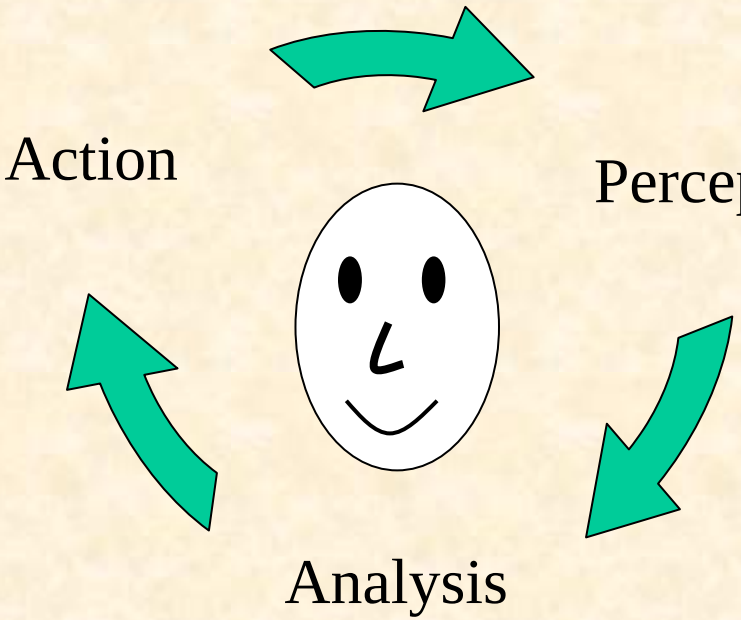
Why do pressure ulcers occur in paraplegics?

Healthy Subject

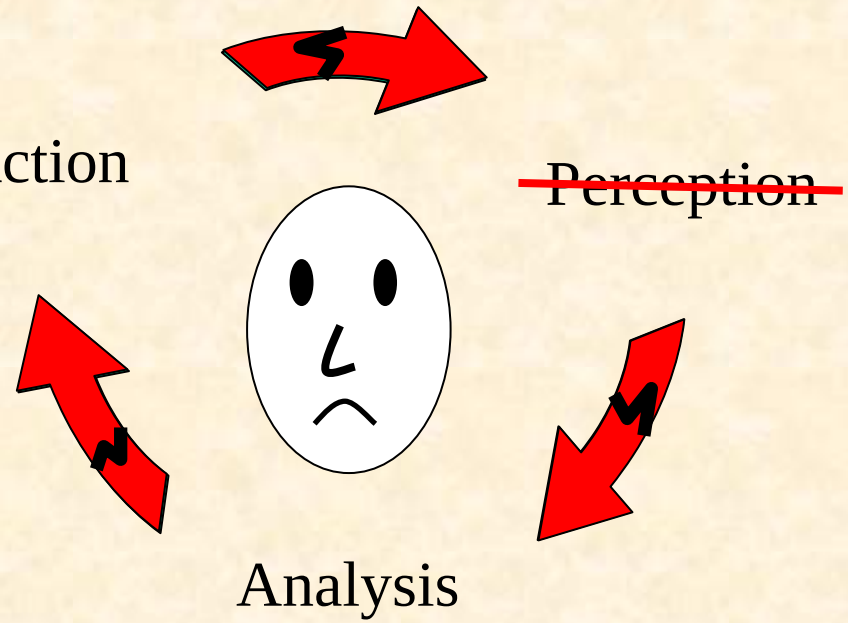
Paraplegics

Control loop for pressure ulcers formation prevention

Functional



Not Functional



A NEW APPROACH

To restore Perception by using **SENSORY SUBSTITUTION** but

- Auditory modality
- Visual modality

are already very often used in everydaylife.

Another « way » of communication ?

Tactile sensory modality of the TONGUE

Sensory and motory nervous pathways for the tongue are preserved in paraplegia after spinal cord injury.

A NEW APPROACH

Literature

P Bach-Y-Rita

- « **We do not SEE with the eyes** » : the visual image does not go beyond the retina, where it is turned into patterns of pulses along nerves. It is the brain which recreates the image from the patterns of pulses.
- **Tactile Vision Substitution System (TVSS)**
  - To deliver visual information from a TV camera to arrays of stimulators in contact with the skin of one of several parts of the body (abdomen, back, forehead, fingertip, …)
  - To perform complex perception and “eye”-hand coordination tasks
- **TONGUE INTERFACE**
  - Oral perceptual and sensory capacities have long been recognized to be superior to other tactile areas
  - the electrode geometry and driving circuitry can be simplified for tongue possibly because the electrode-skin interface on the tongue is very different from that on the fingertips.
  - A cosmetically acceptable interface built into an orthodontic retainer, with FM transmission of the signals from the artificial sensor carrying the information wirelessly to the tongue device unit for relay to the brain.

A NEW APPROACH

Literature

- **No such approach** exists for the pressure ulcer prevention

Introduction

Health education is essential to facilitate the adaptation process of patients who initiate hemodyalisis treatment. Nurse provide individual counseling , at that same that use printed health educational materials. However, printed materials are expensive and not content modifiable, hence in few time these educational resources become moss.

Objetive

On line presentation an educational triptych for the patients who initiate treatment with hemodyalisis.

To know the degree of acceptance this document

Keywords

Kidney Failure, Chronic
hemodyalisis
Patient Education
Medical Records Systems, Computerized
Nursing Records

Methods

AE became a provisional design by Delfhi technique consensus with 42 professionals and 10 people in treatment with Hemodyalisis.

It was validated with the National Association of Renals Patients. After using the document, 34 nurses and 52 patients were questioned to obtain facility, quality and utility data.

Results

The document is a triptych in Word, that includes images and text. Divided in different sections: Presentation, Contact, Hemodyalisis, Organization, Treatment, Signs of alarm, Medication, Quality of life, Diet and Vascular Access

All the fields can be modified, in order to adapt it to each patient. It is included in the Web page of the "Sociedad Española de Enfermería Nefrológica" http://www.seden.org.

The nurses considered the document: very useful (25), useful (5), little useful (4); ready to print it (7) the greater difficulty. The patients considered: very clear (40); clear (7) poorly clear (5). It provides confidence (46) have any influence (6)

Conclusion

An on line educative document, that the content can be modified; it facilitates the adaptation of the patients submissive hemodyalisis

Abstract

The merging of Informatics, Communication Technology, and Microelectronics in the field of Biomedical Technology facilitates gradually the development of a new Hi-Tec home-care environment. The aim of the present project was the development of an integrated system, addressing crucial aspects of contemporary home – care that comprise of: First, the employment of low-cost commercially available components, supporting home-care patient's vital-signs monitoring and mechanical ventilation. Second, software means for the processing of the acquired health data and the evaluation of the treatment schemata. Finally, software tools for the planning, the documentation, and the management of the corresponding home-care case.

Keywords:

mobile homecare, monitor, CPAP, CCR, homecare planning

Introduction and system description

The aim of the present project was the development of an integrated system, addressing crucial aspects of contemporary home – care that comprises of: First, a high-performance, C-programmable controller Rabbit Semiconductor® with a compact form factor supporting home-care patient's vital-signs monitoring and/or regulating mechanical ventilation, second, software means for the processing of the acquired health data and the evaluation of the treatment schema, and finally, software tools for the planning, the documentation, and the management of the corresponding home-care case. The system is designed to cover the monitoring, treatment, and managerial needs for the most frequent home-care case.

The *monitoring hardware* part of the system comprises presently of, first, a custom-made ECG (Eindhoven leads I-III) acquisition module based on a JFET Operational Amplifier TL074 (300 Hz sampling rate), equipped optionally with a 433 MHz RF link between an amplifier and a PC. Second, a Nellcor finger pulse oximetry probe for typical plethysmography based Oxygen Saturation (SpO_2) measurements and the estimation of Heart Rate (HR) and Respiration Rate (RR). Finally, a custom-made Carotid Sounds (CS) acquisition module, comprising of a stethoscope, a microphone, and an amplifier, for the extraction of Heart Rate (HR) and Respiration Rate (RR). The biosignals' sensors can be connected to a commercially available high-performance, C-programmable controller with a compact form factor, equipped with a Rabbit 2000 microprocessor operating at 25.8 MHz providing fast data processing. The system comprises of an additional development board, and the essentials needed for the design of a custom-made microprocessor-based system. A complete software development system (Dynamic C) is also included. The acquired row data and trends of SpO_2, HR, RR, ECG waveforms, Oxygen Therapy advice etc. are appropriately processed to produce decision supportive data.

The *ventilation hardware* part of the system comprises of a custom-made prototype CPAP-ventilator, driven by a brushless direct current (BLDC) motor. A sensor-less signal conditioning method of identifying the rotor position of a brushless DC (BLDC) motor was employed. A six steps technique is applied to drive the motor smoothly from standstill without any position sensors, by monitoring the current responses to the inductance variation on the rotor position. Rotation is achieved by employing a three phase bridge, comprising of six Metal Oxide Semiconductor Field Effect Transistors (MOSFETs). The rotor position at standstill is detected by comparing the first and second differences of six current pulses injected into every two phases of the motor. Once the motor starts up, a pulse train, is injected into the commutation phases corresponding to the maximum torque production and the next commutation phases in alternating fashion. A 6x256 Reference Matrix provides for information about the next commutation timing, when the current responses of the pulses cross each other in the same time delay. The method can drive a BLDC motor smoothly without any vibration or time delay up to medium speed. Beyond this medium speed, the classical back-EMF method is employed to drive the BLDC motor at high speed. The Pulse Width Modulation driven BLDC motor can provide for adequate air – oxygen flow and subsequently an appropriate pressure cycle, for the developed home-care CPAP, to support home ventilation in the case of, for example, of a patient, suffering from Chronic Obstructive Pulmonary Diseases (COPD). The output pressure was measured by employing differential pressure transducers (Freescale MPX 2010, 0-100 cm H_2O

and HoneyWell XCA400.3DN 0.0-0.3 psi respectively) attached to a Data Acquisition Card (16 channels Advantech PCI 1710, 12 bit A/D, and 100 kHz sampling rate). The system is based on relatively low-cost commercially available components and devices, and allows for the creation of various home-care hardware modules, tailored to the specific individual patient.

Processing of the acquired data and management of home-care

The software means of the system, for the processing of the acquired health data and the evaluation of the treatment schemata, comprise presently of, first, software for the detection of Ventricular fibrillation (VF) and malignant ventricular tachycardia (VT), and second, software for producing advice on home-based Oxygen Therapy management. A home computer equipped with the above mentioned 433 MHz RF link between the ECG amplifier and the PC, enables the quasi real time acquisition and processing of the necessary ECG data to recognize critical situations, as Ventricular fibrillation (VF) and malignant ventricular tachycardia (VT) that cause the patient to be pulseless and unconscious are life threatening cardiac arrhythmias. Early defibrillation is the key to achieve a satisfactory survival rate from cardiac arrest and the general medical consensus is that VF and malignant VT should be shocked and all other rhythms should not. The detection of shockable rhythms was made by employing two developed methods, based on Image Analysis and on the CDF-SKEW techniques. Further, a Fuzzy logic algorithm was designed and implemented for producing advice on Oxygen Therapy management. The system's response is best described with the graphical representation of the relationship between a pair of input parameters and the system's output. Three of the physiology parameters acquired by the acquisition modules, the Oxygen Saturation (SpO_2), the Heart rate (HR) and the Respiration Rate (RR) are used as inputs for the algorithm. The change in Oxygen Saturation over time ($dSpO_2$), which is a reliable factor for evaluating stability, deterioration or improvement of patients' health status, is also included in the model as an indication of the effectiveness of oxygen therapy. The inputs are translated from crisp values to linguistic variables and the system's response is dictated by a set of fuzzy rules, which were derived based on well established respiration physiology principles. The system actually produces an advice on the percentage change of Oxygen flow to the patient and the translation of its output back to crisp values is performed with the centroid defuzziation method.

Sharing of healthcare related information among the different healthcare providers is a crucial aspect for the continuity of the provided care. The developed home-care management system is to be used upon the transition or the referral of a patient, and especially in transition from hospital to homecare. The function of the developed system is based upon the creation of a structured subset of data, concerning the most relevant facts about a patient's healthcare, organized and transportable, in order to be employed during the post-discharge homecare period, enabling simultaneously the planning and the optimal documentation of the provided homecare. The structure and the content of the created data sets are complying with the ASTM E2369-0 Standard, Specification for Continuity of Care Record (CCR). The developed system consists of two modules. The first module is responsible for the creation of a typical CCR that contains the appropriate demographic and administrative data, as well as the relevant clinical information, while the second module is responsible for the creation of a homecare plan which will be included in the Care Plan section of the CCR. The system is intended to be used upon the transition of a patient from hospital to homecare, although the first module alone could actually be used in any case of transition or referral. The typical–CCR module can either collect the necessary data from an already installed EHR system or allow the user to enter the data manually by filling special forms. In any case, the user decides which parts of the patient's medical record (electronic or paper) are the most significant ones or are the necessary ones for the description of the current health status of the patient and should be included in the CCR. The second module is responsible for the creation of the homecare plan by creating a structured subset of data, containing monitoring, treatment, diagnostic, and nursing activities that should be employed during the post-discharge home-care period. The developed model allows for every Hospital Department or Medical/Nursing group, to individually assign an appropriate set of homecare activities to specific diagnoses codes that are coded according to Diagnosis Related Group (DRG) codification. These activity sets consist of diagnostic, monitoring and treatment activities that can be actually performed in home-environment, together with an appropriate nursing – activity treatment plan. These profiles of home-care activities are custom-made and every user, i.e. every physician responsible for discharging a patient from hospital, is actually allowed to set up his own profiles. During the formation of these profiles the user can attach to each activity a set of nominal fees. Thus, the developed system ignites, when relevant, the corresponding revision of an implicitly associated latent financial record that allows for an approximation of the individual case-cost.

Results and conclusions

The described solution is set up by employing simple, low-cost, commercially available components, supporting home-care patient's vital-signs monitoring and assisted ventilation. The system includes software means for the processing, the evaluation, and the targeted transmission

of the acquired health-data, and software tools, for the planning, the documentation, and the management of the corresponding home-care case. The on-going testing of the system shows that it is able to contribute to an effective home – care package solution, supporting not only well organized nursing care, but further, a structured total Patient Supervision and Treatment home-care approach.

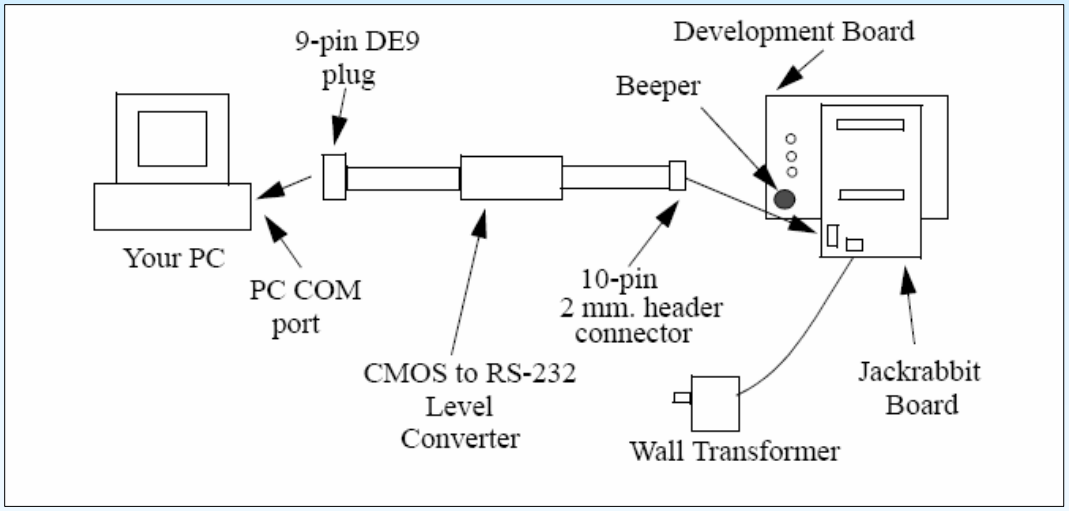
The aim of the project

- The aim of the present project [1] was the development of an integrated system, addressing crucial aspects of contemporary home – care that comprises of:
  - *First, a high-performance, C-programmable controller Rabbit Semiconductor® with a compact form factor supporting home-care patient's vital-signs monitoring and/or regulating mechanical ventilation.*
  - *Second, software means for the processing of the acquired health data and the evaluation of the treatment schema.*
  - *Finally, software tools for the planning, the documentation, and the management of the corresponding home-care case. The system is designed to cover the monitoring, treatment, and managerial needs for the most frequent home-care cases.*
- The system is designed to cover the monitoring, treatment [2], and managerial needs for the most frequent home-care cases.

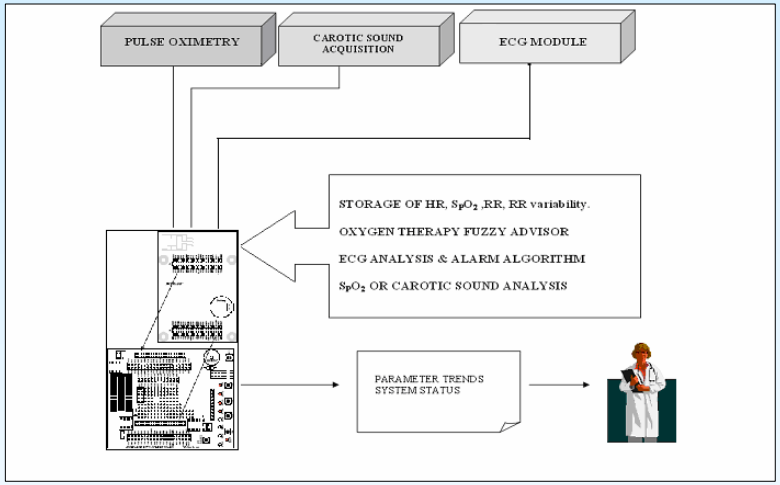
The monitoring hardware part modules of the system

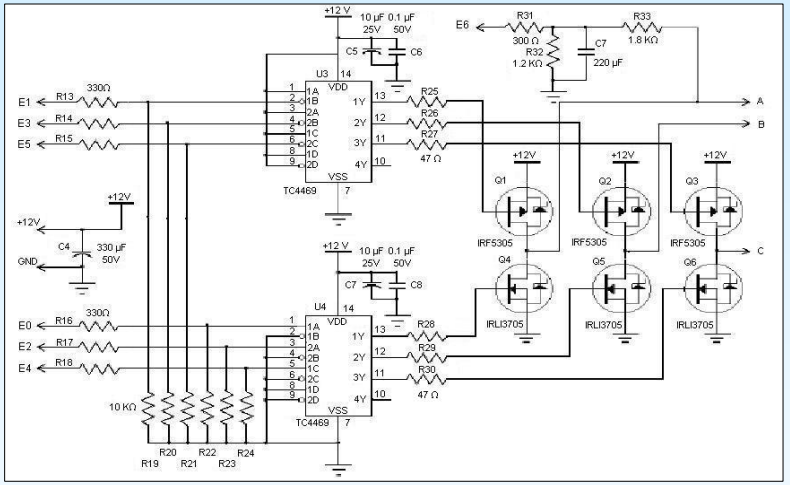


Hook-up connection of the development board (Jackrabbit®) to any PC for the development of software [Source: Rabbit Semiconductor]

- First, a custom-made ECG (Eindhoven leads I-III) acquisition module based on a JFET Operational Amplifier TL074 (300 Hz sampling rate), equipped optionally with a 433 MHz RF link between an amplifier and a PC.
- Second, a Nellcor finger pulse oximetry probe for typical plethysmography based Oxygen Saturation (SpO2) measurements and the estimation of Heart Rate (HR) and Respiration Rate (RR).
- Finally, a custom-made Carotid Sounds (CS) acquisition module, comprising of a stethoscope, a microphone, and an amplifier, for the extraction of Heart Rate (HR) and Respiration Rate (RR).

The monitoring hardware and the BLDC driving system block diagrams





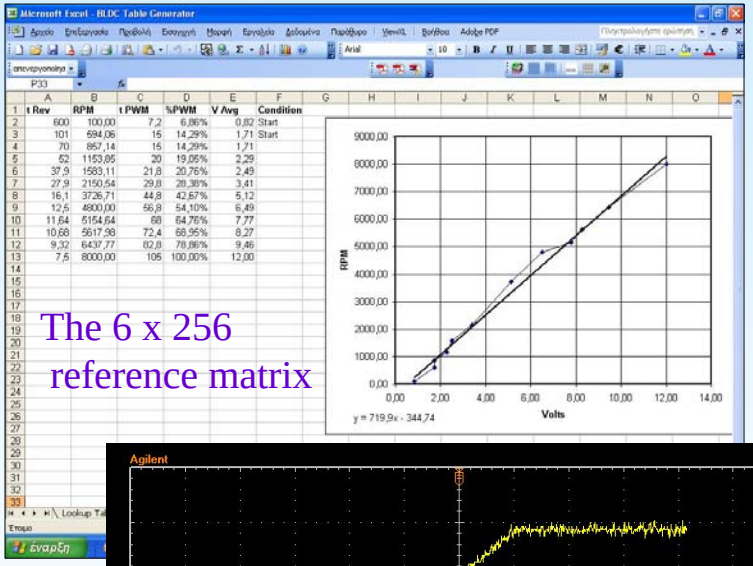
- The biosignals' sensors can be connected to a commercially available high-performance, C-programmable controller with a compact form factor, equipped with a Rabbit 2000 microprocessor operating at 25.8 MHz providing fast data processing.
- The system comprises of an additional development board, and the essentials needed for the design of a custom-made microprocessor-based system. A complete software development system (Dynamic C) is also included.
- The acquired row data and trends of SpO2, HR, RR, ECG waveforms, Oxygen Therapy advice etc. are processed to produce decision supportive data.

The custom-made prototype CPAP-ventilator operation description

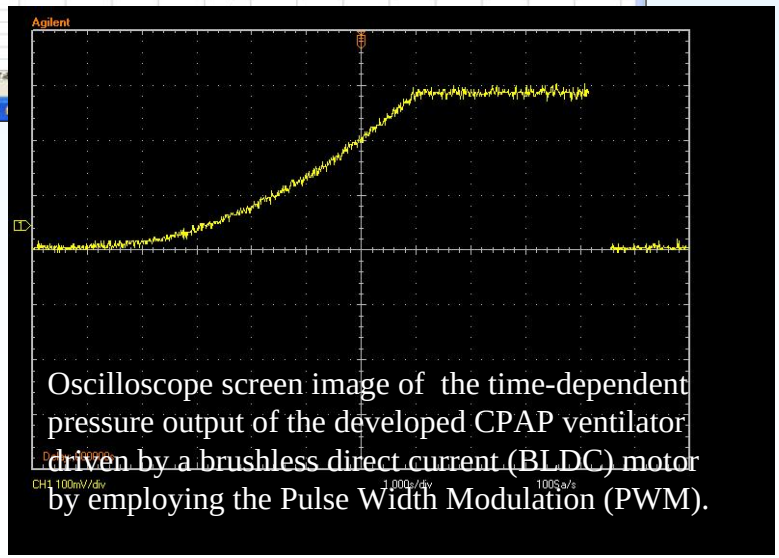
- The *ventilation hardware* part of the system comprises of a custom-made prototype CPAP-ventilator, driven by a brushless direct current (BLDC) motor.
- A sensor-less signal conditioning method of identifying the rotor position of a brushless DC (BLDC) motor [3] was employed.
- A six steps technique is applied to drive the motor smoothly from standstill without any position sensors, by monitoring the current responses to the inductance variation on the rotor position.
- Rotation is achieved by employing a three phase bridge, comprising of six Metal Oxide Semiconductor Field Effect Transistors (MOSFETs).
- The rotor position at standstill is detected by comparing the first and second differences of six current pulses injected into every two phases of the motor.
- Once the motor starts up, a pulse train, is injected into the commutation phases corresponding to the maximum torque production and the next commutation phases in alternating fashion.
- A 6 x 256 Reference Matrix provides for information about the next commutation timing, when the current responses of the pulses cross each other in the same time delay.
- The method can drive a BLDC motor smoothly without any vibration or time delay up to medium speed. Beyond this medium speed, the classical back-EMF method is employed to drive the BLDC motor at high speed.

The switching configuration regulating the cycle of the Pulse Width Modulation driven BLDC motor

- The Pulse Width Modulation driven BLDC motor can provide for adequate air – oxygen flow and subsequently an appropriate pressure cycle, for the developed home-care CPAP, to support home ventilation in the case of, for example, of a patient, suffering from Chronic Obstructive Pulmonary Diseases (COPD).
- The output pressure was measured by employing differential pressure transducers (Freescale MPX 2010, 0-100 cm H2O and HoneyWell XCA400.3DN 0.0-0.3 psi respectively) attached to a Data Acquisition Card (16 channels Advantech PCI 1710, 12 bit A/D, and 100 kHz sampling rate).
- The system is based on relatively low-cost commercially available components and devices, and allows for the creation of various home-care hardware modules, tailored to the specific individual patient.



The 6 x 256 reference matrix

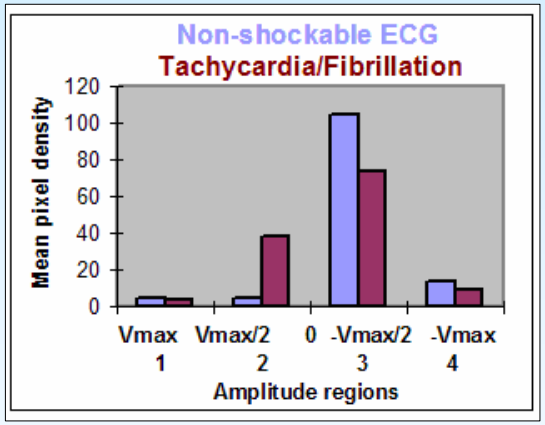


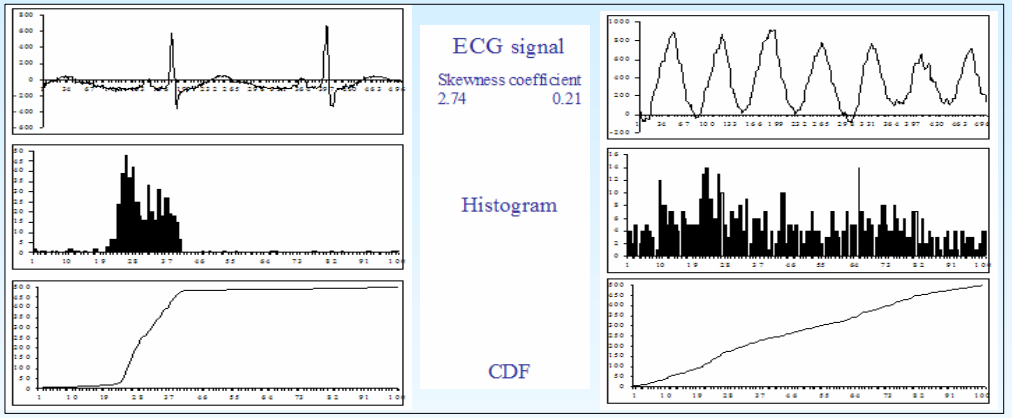
Oscilloscope screen image of the time-dependent pressure output of the developed CPAP ventilator driven by a brushless direct current (BLDC) motor by employing the Pulse Width Modulation (PWM).

Processing and evaluation of the acquired data

- The software means of the system, for the processing of the acquired health data and the evaluation of the treatment schemata, comprise presently of:
  - *First, software for the detection of Ventricular fibrillation (VF) and malignant ventricular tachycardia (VT).*
  - *Second, software for producing advice on home-based Oxygen Therapy management.*
- A home computer equipped with the above mentioned 433 MHz RF link between the ECG amplifier and the PC, enables the quasi real time acquisition and processing of the necessary ECG data to recognize critical situations.

The detection of shockable rhythms

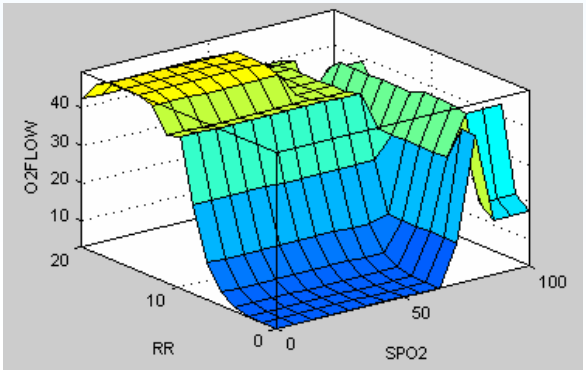




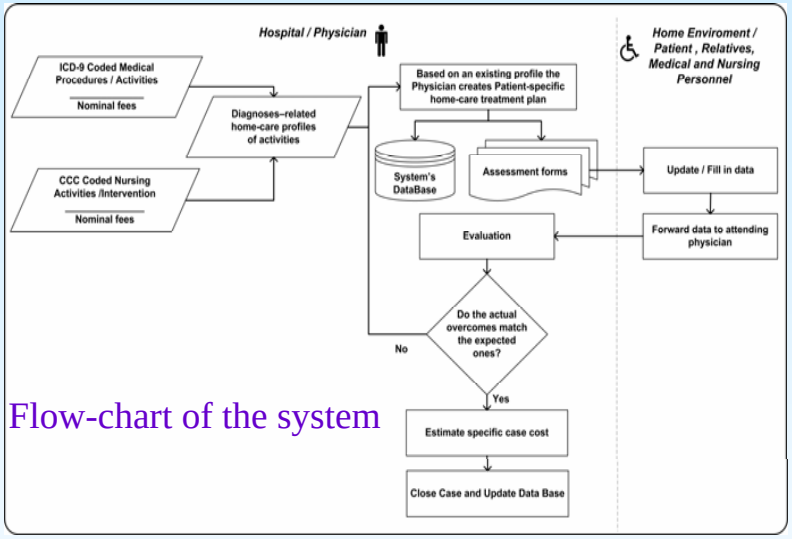
- Early defibrillation is the key to achieve a satisfactory survival rate from cardiac arrest and the general medical consensus is that VF and malignant VT should be shocked and all other rhythms should not.
- Life threatening cardiac arrhythmias are Ventricular fibrillation (VF) and malignant ventricular tachycardia (VT).
- The detection of shockable rhythms was made by employing two developed methods, based on the Image Analysis (left) and on the CDF-SKEW techniques (right).

A Fuzzy logic algorithm producing advice on Oxygen Therapy management

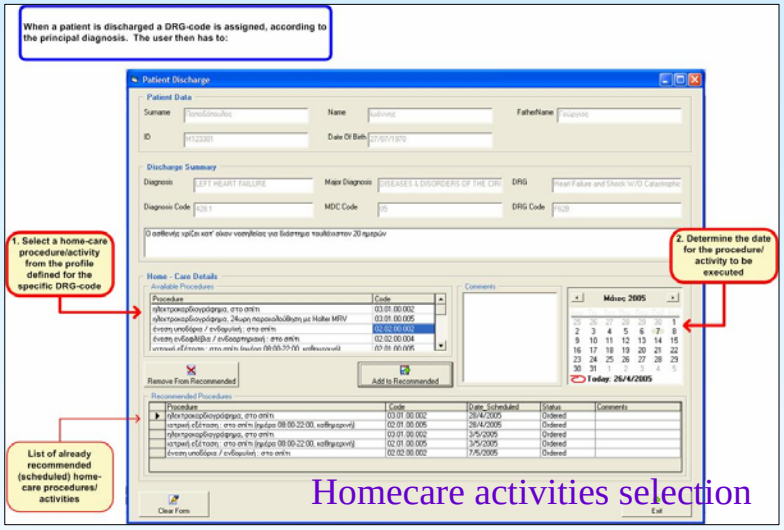
- Further, a Fuzzy logic algorithm was designed and implemented for producing advice on Oxygen Therapy management.
- The system's response is best described with the graphical representation of the relationship between a pair of input parameters and the system's output.
- Three of the physiology parameters acquired by the acquisition modules, the Oxygen Saturation (SpO2), the Heart rate (HR) and the Respiration Rate (RR) are used as inputs for the algorithm.
- The change in Oxygen Saturation over time (dSpO2), which is a reliable factor for evaluating stability, deterioration or improvement of patients' health status, is also included in the model as an indication of the effectiveness of oxygen therapy.
- The inputs are translated from crisp values to linguistic variables and the system's response is dictated by a set of fuzzy rules, which were derived based on well established respiration physiology principles.
- The system actually produces an advice on the percentage change of Oxygen flow to the patient and the translation of its output back to crisp values is performed with the Centroid Defuzziation method.



Management of home-care

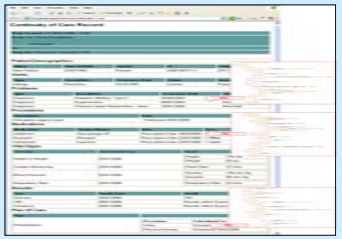


Flow-chart of the system



Homecare activities selection

- Sharing of healthcare related information among the different healthcare providers is a crucial aspect for the continuity of the provided care.
- The developed home-care management system is to be used upon the transition or the referral of a patient, and especially in transition from hospital to homecare.
- The function of the developed system is based upon the creation of a structured subset of data, concerning the most relevant facts about a patient's healthcare, organized and transportable, in order to be employed during the post-discharge homecare period, enabling simultaneously the planning and the optimal documentation of the provided homecare.
- The structure and the content of the created data sets are complying with the ASTM E2369-0 Standard [4], Specification for Continuity of Care Record (CCR). The developed system consists of two modules.



Detailed description of the Home-care Management System

- The first module is responsible for the creation of a typical CCR that contains the appropriate demographic and administrative data, as well as the relevant clinical information, while the second module is responsible for the creation of a homecare plan which will be included in the Care Plan section of the CCR. The system is intended to be used upon the transition of a patient from hospital to homecare, although the first module alone could actually be used in any case of transition or referral. The typical–CCR module can either collect the necessary data from an already installed EHR system or allow the user to enter the data manually by filling special forms. In any case, the user decides which parts of the patient's medical record (electronic or paper) are the most significant ones or are the necessary ones for the description of the current health status of the patient and should be included in the CCR.
- The second module is responsible for the creation of the homecare plan by creating a structured subset of data, containing monitoring, treatment, diagnostic, and nursing activities [5] that should be employed during the post-discharge home-care period. The developed model allows for every Hospital Department or Medical/Nursing group, to individually assign an appropriate set of homecare activities to specific diagnoses codes that are coded according to Diagnosis Related Group (DRG) codification. These activity sets consist of diagnostic, monitoring and treatment activities that can be actually performed in home-environment, together with an appropriate nursing – activity treatment plan. These profiles of home-care activities are custom-made and every user, i.e. every physician responsible for discharging a patient from hospital, is actually allowed to set up his own profiles. During the formation of these profiles the user can attach to each activity a set of nominal fees. Thus, the developed system ignites, when relevant, the corresponding revision of an implicitly associated latent financial record that allows for an approximation of the individual case-cost.

Results and Conclusions

- The described solution is set up by employing simple, low-cost, commercially available components, supporting home-care patient's vital-signs monitoring and assisted ventilation.
- The system includes software means for the processing, the evaluation, and the targeted transmission of the acquired health-data, and software tools, for the planning, the documentation, and the management of the corresponding home-care case.
- The on-going testing of the system shows that it is able to contribute to an effective home – care package solution, supporting not only well organized nursing care, but further, a structured total Patient Supervision and Treatment home-care approach.

Pressure Ulcer: Statistics Analysis of an Electronic Database

Bork Anna[a], Reis Elisa[b]

[a] *Director, Interdisciplinary Care; Chief Nurse Executive, Albert Einstein Hospital, Brazil*
[b] *Senior Nurse, Albert Einstein Hospital, Brazil*

Abstract

An information system is analyzed on defining quality indicators for pressure ulcer which is recommended by the American Nursing Association. Objective: Analyzing statistically a large sized hospital electronic database of São Paulo City. Methods: Descriptive retrospective study, sample frame of convenience of 51,414 hospital discharges. Results: Predominance of female sex 60%; average age 52 years old and length of stay of 4 days. Pressure ulcer occurred in 1% of the sample frame. The statistical analysis pointed out the age and hospitalization time as significant for the appearing of pressure ulcer. The chance rate of occurrence is 10 times higher for patients aged 65 years old compared to the ones of <65 years old ($p<0.001$). When permanence is over 4 days the chance is 18 times higher of developing pressure ulcer compared to patients whose permanence was up to 3 days ($p<0.001$). Final considerations: This study proved the worth of an electronic database about clinical practice in planning and managing nursing assistance; validating the indicator and consequently improving quality.

Keywords:
medical informatics, decubitus ulcer/nursing, decubitus ulcer/prevention and control, quality indicators

Introduction

The comparative analysis results indicators in health care constitutes an important tool for monitoring the performance of service providers, and the contribution of each professional in the attending process. Therefore, many studies have been developed to define indicators which would be specific for showing quality in nursing service.[1] The American Nursing Association (ANA) has developed a project for defining specific indicators for nursing. These nursing indicators intend to capture nursing care and its results, and the impact on nursing practice. Accordingly, the following indicators are recommended by ANA: pressure ulcer, patient's fall, patient's satisfaction on pain management, patient's satisfaction on educational information, patient's satisfaction with nursing care, patient's satisfaction with general care, and staff mix of nurses, technicians and nursing assistants, total of hours of nursing care per patient per day, nursing staff satisfaction.[1]

The use of information technology has contributed to facilitate and provided agility to the evaluation of health services and consequently the nursing services.[2] It can be said that information technology in health services evolved from a situation where the computer was used for simple and isolated tasks to integration of information level, whose objective is integrating through a single system, the diverse recording points and using them into the service, creating great data banks that have often been used on the evaluation of health services performance.[3]

These database avail patients' clinical data about the care they received while in hospital, so this work intends to analyze a pressure ulcer monitoring database which is one of the indicators recommended by ANA. Pressure ulcer is an impact phenomenon that occurs in many health services, affects all ages, has a high cost and causes much human suffering for it affects individuals' life quality.

Cuddigan reports that the incidence of pressure ulcer has an extension from 2% to 29%.[4] The treatment costs of an ulcer can vary from US$ 2,000 to US$ 70,000 according to Gallagher.[5]

Pressure ulcer can be defined as particular areas of skin damage and surrounding tissues. This damage can be caused by pressure, cut and/or friction, combined with effects of intrinsic and extrinsic factors. Among the intrinsic factors stand out the age, nutritional state, tissue pervasion, use of some medicines and chronic degenerative diseases; and among the extrinsic factors the pressure, shear, friction and humidity.[6,7] Although it is known this is a multi-factorial phenomenon, nursing has the unique opportunity of performing on these extrinsic factors preventing its occurrence.

Therefore this study has the objective of analyzing the pressure ulcer monitoring data contained in an electronic data base of a large hospital of São Paulo City.

Material and method

A retrospective descriptive study was accomplished through the analysis of data collected from an electronic system about pressure ulcer, about all hospital discharges from June 2002 to December 2004.

In this hospital all admitted patients are assessed for pressure ulcer risk through the Norton[8] table, which evaluates

five criteria (physical state, mental state, activity, mobility and incontinence and scores from 1 to 4, classifying the risk in: low, moderate and high. Once the risk is assessed, the nurse starts to use practice guidelines for pressure ulcer prevention. The patient is re-evaluated whenever clinical condition changes or every 48 hours.

The criterion for classification of pressure ulcer stage used in this hospital is derived from the National Pressure Ulcer Advisory Panel[7], which classifies pressure ulcer in 4 stages. Stage I corresponds to altering on integral skin color under pressure; in Stage II there is loss of thin skin layer, involving epidermis, dermis or both; Stage III is characterized by signifying loss of skin, involving cellular subcutaneous and adipose tissue damage or necrosis, which can extend to fascia, but does not surpass it; and stage IV is characterized by significant skin loss, with extensive destruction and necrosis of cellular subcutaneous tissue, or muscle, bone, tendon or particular capsule damage.[9]

During the period in hospital, the nurse prescribes and records the provided service to the patient, so at the discharge it is filled in a summary of evaluations and the outcomes of care are described in a proper form called Nurse's Discharge summary. On this sheet it is also noted the moment of risk assessment: at admittance, during hospitalization and presence of pressure ulcer at admittance.

Since 2002 the data from these summaries feed the information system. The risk assessment data, presence and classification of the ulcer are fed into the information system. Each patient has a single hospital record number and at each hospital attendance it generates a passage number which can be internal (admitted patient), external (office appointments and/or exams), emergency (emergency room). This study only analyzed the passages of admitted patients.

Place of study

The study was accomplished in a large hospital of São Paulo City, which has 87,000m2 built area distributed in four buildings, with 460 beds, 30 surgery rooms and 53 ICU beds; the Diagnosis and Treatment Support Service assists more than 220 thousand patients per year. It is classified as a large sized hospital and of high complexity with kidney, liver, marrow, cornea, skin and bone transplants.

In search of solutions for health matters, the hospital started a quality program in 1989. Currently it has various quality certifications and it was the pioneer in the Crediting of the Joint Commission International and the implementation of normative requirements of ISO 9002 among other.

Population

The population was composed by all hospital discharges within 01/ Jun/ 2002 and 31/ Dec / 2004 generating a total of 57,487 discharges; however, mistakes were found on the nurse's discharge summary feeding into the information system. For this reason an audit was necessary and a validation of records on 1,220 data (2.1% of total) and loss of 252 data (0.4%) which had mistakes on hospital records and passage numbers. After these audits a convenient sample was selected for this study, considering only adult patients aged equal or over 18 years old, who were assessed for pressure ulcer risk and had outcomes of clinical practice in the database. Therefore, the sample obtained was of 51,414 hospital discharges, which were analyzed and characterized by age, sex, hospitalization time, presence of pressure ulcer risk, classification of pressure ulcer risk and International Classification Diseases (ICD).

Results

The study analyzed 51,414 hospital discharges of both sexes, with ages between 18 and 103 years old, with length of stay between 0 (admission and discharge on the same day) and 1,346 days.

In the distribution of sample by sex there was predominance of the female sex 60% and 40% of male sex. For this sample, the starting age chosen was 18 years old and the maximum age found was of 103 years old, the average was 52 years and the median 50 years. The age range from 18 to 59 years old corresponded to 66% of the patients, and the age range above 60 years old corresponded to 34%.

For the distribution of sample by days of hospitalization it was considered the patients with zero day of length of stay, that is, when the date of admission was equal to the day of discharge; therefore the period of hospitalization varied from zero to 1,346 days. The average of hospitalization was of 4 days and the median of 2 days, and the highest percentage of patients 79% had a length of stay of until 4 days and only 21% stayed over 4 days.

The general sample frame 21% (10,521) patients had pressure ulcer risk assessed during the hospitalization period, distributed as follows: 12% at admittance and 9% during hospitalization; and the distribution concerning pressure ulcer risk classification for patients who had the risk assessed was 9% high risk, 24% moderate risk and 67% low risk according to table 1.

Table 1 - Distribution of patients with assessed risk according to risk classification

Classification Pressure Ulcer Risk	n	%
High risk	1060	9
Moderate	2751	24
Low risk	7673	67
Total	11484	100

The occurrence of pressure ulcer in the general sample was of 1% of the total; the distribution concerning the stage in the general population was of 0.63% stage I, 0.25% stage II, 0.11% stage III and 0.05% stage IV.

The distribution of total sample per diagnosis shows predominance of five ICD chapters, Chapter XV (Pregnancy, Childbirth and Puerperium) 12.7%, Chapter XI (Digestive System Diseases) 12.2%, Chapter II (Neoplasms (Tumors)) 11.3%, Chapter IX (Circulatory System Diseases) 11.2%, Chapter XIV (Genitourinary System Diseases) 9.2%.

Sorting the patients who presented PU it was verified that 50% of the patients are predominantly distributed in three diagnosis chapters: Chapter X (Respiratory System Diseases) 21%, Chapter IX (Circulatory System Diseases) 16%, Chapter II (Neoplasms (Tumors)) 13%.

Discussion

There is a consensus about the multi-factorial causes for the pressure ulcer event. The present work made it possible to test some of these factors in order to verify if they had statistic significance applied to this population.

Patients have a variety of intrinsic factors which deserve consideration. Age seems to be one of them. Analyzing the data in this study, it was verified that the chance ratio of developing pressure ulcer for a patient aged 65 is 10 times higher compared to a patient aged < 65 years old ($p<0.001$) as displayed on table 2.

Table 2 – Distribution of patients with and without ulcer per age group

	Age Group					
	< 65 anos		≥ 65 anos		Total	
Event	n	%	n	%	n	%
Ulcer	103	0,3	389	2,7	492	1,0
Without ulcer	36945	99,7	13838	97,3	50783	99,0
Total	37048	100	14227	100	51275	100

This finding is confirmed in the literature which reports that elder patients present a great risk related to the skin change that occurs within this age group.[10] Age is also related to other factors as immobility, activity limitation, incontinence (hydration and humidity) and nutritional damage, which have been consistently reported as predisposing factors.[9]

Another factor that presented significant results was hospitalization time. It was noticed that patients with permanence > 4 days have a chance ratio 18 times higher to develop PU compared to the ones whose permanence was up to 3 days $p< 0.001$ as shown on table 3.

Table 3 – Distribution of patients with and without ulcer per hospitalization time

	Hospitalization Time					
	< 4 days		≥ 4 days		Total	
Evento	n	%	n	%	n	%
Ulcer	58	0,2	434	2,8	492	1,0
Without ulcer	35570	99,8	15213	97,2	50783	99,0
Total	35628	100	15647	100	51275	100

This factor may be related to these patients' diagnosis since 21% of them had diagnoses related to Respiratory System Diseases, 16% Circulatory System Diseases and 13% Neoplasms (Tumors), diseases which have a hospital permanence superior to 4 days; of 5 days for Respiratory System Diseases, 6 days for Circulatory System Diseases and 5 days for Neoplasms (Tumors), at the studied hospital.

It was also verified that the use of a pressure ulcer risk assessment is useful in order to identify the higher risk population, that is, the population who developed ulcer 99% and 1% respectively had or not ulcer risk assessment. The patients who had risk assessment have a chance ratio 358 times higher of developing PU compared to the patients who have not had the risk assessed ($p<0.001$). This finding is confirmed in the literature which describes the reliability and validity of pressure ulcer risk assessment.[11]

Analyzing the data related to ulcer stage classification it could be verified that from the total of ulcer assessed they were positioned as: stage I 61%, stage II 24%, stage III 10% and stage IV 5%. It is important to notice that 26% of the identified ulcer was present at patient's admittance. Evaluating only the patients who developed ulcer during hospitalization the distribution was: 62% stage I, 24% stage II, 09% stage III and 04% stage IV.

Table 4 – Distribution of patients with ulcer per ulcer stage classification

PU Stage Classification	n	%
E-I	248	62
E-II	97	24
E-III	37	9
E-IV	17	4
Total	399	100

This classification not only helps selecting proper treatment, but also predicting prognostic.[12] The quality indicator measured at the studied hospital is the ratio between number of new cases of assessed pressure ulcer and the population's total number with assessed risk,[1] incidence was 4%. Tracking pressure ulcer incidence provides a more exact panorama of success and efficiency on risk assessment and prevention, and the policies which identify those people who developed it at a determined time and assistance location.[9] The prevalence of ulcer on this same population was 1%. In the literature the most wide-ranging were accomplished on hospitalized populations and the results show an incidence that varies from 2.7% to 29.5% and a prevalence between 4 and 69%, depending on the population studied.[13] In the United Kingdom (UK), in a district general hospital, new cases of PU strike 4% to 10% of admitted patients. [9,14]

It is understood that assistance quality improvement is certainly an activity which should be carried out in a continuous basis in order to perfect the offered assistance. This is an interactive process which requires a sense of duty from the whole organization. The evaluation of the information database about pressure ulcer proved valuable since this analysis may allow quality improvement implements like patient's more intense monitoring when staying longer than 4 days and aged 65 years old or over.

This analysis can also serve as a feedback to the assisting nurses who generate the data for the information system, validating this information and aggregating value to it in establishing the planning and management of quality nursing care.

Validating the quality indicator, starting from an information system guarantees the establishment of assisting protocols based on pertinent information to this population and consequently training the team related to pressure ulcer.

Nursing Time Analysis in a Tertiary Hospital after ENR Introduction

Doh-Yeon Kim[a], Myonghwa Park[b]

[a]*Dongsan Medical Center, Keimyung University, Korea*
[b] *College of Nursing, Keimyung University, Korea*

Abstract and objective

The purpose of this study was to analyze the direct and indirect nursing time after introducing the Electronic Nursing Record (ENR) system in a tertiary hospital. This research used descriptive survey and the data was collected from 28 nurses from 14 wards in a general hospital. Each nurses recorded their day, evening, and night activities according to time order.

The study results reported reduction of indirect nursing time including recording & reporting and increase of direct nursing time and patient education. In general, they showed satisfaction with the system and revealed positive responses to the IT team's support. The nurses commented on changes to be needed such as computer speed and physical discomfort from computer using. This study identified the positive time effect of ENR and the need for user friendly nursing information system.

Keywords:

electronic nursing record, nursing time

Introduction

The electronic record system is increasingly being deployed within health care organizations to improve the safety and quality of care[1]. However, to achieve these goals, the electronic record system must be verified as effective by clinicians, and this remains a major challenge. Nurses spend the majority of their time providing direct care to patients and expect that an electronic nursing record system could increase the patient-interaction time and consequently the quality of care delivered [2]. Thus, nurses will consider a system to be efficient if the system reduces their indirect nursing time, even if the time savings do not translate into better patient care [3]. For this reason, in evaluating the impact of electronic nursing record on nurses' activities, some studies use activity time as a primary outcome. However, few studies have explored the effect of ENR on nursing staff' activity time.

Methods

This research was designed as a descriptive study and the data was collected from February to April, 2006. The subjects consisted of 28 nurses from the 14 nursing units who have experienced both paper nursing record system and electronic nursing system. The participants worked regularly at day, evening, and night shift. Nurses were requested to record their nursing time at each shift using the checklists provided by the researchers. Group interviews were done about their perceptions of nursing time changes after ENR introduction.

Results

1) During the day shift, direct nursing activities took 37.04% of the whole day time nursing, indirect nursing 40.74%, ward management 18.52%, and personal time 3.70% respectively. In evening shift, nurses used 29.41% of working time on direct nursing, 45.10% on indirect nursing, 19.61% on ward management, and 5.88% on personal time. In night shift, direct nursing time took 17.91% of working time, indirect nursing 46.27%, ward management 17.91%, and personal time 11.98%.

2) The total time of direct nursing was 200.57 minutes (37.04%) in day shift, 150. 71 minutes (29.41%) in evening shift, and 120.42 minutes (17.91%) in night shift. Among the direct nursing activities, observation and monitoring took the most of nursing time.

3) The total time for indirect nursing was reported as 220.28 minutes (40.74%) of the day shift, 230.07 minutes (45.10%) for evening shift, and 310.71 minutes (46.27%) for night shift respectively.

4) Ward management totally took 100.21 minutes (18.52%) of day shift, 100.85 minutes (19.61%) of evening shift, and 120.57 minutes (17.91%) of night shift. Ward meeting and patient reporting took the largest portion of the ward management time.

5) The personal time took 20.57 minutes (3.70%) for day shift, 30.42 minutes (5.88%), and 80.92% minutes (11.98%) for night shift.

6) The analysis of the group interview indicated the following results: improved work speed and convenience in job, the precise and fast recording, reduction of indirect nursing time including management of nursing record and other documents, and increase of direct nursing time and patient education. Along with these changes, the nurses commented about the problems such as computer speed and physical discomfort from using mobile laptop computer with standing position.

Table 1 - Nursing time by shift

Classification	Day	Evening	Night
		Mean (min) (%)	
Direct nursing	200.57 (37.04)	150.71 (39.41)	120.42 (17.91)
Min	168.23	138.58	115.71
Max	204.43	158.34	124.17
Indirect nursing	220.28 (40.74)	230.07 (45.10)	310.71 (46.27)
Min	202.75	218.21	304.59
Max	230.24	240.35	315.09
Ward management	100.21 (18.52)	100.85 (19.61)	120.57 (17.91)
Min	70.92	88.71	101.42
Max	106.74	108.14	126.01
Personal time	20.57 (3.70)	30.42 (5.58)	80.92 (11.98)
Min	10.21	16.04	70.43
Max	30.53	34.50	90.63

Discussion

The study results indicated the introduction of ENR system made a change on nurses' job and nursing time, increasing direct nursing time and decreasing indirect nursing time [4]. Time efficiency can be one of many benefits and especially electronic nursing record systems can generate time savings in activities, such as accessing a patient chart or maintaining patients' report forms [5], [6]. Next steps in our research will involve monitoring nursing time with direct measurement tool such as video-taping and observation.

Conclusion

Future research is required to examine whether the capacity of the electronic nursing record system to improve the overall care delivery process of patients. New methods to measure the impact of the ENR on time efficiency from an organization's level will have to be developed.

Web Components for End-User Computing in Nursing

Shuo-Chi Liu [a,b], Polun Chang [a], I-Ching Hou [a],

[a] *Institute of Health Informatics and Decision Making, National Yang-Ming University, Taiwan*
[b] *Department of HealthCare Management, Yuanpei University, Taiwan*

Abstract

In this paper, we apply component technology to design a shared infrastructure that supports the nursing practice. A component model has been designed to develop flexible and tailorable web applications. The platform called NURSE serves as an environment in which web components can be run and tailored. The environment empowered nurses to create their own web component and creating web application.

Keywords:

web component, End-User Computing, nursing information system

Introduction

The limited available applications that support the tasks of nurses do not yet sufficiently address nursing needs. Nurses are dissatisfied with support provided by the information centers. Component-based Software Engineering (CBSE) has become recognized as a new sub-discipline of Software Engineering. Our work has centered on developing a software sharing environment as a research prototype 'Nurse Utilities Resource Sharing Environment' (NURSE).

The nurse utilities resource sharing environment

The platform is available under Microsoft Windows Sharepoint Services. The NURSE comes with common components that users can use right away. The web components are based on the technology 'Web Part**'.** A Web Part is a modular unit of information that has a single purpose and that forms the basic building block of a Web Page. Based on this environment, nurses are allowed to modify an application by reassembling components without programming. The NURSES deliver a set of core functionalities that allows nurses to develop their own specific web applications through the web-browser. It offer flexibility, ease of use can enhance the productivity of applications.

The architecture

The NURSE is web-based and operated by browser. Using internet based approach build components. Nurses can create more easily customizable application that brings a team together. The architecture forming by the component development steps:

(1) To create the infrastructure with templates to interact. The framework building a catalog of ready-to-use web component templates enable faster development that provides facilities to address a wide range of problems. The templates include: 'survey' ,'announcement list' ,'discussion board' ,' task list' ,' events list' ,'document library'. The ability to quickly develop using web modules componentized web page elements that empower nurses to create their own Web applications.(2) Components were developed for specific information needs. Extensible component architecture gathers various specialists to contribute their artifact. NURSE deposits web component resources. (3) Integration of components makes an application. By the way of providing the standards-based blocks build applications.

Discussion

We proposed an approach to empower nurses to create or assemble web applications, rather than to build the systems from scratch. Component can be reused, once a nurse write a web component and publish it, which can be used in multiple hospitals and nurses. The infrastructure provides a low cost solution to solve nurses' information demand. Future research would need to establish a mechanism to motivate sharing their artifacts and get rewards. Creation, cooperation, contribution for the sharing mechanisms are necessary prerequisites.

A Nursing Minimum Data Set in Occupational Health: Items and elements for professional Practice

Denise Tolfo Silveira [a], Heimar de Fátima Marin [b]

[a,b] *Nursing Informatics Center (NIEn) at the Federal University of São Paulo, Brazil*
[a] *Federal University of Rio Grande do Sul (UFRGS), Brazil*
[b] *Federal University of São Paulo (UNIFESP), Brazil*

Abstract

This article consists of a descriptive retrospective study that describes how the items and elements on the Nursing Minimum Data Set in Occupational Health were determined. The medical files of 106 patients were chosen for study and, from them, 777 records of first and return consultations between August 1998 and August 2003 were identified. They were analyzed on the basis of the categories and elements of the Nursing Minimum Data Set (NMDS) and the Nursing Management Minimum Data Set (NMMDS). The results showed that the lack of specific nursing data and faulty filing of documentation may be related to the failure by professionals to agree on a clear, permanent, validated, reliable and standardized set of data. A Nursing Minimum Data Set in the Occupational Health (NMDSOH) is presented, containing 31 items and divided into four categories: demographic elements, elements on nursing care, elements on the clinic, and elements on occupational health.

Keywords:

occupational health nursing, medical informatics,

data collection

Introduction

Information systems in nursing were first defined and implemented to support the practice of caring and to facilitate the work of nurses in collecting, storing and analyzing data on patients, with the objective of defining needs and planning the care to be provided [1]. However, factors such as difficulties in standardizing nursing vocabulary and the fact that the measures taken are often planned in a more intuitive than systematic way, have led nurses to make little use of computerized systems. They therefore produce little information, based on the data collected, which could describe and sustain their practices.

One of the first attempts at standardizing a set of essential data for the practice of nursing was developed by Werley and Lang [2] in 1988, known as the *Nursing Minimum Data Set* (NMDS). Elements on nursing divided into categories provide much inter-related data through which the essential data is organized, classified, processed, accessed and studied, in order to support the management of the care provided by health professionals in varying contexts. Another set of data, developed with the objective of addressing the needs of data for nursing management, was the *Nursing Management Minimum Data Set* (NMMDS), as presented by Delaney and Huber [3].

In the same vein, it is of utmost importance to standardize and identify a minimum set of data that will provide the necessary information regarding nursing care in occupational health. In other words, it is possible to gather data on the nursing process and standardize it into a set of items that describe nursing activities and serve as support to the work of nurses in occupational health. Such data also makes it possible to produce information aimed at evaluating the quality and results of the health care provided to clients or patients. In the process, the related decision-making and research can also be evaluated.

Considering these aspects, the present study has the objective of describing how of the items and elements on the Nursing Minimum Data Set in Occupational Health (NMDSOH) were identified.

Methodology

The present article consists of a descriptive retrospective study [4]. The data analyzed here were taken from the agenda of Occupational Health Nursing (ESO) at the Public Health Nursing Out-patient Clinic (SESP) at the General Hospital of Porto Alegre (HCPA), Brazil. More specifically, the information was obtained from the nursing records kept at the outpatient clinic and from the records in the institution's database, collected between August 1998 and August 2003. On the 106 medical files analyzed, 777 records of first and return consultations were identified. The categories and elements on the concepts of the Nursing Minimum Data Set (NMDS) and the Nursing Management Minimum Data Set (NMMDS) were used to choose the terms to be used on the basis of the records of nursing consultations. In a second stage, an instrument was submitted to eight specialists in the area of occupational health. This instrument was designed to measure the level of agreement, appropriateness and priority of the data chosen for the proposed model. Preliminary tests on the questionnaire were also carried out in regard to its suitability and pertinence, based on a sample, by conve-

nience, of 19 computerized records of nursing consultations from the agenda at the ESO/SESP/HCPA.

The data were treated and analyzed with the help of descriptive statistics (frequency and percentages) on *Excel for Windows®* and *Statistical Package for the Social Sciences (SPSS)®* [4] [5].

Results

Categories and elements identified in the nursing documentation

Patients/clients demographic items

Among the data on the elements for *Identifying patients/clients,* the most frequent were Name (29.9% of all records) and Age (28.3% of all records). The data include Gender, Date of birth (age), Ethnic group and Residence (phone contact, origin).

Nursing care items

The most frequent data from *Anamnesis* are nutrition (93.0% of all the records), humidity (89.4% of all the records), physical activity (79.9% of all the records) and urinary and intestinal elimination (42.8% of all the records). The most frequent data related to *Physical examination* were blood pressure (96.6% of all records), body weight (95.1% of all the records), behavior (62.3% of all the records), height (29.9% of all the records), laboratory and clinical examinations (28,8% of all the records) and emotional state (28.3% of all the records).

Elements on *Nursing diagnosis* were frequently identified in the documentation (92.3% of all the records). The elements on *Nursing intervention* identified were also categorized for better presentation, including orientation on nutrition and health, physical activity, life-style practices, orientation on measures for occupational promotion, protection and rehabilitation. Among the most frequent findings were data on orientation for improving patients' information regarding the process of the disease and regarding self-care (95.4% of all records). Among the elements on *Nursing results,* the most frequent data identified in the documentation analyzed were related to clients' behavior toward the proposed treatment (84.4% of all the records).

Service items

The data included in the elements in this category (elements on the unit, or clinic, elements on a single patient/ client file, and elements on nurses) are standardized in the identification forms found in the patients' files and made available as data referring to hospital management, taken from the Porto Alegre General Hospital's information system.

Occupational health items

Among the most frequent data found among the elements on Occupational history are "Current job situation" (25.2% of all records) and "Current type of work" (20.8% of all records). Among the most frequent data in the elements on Occupational health and safety are "Symptoms of current disorder" (86.5% of all records) and "Current treatment" (63.3% of all records).

It should be noted that no elements or data were found in the records regarding *Items on the environment, on Nursing resources, or on Financial resources.*

Evaluation by specialists

A questionnaire was prepared for evaluating the elements. A group of specialized consultants was set up consisting of eight persons [n=8], including four university professors and four social service nurses. Using this questionnaire, each consultant was asked to indicate his or her opinion as to each of the elements listed, in terms of the degree of its pertinence as a quality that should appear in the data set, and its degree of priority. It was decided to present only the results shown in the columns of answers [I agree] and [Important], as they addressed the specific objectives for validating the contents based on judgment [4].

According to the specialists, it is important to include data from the patient's/ client's demographic items, service items, nursing care items and occupational health items (100%) on the NMDSOH. The percentage of agreement is lower regarding administrative data involving management of the care provided. These aspects include complaints about the treatment (62.5%), the duration of the nursing consultation (62.5%), availability for treatment (62.5%), time taken to get to the clinic (50%), and number of patients/clients per nurse (50%). These data are all present on the NMMDS.

However, it can be said in general that the specialists agree with the list of data included in the set. Their observations and suggestions were therefore made used of in terms of their understanding, objections and suggestions for refining the instrument, and later definition of the items and elements on the NMDSOH.

Discussion

Very little of the information included in the category of the patients'/clients' demographic data was present in the documents analyzed because it is present on the standard computerized form used at the institution.

The predominance of data from anamneses, physical examination, and laboratory examinations can be understood in the light of Maslow's theory of Basic Human Needs, adopted for the nursing process at the HCPA. The prevalence of the evaluation of nursing in terms of the patients'/clients' biological needs can also be explained by

the fact that professional practices are still deeply impregnated with a tradition of referring only to epidemiological and clinical aspects when planning modes of intervention [6].

The high frequency of diagnostic nursing elements shows the importance attributed to this phase in the nursing documentation at the HCPA. Since the 1970s, this hospital has applied systematic descriptions of the services it provides, and the results are consistent with the frequency of data from anamneses and physical examinations in the files. Evidence also shows that the subsequent stages of the nursing process depend on the quality of the initial evaluations and their respective documentation [7].

In the category of Items on occupational health, the records showed a low percentage of data from elements on environmental risk factors and from elements regarding occupational history. It is especially important to note that the lack of data such as the current and previous types of work performed, work processes, working conditions, working environment, workplace, and work sector in the initial phase of application of the nursing process may indicate a lack of information to support the patients' / clients' real or potential needs, especially in the causal relationship between health and work.

It can be inferred that the lower frequency of the data in the initial gathering does not mean that no data at all were collected. The diagnostic impressions and the nursing interventions mentioned in the records take into account information that indicates that such data were processed. Another possible explanation for this finding might be the precaution by the nurses to avoid duplicating information contained in the records of medical anamnesis. But one can nevertheless criticize the lack of visibility and availability of nursing data that contain specific elements on occupational health to be applied in professional practice.

Unfortunately, in terms of the items listed on the NMMDS, one could criticize the failure of the specialists to evaluate the elements [data] on quality and level of solution of the steps in relation to the attributes of the caring process. It would seem that quality in health has caught the attention of researchers but not of those who actually provide occupational health services, as these latter do not seem concerned with having records that describe information that might facilitate the evaluation of the care provided. Therefore, the commitment of professionals involved in caring – the continual work of defining and measuring the quality of the assistance provided, as indicated by Delaney and Moorhead [8] – loses its importance in the definition of "quality." In addition, as Donabedian [9] has stressed, approaches for evaluating quality in health include components related to the resources needed for treatment, as well as components related to activities carried out between professionals and patients, where these administrative data on care management can be included.

Elements of the Minimum Nursing Data Set in Occupational Health (MNDSOH)

Chart 1 summarizes the list of essential, or minimum, data identified on the basis of the terms chosen in the systematic nursing records and evaluated by the group of specialists for presenting the NMDSOH.

Elements of the Nursing Minimum Data Set in Occupational Health (NMDSOH)

Patient/Client Demographic Elements
- Patient's/Client's Registration Number
- Patient's/Client's Name
- Age
- Ethnic Group
- Gender
- Origin
- Marital status
- Occupation
- Schooling (in years)
- Full address

Nursing Care Elements
- Anamnesis and physical examination (evaluation protocol)
- Nursing diagnosis
- Nursing interventions
- Nursing results
- Patient/client treated
- Accessibility for patient/client

Service Elements
- Name of Institution
- Name of service/clinic
- Type of health insurance plan
- Date of out-patient admission
- Date of out-patient release
- Date of nursing consultation
- Team responsible
- On-duty nurse
- Type of nursing activity
- Volume of nursing care
- Complexity of nursing care
- Costs of nursing Care

Occupational Health Elements
- Professional history
- Environmental risk factors
- Occupational health and safety

Chart 1 - Elements of the Nursing Minimum Data Set in Occupational Health (NMDSOH)

The data included in ***Patients/clients demographic elements*** are described extensively in the literature regarding routine admission records of patients/clients. The basic demographic information allows data to be summarized, which, when combined with other elements or groups of elements, provide important information [10]. Formal education provides information on access to culture, consumption, income, and professional training.

Two pieces of data are found on the NMDS [2,3] regarding these aspects, and, three other types of data were included to cover the occupational health area.

In ***Service elements,*** the data on the element of *Complexity of the nursing care*, which include the perception of factors that are internal to the care given as well as other that are external, and serve as possible indicators for evaluating the results regarding the care aspect.

The data on *Volume of nursing care* refer to the total time dedicated to nursing care and to the size of the nursing team involved in caring. These aspects include the number

of professionals involved and their availability for individual, collective or group support services, and the number of patients/clients per professional.

Nursing information adds a perspective of the patient/client that goes beyond the costs of the disease or disorder and the medical service provided, as it also considers the *Costs of the nursing care.*

These data can be processed to generate useful information for planning strategies to integrate health education, procedures, services and management. Only in this way can the health system be placed under the control of society in order to provide qualified health practices and proper training of health professionals. Four of these elements are included on the NMDS and two on the NMMDS. Other elements were selected according to the specific needs of the area of occupational health.

In ***Nursing care elements,*** the following data are included under *Anamnesis and physical examination:* review of systems, nutrition, humidity, sleep/rest, physical activity, leisure, rashes, family risk factors, elimination, physical measurements, measurement of vital signs, laboratory and clinical examinations and images, capillary glycemia, general conditions of the body and members, mobility and movement, and emotional state.

The data on *Nursing diagnosis* include the description of the current diagnosis based on analysis and interpretation of the information obtained. The patient's/client's health can be evaluated on the basis of such information.

The data on *Nursing intervention* include the description of the intervention performed. Interventions refer to orientation for occupational promotion, protection and rehabilitation, as well as education in health for self-care (nutrition, physical activity and life-style habits), indications for laboratory examinations, referrals to other professionals, and release procedures.

The data on *Nursing results* include the patient's/client's evaluation of the state of resolution of the nursing diagnoses and interventions. This refers to the difficulties in controlling or managing treatment, the need for information about the current disorder or damage and/or treatment, and behavior toward the nurse's orientations: acceptance vs. non-acceptance, decided vs. undecided (transferred or referred).

The data on *Patient/client treated* include the characteristics of the population attended in the area of nursing in occupational rehabilitation (off work or not, pending examination by the federal health program, and follow-up by other professionals).

The data o*n Patient's/client's accessibility* include the time patients take to get to the clinic and the time spent during the nursing consultation.

The data on Nursing diagnosis, Nursing interventions and Nursing results show the characteristics indicated by Werley and Lang [2], whereas the data related to Patients'/ clients' accessibility, Patient/client treated, and Volume of nursing care are in accord with the characteristics indicated by Delaney and Huber [3].

It is felt that the inclusion of the above types of data should improve the production of information on which to base clinical decisions, manage quality, and determine the most suitable care to be given. As Delaney and Moorhead [8] stated, it is important to include nursing data in statistics on health care, both for the health community and for the patients/clients themselves.

In the ***Occupational health elements*** the data included in *Occupational history, Environmental risk factors,* and *Occupational health and safety* were already listed in Lynch's [11] study, where he proposes a structured information system structured around four databases in occupational health.

The data on *Occupational history* include the current and previous types of work, the characteristics of the work, how long the person was on the job or in the occupation, and his or her working hours, in order to understand the relationship between work, occupational health, and disorder.

The data on *Risk factors* include the type of exposure to the risk, the use of individual safety equipment, ergonomic aspects, and workplace, thus completing the study on the factors present in the working environment.

The data on *Occupational health and safety* deal with each patient's/client's morbidity and mortality rate, as this information provides data on working situations, which is important for making health diagnoses.

The use of the NMDSOH facilitates analyses that will identify the structure for determining individual or collective health-sickness processes and the characteristics of social groups where they occur. This makes it possible to draw up a clearer description of the real and potential living and working conditions. The information processed should contain the elements necessary to explain and understand causal processes, together with the list of factors that are sensitive to intervention. This also enables the professionals involved to become more aware of the patient's/ client's health situation before taking decisions and following-up on and evaluating the results of the measures taken.

Conclusions

The final results of this study recommend the inclusion of 31 items on the NMDSOH, divided into four categories, to wit, patient's/client's demographic elements, elements on

the nursing care, elements on the clinic, and elements on occupational health.

The conclusion here is that a Nursing Minimum Data Set in Occupational Health (NMDSOH) based on terms used in nursing records can serve as a frame of reference when groups set out to make changes in information systems in health in the Brazilian context. The frames of reference for the NMDS and the NMMDS adequately addressed the analytic and theoretical needs for including items and elements [data] that described nursing care in the context of occupational health. In addition, the elements [data] on the NMDSOH can effectively be related to a database and a computerized information system in order to address the needs of the practice, research, decision-making and quality of the treatment provided by nursing in this health specialty.

This study also emphasizes the importance of determining a set of minimum data that should be included in the forms and records that make up the databases. The data can thus be better documented and structured in the information systems. There is a real need of adequate methodological tools to provide not only the survey on health conditions and harmful occupational factors, but also the relation or association of elements that comprise the work-health-sickness process, taking into account both organizational and environmental aspects, as well as life conditions of workers. Nurses could then make better use of such data, to the extent that the correct information is produced for the performance and description of their caring practices in occupational health.

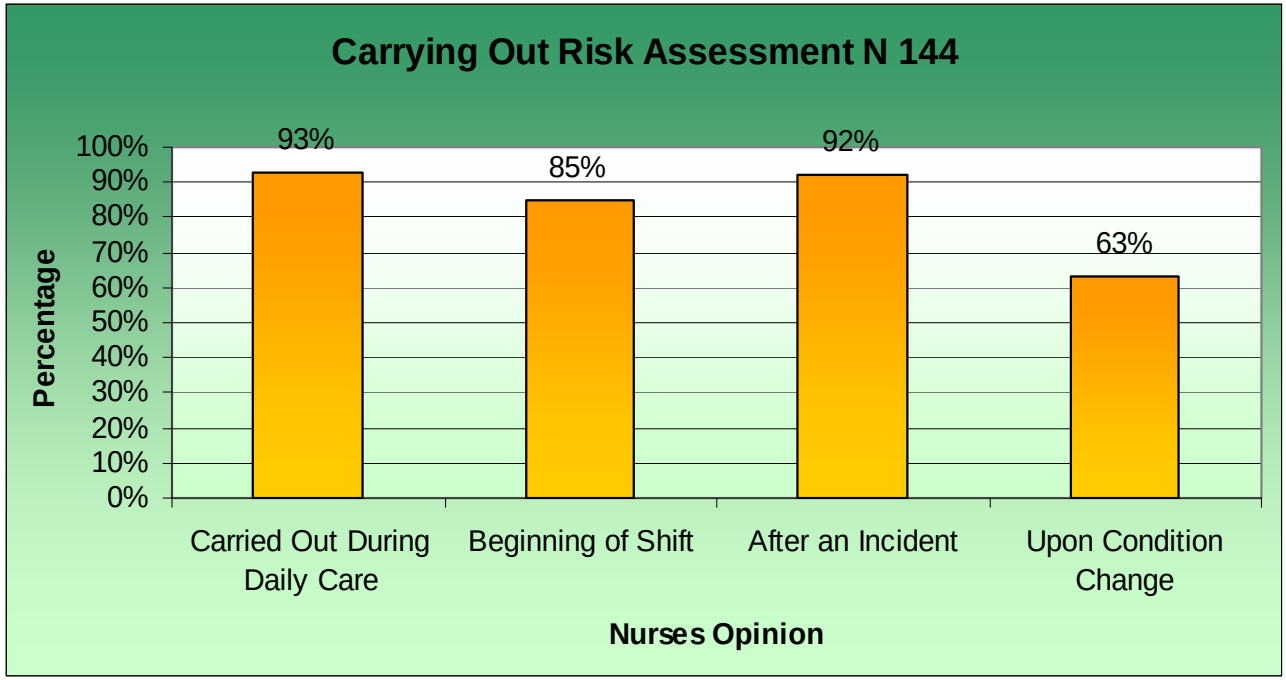
Overview Current Nursing Risk Assessment

- When do nurses carry out risk assessment ?
- Does it assist with care planning?
- Are there time constraints?
- Have they been educated about risk assessment?
- Do they value the current paper based risk assessment form?
- Have they been educated about the current form?
- Would a computerised form assist their practice?

Methodology

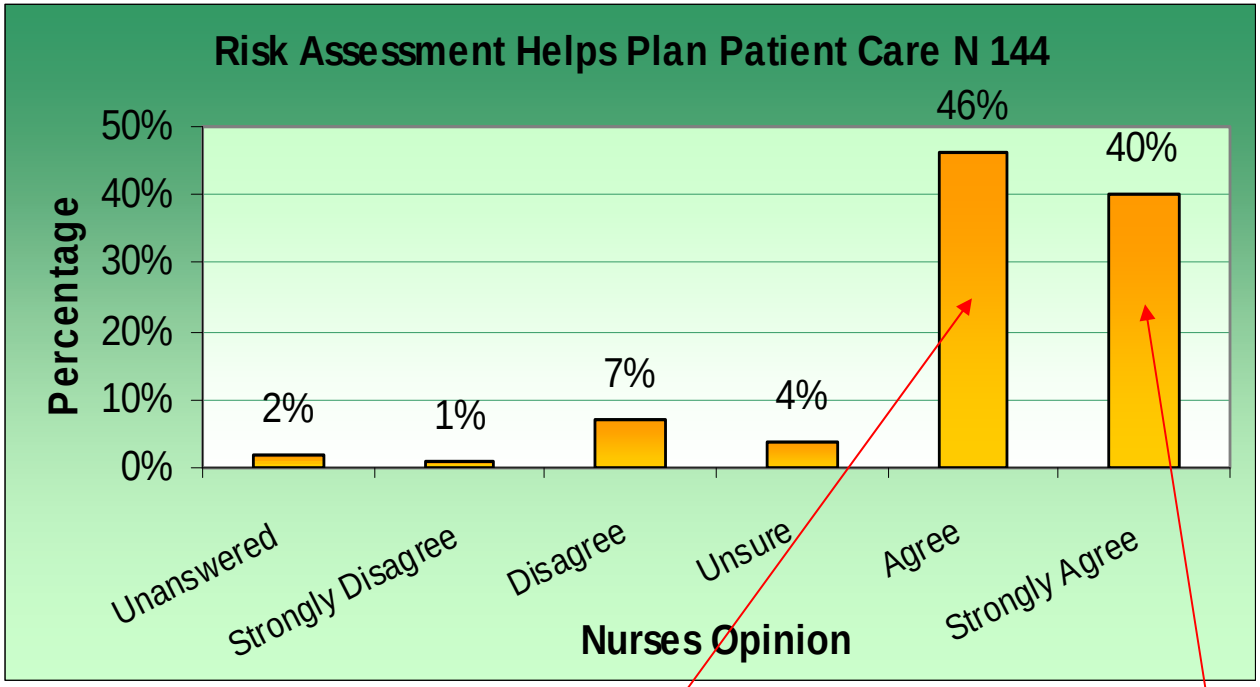
- Purpose developed questionnaire
- 10 randomly selected wards wards surveyed
- Over 3 campuses
- 415 surveys distributed
- 144 completed
- 35% Response rate

When Risk Assessment is Done



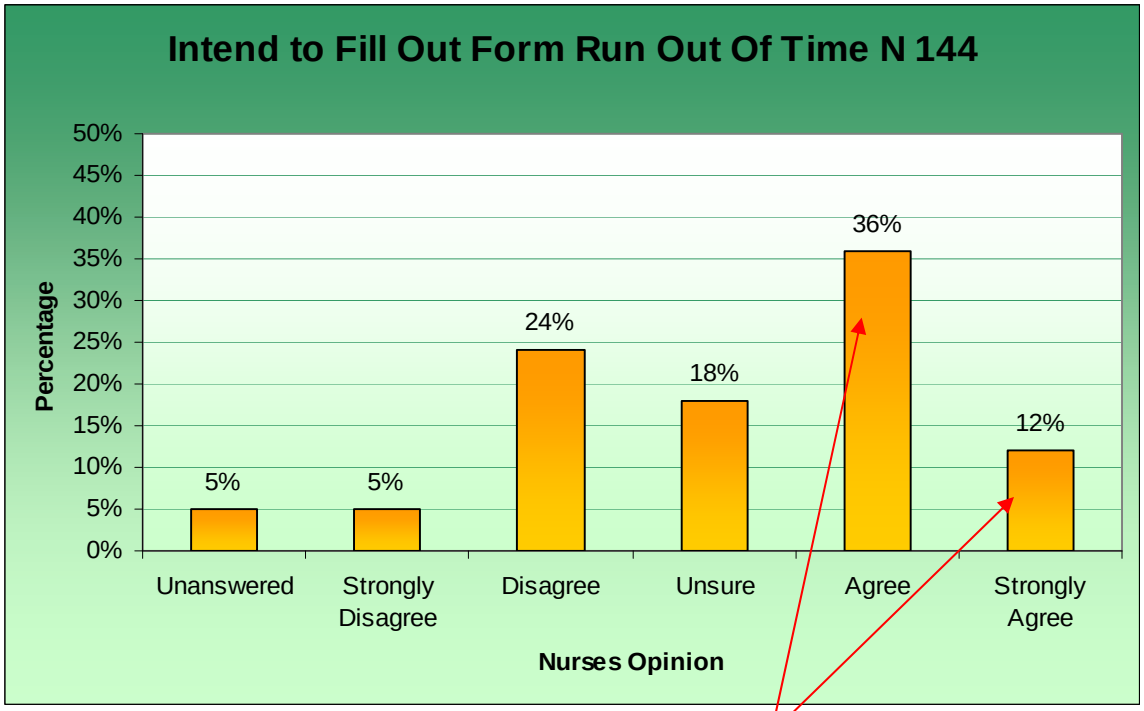
The majority of nurses, > 85% carry out risk assessment during their daily care, at the beginning of a shift and after an incident. However, a lesser number 63%, re-evaluate risk upon condition change.

Assists Nurses Plan Care



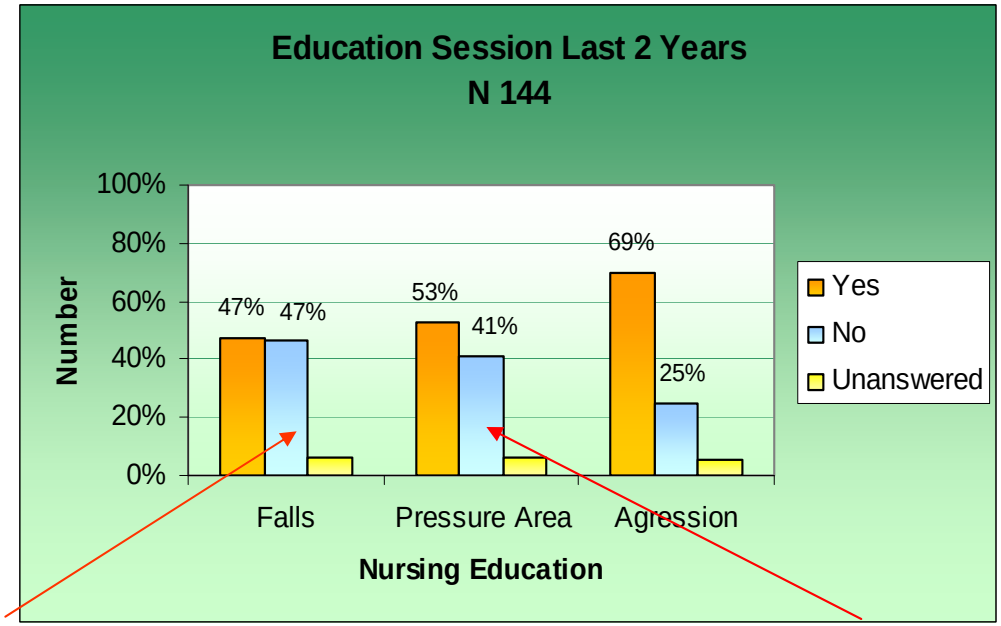
The majority of nurses agree (46%) or strongly agree (40%) that carrying out a risk assessment assists with care planning.

Nursing Time Constraints



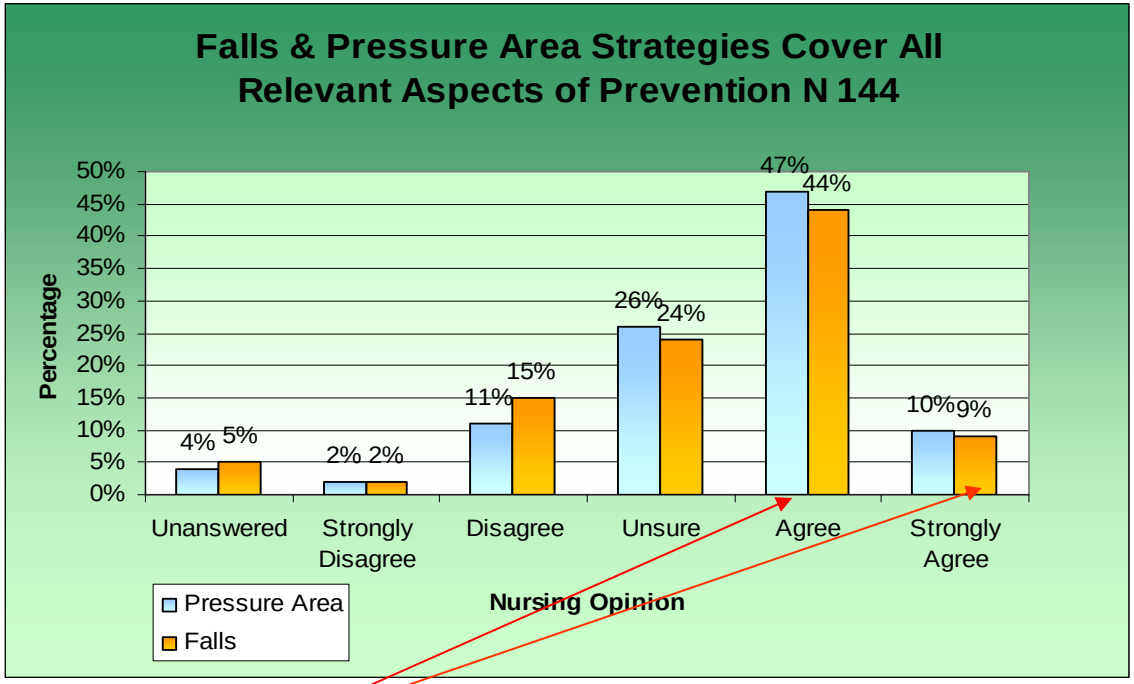
48% of nurses indicated that they often intended to fill out the current risk assessment form but then ran out of time.

Educated on Risk Assessment



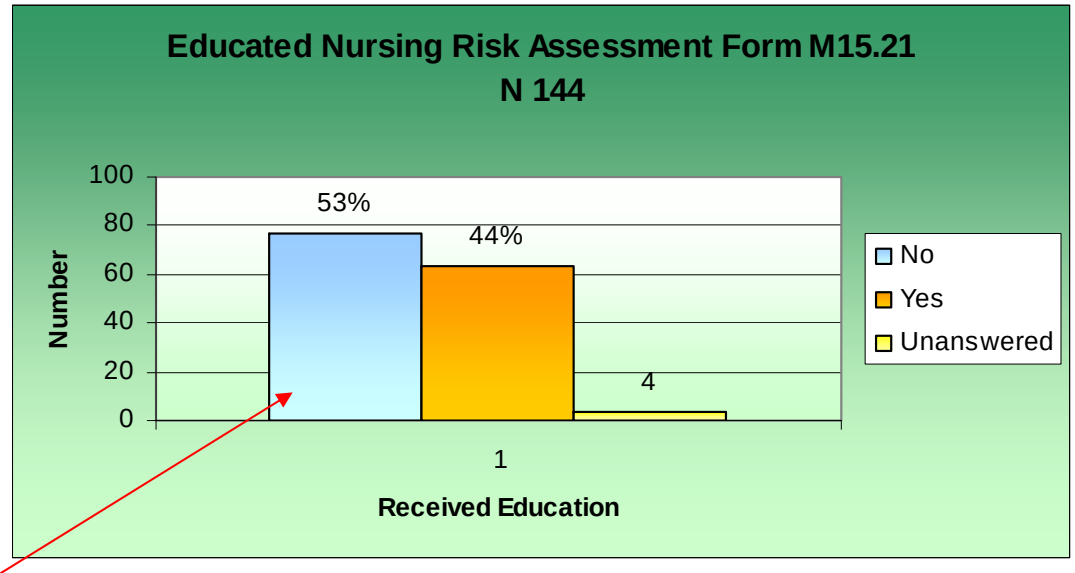
There is still a significant percentage of nursing staff who require education on risk assessment, with pressure areas and falls showing the largest gap.

Value Strategies on Current Form



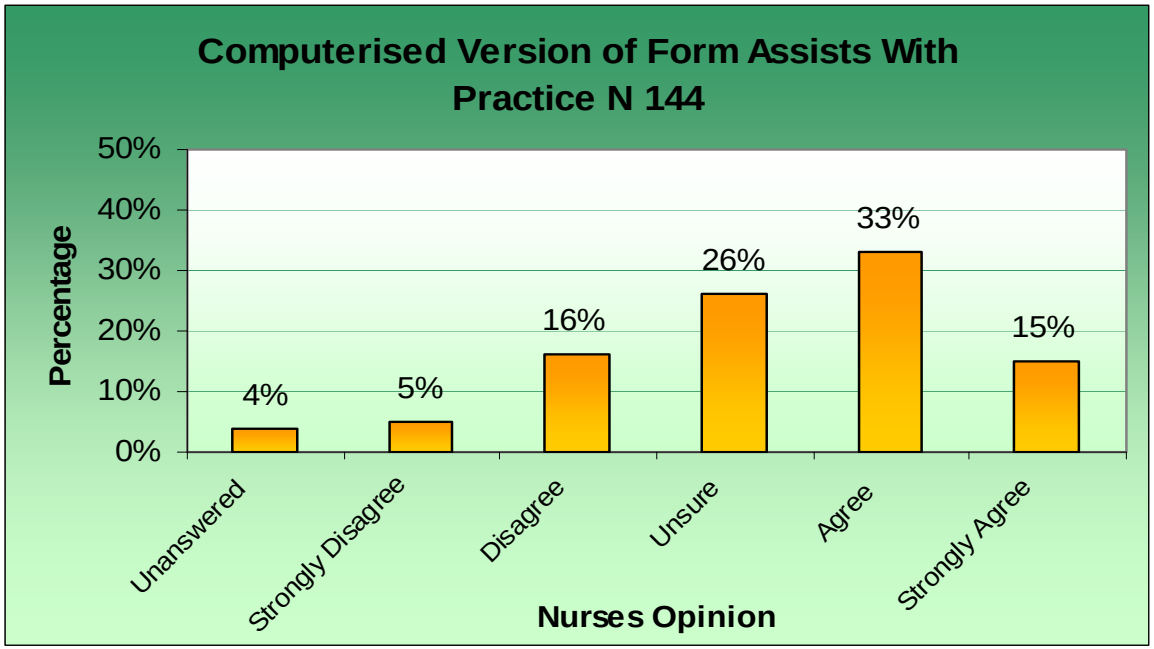
Greater than 50% of nurses agree or strongly agree that the strategies on the current risk assessment form cover all relevant aspects of prevention

Educated on Risk Assessment Form



53% of nurses surveyed indicated that they had not received any education on the use of the current nursing risk assessment form.

Computerised Form Assists With Practice



33% of nurses agreed and 15% strongly agreed that a computerised risk assessment form with risk strategies, equipment ordering, and referral capabilities would assist in their practice. 26% were unsure and 16% disagreed.

Conclusion

Electronic tool development will need to encompass :

- Current nursing workflow
- Interactions within the multidisciplinary team.
- Time saving features
- Decision Support functionality
- Strong change management & education of staff

Abstract

The implementation of any electronic system first requires an assessment of the current system to determine it's effectiveness.[1] This paper reports on results from a nursing survey that was conducted to explore nursing opinion of the current paper based Inpatient Nursing Risk Assessment tool in use at Austin Health. Areas explored focused on a) when nurses carried out risk assessment, b) it's importance to care planning, c)the use of the hospital nursing risk assessment form in relation to their practice, d) time factors d)education pertaining to risk assessment and the form and e) whether a computerised form would assist their practice.

Keywords:

risk assessment, electronic, paper based, acute hospital patients, current use, effectiveness, clinical practice, nursing

Introduction

The Victorian Quality Council identified falls and pressure areas as two components of a strategic approach to reducing the risk of harm and improving health care safety and quality in Victoria.[2] [3] Austin Health introduced a paper based inpatient nursing risk screening and assessment tool [4] in response to these initiatives in 2004. The form was designed to carry out a risk triage for pressure areas and falls, with a single question relating to aggression. The tool is intended to be filled out for every patient upon admission, repeated upon a designated review date, and again, if a patient's condition changes. Once a patient has been assessed at risk of falls, or pressure ulcers, falls minimisation strategies and pressure ulcer prevention strategies are initiated and recorded in the strategies section of the form. Since the introduction of this form the health service has also developed and implemented a comprehensive aggression risk assessment and management form,[5] which has eight risk screening questions, aimed at identifying risk level. It too has actions, interventions and a suggested management plan.

Chart audits of 60 randomly chosen charts, carried out prior to the nursing survey indicated that the inpatient nursing risk assessment form was not being used effectively[6]. Only 68% of charts had the form present, with just 43% of those having the initial triage section of the form completed, or partially completed. With this in mind, it was important to gain a better understanding of nursing staff values and opinions regarding risk assessment and the use of the current paper based forms[7]. This survey forms part of the project designed to address one of the strategic priorities of Austin Health i.e "the development of an IT strategy to support improved safety and quality, including clinical audit"[8]. This will take the form of an electronic risk assessment tool . The initial focus will be upon the development of a nutrition risk screening tool, with pressure areas and falls risk to follow.

Methodology

Purpose developed nursing surveys were distributed to 10 randomly selected acute and sub acute wards on 3 campuses during a two week period. Both division one and division 2 nurses were surveyed. Of the 415 surveys handed out, 144 were completed, giving a 35% response rate.

Results

Risk Assessment

Participants in the survey group indicated that carrying out a risk assessment was important, that it is usually done during day to day care (93%), and that it helps them plan

8 Austin Health Strategic Plan 2006-2008

their patient care (85%). They felt it was important to carry out a risk assessment at the beginning of every shift, when the patient had an incident and when the patient's condition changed.

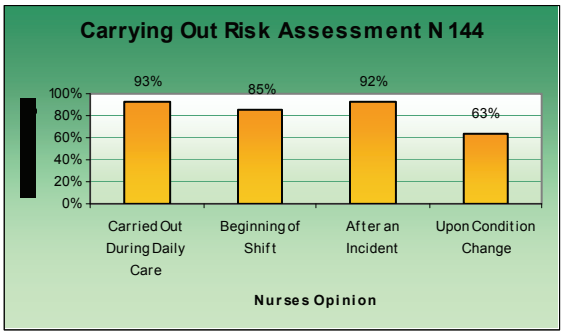

Figure 1 - Nursing Risk Assessment Tool

When the efficacy of the current paper based tool was addressed, the nurses were divided as to whether it fits in with day to day practice, however, 48% of nurses indicated that they often lacked the time to fill it out. They agreed that the suggested falls and pressure area strategies had value and were practical to implement. When questioned as to whether a computerised version of the form, with prompts to assist with initiating risk strategies, such as ordering equipment, and placing referrals to allied health services would assist in their practice, 15% of the nurses strongly agreed 33% agreed.26% were unsure with 16% disagreeing.

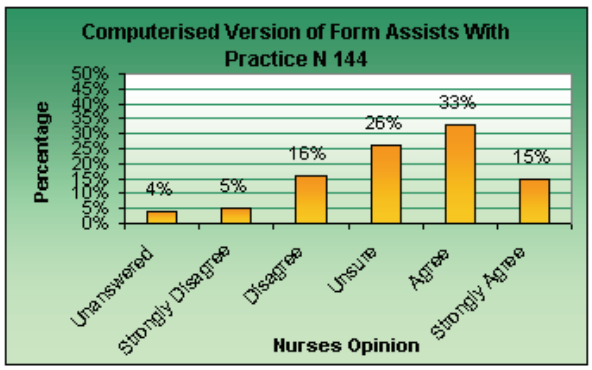

Figure 2 - Computerised version of form assists with practice. Nurses opinion

Education

When questioned about education on risk assessment, a large percentage of the nursing staff reported that they had not received recent education in the areas of; falls (47%), pressure area (41%) and aggression risk (25%). In addition a further 53% of nursing staff still require education on the use of the paper based tool.

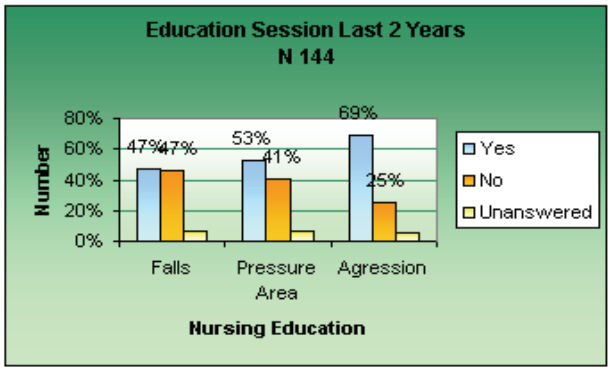

Figure 3 - Nursing Education

Discussion

Within the contemporary health care environment managers are constantly under pressure to find better and more efficient ways of transitioning patients through the system. This quest for streamlining processes needs to be supported by the development of equally streamlined health information management system. Risk Assessment is one component of that system.

The challenges we face in implementing electronic risk assessment are varied and require a multidisciplinary approach. We are relying on the frontline nursing staff to carry out risk screening upon patients, therefore it is imperative that we design a system that can be integrated into the way that nurses work.

Austin Health currently utilises a dual electronic and paper based patient health record. The nursing staff gathering patient information at the bedside are still using paper based nursing documentation which includes the current risk assessment tools.

Our results indicate that nurses believe risk assessment is instrumental in caring for patients, however, it is clear that a significant gap exists between their perceived values and documentation of their practice. To narrow this gap, we need to ensure that we design a system that enables nursing staff to document their practice in a streamlined and efficient manner. We believe the solution to this problem is an integrated electronic risk assessment tool that encompasses time saving features.

We can then improve the quality of nursing documentation. A recent study by Moody[9] of 100 nurses in a large

9 Moody L, Slocumb E, Berg B,Jackson D, *Electronic Health Records Documenation in Nursing: Nurses'Perceptions, Attitudes and Preferences* Comput Inform Nurs 22(6): 337-344, 2004. Lippincott Williams & Wilkins

Florida magnet hospital indicated that 75% of nurses thought electronic health records had improved the quality of documentation and 76% believed electronic charting would lead to improved safety and patient care.

We can further consolidate this practice improvement by the implementation of a planned, recurrent and accessible education programme. This will enable us to raise awareness of patient risk as an issue.

The education programme will be multidisciplinary in focus and be conducted in conjunction with an extensive change management initiative based around the importance of clinical risk management. Moody's study refers to need to seek input from potential users of systems as many problems that occur with the implementation of electronic health records are organizational and behavioural in nature[10].

10 et al

Early assessment of nursing practice will allow for identification of possible barriers to the uptake of an electronic system. In turn, this will enhance our chances of reaching our goal which is to - achieve a world class system which represents best practice principles of clinical risk assessment and subsequent management.

Conclusion

The development of an electronic risk assessment tool will need to encompass current nursing workflows and interactions with the multidisciplinary team. The design will have to take into account the time pressures of nursing and incorporate time saving productivities into the system. Change management and education are an important part of any quality improvement strategy. To improve the usage of the paper based risk assessment tool it is clear that the a concerted effort to educate the staff on it's usage is required. The same will be true of any electronic system.

Nurses as Social Fabric: Role of Nurses in the Implementation of Health Information Systems

Michele Norton[a], Tip Ghosh[b]

[a]*University of Colorado at Denver Health Sciences Center, School of Nursing*
[b]*Department of Healthcare Administration & Policy, University of Nevada-Las Vegas*

Abstract

The social fabric of healthcare can be seen as a set of cultural ideas and practices and the social patterns and organizations by which they are interpreted. (Janzen, 2002). Nurses are now expected to function well within a technologically advanced healthcare environment, carry out higher-level, complex activities, and are held responsible and accountable for the systematic planning of humanistic nursing care for patients and their families.

Keywords:

organizational culture; nursing informatics; nursing care management

Background

Nurses provide the social glue that holds the organizational culture of a hospital together. The social fabric of healthcare can be seen as a set of cultural ideas and practices and the social patterns and organizations by which they are interpreted. (Janzen, 2002). People interact with each other with elements of trust and meaning that is embedded. These embedded social layers have special consequences in the context of implementation. They are the communication coordinators. The successful implementation of health information systems depends on the weaving and social interplay between nurses and other clinicians.

The role of the nurse is not fully understood in light of implementation of health information systems. The nurse's role in the delivery of patient care is intensified by refinement and modification of the practice of nursing (Hannah, Ball & Edwards, 1996). Nurses are now expected to function well within a technologically advanced healthcare environment, carry out higher-level, complex activities, and are held responsible and accountable for the systematic planning of humanistic nursing care for patients and their families. They are expected to keep abreast of technological implementation within their work environment.

Health information technology functions within a social fabric interacting with other individuals in an organization. Nurses are learning to integrate technology into their respective organizational culture. (Richards, 2001). Nurses shape organizational culture through their actions, bearing, conduct, attitudes, narrative and interactions in relation to others (Cronin & Rawlings-Anderson, 2004) Wolf (1988) delineated two main issues regarding nurses and their work environment. One was the underlying notion of doing good and avoiding harm; the second was that the transfer of cultural knowledge was mainly transmitted by word of mouth and demonstration.

Methods

We have utilized a purposive sample of chief nursing officers from across the US. Then we conducted a series of key informant interviews and focus groups with nursing leaders. These organizations were selected for the sample based on actual productive use/deployment of HIS. Multiple interview formats were used with the key informants. We utilized member checking and peer review to corroborate our findings to help ensure trustworthiness of our analysis. (Crabtree & Miller, 1999).

Observations from interviews.

"Involving nursing in the process allows them to understand, use, and value the technology tools that make a difference between safe care and risky/harmful or work around care."

"Our nursing staff was part of the initial phased roll out of HIS. This built in support system has been a critical factor in driving physician adoption. "The reality is at 2 am who are you going to turn to for answers to the questions… nurses are at the center of care for the patient and can provide the insight to those questions".

Conclusion

Organizational culture is the backdrop for all change processes. Nurses can help implement constructive organizational cultures by weaving a complex social fabric (Wooten, 2003).
Constructive cultures create high-performance work environments, increasing both nurse and patient satisfaction. A constructive culture emphasizes people-centered values through a collective mission and a compassionate patient service-oriented philosophy. Furthermore, constructive organizational cultures create work environments where nurses have positive colleague interactions and approach tasks in a manner that helps improve organizational performance.

A Basic Study On Application of Voice Recognition Technology to an Electronic Nursing Record System

Terutaka Marukami[a], Shoko Tani[a], Atsuko Matsuda[a], Akiko Shindo[b], Hiroshi Inada[a]

[a]*Course of Healthcare Informatics, Graduate School of Applied Informatics, University of Hyogo, Kobe, Japan*
[b]*Hyogo prefectural Amagasaki Hospital, Amagasaki, Japan*

Abstract

Computerization of a nursing record has progressed in Japan. However, the present electronic nursing record system using the conventional keyboard operation has some problems such as the input time and operationability for common nurses. In this study, we have planned to introduce voice recognition technology to the system and conducted a basic study for application of the technology. In the present study, a template for a focus chart as a progress record was contrived for simple information entry and easy processing of the entered information. An input experiment for evaluation of the template with the voice input tool was made and it was suggested our method might be useful.

Keywords:

electronic nursing record system, voice recognition technology, information entry, template, focus chart

Introduction

Recently, computerization in the nursing field has been progressing and an electronic nursing record system is gradually introduced in Japan. However, it is not said the present system can increase the time for nursing patients, because information entry for the system must be made by keyboard operation with which a common nurse is not familiar. Therefore, we intended to apply voice recognition technology to the information entry so as to increase in time for nurses to touch patients and improve the quality of nursing by shortening the recording time for an electronic nursing record system. The purpose of this study is to conduct basic investigation for applying a voice recognition tool as substitution of keyboard aiming at construction of the system which is appropriate to the field of nursing practice.

Method

In case of utilizing a voice recognition tool for only input of free sentences like input by using a word processor, it is very difficult to process the entered information. Therefore, we contrived a template for the information entry of an electronic nursing record system by which not only reduction of the input time and improvement of operationability but also easy processing of the entered information can be realized. The object of information entry for the system is fundamental nursing information by using Gordon's health pattern, information of a progress record by using a focus chart of patients and time-dependent record. For the focus chart, we made the template for the "focus", "action" , "data" and "response" in which words and phrases necessary for nursing registered in advance should be uttered by using Dragon Naturally Speaking ™ as a voice input tool. These words and phrases are hierarchically selected from the registered lists and have a dynamic connection to each other. Then, by using the template for the focus chart, a voice input experiment by four nurses as subjects was conducted for proving its utility and the input time, operationability and exactness of the information entry was evaluated.

Result

As the template, we tried to make windows for data of entering a progress record and time dependent record and a list of progress records. Figure 1 shows an example of the window templates for a focus chart as a progress record which is composed of entry items of a focus, data, action, responses etc. An example of a window of focus name selection for a respiratory conditions of a patient is shown in Fig 2. Figure 3 shows an example of the list. We can retrieve items shown in the list.

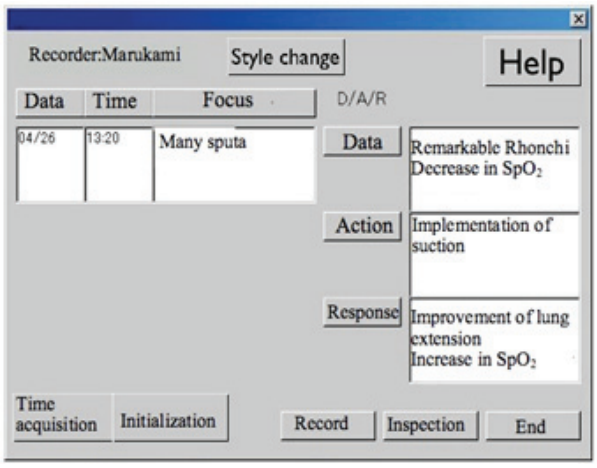

Figure 1 - Example of input screen of focus chart of voice input

We executed the afore-mentioned verification experiment by using the templates compared with keyboard input. The experiment revealed that the input time and operationability of the voice input was superior to the keyboard input although subjects who were nurses had no experience of the voice input. In addition, the misinput rate in the input of the free text part by the voice was 1.5% on the average and the misinput rate became 0% in the input of the selection part (Table1). Furthermore, it was clear that the words and phrases for the focus chart were exactly entered by using the template with the voice input tool.

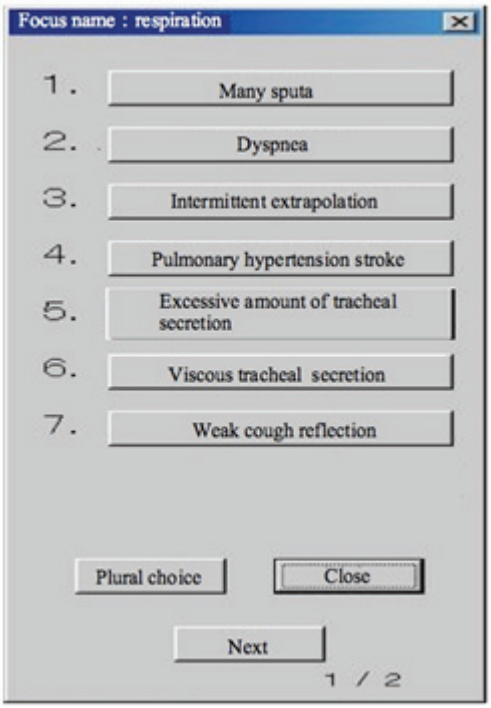

Figure 2 - Window of focus name selection of a respiratory cassification

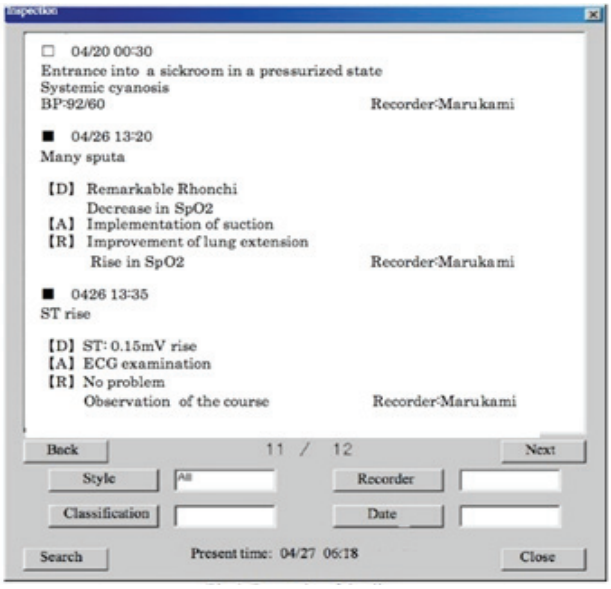

Figure 3 - Example of the list

Table 1- Result of the verification in experiment

Mis-input/Voice (Selective part)	Mis-input/Voice (Free input part)	Input time-Keyboard (Correction time is included)	Input time-Voice (Correction time is included)
0%	3%	520 sec.	155 sec.
0%	1.5%	899 sec.	197 sec.
0%	1%	294 sec.	204 sec.
0%	0.5%	500 sec.	122 sec.
average→ 0%	1.5%	533 sec.	170 sec.

Discussion and conclusion

From the experiment, it was suggested that the voice input using the template made by us was useful for information entry of the system. However, there is room for improvement of the operationability and exactness of the information entry concerning the template. In order to promote a voice input tool for an electronic nursing record system, it should be considered to use the tool together with the conventional keyboard input investigating the characteristics of the nursing field. Nevertheless, this study is thought to be significant, as it is the first trial of applying the voice recognition technology with the template to an electronic nursing record system.

Introduction

Computerization in the nursing field has been progressing and an electronic nursing system is gradually introduced in Japan.

But

- The present system cannot increase the time for nursing patients.

Because

- Information entry for the system is made by keyboard operation.

Common nurses are unfamiliar with keyboard operation.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

Purpose

We intended to apply voice recognition technology to the information entry of an electronic nursing record system.

To increase in time for nurses to touch patients and improve the quality of nursing by shortening the recording time for the system.

- Purpose of this study : Basic investigation for applying a voice recognition tool as substitution of keyboard.
- Construction of the system suitable for the filed of nursing practice.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

Method

- Contrivance of a template for the nursing record
  - Quick and easy input operation by voice recognition
  - Easy information processing after input
- Patient foundation information
  - Gordon's Health Pattern typology

The nursing record of the object

- Progress record
  - Focus charting
  - Time-dependent record
- Verification experiment
  - The comparison of the input time with the keyboard operation
  - Questionnaire investigation

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

The input screen of the progress record
(focus charting)

The window selection can be made by saying “style change”.
Styles :
①focus charting
②time-dependent record
③summary

Navigation function.
The next procedure is guided by saying "help."

Referring to Screen shot 4.

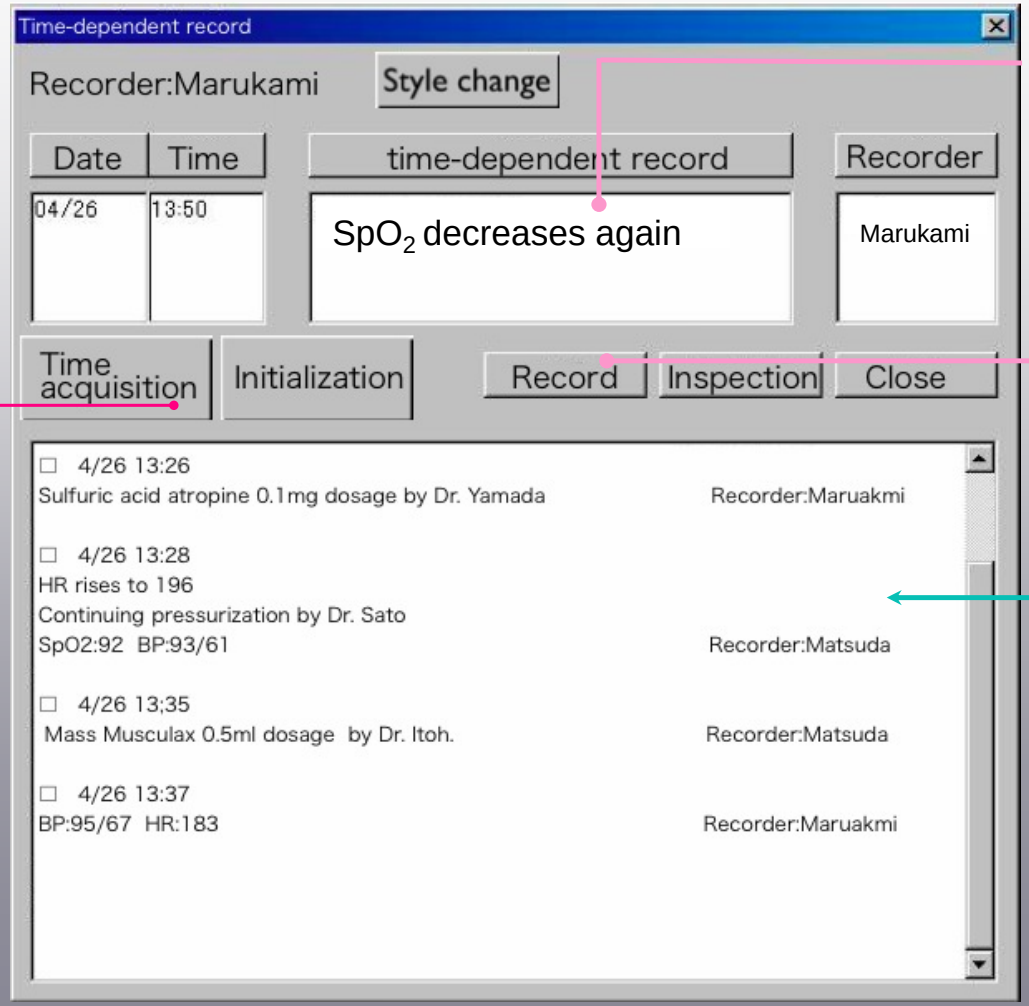
The date and the time is automatically entered by saying "time acquisition".

The entered contents are converted to a database by saying “record”.

All the records can be read by saying "inspection".
Referring to Screen shot 4.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

The input screen of the time-dependent record



Right after "time" is said, input of the time-dependent record becomes possible at once.

The date, the time and the name of the recorder is automatically entered by saying "time acquisition".

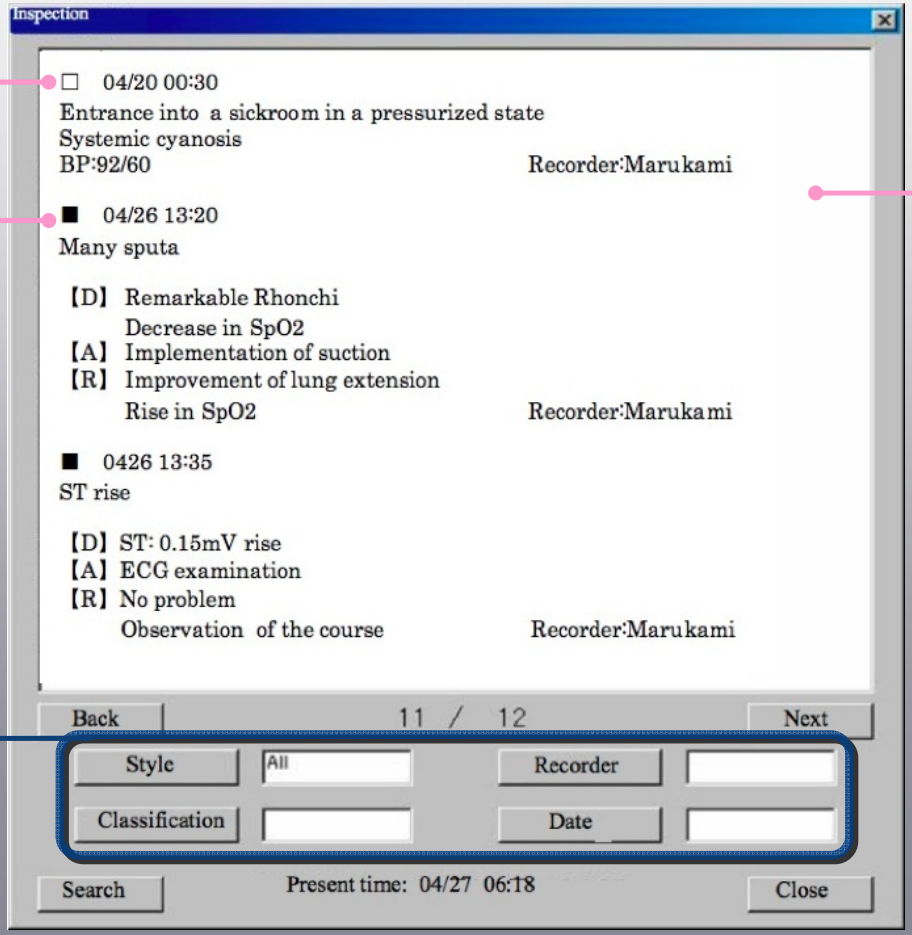
The content of the record is converted to a database by saying, "Record", and the content of the record is enumerated under the window in detail.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

A display and a search of the record

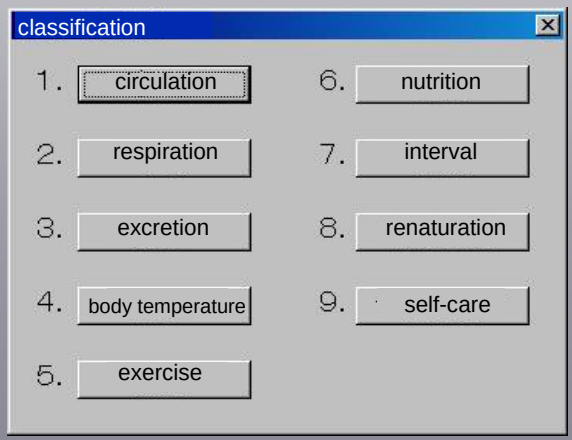
input screen of focusing or time-dependent record, this window is indicated by saying "inspection".

"□" should be inserted before showing the time-dependent record.
"■" should be inserted before showing the focus charting.



In default, the patient's latest record is indicated.

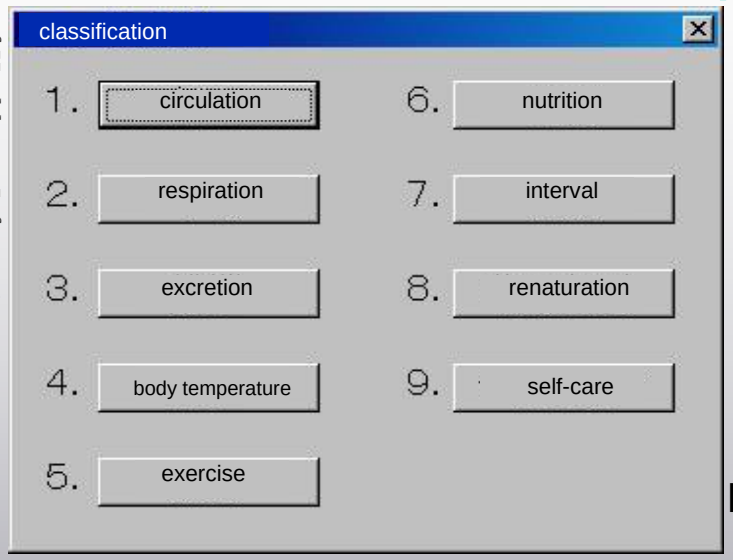
A record can be referred by the voice of keywords, "style", "classification", "recorder" and "date". When each keyword is given, the selection window is indicated except for the date.



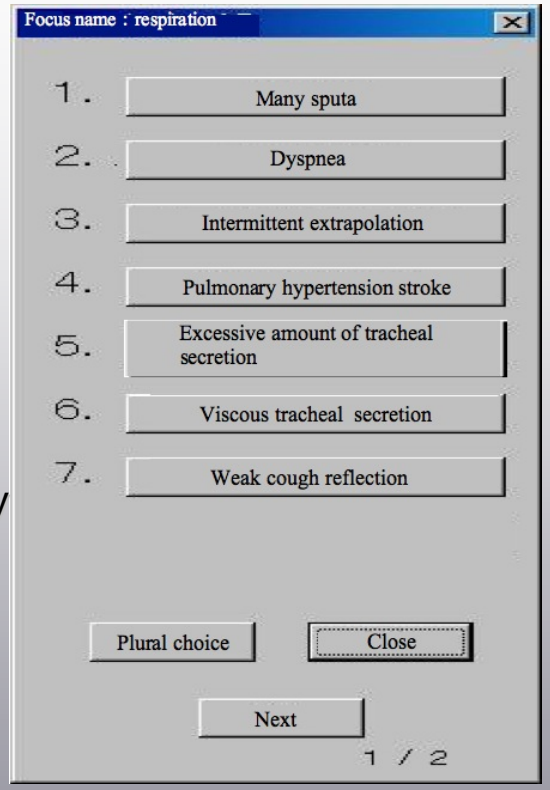
An example of selection window

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

An example of the selection window



hierarchially



- Item selection is able to be made by saying not only the name of item (keyword) but also the number of the corresponding item.

- In the input window of focus charting, the selection window of classification is indicated first by saying "focus".

- An item is entered with a voice of the corresponding item with visual observation under the condition of the active window.

- The window of the classification is hierarchially linked with the focus name window.
- The window is indicated by saying “action”.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

Results of the verification experiment

	Mis-input/Voice (selective part)	Mis-input/Voice (Free input part)	Input time/Keyboard (correction time is included)	Input time/Voice (correction time is included)
subject 1	0%	3%	520 sec.	155 sec.
subject 2	0%	1.5%	899 sec.	197 sec.
subject 3	0%	1%	294 sec.	204 sec.
subject 4	0%	0.5%	500 sec.	122 sec.
average→	0%	1.5%	533 sec.	170 sec.

Touch typing

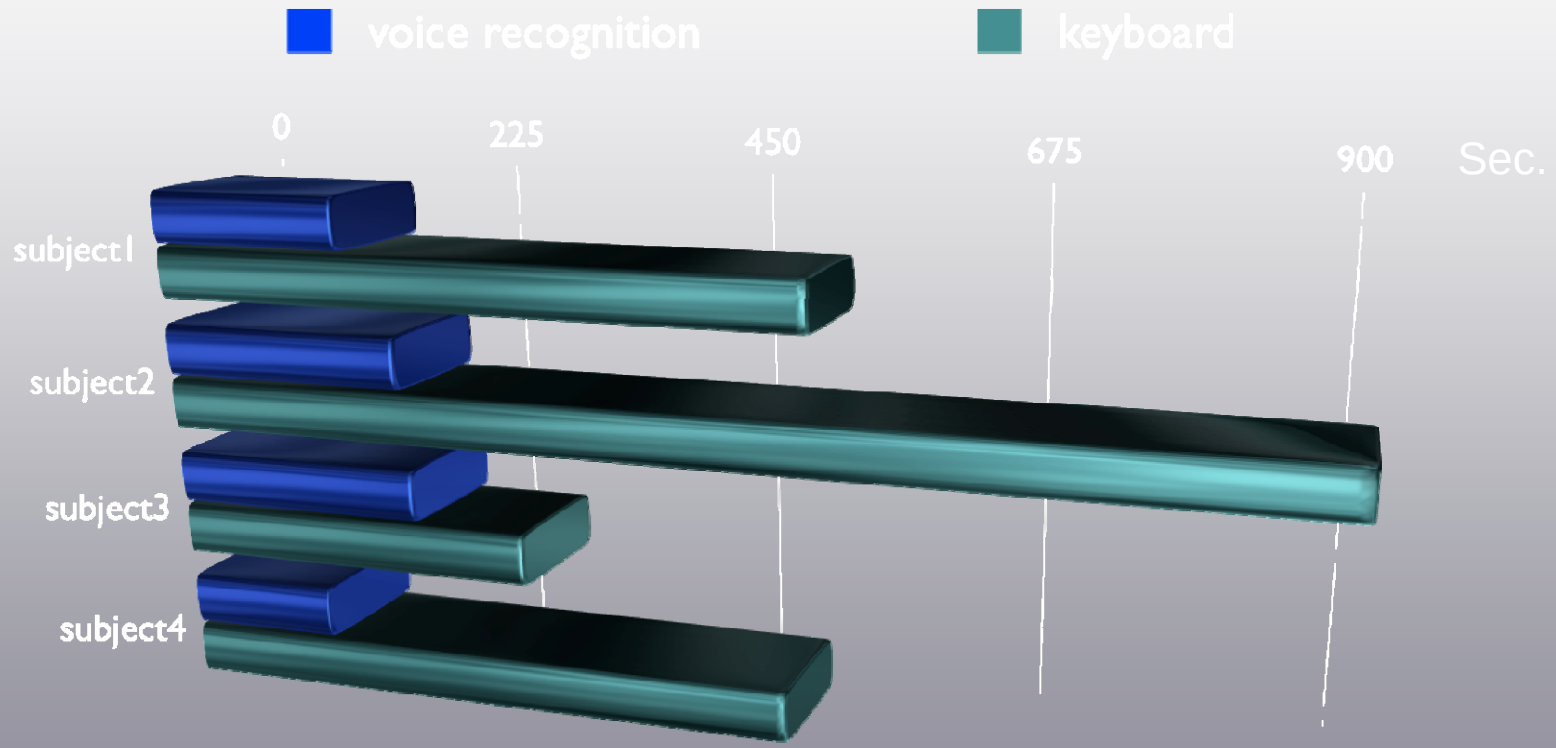
Usability→ keyboard ＜ Voice recognition

by questionnaire investigation

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

Result 2

Comparison of input time between voice recognition and keyboard operation.



- Subjects are nurse.
- Touch typing is possible by two people.

Department of Healthcare Informatics,
Graduate School of Applied Information,University of Hyogo

Discussion and Conclusion

From the experiment, it was suggested that the voice input using the template made by us is useful for information entry of the system.

- However,
  there is room for improvement of the operationability and exactness of the information entry concerning the template.
- In order to
  promote a voice input tool for an electronic nursing record system, it should be considered to use the tool together with the conventional keyboard input investigating the characteristics of the nursing field.
- Nevertheless,
  this study is thought to be significant, as it is the first trial of applying the voice recognition technology with the template to an electronic nursing record system.

Abstract

The purpose of this study is to analysis and to develop a well-defined electronic nursing record system integrated with nursing clinical pathway for improving the proficiency and accuracy in nursing process. We try to distinguish three major factors which is schema, terminology, and working flow will figure out how to and what to construct a well-defined electronic nursing record system integrated with nursing clinical pathway.

Keywords: electronic nursing record, nursing clinical pathway

Introduction

The health insurance policy such as Diagnosis Relationship Group (DRG) and global budget always changes and influence clinical care style in Taiwan recently. Thus, the Clinical pathway gradually becomes a major care index for nursing care. [1]

Clinical pathway is a standard style for specify disorder that examination, treatment, nursing care, and health education since patient admission through discharge.

In Taiwan, there are 55 clinical pathways guiding support clinical practice in Medical, Surgical, Cardiologic, Obstetric, Urologic, Ophthalmologic, Orthopedics, and Pediatric department. [2] But many formats duplicate between clinical pathway records and nursing records. It makes double working for nurse in these records. Although computerize nursing record is develop for many hospitals, But defect the same style and couldn't to exchange for share patient's data and knowledge management. Therefore, it is importance for analysis and constructs well-defined electronic nursing record integrated with nursing clinical pathway.

Method

There are three ways for this feasibility study.

First, we will analysis some references by the PubMed and local database related to clinical pathway in policy, format, and information system were discussed. It will figure out what are important factors to construct a well-defined electronic nursing record system.

Second, we will collect information and problem about nursing clinical pathway in clinical practice by

questionnaire of 17 medical centers. It will figure out what are implication and limitation about integrate to electronic nursing record.

Finally, we will combine previous methods to integrate with standard of electronic health record such as Health Level 7(HL7) and Clinical Document Architecture (CDA), North American Nursing Diagnosis Association (NANDA), International Classification for Nursing Practice (ICNP), Nursing Intervention Classification (NIC), and Clinical Care Classification (CCC). It will become the three major factors which are schema, terminology, and working flow. We hope to figure out how to and what to construct a well-defined electronic nursing record system integrated with nursing clinical pathway.

Future works

To develop nursing care plan is helpful for personal interaction with in environment to got health. When set a nursing diagnosis will decide what nursing intervention to use. That is potential contribution of nursing diagnosis. [3]

Under challenge in DRG, nursing care model will toward to case management style. Therefore, the nursing care planning system will base on case management. Such as Clinical pathway that clarify important exam, treatment, health education, and care plan in everyday from patient admission through discharge. [4]

We had proposed to build a comprehensive ENR system based on the creative thinking model last year. [5] Therefore, a well-defined electronic nursing record system integrated with nursing clinical pathway is an important step and could more fit other information systems. We hope to create this research idea that will bring a new trend to the development of nursing informatics in Taiwan.

Development of a Web-Service PrototType for Blood Bank Product Management According to the ISBT 128 Standard

B. Spyropoulos, D. Dimitriadis, M. Botsivaly

Technological Education Institute of Athens, Medical Instrumentation Technology Department Athens, Greece

Abstract and objective

The aim of this project was the development of an ISBT 128 compliant prototype of interface descriptions, in Web Service Definition Language (WSDL), for Blood products management. ISBT 128 sets a global standard for the identification, labeling, and information processing of human Blood, Tissue and Organ products across international borders and disparate health care systems, and WSDL is an XML format for describing network services as a set of endpoints operating on messages containing either document or procedure oriented information. The web-services for Blood-Bank management of the developed system are grouped in Donation Centre, Laboratory, Transportation and Storage, and Hospital Services, according to the pending organizational reform in the Blood-Bank network in Greece, and the system is presently running successfully in a web environment in our laboratory.

Keywords:

ISBT 128, Blood Bank, web services

Introduction

ISBT 128 sets a global standard for the identification, labeling and information processing of human Blood, tissue and organ products across international borders and disparate health care systems. The standard has been designed to ensure the highest levels of accuracy, safety, and efficiency for the benefit of donors, patients and official ISBT 128 licensed facilities worldwide. The aim of this project was the development of an ISBT 128 compliant prototype of interface descriptions, in Web Service Definition Language (WSDL), for Blood products management. In the following, the approach of these tasks will be described in details.

The ISBT 128 compliant prototype of interface descriptions in WSDL

The developed Web service is a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface that is described in a machine process able format such as WSDL. Other systems may interact with the Web service in a manner prescribed by its interface, by employing appropriate messages. These messages are typically conveyed using HTTP, and normally comprise of XML in conjunction with other Web-related standards.

Table 1 - The ISBT 128 specified entities of the developed web service system

Item	Description
1	A donation numbering system that ensures globally unique identification.
2	The information to be transferred, using internationally agreed reference tables.
3	An international product reference database.
4	The data structures in which this information is placed.
5	A bar coding system for transfer of the information on the product label.
6	A standard layout for the product label.
7	A standard reference for use in electronic messaging.

Software applications written, first, in various programming languages, and second, running on various platforms can use the web services, in order to exchange data over computer networks and over the Internet. The web services for Blood Bank management comprise of first, the Donation Centers Services, second, the Laboratory Services, third, the Transportation and Storage Services, and finally, the Hospital Services.

The ***Donation Centre Services*** group includes the Personal Data, Donation Data, Label and Transportation Services. The Personal Data Service registers the personal data of the donor, his medical history, and the examination results before the donation, and assigns a new Donor ID, according to the ISBT128 rules. The Donation Data Service assigns a new Donation ID and stores the Blood product type, the determined Blood group, the donor ID, the collection date and time, the container manufacturer catalogue number and LOT, and the Staff ID. The Label Service returns the ISBT128 codes for the labels on the container. The Transportation Service stores the data of the Blood product carrier, its destination, and forwards the Donation Data to the Transportation and Storage Services Group Server.

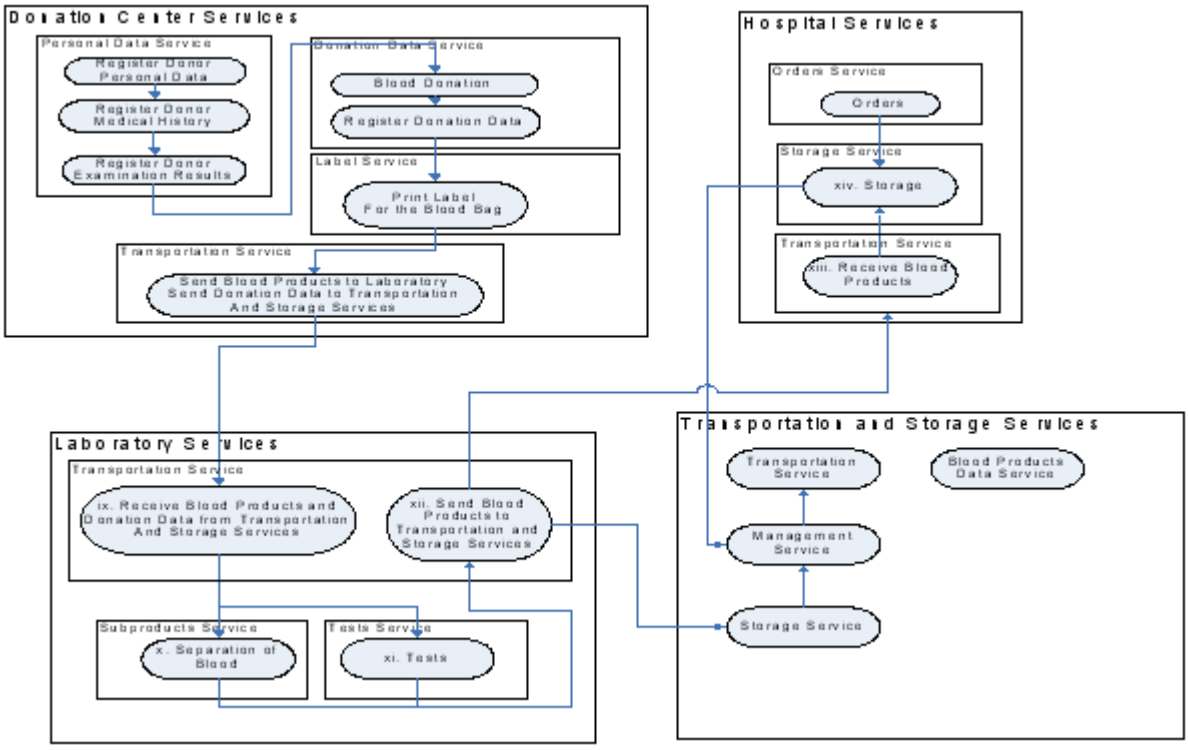

Figure 1: Schematic representation of the proposed work flow of a typical Blood Donation Centre.

The ***Laboratory Services*** group comprises of the Transportation, the Sub products, and the Tests Services. The Transportation Service records the incoming and outgoing Blood products, receives the donation data, and updates the Storage Services Group Server for the availability of Blood products. The Sub-products Service records, which products have been extracted from each donation. The Tests Service records the results of the Antigens tests, and of the HIV, HBV, HCV, HTLV, RPR etc. tests. The ***Transportation and Storage Services*** group runs the Transportation, Blood Products Data, Storage, and Management Services. The Storage Service provides information about the transportation availability of Blood products, from the Laboratory or from one hospital to another. The Blood Products Data Service stores the all the information about Blood products based on the Donation ID. The Management Service checks the availability of Blood products, administrates the orders, and manages the final destinations of the products. The Transportation Service stores the information of the number of Blood products are on their way, and the estimated transportation time. The ***Hospital Services*** group includes the Order, Storage and the Transportation Services. The Order Service takes orders for direct donation from the client program of the physicians in charge. The *Storage Service* manages the Blood products available in the Hospital and forwards the Orders to the Management Service of the Transportation Group. Finally, the Transportation Service stores the information of the overall Blood product movements.

Concluding remarks

The Hospital Blood-Banks in Greece are presently working almost quite independently from each other, they employ their own work-flow and the corresponding software from different vendors and it is rather difficult to find out the availability of Blood products. The developed system covers an existing managerial gap, by proposing a standard way of information and products exchange, between Blood processing and transfusion points, fully complying with ISBT128, 2002/98/EC and HL7. We have implemented one possible scenario of the pending organizational reform in the Blood-Bank network in Greece, however, the Donation Centre, Laboratory, Transportation and Storage, and Hospital Services grouping approach, allows for, the fast redesign of the system, in order to be easily adapted, to the final decisions of the Ministry of Health, to be made in the future. The system is presently running successfully in a web environment in our laboratory, and the next stage under development, will attempt to extend international consistency to support the transfer,

transfusion or transplantation, beyond the Blood, of cell and tissue products, according always to the ISBT 128 standard.

Differences in Nursing Time Spent Performing Work by Task Category Between Intensive Care Units With and Without Computerized Provider Order Entry

Anita Ground

University of Wisconsin and Cerner Corporation, USA

Abstract

Previous studies of the impact of information technology have primarily focused on the impact of systems designed for use by the nursing staff, primarily documentation systems. This article focuses on the changes in nursing tasks between the medical and cardiac intensive care units of two hospitals. One hospital's two intensive care units (ICU) have computerized provider entry (CPOE) installed, while the other hospital did not installed CPOE in the two intensive care units studied.

Methods: Direct observation of nurses as they performed nursing tasks was conducted using work sampling technique. Observations were performed over ten 3-hour periods in each hospital. The data collected included the task being performed and the duration of each task performed by the nurse.

Results: The amount of time nurses spent conducting certain types of tasks was different between the two hospitals. Nurses in the ICUs with CPOE installed spent more time performing education and housekeeping tasks at the patient bedside. Nurses in the ICUs without CPOE installed spent more time on nursing documentation. Time spent performing personal and administrative tasks remained the same in both sites.

Keywords:
CPOE, nursing work, work sampling, activity theory

Introduction

Nursing has been described as job that involves considerable coordination and management of the patient care [1]. Previous studies examining the impact of information technology on nursing work have primarily been conducted upon the implementation of clinical documentation in an inpatient setting [2-5]. Nursing work has been described by the researchers as having different categories of tasks, including documenting or charting,, and patient care [2], with orders considered part of the charting activities of the nurse. The impact of these systems has been studied because there is a possibility that a change in the method of performing a task, for instance changing from documenting on paper to documentation on a computer, may impact the time available to perform patient care.

There has been a recent impetus toward implementing computerized provider order entry (CPOE) in the inpatient hospital setting. The primary drivers to the implementation of CPOE include increased patient safety [6] and private corporate pressure [7]. It has been proposed the implementation of CPOE will result in decreasing errors in medication order entry [8]. Although 9.6% of hospitals in the United States claim to have implemented CPOE, only 46.2% of these hospitals require use of the CPOE system by the physician [9]. Computer-based order review and order coordination result in nurses being indirect users of the CPOE system.

Nurses are also the direct users of CPOE system, by transcribing physician orders written by the physicians on paper into the CPOE system and entering verbal and telephone orders for future cosigning by the physician. Understanding the impact the implementation of CPOE would have on nursing work would enable clinical informatics and nurse managers to understand how to prepare clinical nurses for the change the implementation will bring to the work in the ICU.

With the current nursing shortage, the burden the working nurse performs under, and the increasing impetus to install CPOE systems, it is necessary to understand whether this system changes the work nurses perform to insure the implementation does not increase the workload of these nurses. Decreasing nursing time with the patient has the potential to negatively impact patient outcomes.

The Activity Theory, a structural theory of work having six concepts that could impact the work and the worker, was used to define the study. These concepts include the task, the environment, the organization, the worker, the role of the worker, and the technology being used to perform the task. Only a selected set of results are discussed here that pertains to the tasks the nurses performed.

Methods

Sample and site

The researcher observed nurses as they performed their work in two intensive care units located in two different sites. The first site did not have CPOE installed. This site was a large academic medical center in the upper Midwest. The medical ICU contained 24 beds and the cardiac ICU

had 8 beds. The nurse patient ratio was 1:1 or a maximum of 1:2.

The CPOE site was a large academic medical center in the southern eastern seaboard. The medical ICU contained 12 beds and the cardiac care unit contained 16 beds. Both hospitals had an all-registered nurse staff.

Permission was obtained from both hospitals institutional review board to conduct the study. Additionally, the medical directors, nurse managers, and clinical informatics personnel were informed of the study and permission was requested and granted to approach and observe the clinical nurses in the ICU.

Ten clinical nurses were observed at each site for a total of twenty nurses observed performing their work. The researcher followed the ten clinical nurses while they performed their work during a three-hour observation period during their normal workday.

Data collection

All tasks the nurses performed were entered into a computer-based instrument. The instrument consisted of 65 separate tasks divided into 11 different task categories (Table 1). The instrument was derived from an instrument used to observe nursing work in the ICU in earlier research [10]. Task categories included documentation, assisting, conversations, manual tasks, housekeeping, personal tasks, teaching/learning tasks, administrative, observational, conversational, transportation, and miscellaneous tasks. The instrument was developed with the cooperation of Dr. Matthew Weinger of the University of Vanderbilt. The instrument was reviewed by clinical nurses and nurse informaticians at a large Midwest University hospital to insure all the appropriate tasks were included. The instrument was installed on a tablet personal computer for use during the observations.

The instrument allowed the researcher to note the order of the tasks, the duration of the tasks and the number of instances of the tasks that were performed during each observation period. The instrument supported the ability to collect simultaneously performed tasks as well as tasks that were performed consecutively. Notations could also be made on the instrument by the observer. The eleven task categories were divided based on specific criteria shown in Table 1.

Table 1: Task category definitions

Task Category	Description
Manual	Care tasks provided to the patient at the patient bedside
Housekeeping	Cleaning tasks in the patient room or bed area
Transportation	Moving the patient
Observational	Looking at the patient or patient monitoring devices, but not performing care tasks
Documentation/ Reading	Reading or writing on the electronic or paper chart
Conversational	Talking to another caregiver
Assistance	Helping another caregiver perform work
Administrative	Performing schedules, email etc.
Teaching/Learning	Performing education for the patient or family
Personal	Taking a break away from patient care
Miscellaneous	Any task not easily categorized

Method

Observations were performed over a 14 day period. Each observation period lasted approximately three hours with observations conducted during both night and day 12-hour shift during the week and the weekend. Informed consent was obtained from the observed nurses before the observation was begun. Patients and family under the care of the nurse were informed of the research and were given the option to end the observation. No family or patient asked for the observation to end. No patient data was collected at any time.

Each task the nurse performed was selected on the instrument. Each observation period resulted in a text file consisting of the tasks, notations made by the researcher, task start times and task duration. The file was saved to the tablet hard drive. The text file was converted to a Microsoft Excel© file to enable data review and analysis.

Data analysis

Upon completion of the data collection, twenty files were available for analysis. Each file contained information about one observation period. Ten files were from observations performed in the ICUs with CPOE implemented; ten files were from observations from the ICUs without CPOE implemented. The tasks were aggregated into the eleven task categories. The percentage of time spent performing each task was calculated. Additionally, the percentage of time spent in each task category was calculated. A comparison of the means of the task categories of

the observations performed in the ICU with CPOE implemented and the means of the task categories of the observations performed in the ICU without CPOE implemented was performed.

Results

Table 2 shows the total time of observation at each site and total time spent performing each task category.

Table 2 - Observed time in minutes

Task Category	Non-CPOE	CPOE
Manual	635.20	637.15
Housekeeping	31.03	49.30
Transportation	3.18	6.62
Observational	5.80	62.40
Documentation/Reading	427.48	322.42
Conversational	671.22	490.87
Assistance	12.78	35.60
Administrative	46.85	57.60
Teaching/Learning	54.78	71.23
Personal	16.82	84.13
Miscellaneous	20.92	53.95
Totals	**1926.07**	**1871.27**

The percent of time the nurse spent performing tasks in the different categories in the ICUs for the non-CPOE hospital is illustrated in Figure 1.

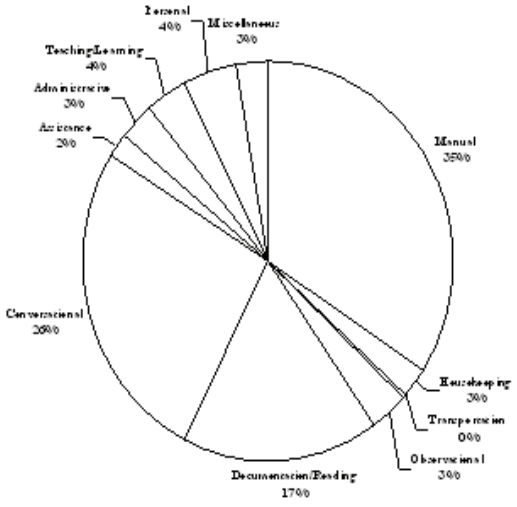

Figure 1- Percentage of work by Task Category in ICUs of non-CPOE hospital

The same task categories of nursing work obtained from the observations in the ICUs of the hospital where CPOE was installed are presented in Figure 2.

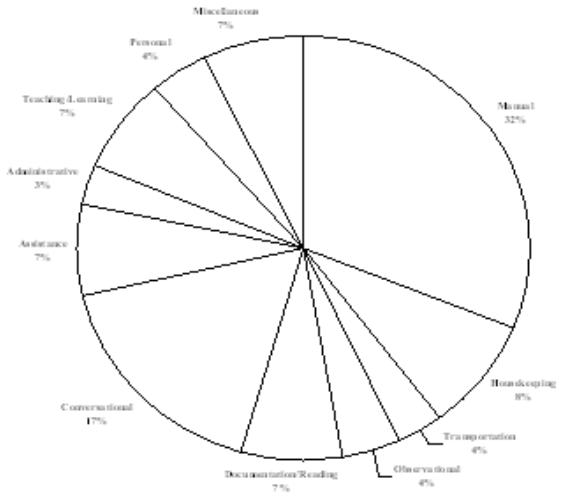

Figure 2 - Percentage of work by Task Category in ICUs of hospital with CPOE

Figure 2 above has larger sections than the equivalent sections of Figure 1; indicating more time performing housekeeping tasks, manual patient care tasks, and observing the patient, implying the nurses had more available time when CPOE was installed. Additionally, the nurses spent less time than in the non-CPOE site documenting, conversing with other clinicians, and on miscellaneous tasks.

Table 3 illustrates the percentage of time nurses spent performing work in each task category. Statistical significance was evaluated for each task category.

Task Category	Non-CPOE	CPOE	Significance
Manual	30.55	34.29	>0.05
Housekeeping	1.50	2.64	>0.05
Transportation	0.33	0.32	>0.05
Observational	0.39	3.34	>0.00
Documentation/Reading	21.25	17.38	>0.05
Conversational	35.59	26.05	>0.05
Assistance	0.63	1.83	>0.05
Administrative	2.13	2.89	>0.05

Table 3 - Percentage of time worked by task category

Discussion

As Murphy points out, nursing is performed as part of a complex system [1]. A change in this complex system has the potential to increase nursing workload and burden for an already heavily burdened worker. The implementation of CPOE does have an impact on nursing work. The consequences of that impact have not been closely examined at this time. Because CPOE has not yet been implemented widely, although according to Ash there are many hospitals considering or beginning to implement this innovation [9], now is the opportune time to better understand the impact these systems will have on nursing.

The consequences of the additional time available to the nurse to perform manual patient care tasks and education/ learning tasks are also not clearly understood. It is assumed there would be improved patient outcome, however further research may be needed to verify this hoped for result of the implementation of CPOE.

Another area not understood that this study illustrates is the impact of decreased time spent on documentation/reading and conversing with other clinicians. The decrease of time spent in these tasks does not reflect the quality of the communication. Further research is needed to discover if less documentation and communication equates with better information communicated and if the communication results in a clear understanding of the patient care needs.

Conclusions

The results indicate there is a significant difference in the way nurses in an ICU utilizes the time at work. The impact of the implementation of CPOE on the division of time a nurse spends performing tasks would, at first, seem to show the nurses job tasks change with this information technology change. The nurse spends less time on work related to supportive tasks such as documentation and conversing with clinicians and more time performing manual and observational work at the patient bedside. The implementation of any information technology, even when not primarily designed for use by the nurse, should be examined to determine the possible impact the new system could have on the nurse.

Development of a PDA-based Minimum Data Set for the Screening and Management of Type 2 Diabetes Mellitus in Primary Care

Ji-Young An[a], Barbara Carty[a], Caroline Dorsen[a], Wayne Woogen[b]

[a] *College of Nursing, New York University, New York, NY, USA*
[b] *Advanced Logical Solutions, Inc., New York, NY, USA*

Abstract

The ultimate goal of this project is to develop an informatics practice model in primary care to enhance evidence-based practice (EBP) by increase advanced practice nurse (APN) students' informatics competencies. This abstract describes a process of development of a PDA-based minimum data set (MDS) for the Screening and Management of Type 2 Diabetes Mellitus (DM) in primary care.

Keywords:
primary care, diabetes, minimum data set, PDA

Introduction

Past projects had been successfully developed in which informatics students had worked with APN students to develop their capstone projects that reflect the combined expertise of the informatics students and the APN students.[1] In the U.S., about 20.8 million people have diabetes, and surprisingly 30% of those are not aware that they have diabetes until they have developed this chronic condition that requires long-term management.[2] Based on the success of the collaborative projects, faculty from informatics and adult primary care, diabetes educators, and 3 APN students were involved with the development of the MDS for the screening and management of Type 2 DM to promote the delivery of EBP in primary care.

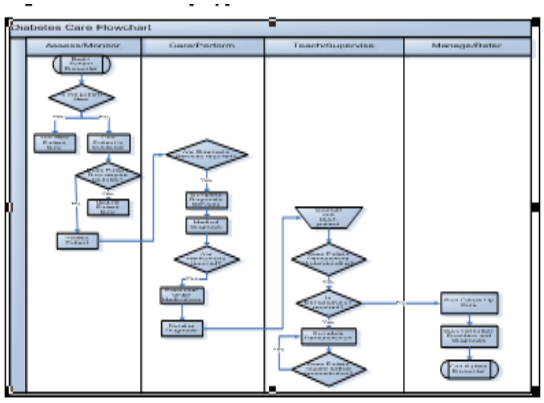
Methods

Literature on primary care database was extensively searched and retrieved in the U.S., the U.K. and Canada. The team basically considered the clinical practice guideline (CPG) recommended by the American Diabetes Association (ADA),[2] the Diabetes Continuing Care Reference Dataset (DCCRD)[3] published by the Primary Care Information Service (PRIMIS),[4] nursing minimum data sets (NMDS) published,[5] and additional indicators that meet the federal health indicators for this project.

Results

The following 4 modifiers- Assess, Care, Teach, and Manage- of the Clinical Care Classification (CCC) System[6] were used as a framework for nursing interventions of Type 2 DM (Figure 1)

d



. Figure 1 Flowchart of Type II diabetes care

Figure 2 shows part of the PDA screen shots based on the MDS developed.

Figure 2 - PDA Screen shots of the PDA-based Minimum Data Set developed

Conclusions

Ultimately, this data set will be served as a research repository for future EBP planning in primary care. In

addition, this collaborative approach has resulted in the increase of informatics competencies for both APN students as well as faculty in various specialties.[1]

The Cognitive Work of Nursing

Catherine M. Burns [a], Yukari Enomoto [a], Kathryn Momtahan [b]

[a] *Systems Design Engineering, University of Waterloo, Canada*
[b] *University of Ottawa Heart Institute, Canada*

Abstract

To build effective and sustainable health care systems, the design of these systems must be informed by an accurate understanding of how healthcare workers do their jobs. We show how we used this technique to develop requirements for a mobile decision support system for telephone triage. Finally we discuss the opportunities and challenges inherent in applying CWA to the design of healthcare systems

Keywords:

clinical nursing research, nursing models, psychological models, clinical decision support systems

Introduction

In this project, we explored the design of a mobile healthcare system for cardiac nursing coordinators (NCs). We began our design process phase by looking at the cognitive work of the NCs. We used an approach called Cognitive Work Analysis (CWA) for this phase of the project. From the CWA we developed information requirements that guided our design. We found CWA to be a useful tool for understanding cognitive work in a healthcare context.

Method

We followed the CWA approach of Vicente (1999) and used the phases of work complexities, task analysis, and strategies analysis. We did not perform a complete five analysis CWA. While a full CWA would provide a richer picture of the work of the nurses, the three phases were chosen strategically to maximize the information needed to provide effective decision support.

We used structured interviews and a case recall approach with nursing coordinators at the Ottawa Heart Institute.

Structured interview

We interviewed all the NCs using a predetermined question set. We did allow the interviewers to probe the NCs for more information at the interviewer's discretion. Our questioning process concentrated on the following elements:

- Were different strategies used for different types of patients?
- How do they accommodate initial conditions (e.g. patient's most recent surgery) in their subsequent strategy?
- How do they probe for information and what comparisons or references do they use to understand that information?
- At what point do they develop concepts or mental models?
- How do they perform differently with straightforward calls compared to more complex or difficult calls?
- Following the structured questions, the interviewers were allowed to probe opportunistically. The probing was to determine:
  1. Strategy differences between nurses
  2. Strategy differences by type of patient or condition
  3. Complex relationships that could benefit from decision support
  4. The differences between expert and novice nurses

Case recall

We asked the NCs to generate a number of typical calls representative of the types of calls that they receive from cardiac patients who have been discharged from hospital. The sequence was not constrained in any way and the NCs were able to answer freely. Twenty-five call types were generated.

The objective of the case recall was to develop best practice question algorithms for commonly seen cardiac symptoms.

Results: cognitive work analysis

We discuss the results of the CWA in three phases, the examination of work complexities, examination of tasks, and examination of strategies.

Phase 1: work complexities

The first phase of a CWA looks at complexities in work caused by features of the work environment itself. The objective of this analysis is to extract information requirements and to develop an understanding of complexities in the work. By complexities, we are looking for challenging problems to solve and tight relationships between different

factors. As these are identified, they are then explored further.

Specific work complexities that we examined through this analysis were:

1. Medications and their effect on patient health
2. Pain assessment
3. Patient care timelines

Phase 2: tasks

The tasks phase looks at sequences of tasks, task allocation and hand-offs between people, and various modes of operation.

Modes

Two clear modes were apparent, one mode for cardiology patients who were patients in cardiac treatment not directly related to a recent surgery, and cardiac surgery patients, who had recently had surgery.

Task allocations

Analyzing task allocations revealed that there were multiple decision makers in this environment. The first decision maker is the patient or their designate (usually a family member), who has direct experience with their condition, can monitor it regularly, and must at some point make the decision to call the NC for additional advice. Decision making is then allocated to the NC who can proceed to assess the patient further and make a recommendation, or in some cases, contact a physician for further advice. The final decision maker is the physician, who is contacted on a smaller number of more complicated cases.

Task sequencing

We focused on the sequencing of the nursing tele-triage task. Most nurses begin in an observational phase, often asking an open-ended question or letting the patient describe the situation. Their first decision is an assessment of the severity of the patient's condition, i.e. should the patient move to an emergency facility immediately, or should they proceed to describe their condition. If the patient is not in acute danger, the nurse may proceed to follow one of several questioning strategies to extract more information from the patient. These observations are used to make an assessment of the patient's condition and formulate a recommended procedure or action for the patient.

Phase 3: strategies for efficient work

We identified strategies from our semi-structured interview process and responses to typical questioning scenarios. We observed that NCs may ask open ended questions, may work from a standardized question list, may question for symptoms topographically, may build a hypothesis of the situation and test for confirming or refuting information, or may use a strategy of deliberately ruling out possibilities.

Discussion: requirements for design

The following list provides a summary of how each analysis phase contributed to our understanding of cognitive work. More importantly, each contribution maps to a specific design requirement.

CWA Phase: work complexities
Information on medication and side effects, pain assessment points, timeline points

Design requirements:

1. Medication reference

2. Pain assessment visualization

3. Timeline visualization

CWA Phase: Tasks
Teletriage task support, connection to patient and physician, support for cardiac surgery and cardiology modes

Design requirements:

1. Distinct modes for cardiac surgery and cardiology

2. Task stage support with support for observations and guidance

3. Information exchange with physicians

CWA Phase: strategies for efficient work
Multiple types of parallel support. support for mnemonic memory tools, standardized questioning patterns, hypothesis testing and rule out, topographical search

Design requirements:

1. OLDCAR support (onset, location, duration, characteristics, associate symptoms/aggravating factors, and relieving factors)

2. Decision trees with standardized questioning

3. Body topography mapping

4. Hypothesis test and rule out visualization

Conclusion

CWA developed a rich set of information requirements and led to the successful design of a tool that was flexible and able to support multiple tasks. The approach is unusually fruitful in generating design ideas. The support system that was developed and the results of the evaluation of the system are available in Momtahan et. al (2007) being presented at this conference.

Three Month Trial of Networked System that Improves Quality of Life of the Elderly

Kaori Fujimura, Tatsuaki Ito, Setsuko Murata, and Toshiaki Tsuboi

NTT Cyber Solutions Laboratories,

Nippon Telegraph and Telephone Co.

Introduction

Background

- It has become increasingly urgent to prevent elderly people from falling ill and eliminate the need for nursing care.
- However, we don't have enough preventative-care specialists.

Abstract

- In order to offset the shortage of these specialists, we have developed a support system that uses broadband and video-communication technologies.
- A care-prevention system aims to prevent a person from becoming bedridden due to "old-age syndrome", which frequently involves falls and broken bones, poor nutrition, incontinence, and home confinement.
- A three month trial of the system (focusing on the prevention of falls and broken bones) at a day-care center for elderly people is described.

System Structure

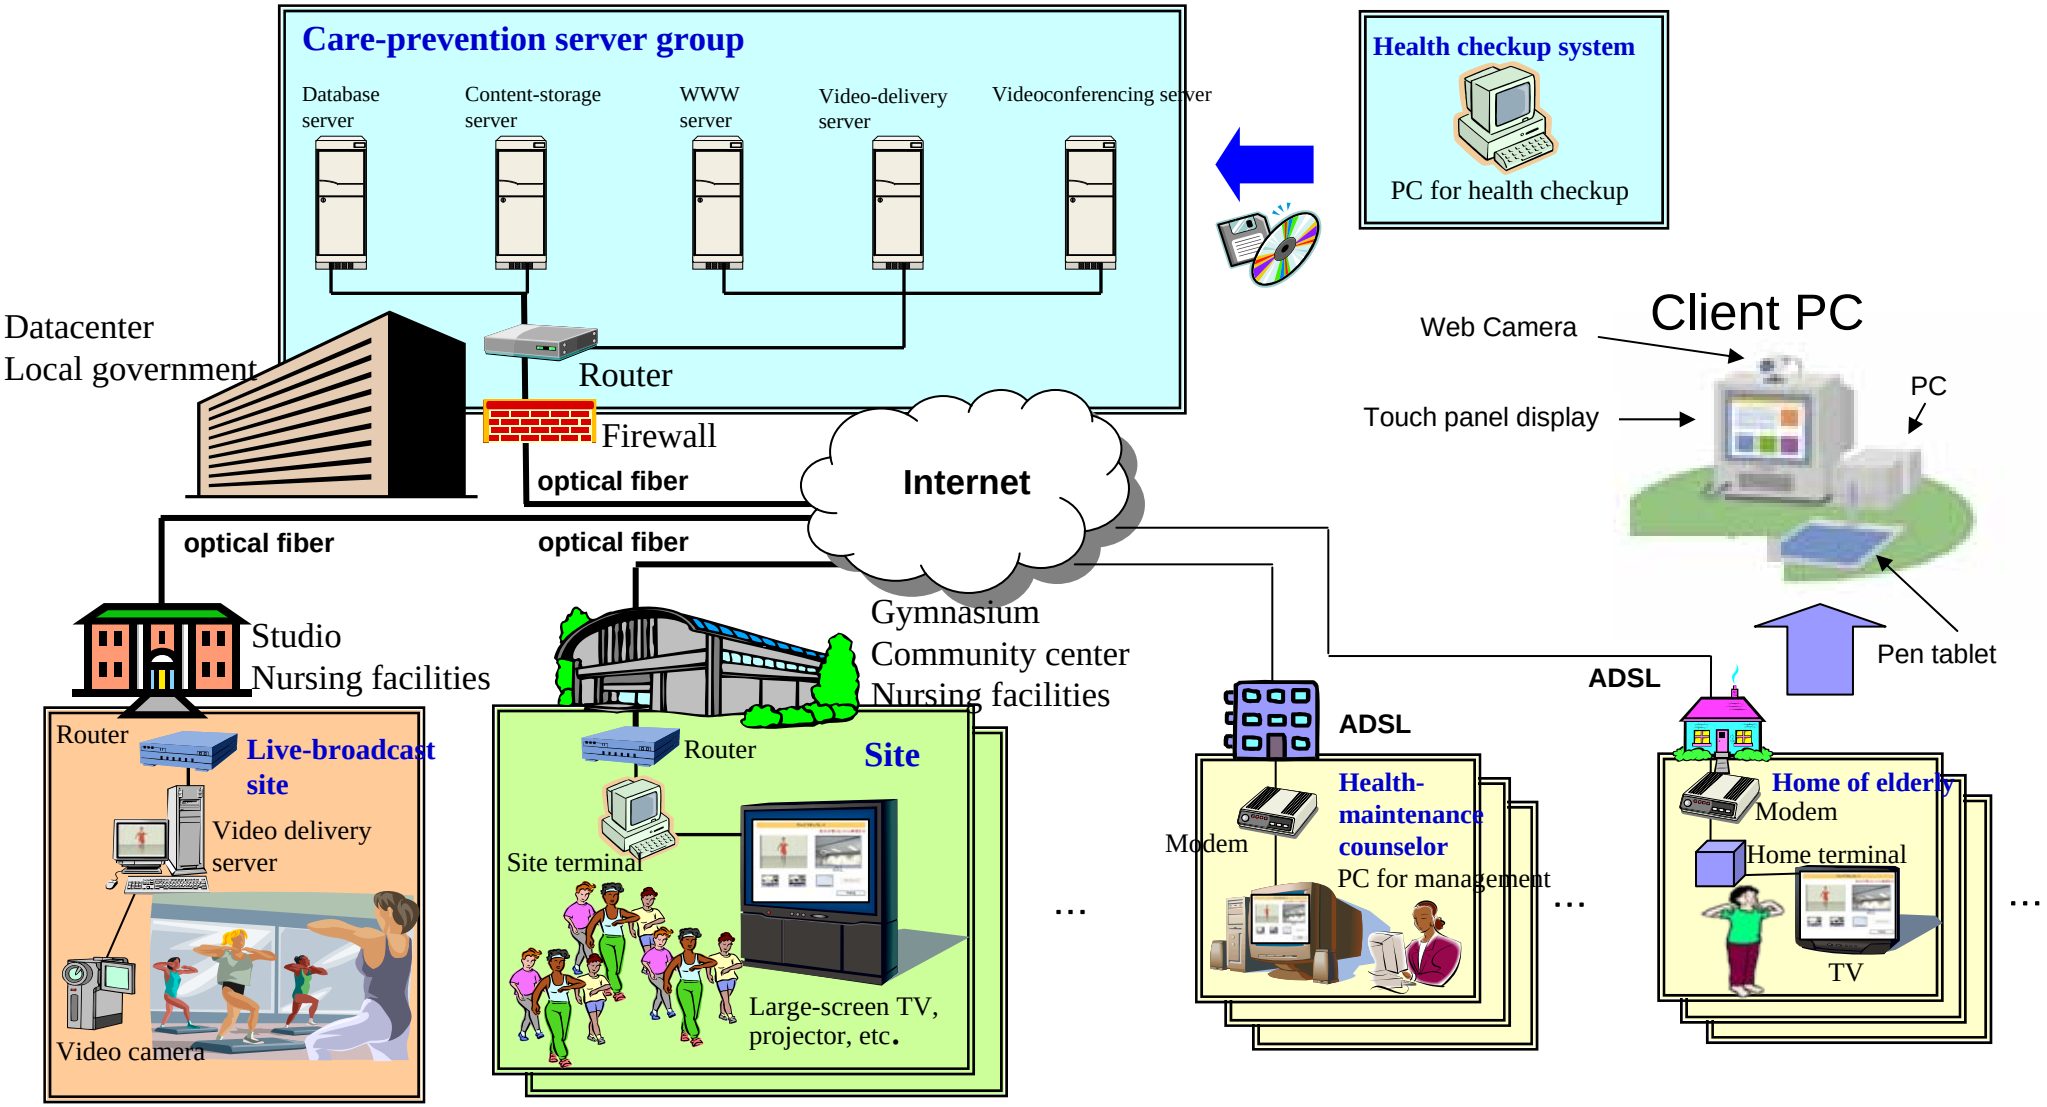

Fig. 1. Configuration of care-prevention system.

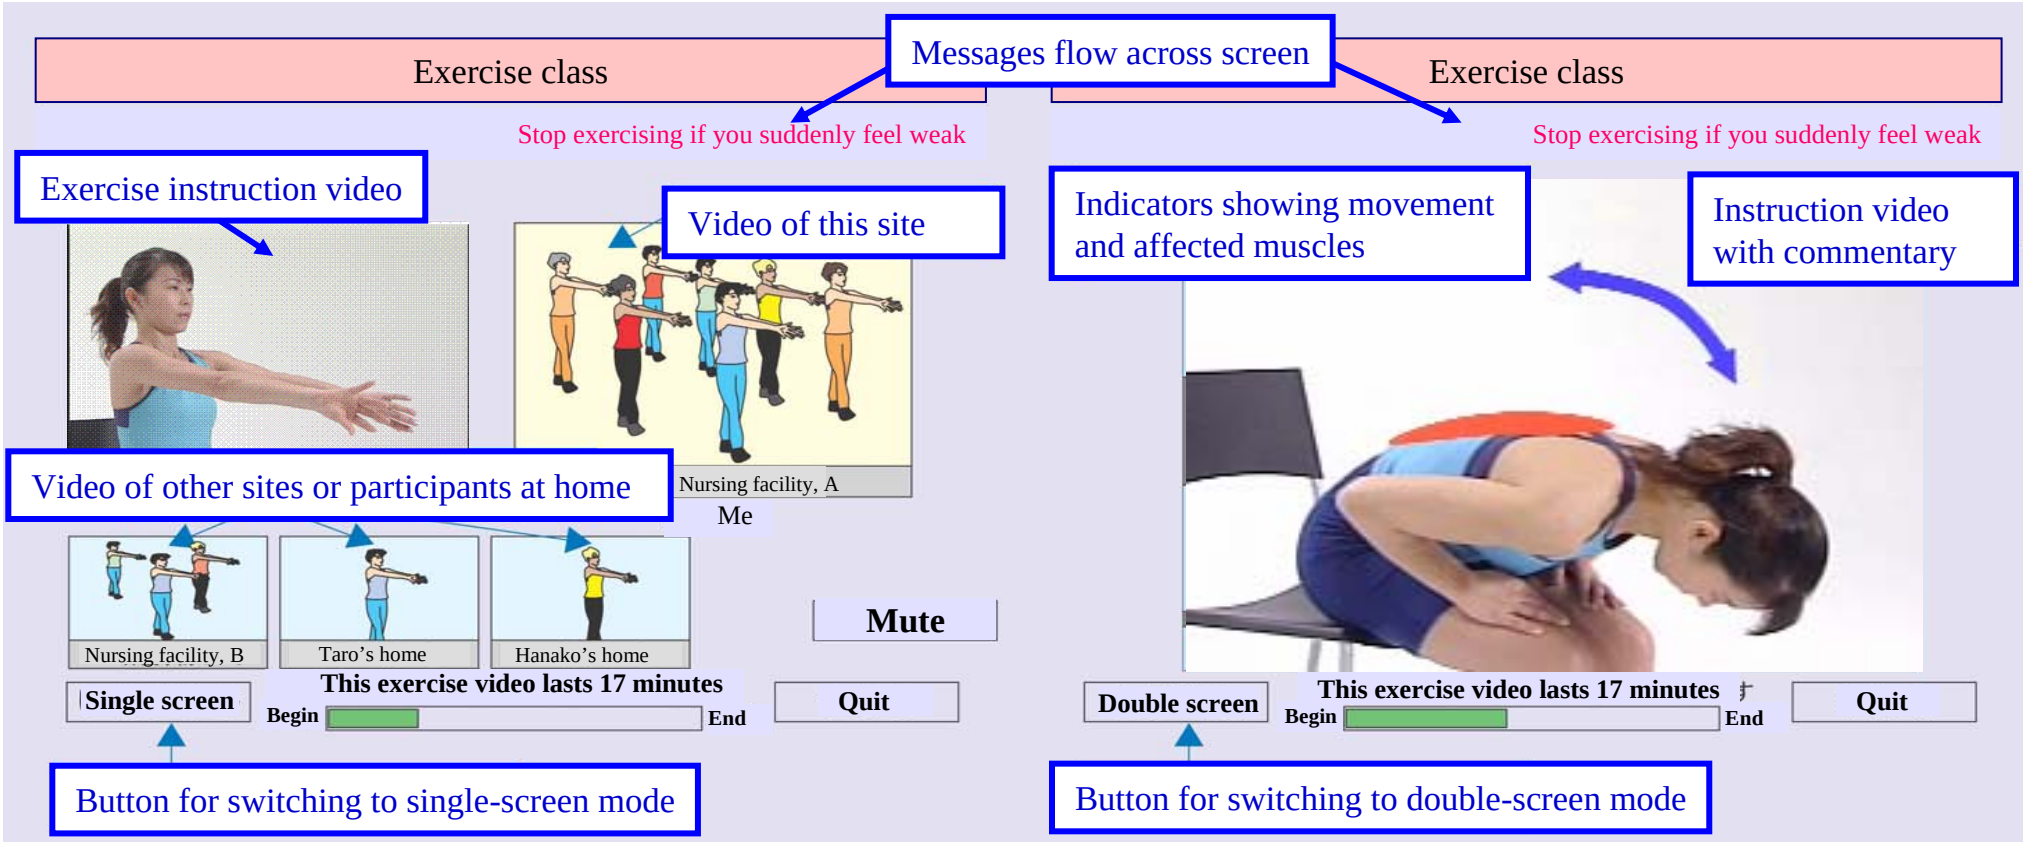
Client System



(a) Double-screen mode

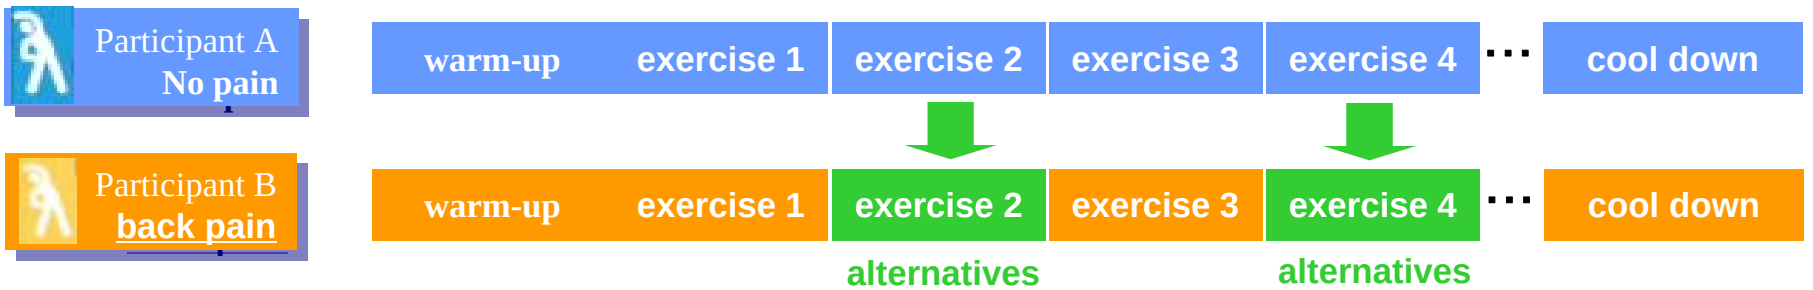
(b) Single-screen mode

Fig. 2. Screen modes for exercise classes.

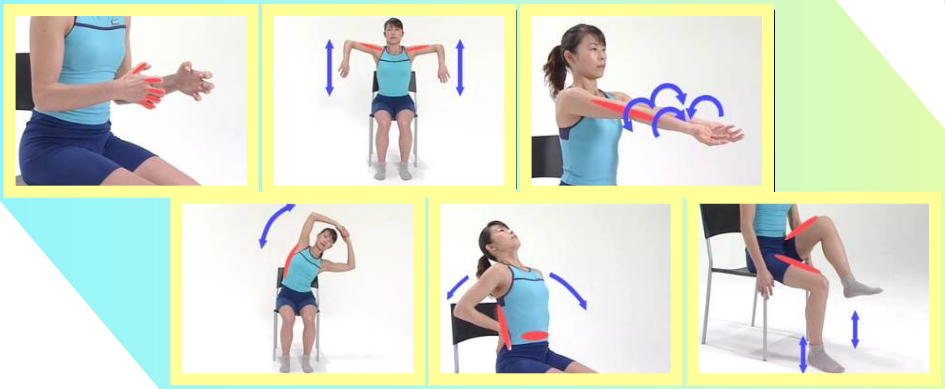
Features

- Networked System
  - Personalized program is available for people who have pain.
  - Data management is available. It makes it easy to give advice using exercise logs.
  - Having fun with exercising with people at other sites.
- Usability
  - Once client PC is powered up, the application starts automatically.
  - Most operations require only simple button pushing.

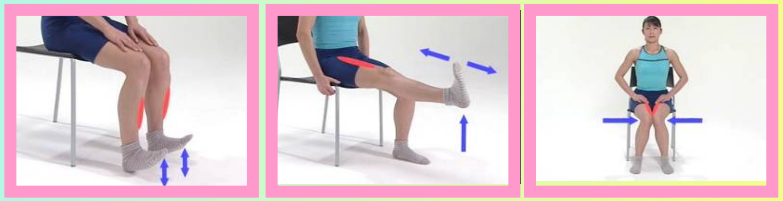
e.g.) Personalized program: Before the exercise, participants answer questions about their condition; the answer is reflected in the program.



Three Month Trial



warm-up exercises (5 min.)



strength training

cool-down (2 min.)

Trial term: 08/2005 to 11/2005
at Care-port Yahata, Telwel East Co.
Participants: 47 elderly people who need nursing care
Exercise class: 20 minutes consisting of exercises that were to be performed while sitting on a chair including exercises with rubber bands and balls

Check-up

Check-ups were held twice, before (a) and after (b) the trial.

Check-up Items:

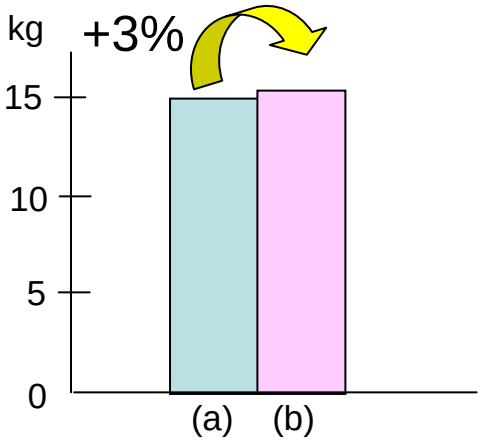
- Measurement of physical fitness
  - grip strength
  - balance on one foot (with eyes open)
  - walking speed
  - knee extension power
  - functional reach
- Interview
  - iADL (Instrumental Activities of Daily Living)

Results of Physical Fitness

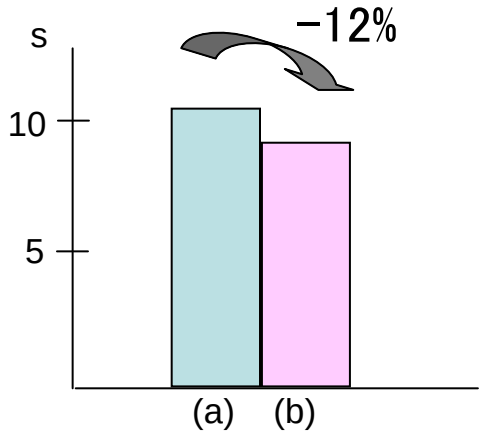
Check-up items		Mean	SD	Number	improvement rate (%)	significance probability
grip strength (kg)	(a)	14.9	6.96	47	+3	0.442
	(b)	15.3	6.56	47		
balance on one foot with eyes open (s)	(a)	10.7	10.69	29	−12	0.204
	(b)	9.4	11.43	29		
walking speed (m/s)	(a)	0.42	0.37	39	+2	0.708
	(b)	0.43	0.34	39		
knee extension power (N)	(a)	125.3	90.57	35	+30	0.010
	(b)	163.1	98.50	35		
functional reach (cm)	(a)	22.6	7.87	37	+10	0.067
	(b)	24.8	8.95	37		

Items whose average values were improved.

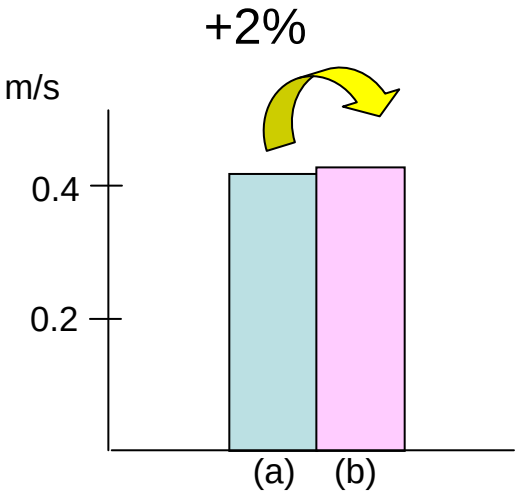
Results of Physical Fitness



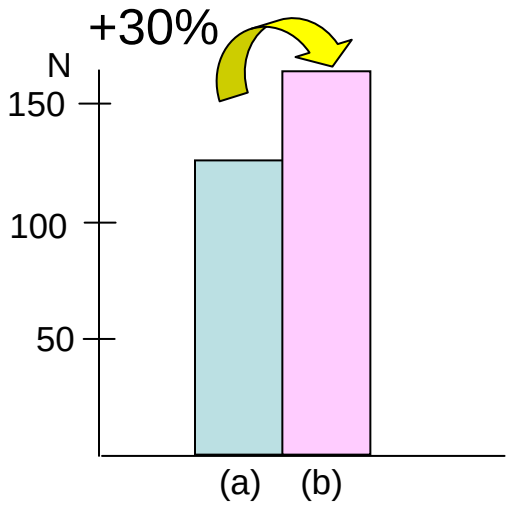
A. grip strength



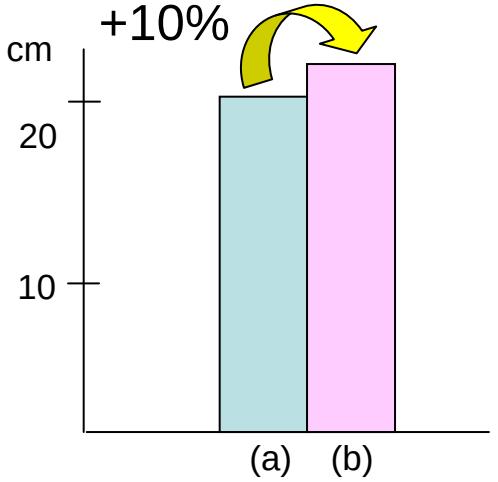
B. balance on one foot



C. walking speed

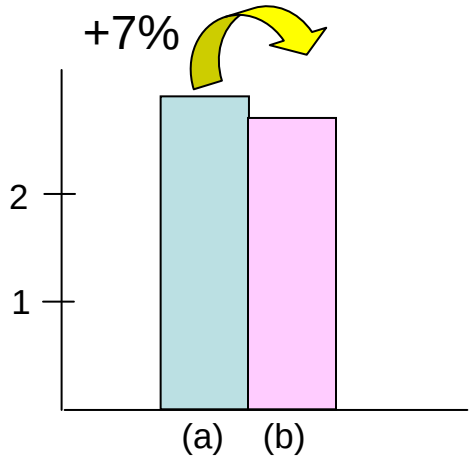


D. knee extension power

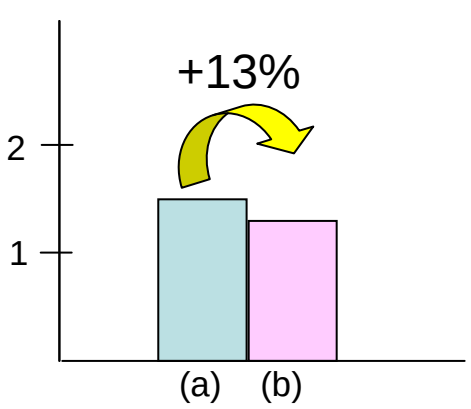


E. functional reach

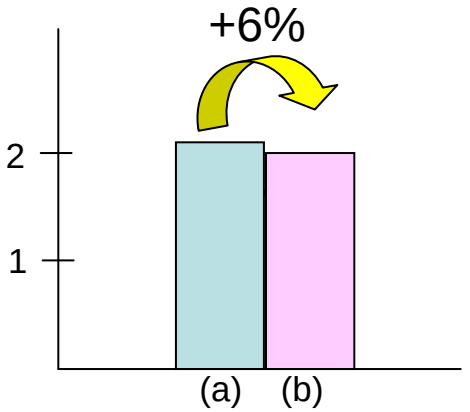
Interview Results:



A. Basic self-sufficiency



B. Intellectual Activities



C. Social Role

	A. Basic self-sufficiency		B. Intellectual Activities		C. Social Role		Total	
	(a)	(b)	(a)	(b)	(a)	(b)	(a)	(b)
mean	2.9	2.7	1.5	1.3	2.1	2.0	6.5	6.0
SD	1.9	2.0	1.1	1.1	1.3	1.4	3.5	3.9

Conclusion

While it is hard for elderly who need nursing care to maintain own strength, the results show a significant improvement in leg strength and iADL after the three month exercise.

The proposed support system has been proven to be effective for those who need nursing care. It can be expected to not only offset the shortage of preventative-care specialists, but also reduce the need for and costs of nursing care.

Life Line Management System for Medical Records

Christine Verdier[a], Salma Sassi[b], André Flory[b]

[a] *LSR-IMAG laboratory – University Joseph Fourier, Grenoble, France*
[b] *LIRIS laboratory– INSA of Lyon, France*

Abstract

We present in this paper a new approach to share medical information in community health networks. We propose a graphical user interface management system based on a chronological representation of medical information called Life Line. The Life Line is useful to access all medical documents represented on a temporal axis; documents can be locally created or removed from external information systems. The Life Line Management System can be adapted on any legacy systems; can push local medical data towards other information systems and the opposite.

Keywords:

user computer interface, community health network, temporal axis

Introduction

Regional health networks have been proposed last ten years. These networks gather and share medical information about patients from different care places, essentially hospitals. The most frequent architecture of such networks is based on a pointer management system that stores in a server the addresses of each medical treatment. About medical data, they are stored in the legacy systems.

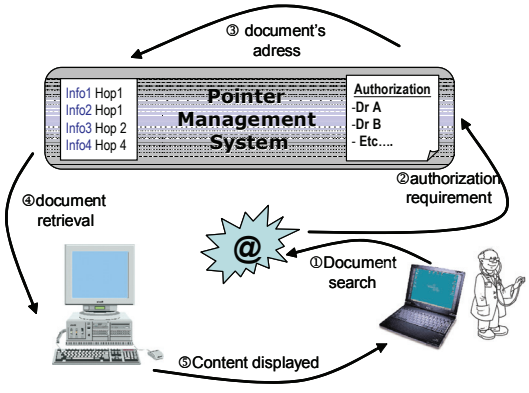

Figure 1- Network architecture

Such architecture is today very interesting to ensure data sharing in order to improve continuity of care. It will be used by the future French personal medical record called DMP.

The Life Line management system is complementary to this architecture in improving communication between general practice and hospital. It allows sending automatically data addresses to a platform called Life Line platform. It is quite similar to a semantic middleware between legacy information systems. The Life Line Management System is designed as a chronological axis on which a representation of medical documents is displayed. Such an ergonomic interface improves greatly information research and gives a synoptic view of the medical record.

The following paragraph describes the Life Line Management System according to different aspects (description, architecture, data transfer). A short paragraph concerning the related works is presented just before a conclusion.

Life Line Management System

Presentation

The Life Line Management System is both a data representation system (object types design), a graphical user interface to display data and a data exchange platform (to retrieve, display and send data).

The data representation system defines an iconic structuring (at interface level) for each parts of document (called objects) whatever their data source format in legacy systems.

The graphical interface is based on a chronological representation of the medical record on which every document (broad sense) is displayed wherever it has been created.

The data exchange platform is used to extract objects from a server, to display them on a local system and at the opposite, to send them from a local system to another legacy system. These information systems can be hospital IS or GP IS.

The Life Line Management System is associated to the Rhône-Alpes Regional Health Platform (SISRA) [1] to help the connection between GPs information systems and hospitals to share information about patients. Rhône-Alpes is the second largest administrative region in France after Ile-de-France (which includes Paris). As large as Denmark in size and with 6 million inhabitants, it is comparable to a European country. Rhône-Alpes has 300 healthcare facilities, three academic medical centers (based in the cities of

Lyon, Saint Etienne and Grenoble), one regional comprehensive cancer center, more than 20 000 physicians and over ten thousand caregivers. The concept of a universal electronic patient record (DPPR) was initiated in 2000 by health professionals from the regional comprehensive cancer center of Lyon (Centre Léon Bérard) and the ONCORA community cancer network (ONCOlogy Rhône-Alpes).

Iconic structuring

Object definition

The iconic structuring has two conceptual parts: a definition of objects according to criteria and a screen representation as icons.

The criteria chosen are: composition, communication and abstraction.

- Composition criterion: objects are classified into simple and complex object.
  - A simple object has only one type which is: text, image, number, etc.
  - A complex object is composed of simple objects and/or complex objects. As an example, an X ray is a complex object composed of two simple object (image) and a summary (text).
- Communication criterion: objects are classified according to their sharing possibilities. We define specialty objects, private objects and communicating objects.
  - A specialty object is only readable by his creator and by doctors with the same specialty (a chemotherapy guideline can be seen by the "owner" of the object and by all the oncologists that may care the patient) but not by specialists of another domain.
  - A private object is protected at the local level and never sent throughout the network. As an example, a sport medicine object is private and so not shared.
  - A communicating object is seen by all medical partners.
- Abstraction criterion: objects have a basic structure defined by experts of the medical domain. The instantiation of abstract objects produces concrete objects. This structure encapsulates an identifier, a name, a type and a iconic representation.

Object types		
Composition criterion	*Abstraction criterion*	*Communication Criterion*
Simple object	Simple abstract object	Specialty simple abstract object
		Communicating simple abstract object
		Private simple abstract object
	Simple concrete object	Specialty simple concrete object
		Communicating simple concrete object
		Private simple concrete object
Complex object	Complex abstract object	Do not exist
		Do not exist
		Do not exist
	Complex concrete object	Specialty complex concrete object
		Private complex concrete object
		Communicating complex concrete object

Figure 2 - Object types classification

Iconic interface representation

The second part of the Life Line Management System is a graphical user interface useful to identify the different objects according to shapes and colors.

Figure 3 shows the interface with icons and the chronological representation of the medical record.

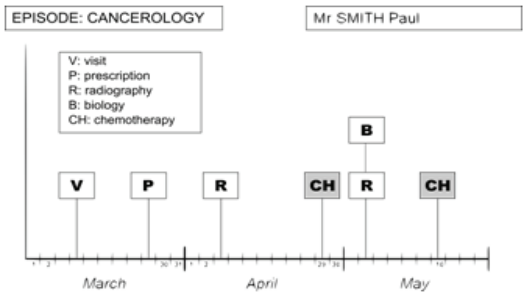

Figure 3- Graphical interface

The graphical interface has been made with different levels of granularity. A synthetic view displays all diseases on the axis and a focus on a particular episode (here Cancer) displays the objects useful to follow up the disease. In the example, the icon **CH** is a specialty object; the others are communicating objects. The difference between abstract and concrete objects is not obvious on this screen: the content of each icon is a concrete object because a click on each icon gives the content of the document. For example, a click on **R** shows the result of the X ray. The structure of

each icon corresponds to an abstract object and its content to a concrete object.

Architecture

The Life Line Management System is represented by a Life Line platform that directly connects GPs information systems to hospitals information systems (fig.4). Every server (hospital or GP) can push data on the Life Line platform and share medical information about patient. As a consequence, on a local user information system, data are displayed wherever they are created and stored.

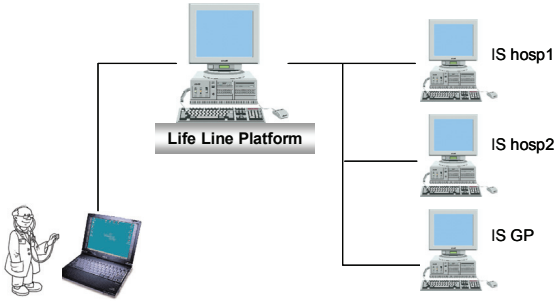

Figure4- Global architecture

A list of shared objects is sent to the platform that enhances the list of objects addresses. A click on a shared object on the Life Line interface opens directly the content of the object: in fact, the object address is automatically opened and its content displayed on the screen. When an object is not readable by a given doctor, this object does not appear on the Life Line.

Transfer of data on the network

For each object, a URL is defined. This address is automatically sent to the Life Line platform and added to the addresses list. A remote or local object is added to the patient's medical record and its content displayed as required. Fig. 5 shows how the data transfer can be done. A user request (simulated by a click on the object) send a query to the different servers and when the server which stored the object is found, an extraction is made and the content is displayed on the user's screen.

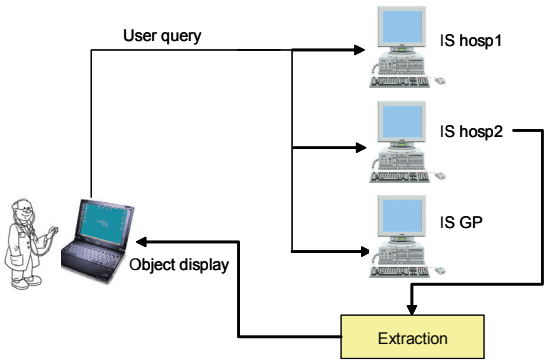

Figure 5- Extraction process

Interface

The interface is separated out in 3 parts: the first part is dedicated to the objects knowledge base. The second part is a part of abstract objects instantiation. The third part represents the chronological axis with objects (fig. 6).

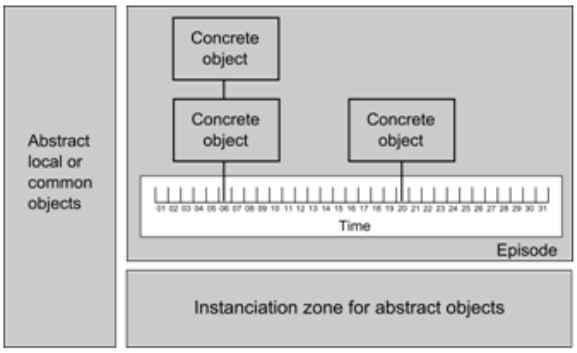

Figure 6- General architecture of the interface

The different following screens show different ways for displaying and sharing objects.

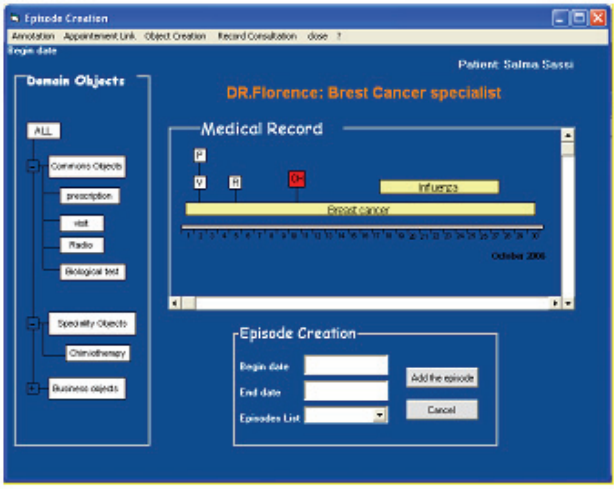

Figure 7- Concrete object instantiation

In this screen, the user creates his concrete objects concerning a disease episode. Objects are retrieved from the knowledge base and episode from a disease classification or ontology.

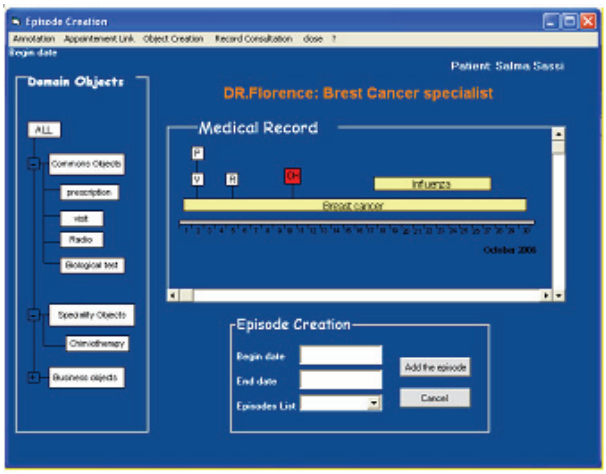

Figure 8- Interface for a specialist

In this screen, chemotherapy is a specialty object which is locally created by the oncologist. This object will be only shared by same specialists.

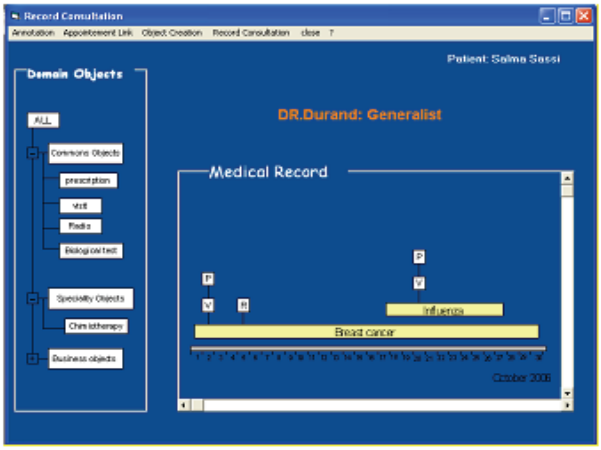

Figure 9- Interface for a GP or another specialist

In this screen, are only displayed the objects shared by everybody in the health networks.

Related works

Many groups are currently investigating medical platforms using different approaches: the first approach consists of considering the web as a useful medium to link medical data and facilitate patient follow-up. In [2], the authors describe the automation of processes between ambulance services and emergency units. The system is based on web services and workflow systems. Another interesting work addresses the transfer of information within a hospital: documents created in various formats and stored in different subsystems are made available to authorized persons for the follow-up of cardiac patients [3].

Other systems have been developed in telemedicine using standard tools. For example: Telemed [4] uses Corba [5] to connect multiple health information systems.

Other works have addressed the issue of interoperability between heterogeneous medical information systems. [6] and [7] have created Pilot, an application program interface that serves as a mediator between different information systems. [8] have proposed an upstream system which creates an exchange format at the conceptual level (use cases). Semantic integration is also a very important topic of research, with interesting studies published by [9], [10], [11].

Some approaches are more centered around the users and propose navigation tools: the project by Ouziri et al. [12] displays medical data using a concept configuration which represents a secured and semantically correct information space. This approach is based on Topic Maps and Description Logics. Users build their own data interface. Another interesting work concerns the integration of interfaces [13]. Finally, some studies have been carried out to promote evaluation in health networks [14] and [15].

Conclusion

To share medical data between heterogeneous information systems is not easy. Some platforms exist to help for data communication. We have proposed in this paper a new architecture with three different aims: a interface structure for objects, an exchange platform and a chronological representation of the medical record. This system can be used as a middleware between legacy information systems.

MG-RBAC: Using Medical Guidelines as a Source of Contextual Information to Activate and Deactivate Roles and Permissions

Lillian Røstad[a]

[a]*Department of Computer and Information Science, Norwegian University of Science and Technology, Norway*

Abstract

Controlling access to information is a key concern in healthcare systems. Some form of Role-Based Access Control (RBAC) is implemented in most healthcare systems. A problem with existing RBAC models used in healthcare is their static nature which doesn't capture the dynamic needs of healthcare providers. In this paper we propose an enhanced access control model combining RBAC with the use of Medical Guidelines, MG-RBAC. Medical guidelines contain temporal and contextual information that may be used to make more informed, dynamic access control decisions.

Keywords:

access to information, computer security, privacy

Introduction

Access control is a key concern in healthcare systems. In order to ensure privacy of patient data, the systems has to provide suitable mechanisms to control access to information. Many existing healthcare systems use some form of Role-Based Access Control (RBAC) Ferraiolo D.F., Kuhn D.R., Chandramouli R., Role-Based Access Control, Artech House Publishers, 2003, ISBN 1-58053-370-1. . Access decisions are typically based on a user's role (e.g. nurse, medical doctor etc) and workplace (department, ward). A user is granted access according to his/her role's permissions for patients that are admitted the ward where he/she is working.

However, these static properties are often incapable of capturing the dynamic needs of healthcare personnel. In this paper, present a model for using Medical Guidelines (MG) as a source of information for access control decisions as a way of creating more dynamic access control for healthcare.

MGs (or clinical practice guidelines) are defined by Field M.J, Lohr K.N., Clinical Practice Guidelines: Directions for a New Program, The National Academy of Sciences, 1990. as:

"Practice guidelines are systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific circumstances."

There exist several formalized notations for computer-interpretable MGs. MGs may include temporal and event information that implies information needs and therefore may be used in access control.

Computer-interpretable medical guidelines

The Asbru MG notation has been chosen as the notational example used in this paper because it contains constructs for defining periodic and event-triggered clinical tasks that suits our demonstration needs, and because Asbru MGs are encoded in XML (eXtensible Markup Langua[1]ge) which is a widely used format for exchange of data.

The Asbru Language

Asbru is a time-oriented, intention-based, skeletal plan-specification representation language [3]. A skeletal plan specified in Asbru consists of a name and a plan body and may additionally contain (optional): a set of arguments, a time annotation, preferences, intentions, conditions and effects. The plan body contains a set of plans (child plans) and information about how/in which order these plans should be executed and also conditions on which child plans must be completed in order to complete the parent plan.

An example MG in Asbru

An example of use of Asbru for encoding a guideline for treatment and observation of Gestational Diabetes Mellitus (GDM – a form of diabetes found in pregnant women) is available at [3]. Use of the guideline is initiated if a glucose tolerance test in the third trimester shows a blood sugar level between 140 and 200 mg/dl. The guideline consists of three main parts:

- Glucose monitoring: measurements performed by the patient herself and/or by the physician. Check to verify that glucose level kept below a limit of 130 mg/dl for 1-hour post meals, < 100 mg/dl fasting and preprandial.
- Nutrition: treatment is based on teaching patient a diet. The goal is to manage GDM with diet and without insulin therapy for as long as possible. Regular follow-ups (every 1-4 weeks) are recommended.

1 http://www.w3.org/XML/

- Insulin therapy: initiated if blood sugar consistently > 100 mg/dl fasting and/or one hour postprandial consistently higher that 130 mg/dl and attempts at diet modification has failed.

MG-RBAC

The Asbru guideline for GDM contains both temporal and contextual information that may be used for access control:

- Periodic information needs: visits to physician while under treatment every 1-4 weeks (specific value set for a patient). The EPR does not need to be accessible to the physician in-between visits.
- Events that trigger information needs: when blood sugar readings are too high the patient needs to visit her physician and review treatment. The EPR should be made accessible to the physician when too high readings occur.

A few UML use cases have been created to illustrate the envisioned use of medical guidelines in access control for healthcare systems.

Periodic consultations are part of the guideline for GDM. Even if the physician is regularly seeing the patient he/she does not need access to the EPR at all times. The physician might need to prepare for an appointment and enter some information after the appointment, but it should be sufficient for the EPR to be accessible e.g. two days prior to and two days past the next scheduled visit for a patient. Figure 3 - Guideline: periodic access3 illustrates how this may be done. The physician will have an assigned role that includes permissions to this patient's EPR as he has a responsibility for this patient. But this role is only activated around a scheduled visit.

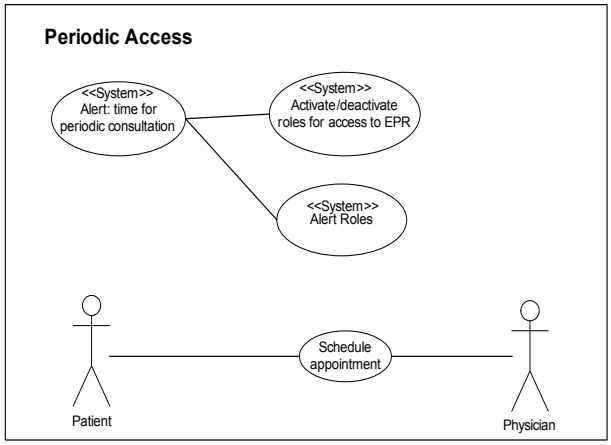

Figure 3 - Guideline: periodic access

The other example of use of guideline information for access control decisions is the occurrence of events that trigger information needs. A typical example of such an event is a measurement of some sorts, made manually or by a sensor, which triggers further actions. For the GDM example the glucose monitoring illustrates such an event. The patient is to measure her own blood sugar level 4 times a day. If the measured level is above some specified limit further action needs to be taken. To determine further actions the physician needs access to the patient's EPR. Figure 4 - Guideline: event trigger4 illustrates how roles are activated if the guideline specifies that a measure results in an action that requires access to the EPR and the relevant role (or roles) is activated.

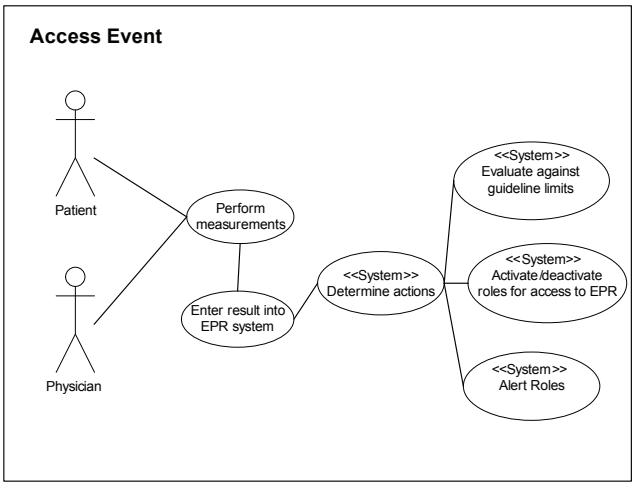

Figure 4 - Guideline: event trigger

Discussion

The model presented here for MG-RBAC is only very preliminary and serves to inform about a promising idea that requires further work.

The examples presented are based on a guideline representation in the Asbru language. Certainly for such a model to be useful it should be able to use guidelines in many different notations. One possible solution would be to integrate a guideline translation engine in the Guideline Monitor module. Work remains as to examine in details information contained in other guideline specification languages and how they may be translated.

The examples presented here only illustrate triggered and periodic events. There may be additional information contained in guidelines that could be utilized in access control, but this has not been fully explored yet.

Conclusion and future work

In this paper we have presented an idea and a preliminary model for using medical guidelines as input to access control. The idea is that guidelines contain information that can assist in creating a dynamic and context aware access control model for healthcare.

We intend to continue to explore this idea further by creating a more detailed model and developing a proof-of-concept implementation.

A Holistic Approach for Prevention and Early diagnostics:Personal Health Management With Web-Based Personal Health Records

Georgio Mosis[1], Ersen B Colkesen[2,3], Bart S Ferket[2], Joost J Mathijssen[2], Ron JG Peters[3], Roderik A. Kraaijenhagen[2], Coenraad K. van Kalken[2]

Abstract

Prevention and early diagnostics are actual topics in today's healthcare. A structured and integrated approach is desired to optimize and benefit from preventive healthcare. We envision personal health records (PHRs) to be a platform for personal health services. The current PHRs, however, mainly provide services that are focussed on cost reduction and management of specific diseases. Integrated prevention and early diagnostics approach is currently not a part of PHRs, whereas an expansion with such a service is desired to create a direct value proposition for health consumers. PHR-based services thus need to focus on prevention, early diagnostics and subsequent early intervention, next to disease management. In this paper we propose a holistic approach for preventive health services via PHRs and identify the issues related to this approach.

Keywords:

personal health records, medical records, prevention, early diagnosis, personal health management

Introduction

The rising costs in healthcare are mainly due to the major burden caused by diseases for which prevention and early intervention options are gaining scientific acceptance [1, 2]. As a consequence, there seems to be an increasing consensus that prevention and early diagnostics deserve more attention. Diseases and other conditions that are recognized early, often have better treatment options and better changes of success.

The efforts to realize a more preventive healthcare are countless, ranging from over the counter diagnostic tests, to warning stickers on lifestyle consumables. The same is true for personal healthcare services via the Internet. Several population based screening programs are offered, each with its own infrastructure and analytic process. Studies on efficacy of preventive healthcare and screening methods have shown that a fragmented approach of prevention, early diagnostics, and possible subsequent early intervention, lack efficacy. Instead, an integrated approach is opted for an optimal system.

Another important disadvantage of the current lack of structure for prevention and early diagnostics is the existing gap between relevant evidence-based advances and the actual implementation of these in preventive services [2-4]. A structural approach can play a crucial role in overcoming this problem as well.

The objective of this paper is to:

1. Identify issues in personal health services via web-based personal health records (PHRs).
2. Propose a framework for a holistic approach for services targeting prevention and early diagnostics.

First, we describe how PHRs have evolved to become a potential platform for personal healthcare services. Second, we describe a holistic approach for the provision of personal health services via PHRs.

Web-based Personal Health Records:first generation

The emergent PHRs development is the results of increasing concern about extent to which decentralization of healthcare has lead to scattering of personal medical information [5, 6]. The dispersal of individual health information is the consequence of increasing mobility and freedom to seek care from different providers and on-line personal health services. Due to this trend, consumer advocates have recommended patients to adopt a more proactive attitude towards collecting and organizing their own medical information [7].

The first description of an electronic PHR was in 1978, but it was not until the recent years that a number of online applications allowed patients to enter and manage information abstracted from medical records [8-10]. Currently, an increasing number of Internet users are adopting PHRs to control and manage their health data [11].

The first generation PHRs are characterized by the fact that they were created, owned and managed by individual patients, as opposed to provider-entered records. Configured along the lines of the professional medical records, these PHRs allowed patients to directly enter health information. Some of these PHRs were stored on standalone

devices such as UBS sticks or standalone applications on personal computers, while others were web-based systems (Figure1). The web-based applications use stored information to generate records that could be reviewed or transmitted to reviewers who are authorized by the patient. The main pitfall of the first generation of web-based PHRs is that professional caregivers did not adopt these systems, mainly due to conflicting workflows and distrust of stored information [7].

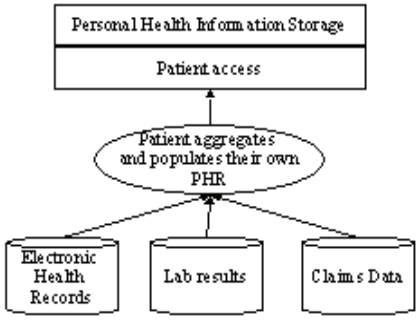

Figure 1 - Architecture of the first generation PHRs. Here the main focus was on aggregation and personal management of data from different sources in the healthcare system. Most of these systems are standalone application e.g. USB sticks, CDs, desktop application

Second generation of web-based PHR

The first generation web-based PHRs were promoted as a mean of providing patients and providers with universal access to up-to-date medical information. Evaluation shows that the primary focus on universal access resulted in limited functionalities [7].

The second generation web-based PHRs comprise longitudinal health information, sourced by both the patient and healthcare professional (Figure 2). This information typically comprises major illnesses, family history, medication, allergies, immunizations, social history, lifestyle data, diagnostic test results and sometimes home-monitored data like blood pressure and glucose levels. While first generation PHR vendors focused on users sourcing their own records, second generation PHRs are also populated by linkage with professional electronic medical or patient records and insurance claim databases. Hence, they are classified as integrated PHRs and enable additional services based on reliable data.

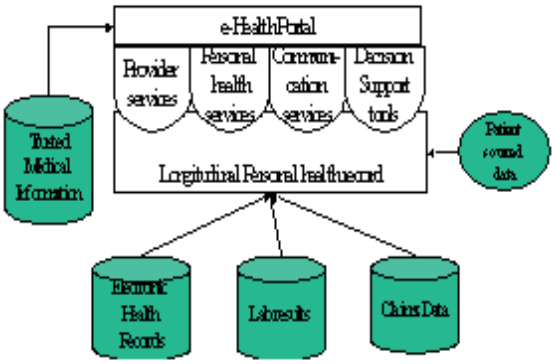

Figure 2 - Architecture of second generation PHR. Through an e-health portal, users can access trusted medical information. In addition, users can make use of different kind of services ranging from provider specific services to decision support tools. Web-based PHR integrates the patient's information from different sources

While many studies demonstrated the potential benefits of integrated PHRs [7, 12, 13], evaluation exposed concerns about lack of value proposition for the individual [7]. Most of the integrated PHRs were develop to lower healthcare expenses and not mainly to empower health consumers. As a consequence health consumers adopt the second generation PHRs very slow. As for now, vendors recognize that the value for the individual lies in the transformation of data into information that empowers individual health management [14]. As a means to this end, integrated PHRs also comprise decision support tools ranging from generating alerts and reminders to treatment comparisons.

Interactive prevention and early diagnostics services

The majority of online personal health services today are much more like the healthcare system itself. Online personal health services mainly focus on diseases or a particular health condition like diabetes and related self-management tools. Prevention and early diagnostics services seem to be in the scope of personal health services providers but they lack a holistic approach.

We spotted an opportunity to propose a holistic health management approach by incorporating an integrated tool for prevention and early diagnostics into a web-based PHR (Figure 1).

A holistic approach for prevention and early diagnostics

Healthy consumers could know their health status if PHR vendors would incorporate an integrated health risk assessment and management tool, based on a knowledge system for prevention and early diagnostics. The knowledge system itself should be based on evidence-based medicine

rules and methods, and should also be supported by the medical profession, to guarantee acceptance and for quality assurance.

Evidence-based algorithms within the knowledge system can processes data in the PHR into personal risk profiles for specific disorders. A risk profile indicates the risk of 'catching' a particular disorder, given the presence of the risk factors within a predefined time frame in the PHR. The risk profiles can than be communicated through personalized health services to educate the individuals how to reduce high-risk or maintain low-risk for a specific condition.

The personal health service could comprise a personalized health plan, that empowers individuals to be a 'co-pilot' own health by offering advise on how to adjust lifestyle variables (e.g. smoking, activity or nutritional habits) or implementing early intervention (e.g. a prescription drug). Guidance towards risk reduction could continue until the risk for a specific condition reaches a certain target, from whereon the focus shifts to low-risk maintenance. The workflow in this approach can be done simultaneously for all disorders with solid evidence-based prevention and early intervention options, creating the desired holistic approach. The PHR serves as a platform to incorporate the risk assessment, risk profile generation and health plan.

Challenges posed by the holistic approach

The proposed holistic health management approach pose some challenges that needs to be address before this can be a reality.

Data quality assurance
The first challenge that needs to be addressed is the completeness of the data in order to calculate risk profiles. As one can imagine, not all information will be stored in PHRs, not even when the PHR is linked with professional electronic medical records. As a consequence the risk profiles may not be based on complete datasets. To deal with this issue we may have to introduce a periodic health assessment check in which a minimal dataset of health variables are measured from the patient directly. The frequency of these health checks may depend on the patients' risk profiles. High-risk individuals can be advised to do a follow-up check at smaller time intervals as opposed to low-risk individuals. The check itself may consist of questionnaires to acquire or update the minimal dataset, combined with a standardized physical and laboratory examinations.

Between health assessment checks, changes that affect health status could occur. If the changes are severe, however, it may result in a reason to encounter the general practitioner or the specialist. Given the presence of integrated PHR systems, the data will automatically end up in the PHR.

The gap between health check may also be filled with sensor technology. In the past decade sensor technology build to measure and store medical signal information, such as blood pressure, have reached a stage of maturity. Depending on the disease and which variable is required, these sensors could be of value for the continuous update of the PHR content.

Compliance
Compliance of health consumers to health plans is known to be an issue in preventive medicine [7]. Patients usually comply but lose interest or fail to finish programs before predefined targets have been reached. One of the key issues here is the absence of immediate observable results for the patient. There is a need for an overall objective measure indicating one's health based on measurable health variables, e.g. a 'health index'. This measure or index could serve as a mean to help individuals observe the effect of compliance to formulated health plans. The health-index itself poses the requirement that it should be sensitive enough to generate changes between short periods of time. Technically this means that the PHR should include tools to create awareness about the effects of compliance to tailored health plans.

Recurrence of interaction
Many web-based personal health services face the problem of low recurrence of interaction rate [15]. This issue is related to the compliance. Providers, aware of this issue, engaged their subscribers by providing them e-health portal functionalities with personalized and accurate medical and health information services.

An e-health portal is a framework for integration of health information, applications and services. E-Health portals should play a key role in the housing of integrated PHR systems and the provision of different services and personalized health information (Figure 2).

Medical literacy
Even though there is a growing amount of individuals using the web for medical information, medical literacy is still an issue. Medical literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions [16]. Since medical literacy is regarded as a problem to effectively consume medical information, an e-health portal should provide interpretive information. The portal should be able to adjust its content to the individual's level of understanding, i.e. educational or predefined level of understanding of the end-user.

Providers of PHRs and personal health services will face the challenge to communicate their services and information in such a way that it fits all user groups with respect to difference in level of medical literacy.

Discussion

Integrated personal health records incorporated in e-health portals could serve as a platform for the provisioning of preventive and early diagnostic services. While most preventive and early diagnostic services are scattered over a number of service provider locations, this platform provides a unique opportunity to implement a holistic approach for prevention and early diagnostics. Current PHRs and e-health portals are rather disease oriented and do not go beyond disease management. To broadly implement effective prevention, early diagnostics and subsequent early intervention, a PHR with the functionality of health risk assessments and tailored health plan generation is necessary. The proposed approach can forfill this need. Most of the components to implement this approach are already at hand.

Web-Based Personal Health Records

A holistic approach for health management, prevention and early diagnostics

Georgio Mosis

Ersen Colkesen

Background

- A structured provision of Prevention and Early Diagnostics is needed to significantly improve healthy life years
- Empowerment of individuals in their health management is crucial in realizing prevention
- Personal Health Records can fulfill these needs

niped

PHILIPS
sense and simplicity

Objective

- To identify issues in preventive health services via web-based PHRs

- To propose a framework for a holistic approach for prevention and early diagnostics via web-based Personal Health Records

niped

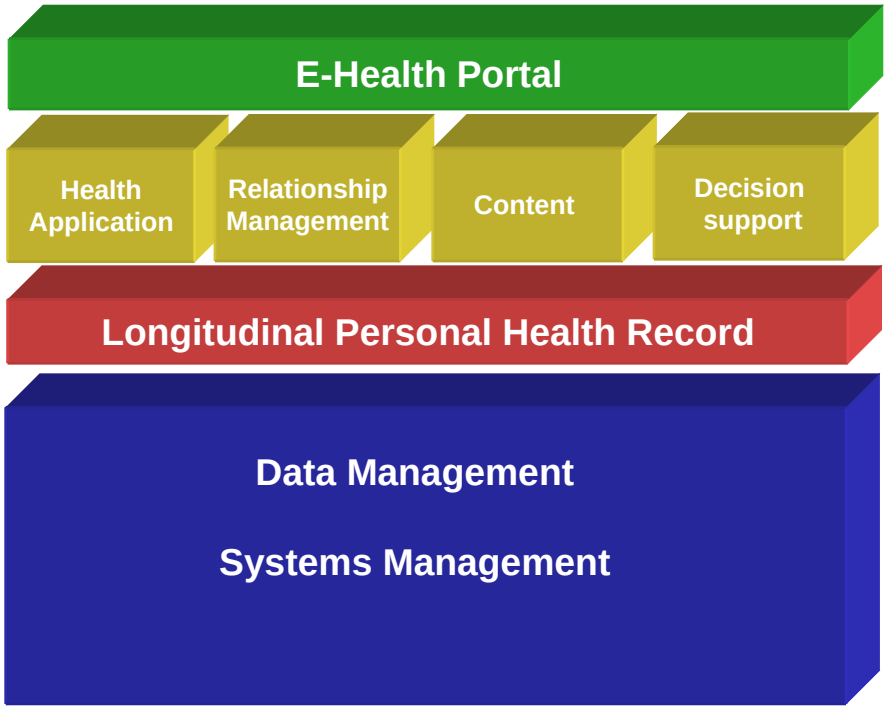
PHILIPS
sense and simplicity

Web-based Personal Health Records

- **Web-based PHRs:**
  - **contain longitudinal health information**
  - **are sourced by both the individual as well as the health care professional**

- **Contained information comprises:**
  - **major illnesses**
  - **family and social history**
  - **medication, allergies and immunizations**
  - **lifestyle data**
  - **diagnostic test results**
  - **Home-monitored data**

→ **Web-based PHRs therefore enable additional services based on this information**



niped

PHILIPS
sense and simplicity

Interactive prevention and early diagnostics services

- Current online health services mainly have a disease management focus
- Currently a holistic and structured approach for Prevention and Early Diagnostics services are lacking

→ A more prevention and early diagnostics focus is needed to improve individual health

→ A common structure is needed for provision of preventive services

→ Web-based PHRs can do just this

niped

PHILIPS
sense and simplicity

Empowerment of individuals

- Web-based PHR can also provide preventive decision support for the individual, making the individual in charge of its own health

- Algorithms providing this functionality should therefore be:
  - Evidence-based and quality assured
  - Supported by healthcare providers to guarantee acceptance

- Process flow of individual decision support:
  - Knowledge system processes PHR data into personal risk profiles
  - Risk profiles are communicated to the individual
    → health education
  - Risk profiles are converted in tailored health plans
    → health improvement
  - Repeating the cycle gives insight in advances
    → health monitoring

niped

PHILIPS
sense and simplicity

Discussion and conclusion

- Currently preventive and early diagnostic services are scattered and structural provision is lacking
- Web-based PHRs provide a unique opportunity to implement a holistic approach for prevention and early diagnostics
- To broadly implement effective prevention, early diagnostics and subsequent early intervention, a PHR with the functionality of health risk assessments and tailored health plan generation is necessary.

Wireless Communication Technology to Support Rural Primary Health Care Management In South Africa

Lulama Dikweni [a], Lyn A Hanmer [a], Jalal Ghiassi-Razavi [b], Jean Jacques Minnaar [c]

[a] *Medical Research Council, South Africa*
[b] *Cell-Life, South Africa*
[c] *Geospace International (Pty) Ltd, South Africa*

Abstract

The aim of this study is to investigate the potential of wireless communication technology to improve in rural primary health care services. A cell-phone-based patient tracking system for use by home-based carers and a basic electronic clinic patient record system are being implemented in two sites. Summary data from the clinic patient database is transmitted wirelessly to a central database. Preliminary results indicate that electronic information systems have the potential to improve communication between clinic staff, home-based carers and sub-district managers.

Keywords:

primary health care, wireless communication technology, patient information system

Introduction

Primary health care (PHC) providers in rural clinics and those providing home-based care have difficulties in reporting and receiving feedback from management due to poor communication infrastructure and the use of manual systems to register patients' details. This study investigated the effect of implementing electronic patient record systems in two rural sites in the North West Province of South Africa (SA).

Description of the project

Two systems have been implemented: The patient tracking system (PTS) for use by home-based carers (HBCs), is cell-phone based, and the basic electronic clinic information system (CIS) is implemented on laptop computers at clinic level. A summary record of each patient clinic visit is included in the clinic database on the laptop. The data for the routine monthly report for the DHIS (district health information system) is transmitted wirelessly from the clinic to a central database via the cell-phone network, using a triband GPRS PC radio card. The PTS supports both reporting on all visits to chronically ill patients by home-based carers, and management of the home based care providers. Data from both systems is accessible via the Web to appropriate sub-district management personnel.

At initial implementation the two electronic systems operated separately, with data being consolidated in separate centralised databases. Data from the PTS and the CIS will be combined in a common database at clinic level, using the patient clinic number as the key. This will allow the clinic personnel to access full details of clinic and HBC services of patients.

The key users of the CIS at the clinics engage in diverse roles: nurse professionals can update patient data, and collate and compile data to create management reports. Data capturers transferred the details of all the patients who were registered in the manual clinic records to the electronic database on the laptop. The data capturers will be phased out as health professionals take control and operate the integrated system. HBCs enter data on patient visits on their cellphones and it is transmitted to a central database. The local sub-district information officers provide ongoing support to the system users.

Results and discussion

Ongoing monitoring of the operation and use of the electronic systems has led to significant updates of both systems. Communication costs are reasonably low. The implementation of the PTS has resulted in standardisation of the reporting on HBC visits. Experiences to date indicate that electronic information systems have the potential to improve communication between clinic staff, home-based carers and sub-district managers, and that wireless communication technologies can help to address infrastructure limitations.

Acknowledgments

The ongoing support of colleagues in the North West province and in our organisations is gratefully acknowledged.

Abstract

Information availability is a major concern when the provision of care is at stake. Physicians make their decisions based on the information at hand. Several Electronic Patient Record (EPR) systems have been developed in order to make available to physicians structured and helpful information. However most of these systems are unarticulated and usually address only the specificities of a single medical specialty. Virtual Electronic Patient Records (VEPR) such as MAID (Multi Agent system for the Integration of Data) system provide for the necessary means for intra-institutions departmental information integration. Nevertheless, patients are mobile entities, visiting multiple institutions during their life time and leaving a trail of information scattered around. In this paper is presented a mobile agent based extension to the agent based MAID system in order to enable inter-institution patient data integration.

Keywords:

mobile agents, computerized medical records systems, hospital information systems, systems integration

Introduction

Healthcare is information and knowledge driven. Good healthcare depends on taking decisions at the right time and place, according to the right patient data and applicable knowledge. Communication is of most relevance in today's healthcare settings, as health related activities, such as delivery of care, research and management, depend on information sharing. As more data on patients are now recorded than ever before [1] the economical impact of their management is high. In a single healthcare institution, information technologies usually tend to combine different modules or subsystems, resulting in a "best-of-breed" approach [2]. This leads to a great demand on creating efficient integrated electronic patient records that would facilitate the communication process. Centralized solutions are often infeasible and expensive. Thus, integration with legacy systems is a key issue in order to provide physicians with complete and reliable information. The combination of data from heterogeneous sources takes a great deal of effort because the participating systems usually differ in many respects, such as functionality, presentation, terminology, data representation and semantics [2]. Interfaces are needed in order to retrieve useful information. Taking into consideration the intra-institutional level, and departmental systems, Virtual Electronic Patient Records (VEPR) systems approach can provide for the necessary means for departmental systems integration, enabling, at the point of care, a single integrated view of all patients' clinical information existing on the institution. We could say that at the institution level local information integration could suffice to provide doctors with all the necessary information to deliver care to a given visiting patient. However, patients are mobile entities, they visit multiple institutions during their life time and leave a trail of information scattered around laboratories, primary care units and other hospitals. The patient clinical history available to the doctor should not be resumed only to the information produced locally in the institution but also to include external data. The lack of articulation observed at the institution level, in what information systems integration is concerned, is also present when looking at the inter-institution integration level. Usually data integration relies on patients carrying their paper lab reports, x-rays and other clinical documents themselves. In order to provide consistent and complete clinical data availability, solutions must be provided for bridging inter-institutional systems integration gap.

Methods

The implemented system was design for extending MAID patient data integration features [3]. MAID system was developed for patient data integration within hospital S. João, the second largest in Portugal. The MAID system was designed for gathering clinical documents such as lab results and discharge letters from several internal departments. MAID system makes use of agent paradigm in order to build an autonomous and scalable system running since 2004.

Our aim is to extend MAID enabling data integration at the inter-institutional level. In order to accomplish this, modules for external data discovery and collection need to be designed and developed. Given the error prone and instability of large networks, like the national health network, additional care must also be taken in consideration in order to enable data collection and data availability within a useful time frame.

Besides the social and autonomous behavior of agents, the system implementation makes use of their mobile capabilities. This mobility can eliminate the necessity of long running communication channels between institutions and can provide for stronger external data discovery procedures that don't lead to local communications system overloading.

Data collection activities will be trigged by surgeries, consultation appointments and other scheduled events within a health providing unit. The system is intended to be integrated not only with MAID system but also to be able to provide data search mechanisms to other existing systems. Given the widespread inexistence of international standards adoption in most of the Portuguese electronic patient record systems collection actions, at this point, will be directed only to formatted documents such as PDF files and will not retrieve data individually.

Results

Implementation

The implementation consists in three phases: Event Management, Document Discovery and Document Retrieval.

On the first phase each event corresponds to the schedulling of a new clinical episode (consultation, surgeries, etc). To each scheduled episode is associated a set of information that will be used latter for data discovery scheduling. Besides the patient identification a time interval is provided indicating the urgency of information retrieval. External systems where information is known to exist can also be added to this set.

Phase two is initiated by the event scheduler. It triggers a mobile agent for document discovery activities giving him a patient id and a set of starting locations of external systems.

Mobile agents will travel trough remote platforms asking for documents and additional locations for patient documents. In each remote platform a local broker agent will give the mobile agent a new procedure. This procedure contains all the necessary new actions for the agent to retrieve the desired information. When the procedure finishes the mobile agent will have retrieved a set of new locations and a list of remote document references and is ready to travel to a new system. When the agent is unable to move to the desired destination it will postpone the visit and continue to next available location. After a few attempts to visit a designated location the reason for failure is registered and the location is eliminated from the agent's itinerary.

After completing its itinerary the mobile agent will return to the home system and store the gathered information. This will trigger phase three were discovered documents are retrieved from remote systems by a local broker agent. After collection documents are made available within the hospital system.

The system is based on the widely used JADE multi-agent platform with the inter-platform mobility add-on.

Conclusion

Several efforts are being developed in order to make available the maximum amount of valuable health information when and where needed. Patient mobility, within a country and between countries is now more common than ever before. Health record systems should adapt to this reality and be able to cope with their patient's mobility. The implemented system is intended to enhance an existing institutional system in order to make available to care providers a more complete patient clinical history and consequently enabling patients better and faster care provision. Additional work is planned for this system regarding security and ontological issues regarding data transport and data integration respectively.

INTRODUCTION

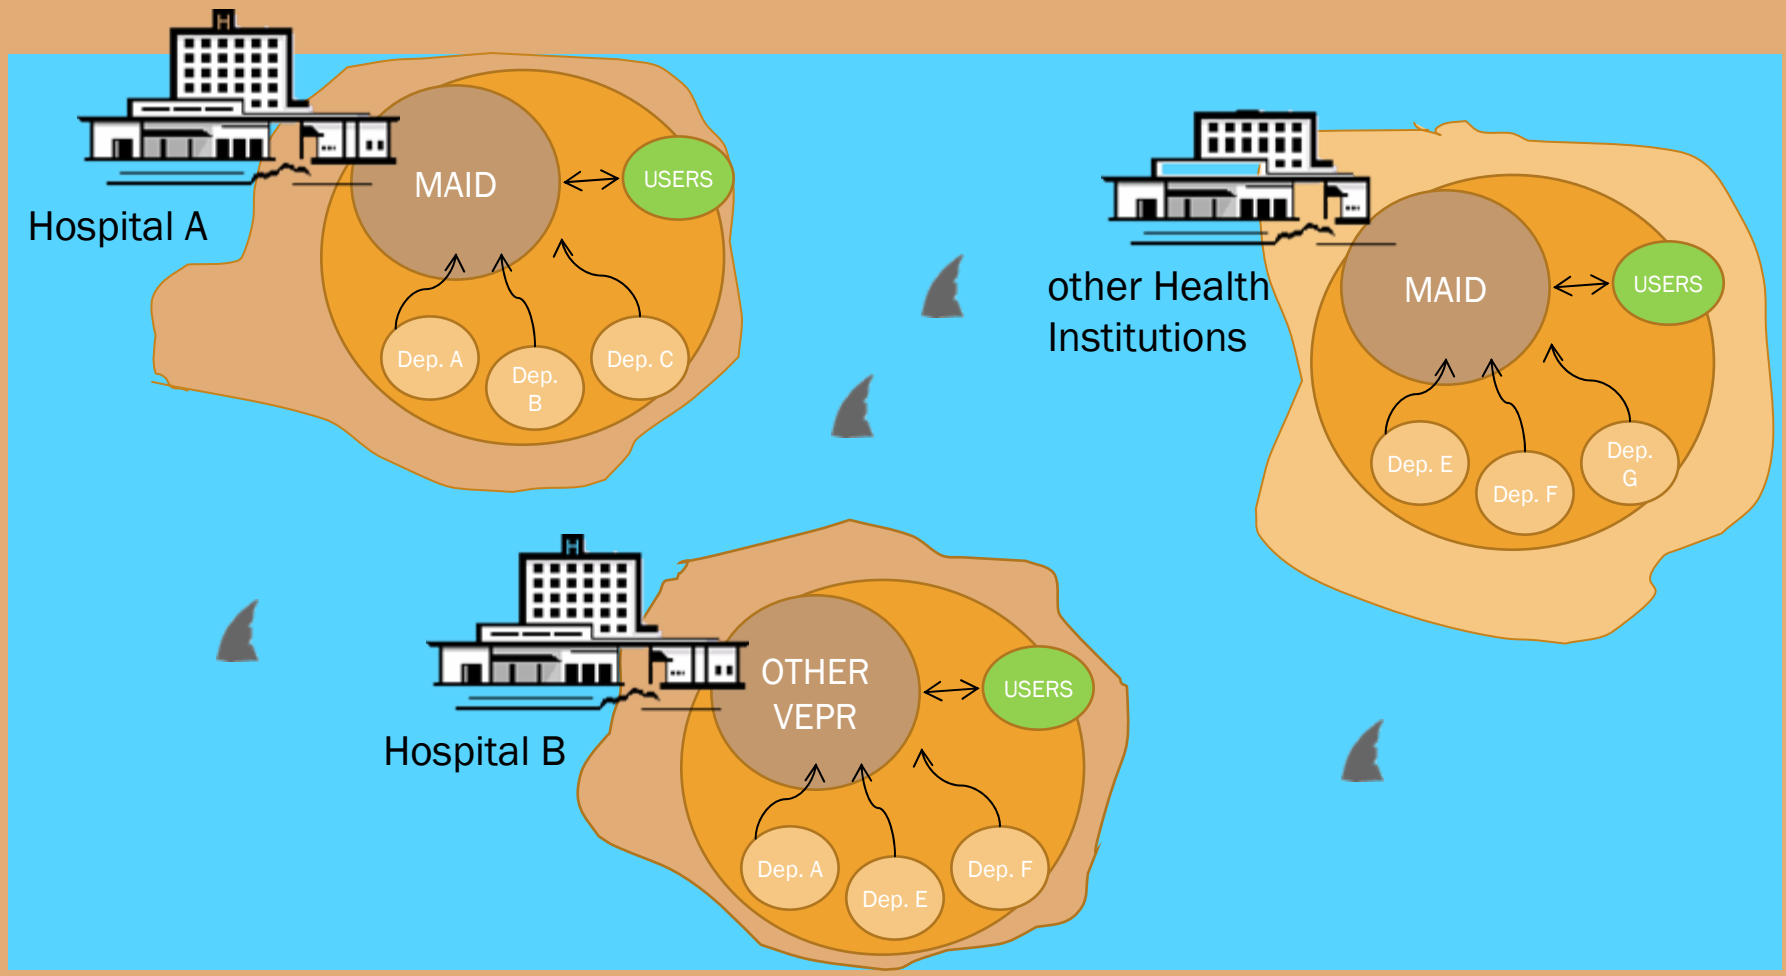
- Information availability is a major concern when the provision of care is at stake.
- Physicians make their decisions based on the information at hand.
- Most of EPR systems are unarticulated and usually address only specificities of a single medical specialty.
- Virtual Electronic Patient Record (VEPR) systems such as MAID - (Multi Agent system for the Integration of Data) provide for the necessary means for intra-institutions departmental information integration.

INTRODUCTION

- However patients are mobile entities, visiting multiple institutions during their life time and leaving a trail of information scattered around.

- In order to overcame the institutional information systems islands, a inter-institution information integration is necessary.

SCENARIO



Extending a VEPR system institutional boundary
P. Vieira-Marques et al.

CINTESIS
CENTER FOR RESEARCH IN HEALTH INFORMATION SYSTEMS AND TECHNOLOGIES

U.PORTO
FMUP FACULDADE DE MEDICINA UNIVERSIDADE DO PORTO

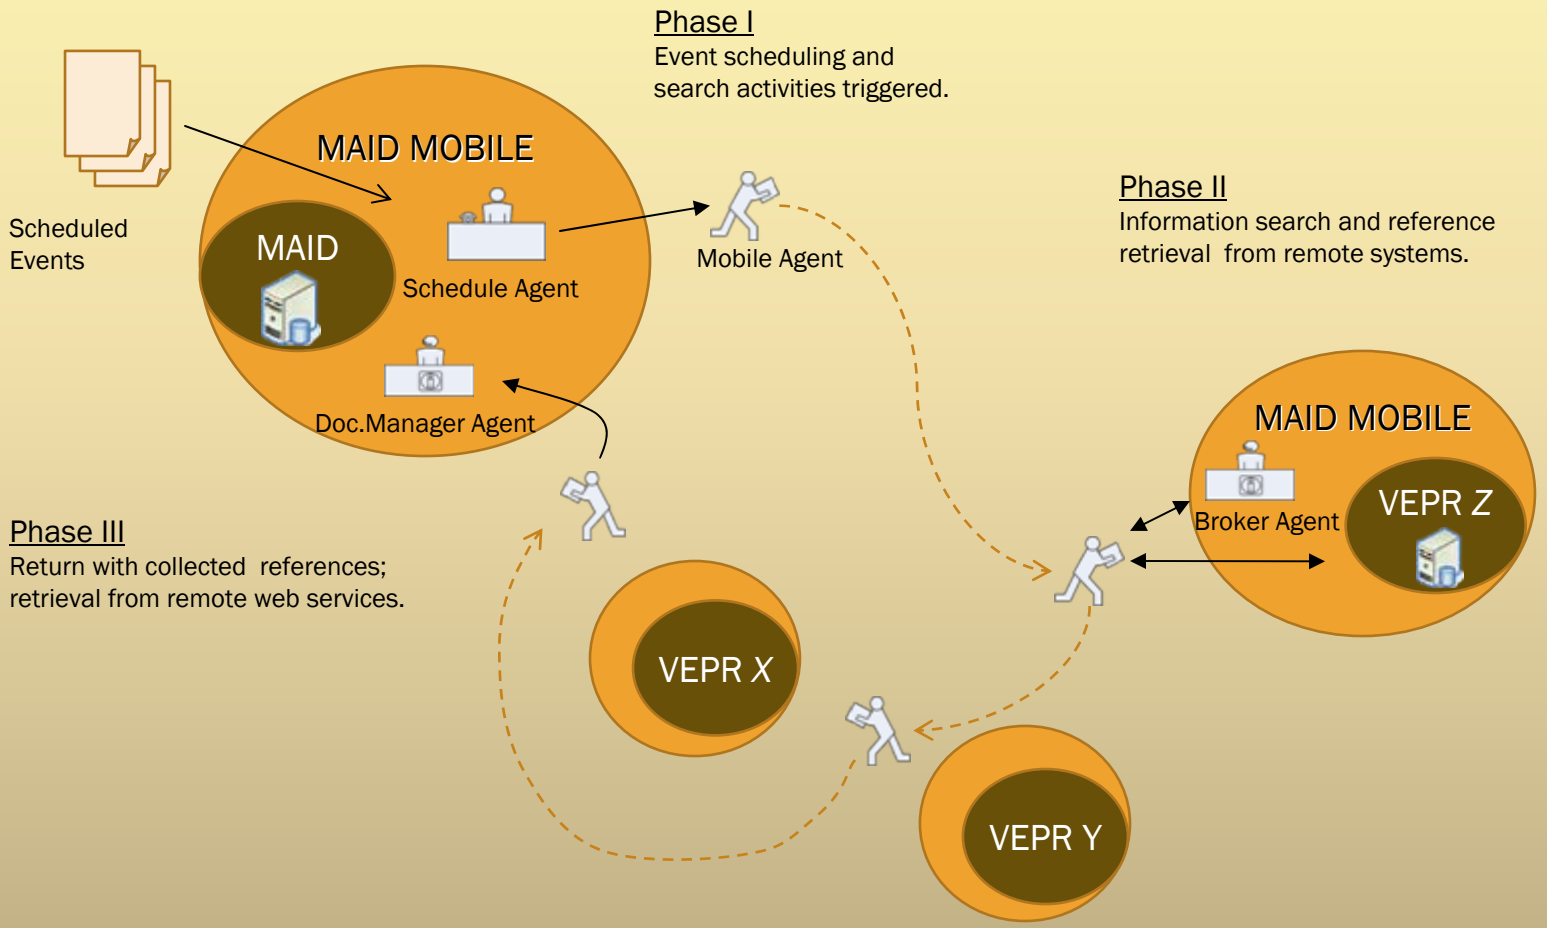
QUESTIONS

- How to bridge the institutional information systems islands?
- How to enhance the provision of up to date and, as much as possible, complete patient information?

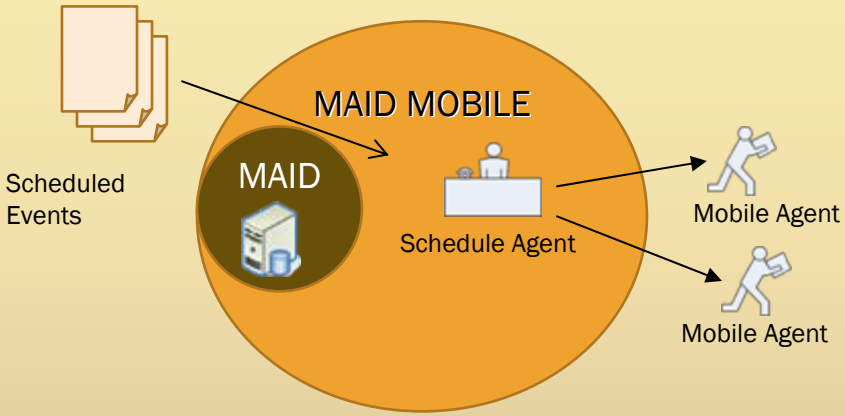
METHODS

- We start from a multiagent based VEPR system.
- Extend it with inter-institutional information search and retrieval capabilities using mobile agents.
- Test pilot system implemented using Jade multi agent platform with the inter-platform mobility add-on.

SYSTEM OVERVIEW

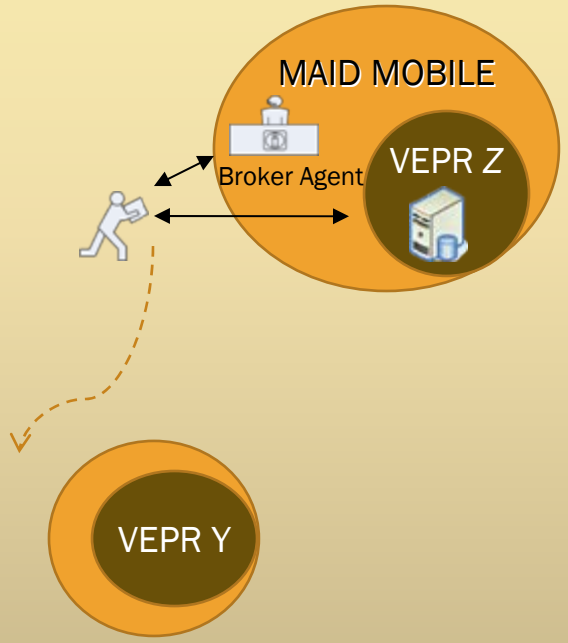


PHASE I – Event Scheduling



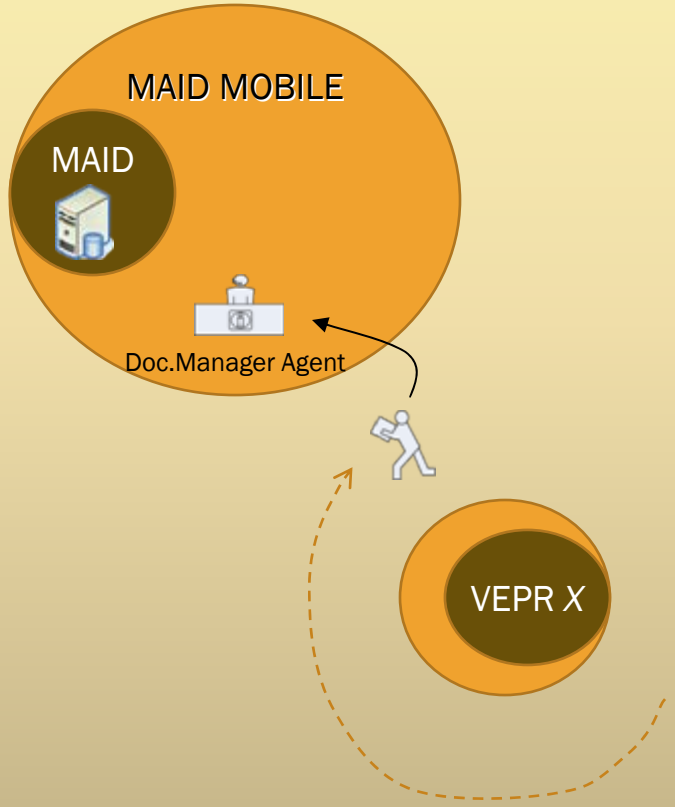
- For each patient, two mobile agents are sent looking for information.
- Along with the patient id
  - One agent receives a set of locations known to have information.
  - The other agent, the complementary set of all locations.
- New locations can be discovered along the way.

PHASE II - Retrieving references



- Mobile agent moves through a set of remote systems contacting the local broker.
- The broker agent manages incoming agents request providing the mobile agent with interfaces which enable querying the local VEPR.
- The mobile agent asks for document references from a given patient and other systems that are known to have additional patient information.
- Mobile agents stores all information adding new systems to its itinerary.
- Continues to the next system.

PHASE III – Returning results



- Document references collected are delivered to the Document Manager Agent along with a set of new contacted remote systems.
- Referenced documents are scheduled to be collected from remote webservices.
- Upon retrieval documents are made available to local users through the VEPR.

CONCLUSIONS

- The system is intended to enhance an institutional VEPR system in order to make available to care providers a more complete patient clinical history.

- The mobility behavior eliminates the need for long running communication channels between institutions and provide for stronger external data discovery procedures that don't lead to local communications system overloading.

- Additional work is planned for this system regarding security and ontological issues regarding data transport and data integration respectively.

Understanding the Profile of Errors That Cause Duplicate Entries in a Patient Registry

Scott L. DuVall[a], Janice Conrads[b], Alison Fraser[b], Geraldine Mineau[b,c]

[a] *Department of Biomedical Informatics, University of Utah, United States of America*
[b] *Pedigree and Population Resource, Huntsman Cancer Institute, University of Utah, United States of America*
[c] *Department of Oncological Sciences, University of Utah, United States of America*

Abstract

Duplicate entries in patient registries are a significant problem facing healthcare master patient indices and public health data sources. Patterns exist in the demographic information of these records that can be used to better understand what causes duplicate entries to appear. The University of Utah contracts the Pedigree and Population Resource group at Huntsman Cancer Institute to link demographic records from its Enterprise Data Warehouse (EDW) to the Utah Population Database (UPDB). An additional benefit of this linkage is the discovery of duplicate records in the EDW. From one million EDW records, 76,922 have been identified as duplicate. A profiler was built to extract the patterns of errors from these duplicate records. Frequencies of error types found in the EDW were compared with those in existing literature.

Keywords:

record linkage, patient record management, patient registries

Introduction

Duplicate records are detrimental to the cost-effective and efficient delivery of health care.[1] Manually identifying and resolving duplicates can cost $60 per case.[2] Patterns have been found in the types of errors that occur in patient registries, suggesting that undetected duplicate records may be similar to those already identified.[3,4] The purpose of this study was to compare the frequency of error types in the University of Utah Enterprise Data Warehouse (EDW) with existing literature.

Methods

Patterns of errors in existing literature were extracted. State machine[5] templates were created for each error type as Java classes. As a potential duplicate record pair was examined, an instance of each state machine was created with one record and tested with the other record. A test resulting in an "accept" state resulted in the pair being classified as that error type.

Results

As shown in Table 1, the EDW records show some differences from published literature in patient name types.

	EDW	Friedman[4]
Extra names and titles	34.3%	36.9%
Nicknames, spelling variations	21.8%	13.9%
One letter substitutions	13.6%	13.7%
One letter added or deleted	7.6%	12.9%
Punctuation or spaces	1.9%	11.8%
Different last names for females	12.9%	7.8%
Permuted parts of names	3.2%	1.4%
Different first names	2.8%	1.4%
One letter transposed	1.9%	0.8%

Table 1 – Error types of patient names

Similar frequency discrepancies were found in error types of other demographic fields, including Social Security Number.

Discussion

Despite differences found in the frequency of error types that occur in the EDW data set from published literature, it is clear that patterns of error types do occur in duplicate records. Understanding which errors are likely to occur in a dataset can aid in the detection of duplicate records.

Alternative Approach to Compliance of Antiepileptics and Its Clinical Meanings

Hsiu-Li Lin, Yu-Chuan(Jack) Li

Graduate Institute of Medical Informatics, Taipei Medical University, Taiwan

***Abstract**:*
Though compliance of antiepileptic drugs (AED) is key issue treatment of epilepsy, the only two ways to determine that are (i) interviewing patient (ii) monitoring serum level. We propose another approach by analyses the medication records of National Health Insurance Research Database (NHIRD) because it contain complete medication records of every insured person.

Keywords:

compliance, anticonvulsants, epilepsy

Method

The epileptic group are identified as diagnosed epilepsy (ICD-9CM code 345, 780.3, A-code A225, A469 in NHIRD) and receiving AED treatments.The disease duration is calculated as the period from first time diagnosis of epilepsy to the day when patient was not insured. If the patient was insured up to the final day of 2003, it is the end of duration. The drug days is calculated as total days of AED patient having during the disease duration. The times of hospitalization is also recorded. We examine the correlation between the outcome index, including hospitalization frequency, total medical payment, emergency service (ES) visiting and independent variables including age, gender, ratio respectively.

Result

The rate of epilepsy in this diseased group is 0.993%. The epileptic group is significantly older and more hospitalization than non-epileptic group. There is no difference if gender distribution between these two group. The all admission frequency increases significantly with the growing age and increasing ratio of AED days to the disease duration but oppositely with less AED days. There is the similar correlation between the total medical payment and age and ratio, but not to AED days. The ES visiting frequency is positively related to the AED days only.

Conclusion

This study suggests that NHIRD is a adequate resource in surveying compliance of specific drug in Taiwan. The result reveals that good AED compliance does not lessen frequency of hospitalization and ES visiting as expect. But the more AED taking, the less admission is noted in this study.

Alternative Approach to Compliance of Antiepileptics and Its Clinical Meanings

Hsiu-Li Lin[a] Yu-Chuan(Jack) Li[b]

[a]Graduate Institute of Medical Informatics,
Taipei Medical University, Taipei, Taiwan

[b]Institute of Biomedical Informatics,
National Yang-Ming University, Taipei, Taiwan

Object

- Compliance is the key in controlling epilepsy
- Traditional method to estimate compliance of antiepileptic drug (AEDs)
  - Interview or questionnaire
  - Drug level test by saliva, serum, or hair sampling
- Complete medication record could be an alternative approach in estimating AEDs compliance

Materials

- In Taiwan, *National Health Insurance Research Database (NHIRD)* contain complete medication records of every insured person

- NHIRD
  - Out patient service
  - In patient service
  - Contract pharmacy

Materials

- NHIRD cohort sampling

- Population
  - 100,000 persons from 1987 to 2003
- Enrolled criteria (meet both)
  - Epilepsy diagnosis
    - ICD-9CM code 345, 780.3, A-code A225, A469
  - AED treatment

Method

- Independent variables
  - Age
  - Gender
  - Disease duration (DD)
    - Initial date : earliest date of epilepsy diagnosis
    - Final date : the end of study period or the day drop out from health insurance
  - Total AED days during disease (AD)
  - Compliance ratio (CompR) = AD /DD

Method

- Dependent variables
  - Frequency of emergency service (ES) visiting
  - Frequency of admission to hospital
  - Total medical payment
- Compare distribution of gender and age and hospitalization frequency between epileptic and non-epileptic groups
- Multiple regression model for each dependent variables
  - SAS 9.0 Reg procedure
  - Stepwise method

Result

- Study group
  - 993 observations in this diseased group (0.993%)

	Epileptic Group	Non-epileptic Group	Statistical Tests	p Value	Statistical Significance
Gender(F/M) in %	43/57	49/51	Chi-Square Test	0.055	Negative
Age	49±24	38±21	T-Test	<0.0001	Positive
Hospitalization Frequency	2.99	0.76	T-Test	<0.0001	Positive

Result

- Admission frequency = 0.57 +

  0.028 x age – 0.001 x AED days + 5.39 x CompR

  - Model R square = 0.0798

- Total medical payment = - 42142 +

  3614 x age + 496823 x CompR

  - Model R square = 0.1347

- Emergency service visits = 0.39 +

  0.0003 x AED days

  - Model R square = 0.0359

Conclusion

- Epileptic patients : older and more admission to hospital

- In epileptic patients
  - Aging more admission and more medical payment
  - More AED, less admission
  - Good AED compliance no guarantee of less hospitalization and ES visiting

Discussion

- More admission and more payment
  - = more severe and more care
  - = better compliance

- Limitation
  - Short study period in life-long disease such as epilepsy
  - Diversity of cause of admission and ES visiting

Future Application

- Correlate this compliance result with traditional drug level monitoring
- Further analysis in correlation of compliance with frequency of medication
- Study in compliance of medication for chronic diseases and correlate with outcome

Development of a Personal Medical Recorder on Cell Phone

Akihiro Takeuchi [a], Katsura Kobayashi[b], Noritaka Mamorita[b], Noriaki Ikeda[a]

[a] *Departments of Medical Informatics, School of Allied Health Sciences, Kitasato University, Japan*
[b] *Graduate School of Medical Sciences, Kitasato University, Japan*

Abstract

Paper medical records have effectively been used in chronic diseases without information technology. To facilitate self-control in hemodialysis and observe a patient's condition continuously, we developed a mobile phone-based personal medical recorder for patients suffering chronic renal failure. The application is based on Java2 Micro Edition and operates like a scheduler. The application stores laboratory data, such as BP, BUN, creatinine, HbA1c, etc., and other pertinent clinical comments into memory on a cell phone. The application can also customize, add or delete items (laboratory data, medications, questions, etc.). Detailed graphic displays of the data are shown. The data can also be sent to a PC with infrared communications. In a usage trial, patients were favorably receptive about this application and indicated that they wanted to continue using it.

Keywords:

cell phone, medical records, infrared transmitter

Introduction

Using a notebook-type diary, a chronically ill person can get an overview of his or her medical situation [1]. Although patients with chronic renal failure can maintain an adequate nutritional intake, they might also be able to recognize their own pathophysiological state and be aware of the settings for their own hemodialysis. Although data collection was more reliable with a palmtop computer than with paper diaries [2], there have been no reports presenting a PDA/cell phone-based clinical recorder for chronic hemodialysis other than for dietary monitoring [3]. Therefore, we developed a cell phone-based medical recorder for self-management of chronic diseases.

Materials and methods

An application on a cell phone was designed as a self-control tool for patients who are familiar with cell phone applications such as games. The application is based on a scheduler consisting of 3 canvases, a calendar, data entry and a plot canvas, and memory control and infrared modules (Figure 1). The plot canvas shows colored lines of selected clinical and laboratory data, such as BP, BUN, creatinine, HbA1c, etc.

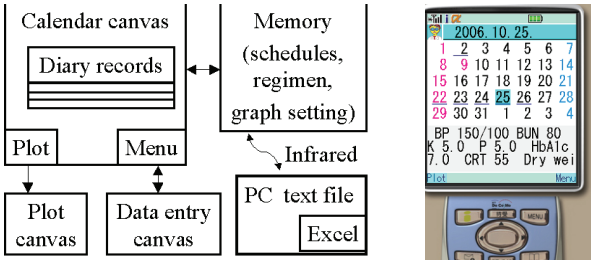

Figure 1 – An overview of the application and a calendar canvas

These data are stored in a textile format in the memory of the cell phone (maximum 200 kB). Because the record size of one schedule is estimated to be about 100 bytes, a maximum of 2000 records may be stored. An infrared module sends records in day or month units to a PC as a textile file. The records on the PC are automatically tabled and tallied on Excel with a customized VBA program.

The application was based on Java 2 Platform, Micro Edition (J2ME), and developed with an "i-appli Development Kit for DoJa-3.5" on a PC [4]. (The Doja is a version of the Java platform specially tailored to a mobile environment for NTT cell phones.) The application, a medical recorder (medData.jar 100kB), was uploaded with 2 files (medData.jam and medData.html) into our Web server. The application was then downloaded via the Internet and automatically installed into a Java-enabled cell phone in the usual way of a Java applet.

Results

For clarity, PC screens are shown in the regular order of usage rather than using photographs of cell phone screens (Figure 2). The application operates like a scheduler. Today, on the calendar, is highlighted in yellow. The selected day is highlighted in light blue and moved by operating the arrow keys. Each colored line on any day, e.g., 7th and 21st, corresponds to each clinical event or data and appears with comments and/or a graph in the lower area (Figure 2a).

Two records, pairs of the time of day and prescriptions (with laboratory data), are shown in this case (Figure 2b). Pushing the select key on a target record shows a data

entry canvas with laboratory item names and values. Numeric data are typed in by the patient. An adaptive submenu is automatically shown on the right side of the item along with a blood-flow setting for hemodialysis. All these values, including the time span, can later be edited.

Detailed graphic displays of data are sequentially shown on a plot canvas (Figure 2c). A trend graph of potassium for 1 year is shown in light blue (Figure 2d). The values in the last half of the year are higher than the target range shaded in the same color as the item in half tone. A horizontal scale of the graph is set to day, week, month or year by pushing 2, 5, 8 or 0, respectively. Graph properties of each item (vertical scale, normal range, line color, line mode and symbol) can be customized via a submenu on the calendar canvas (Figure 2e), e.g., a graph of BUN is shown in yellow bars (Figure 2f). In a selection canvas, plot items are marked with a black diamond (Figure 2g). A submenu of the calendar canvas includes functions: setting the system font, controlling infrared communications, customizing item/plot items, copying & pasting records, etc. (Figure 2h). Items (laboratory data, medications, prescriptions, questions, etc.) can be customized, added or deleted for each patient's disease.

The application was adapted for several patients in one trial. The patients were positive about this application and said that they would like to continue using it.

Discussion

Our application imposed upon the user to manually enter his or her own clinical data. The operation and graphics may deepen the patient's awareness of his or her symptoms, laboratory data, diseases, and prescriptions for self-managing therapies. The act of consciously entering and organizing data may be relevant to promoting desired behavior changes [5].

The application recognized only numeric keys where a numeric value should be entered: hour, minute, dosage, etc. Alphabetic characters are only used to enter comments. A menu is automatically shown when answers are ready. These functions do not allow any error messages that are objectionable when entering data to appear.

Graphs of clinical data are useful for awareness and self-management of chronic diseases. The system shows daily data and trend graphs of all plot items together on a calendar canvas and separately on a plot canvas. Arbitrarily selecting a horizontal term of the graph can be adapted to various data with a quick variation in minutes such as blood sugar and/or with a slow response in months for such items as glycosylated HbA1c. However, the system could be improved on the plot routines, since many daily records take about 1 second to make a graph of the data for each day of a month.

Conclusion

This personal medical recorder on a cell phone could be useful for patients requiring hemodialysis, since actively processing and managing data may improve their understanding and situational awareness. Our cell-phone application will record medical events at anytime and anywhere in a person's life.

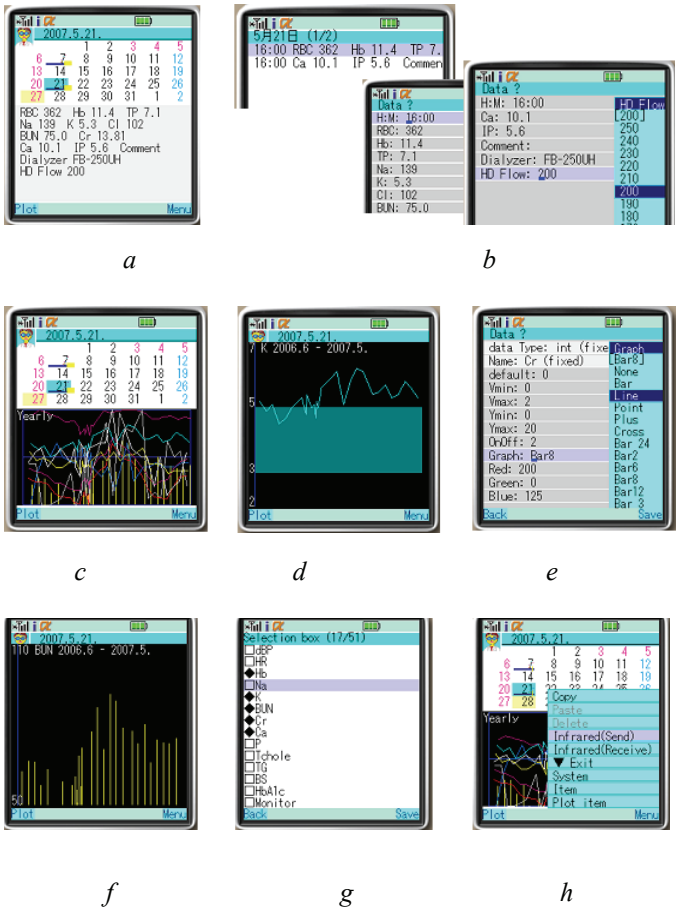

Figure 2 – Captured screen of (a) calendar canvas, (b) diary canvas and data entry canvas, (c) calendar canvas with a graph plot canvas, (d) plot canvas, (e) edit canvas to modify plot item properties, (f) a bar graph on the plot canvas, (g) selection canvas of plot items and (h) a submenu of the calendar canvas

Abstract

Paper medical records have effectively been used in chronic diseases without information technology. To facilitate self-control in hemodialysis and observe a patient's condition continuously, we developed a mobile phone-based personal medical recorder for patients suffering chronic renal failure. The application is based on Java2 Micro Edition and operates like a scheduler. The application stores laboratory data, such as BP, BUN, creatinine, HbA1c, etc., and other pertinent clinical comments into memory on a cell phone. The application can also customize, add or delete items (laboratory data, medications, questions, etc.). Detailed graphic displays of the data are shown. The data can also be sent to a PC with infrared communications. In a usage trial, patients were favorably receptive about this application and indicated that they wanted to continue using it.

Introduction

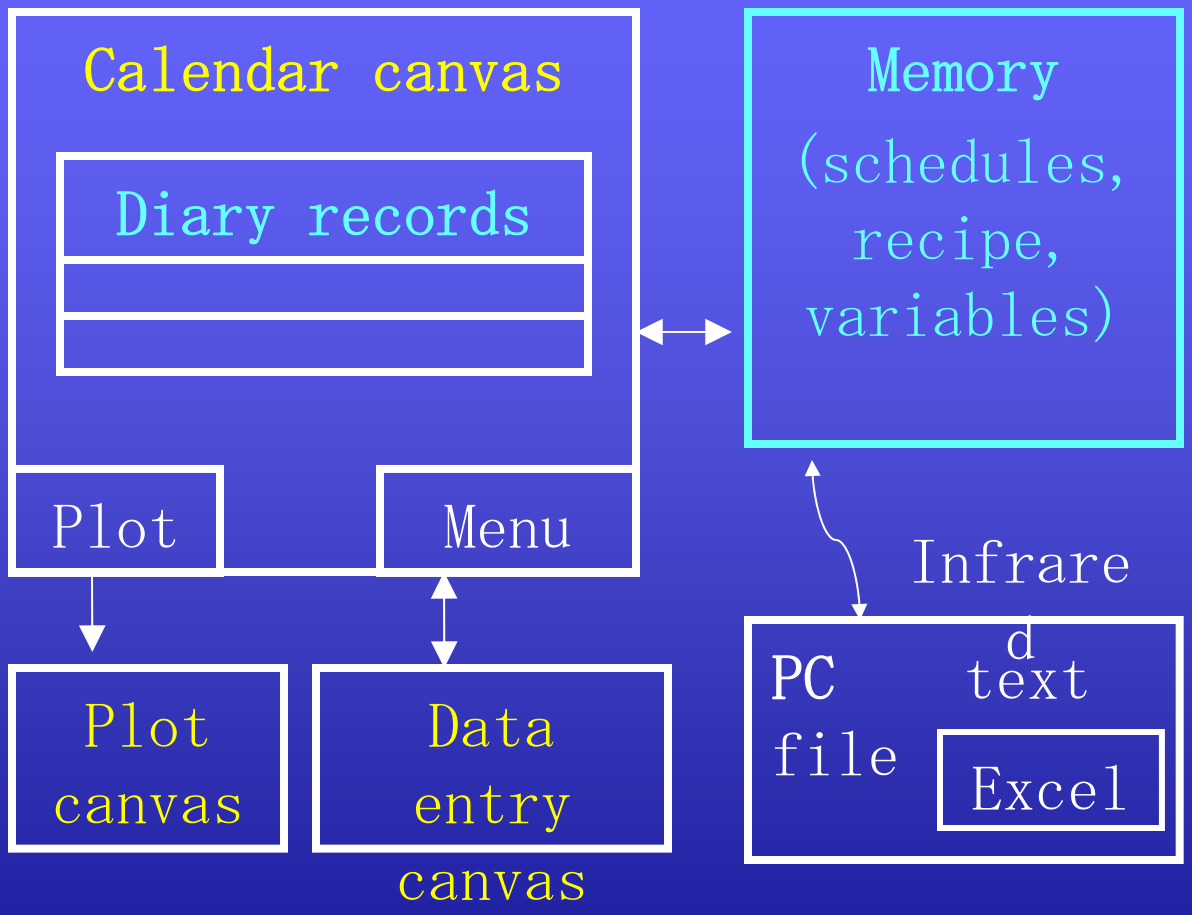
Using a notebook-type diary, a chronically ill person can get an overview of his or her medical situation [1]. Although patients with chronic renal failure can maintain an adequate daily nutritional intake, they might also be able to recognize their own pathophysiological state and be aware of the settings for their own hemodialysis. Although data collection was more reliable with a palmtop computer than with paper diaries [2], there have been no reports presenting a PDA/cell phone-based clinical recorder for chronic hemodialysis other than for dietary monitoring [3]. Therefore, we developed a cell phone-based medical recorder for self-management of chronic diseases.

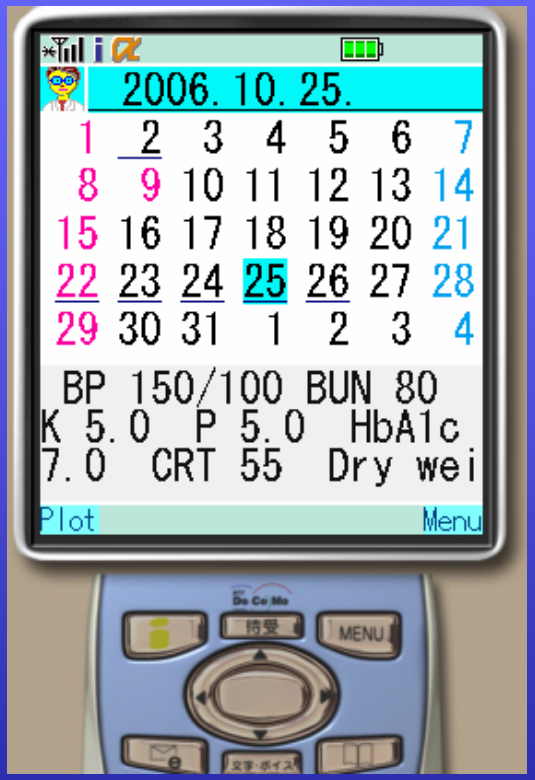
Materials and Methods

An application on a cell phone was designed as a self-control tool for patients who are familiar with cell phone applications such as games. The application is based on a scheduler consisting of 3 canvases, a calendar, data entry and a plot canvas, and memory control and infrared modules (System design p5). The plot canvas shows colored lines of selected clinical and laboratory data, such as BP, BUN, creatinine, HbA1c, etc.

These data are stored in a textile format in the memory of the cell phone (maximum 200 kB). Because the record size of one schedule is estimated to be about 100 bytes, a maximum of 2000 records may be stored. An infrared module sends records in day or month units to a PC as a textile file. The records on the PC are automatically tabled and tallied on Excel with a customized VBA program.

System design





Software specifications

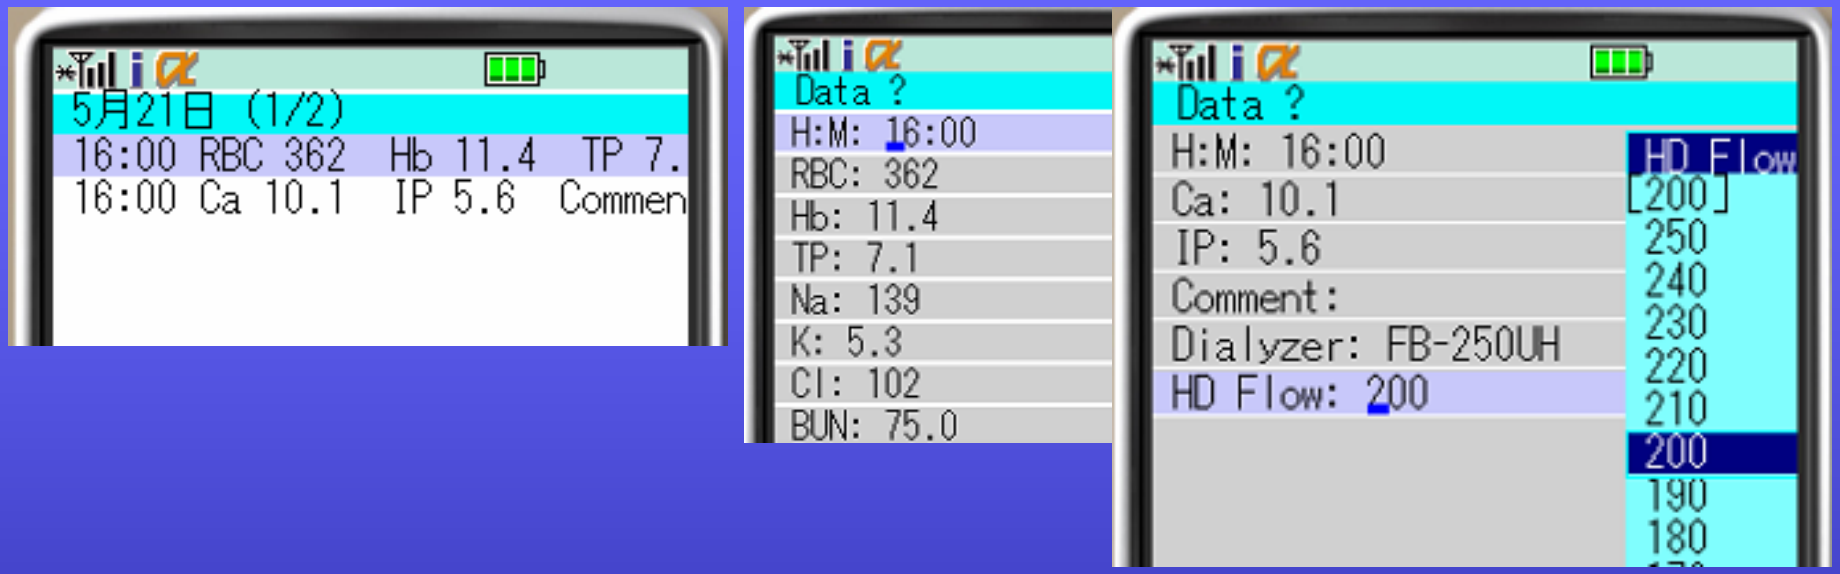
The application was based on Java 2 Platform, Micro Edition (J2ME), and developed with an "i-appli Development Kit for DoJa-3.5" on a PC [4]. (The Doja is a version of the Java platform specially tailored to a mobile environment of NTT cell phone.)

The application, a medical recorder (medData.jar 100kB), was uploaded with 2 files (medData.jam and medData.html) into our Web server. The application was then downloaded via the Internet and automatically installed into a Java-enabled cell phone in the usual way of a Java applet.

Sample runs

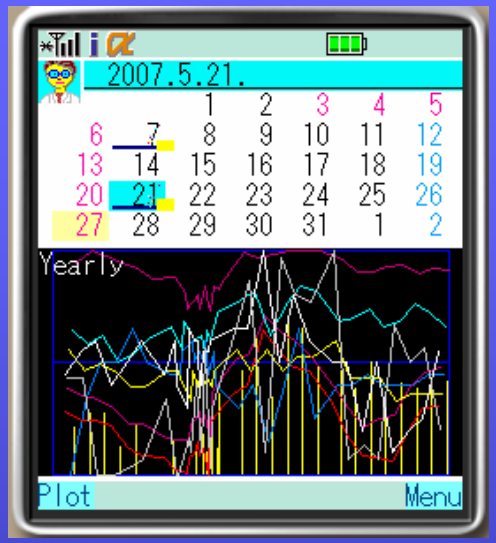
For clarity, PC screens are shown in the order of frequency of usage rather than using photographs of cell phone screens. The application operates like a scheduler. Today, on the calendar, is highlighted in yellow. The selected day is highlighted in light blue and moved by operating the arrow keys. Each colored line on any day, e.g., 7th and 21st, corresponds to each clinical event or data and appears with comments and/or a graph in the lower area.

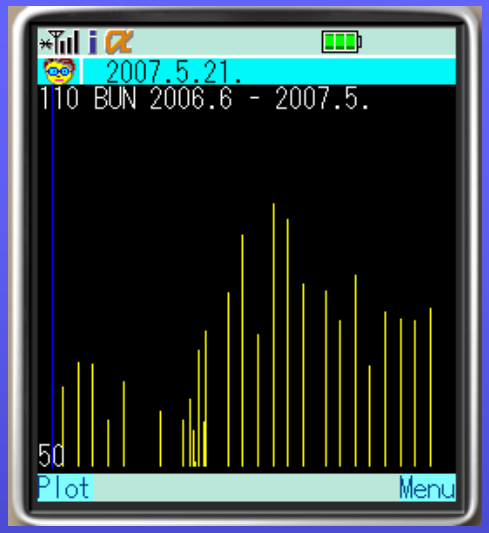
Entering/editing data



Two records, pairs of the time of day and prescriptions (with laboratory data), are shown in this case. Pushing the select key on a target record shows a data entry canvas with laboratory item names and values. Numeric data are typed in by the patient. An adaptive submenu is automatically shown on the right side of the item along with a blood-flow setting for hemodialysis and a brief comment. All these values, including the time span, can later be edited.

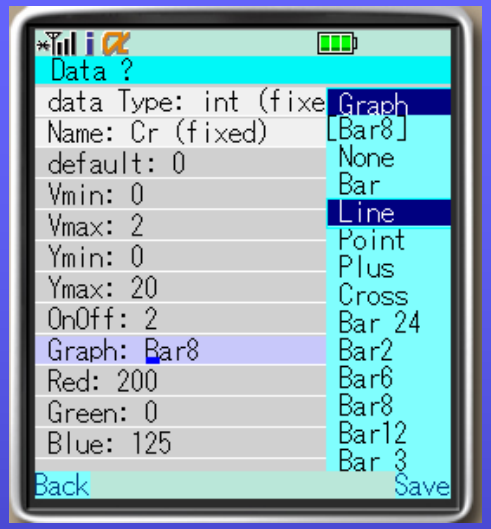
Graphics

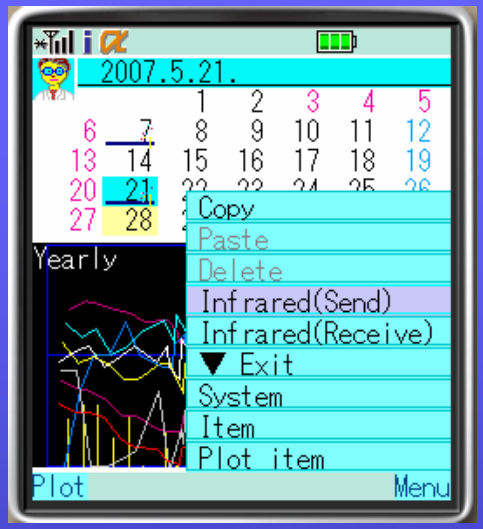




Detailed graphic displays of data are sequentially shown on a plot canvas (left). A trend gram of potassium for 1 year is shown in light blue (middle). The values in the last half of the year are higher than the target range shaded in the same color as the item in half tone. A horizontal scale of the graph is set to day, week, month or year by pushing 2, 5, 8 or 0, respectively.

Customizing





In a selection canvas, plot items are marked with a black diamond (left). Graph properties of each item can be customized via a submenu on the calendar canvas (middle), e.g., a graph of BUN is shown in yellow bars (Graphics p9, right). A submenu of the calendar canvas includes functions: setting the font, controlling infrared communications, customizing item/plot items, copying & pasting records, etc. (right). Items (laboratory data, medications, prescriptions, questions, etc.) can be customized, added or deleted for each patient's disease.

Discussion

Our application imposed upon the user to manually enter his or her own clinical data. The operation and graphics may deepen the patient's awareness of his or her own symptoms, laboratory data, diseases, and prescriptions for self-managing therapies. "The act of consciously entering and organizing data may be just as relevant to promoting the desired behavior changes" [5].

The system draws daily data on each day, and trend graphs of all plot items together on a calendar canvas and separately on a plot canvas. Selecting arbitrarily a horizontal term of the graph can be adapted to various data with a quick variation in minutes such as blood sugar and with a slow response in months for such items as glycosylated HbA1c.

Conclusion

This personal medical recorder on a cell phone could be useful for patients requiring hemodialysis, since actively processing and managing data may improve their understanding and situational awareness. Our cell-phone application will record medical events at anytime and anywhere in a person's life.

Abstract

The family-based information is the foundation for family care and community health promotion. Based on the multiple diseases integrated screening project and the completed popultion household registry system, we developed the efficient and flexible algorithm to asscertain the family-based structure for community public health management. We use the house-hold registry system to developed family-based pedigree and degrees of relatives on the basis of two-stage procedure. The algorithm followed the rule of family case-control proband method to catch other family members, not only for specific one type of disease, but also for various types of diseases. All relationship would be changed according to the proband located. During this algorithm development, we took the case-control family-proband study of hypertension to demonstrate the application and used proportional hazard model of Cox regression to compare the onset age of hypertension. Both random sampling and optimal relationship methods were revealed well for familial aggregation study of hypertension.

Keywords:

family-based, proband, population-based, screening

Introduction

Primary care is a critical role to identify individual risk of disease, including the inherited disease. However, the primary tool for the inherit risk assessment is family history and onset age of relatives, but there are few data can be taken, hence, how to build up the database is the important issue for preventive medicine, especially for community-based and population-based application. The development of population-based and family-based data has now increasingly gained attention in studies related to population genetic epidemiology. The process of genetic epidemiology includes a spectrum of stage from descriptive epidemiology, familial aggregation, segregation analysis, linkage analysis, fine mapping, the assessment of candidate gene associations, and gene characterization. Studies on each stage call attention to the requirement of population-and family-based data. The multiple disease screening model was initiated from 1999, which combined 5 types of cancers and 3 types of chronic disease, named as Keelung Community-based Integrated Screening (KCIS) project [1]. To deal with the large and complex data management, the health information management system has built up for referral and follow-up mission [2]. To date, this project served 85956 residents for screening from 1999 to 2005. According to the contents and relative information of house-hold registration system, KCIS project offers an opportunity to spawn population-based and family-based data for a series of diseases with the potential of familial aggregation. This novel idea and development has provided the efficient practice for epidemiological research and preventive medicine.

Material and methods

Data resource and structure

To understand and to elucidate the data resource and structure are very important for this population-based and proband-initiated study. The household registration of Taiwan inherited from the governed period of Japanese. The registration system is through two major ways for household management, one is personal identification registration and another is booklet of household registration. Both were performed from 1947 and computerized from 1985. The personal identification registration not only includes unique personal identification number, name, but also gender, birthday, names of father, mother and spouse, address, marriage or devoice, adoption or not, and date of death. Every household is provided unique household number and booklet which was listed and updated all family members' personal identification information as above.

Construction algorithm of trans-generational pedigree

A prospective cohort design was adopted using the community-based multiple screening program in Keelung, the northernmost county of Taiwan. All participants were informed the associated data management. We link the

house-hold registry system to developed family-based pedigree and degrees of relatives on the basis of two-stage procedure. Since the record for each resident of population registry contains the name of parents and household number both variables enables us to identify offspring descended from the same parents. The first stage was to link probands derived from the KCIS data with population registry by identical name of father and mother to construct three-generational pedigree for proband's family. The second stage was to ascertain degrees of relatives constructed in the first stage by identical name of spouse, mother and father for maternal series, paternal series and spouse, respectively, of relatives. The KCIS data was further linked with population registry by identical name of parents to construct trans-generation pedigree (at first stage) and to ascertain degrees of relationship at the second stage (Figure 1). In our study, we developed array algorithm to change the relationship for different proband, which is usable for familial aggregation studies of various diseases, please see Figure 2. Now, the family-based data was applied to study familial aggregation of hypertension with family case-control proband sampling design and of hypertension with entire cohort.

Statistical analysis

We took the proportional hazard model of Cox regression to compare the onset age of hypertension. Cox proportional hazards model was performed to model the hazard ratios (HR) for hypertension-onset age among cases and controls of the first-degree relatives, including parents, siblings, and offspring. The previous hypertension cases were taken the onset age from self-reported questionnaire as affected duration. The age at screening attendance of new diagnosed hypertension was also too. The exact ages at screening of normal cases were collected as censoring time. All models were adjusted for independent variables, such as gender, education levels, drink, hypertension history of parents and well-known biomarkers.

Results

There were a total of 8581 families with at least two family members who attended the KCIS between 1999 and 2004. Each relationship was defined by index case of family unit. Besides the 8581 index cases, there were 4925, 1863, 2448, and 9066 of spouses, parents, children and siblings, respectively. For example by offspring, the familial aggregation HR was 3.86 after adjusted for gender, education, triglyceride and waist (Table1).

Conclusion

The health information system of KCIS is not only provided the management of workflow and data, but also supported the management and applications by family-based approach. Our study based on family-based and family-proband methods to explore the familial aggregation of hypertension by relationship ascertainment from the population-based screening data. Familial aggregation of hypertension was modeled and demonstrated by Cox regression model.

“Toughclinic” – modern medical informatics under extremer conditions

Prof. Dr. med. **Frank Ückert**, MD, PhD

Department of Medical Informatics and Biomathematics

University Hospital, University of Muenster, Germany

Abstract

- Care for seriously injured persons has to be guaranteed even under bad conditions.
- Paper based documentations have disadvantages.
- “TOUGHCINIC” as a solution:
  - Electronic system for emergency patients or refugees.
  - Can be set up very fast.
  - Any facts can be documented.
  - Digital photos can be added.
  - Software components are able to be adapted locally.
- Wireless linking of many individual and extremely robust notebooks without central infrastructure.
- The three principles:
  - Simple handling,
  - possibility of total configuration by non technical personnel and
  - extremely fast operational readiness as well as toughness under extreme environmental conditions without cabling.

Introduction

- Two target groups: Seriously injured persons (like victims of catastrophes) and refugees.
- On the one hand: Paper based documentation is not resistant, copies are not automatically updated, automatically analysis is not possible.
- On the other hand: Computer based documentation is not advisable. Standard hardware is under extreme environmental conditions not reliable, computer solutions often demand expert-knowledge, extra cables add logistical problems, personnel outside the base is hardly supported and available software solutions are too complex.
- With TOUGHCLINIC target groups can be cared for fast: It supports a medical and/or administrative all-embracing care.
- **A hospital information system is a “conceptual bound”, in which single appliances develop and can be integrated as an acting whole system. The system TOUGHCLINIC offers such a bound.**

Necessary equipment

- About 50 percent of all damages of notebooks go back to transport accidents.
- The expected environmental conditions like aridity clamminess and extreme temperatures let notebooks not appear as adequate equipment in areas of catastrophes or crisis.
- Special notebooks e.g. Toughbooks of Panasonic have several mechanical protections.
- Also the photo industry made progress and offers digital waterproof and sand resistant cameras like Olympus µ720SW or Pentax Optio Wpi.

Examples of equipment

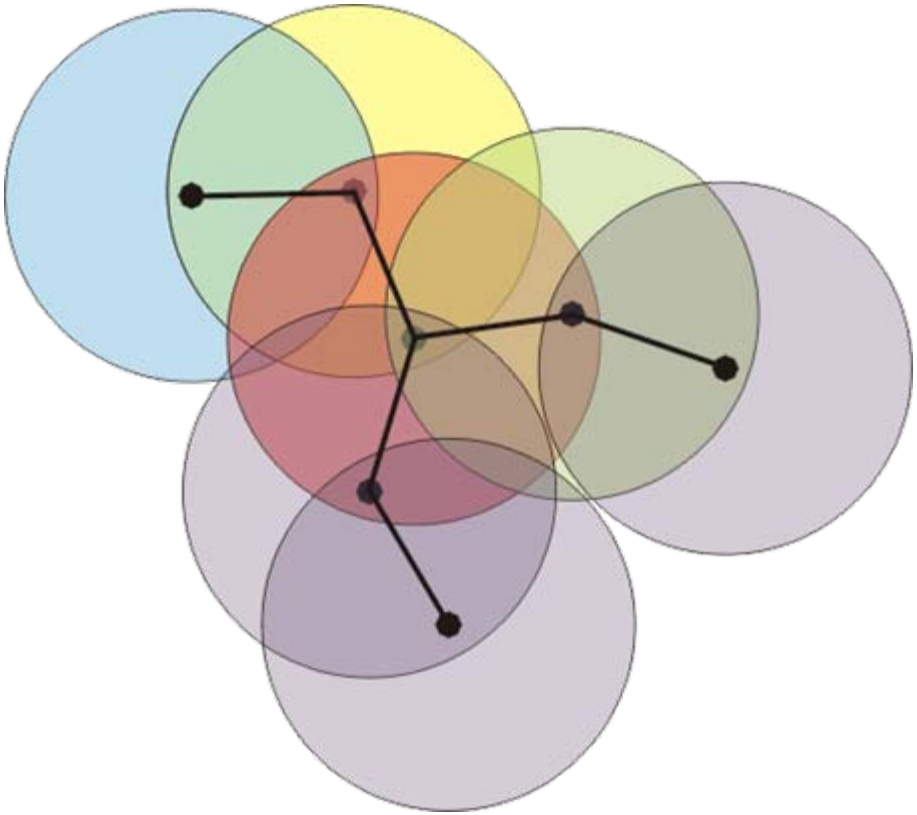
Computer language and architecture

- Modular and platform independent software concept is necessary for future flexibilty: Java with Java Runtime Environment (JRE).
- Usage of “best-practice” frameworks for easier multinational development.
- Architecture bases on a three-tier-model with data management, business logic and presentation.
- HSQLDB and Java DB as two effective Java data bank systems with support of the “embedded mode”.
- Exchange local data with every reachable co-equipment (unit, device) and to synchronize one another automatically: SyncML (Synchronization Markup Language).
- Java Foundation Classes as a comprehensive collection of GUI-components and Services.
- **Modular design leads to potential add-ons: Worldwide telemedicine or stack management.**

MANET radio communication network

- So far in a WLAN only one notebook can be connected with exactly one central router or exactly one additional notebook. → Wireless Communication is depending on central architecture and bandwidth is limited.
- Solution: Mobile ad-hoc networks (MANET).
  - Individual notebooks are nodes, which serve as a repeater for one or more other nodes.
  - The resulting network can overcome long distances, especially in uneven or challenging terrain. Furthermore MANETs are very reliable, because every node is connected with many other nodes. If a node breaks down, the surrounding nodes search for an alternative route.
  - Usage e.g. of Optimized Link State Routing Protocol (OLSR).

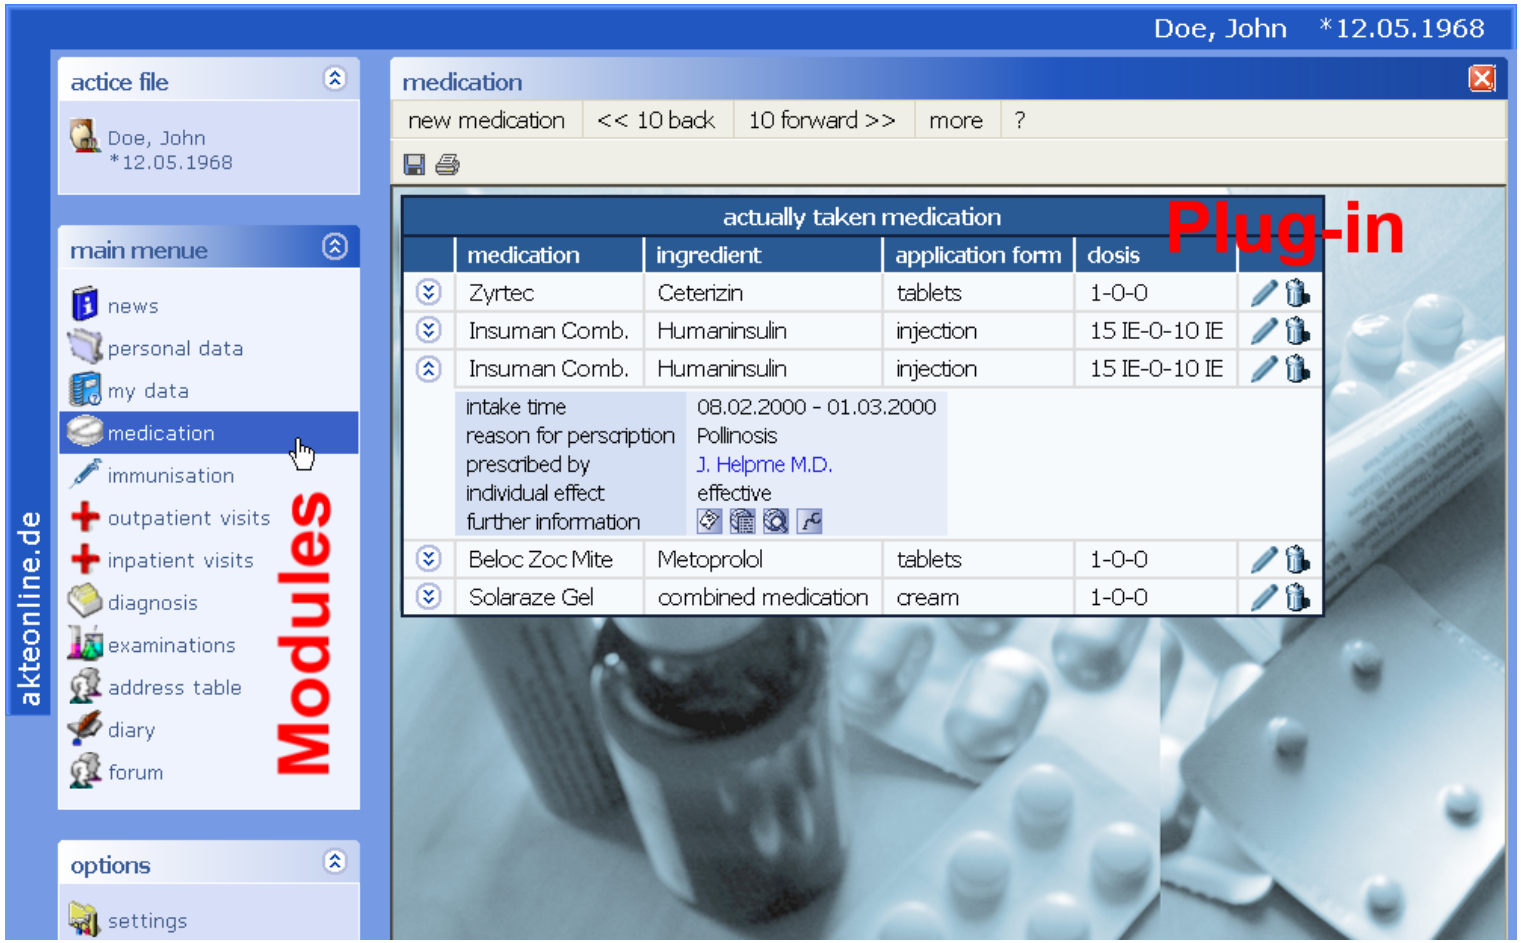
Schematic representation of a MANET wireless network



Structure of the electronic file and the form based additional documentation

- A root-appliance and a plug-in-architecture make the adding and changing of new content containers (modules and plug-ins) easily possible.
- Every installation of TOUGHCLINIC can be pre arranged with a standard set of modules and plug-ins.
- The record structure can include forms as basic modules:
  - Basic type of mask.
  - A special component enables the administration of forms.
  - Changes and add-ons can be made locally even by IT-laymen.
  - Aim: Cover as many possible intended uses, especially to cover the non-planable.
- English language and international personnel:
  - Preferably input masks should be done by selection boxes or depend on annotatable graphic illustrations of body parts.

Presentation of modules and plug-ins with an example



Results

- Many circumstances can be securely documented. Software components are adjustable for the specific intended use on-site.
- Wireless networking of individual, extremely tough computers without any infrastructure.
- Breakdown of one component does not affect others.
  - It can even be replaced immediately by another one (without bothering about manually restoring or copying of data).
- Used applications in wireless reach are synchronized automatically with the others and so they always receive an actual dataset.
  - Especially helpful for notebook usage outside the base: At return the data synchronization will be done automatically.
- No central hardware effort necessary.
- Due to encryption loosing of one of the workstation is limited to the financial loss.
- Language barriers between employees from different countries are reduced.
- Three principles are met.
- **At the actual early status of development cooperation partners for processing and use are sought-after, as well as sponsors.**

[c]*Division of Biostatistics, National Taiwan University, Taiwan*
[d]*Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, Canada*

Abstract and objective

In evaluation of cancer screening, comparison of survival between cases detected by screening and cases detected clinically was often made as the effectiveness of screening. However, this comparison is not valid due to several biases including lead-time bias, length bias, etc.. Stochastic model depicting the process from normal, preclinical phase while the cases were detected by screening, via clinical phase to cancer death can be used to obtain the mean lead-time and real survival time for screen-detected cases which is free from lead-time bias and length bias. To facilitate the application of lead-time bias and length bias adjustment for survival by stochastic modelling, a SAS macro program was developed. The program is very flexible and enables the user to specify homogeneous and non-homogeneous (i.e. Weibull distribution, log-logistic, etc.) Markov models for each transition. The program was successfully applied to an example of prostate cancer screening.

Keywords:

Stochastic model, lead-time bias, length bias, screening, survival

Introduction

In evaluation of cancer screening, comparison of survival between cases detected by screening and cases detected clinically was often made as the effectiveness of screening [1-3]. However, this comparison is not valid due to several biases including lead-time bias, length bias, etc. [4-5]. For instance, it is possible that early detection of some prostate cancers may simply advance the date of diagnosis, i.e. lead-time gain, without prolonging life, namely lead-time bias. Moreover, screen-detected cases may include a higher proportion of slowly growing cancers with a long sojourn time, which results in length bias. Due to these sources of error, the magnitude of benefit achieved from early detection estimated by comparing the survival of screen-detected cases with that of clinically detected cases is elusive.

Stochastic model depicting the process from normal, preclinical phase while the cases were detected by screening, via clinical phase to cancer death, can be used to obtain the mean lead-time and real survival time for screen-detected cases which is free from lead-time bias and length bias [1]. Nevertheless, the complexity of computer computation of the Markov model may limit the use of this method. The aim of the current study is to develop a SAS macro program to facilitate the application of lead-time bias and length bias adjustment by stochastic modelling.

Methods

Model specification

The observed survival time of screen-detected cancers consists of lead-time gain and the real survival time in absence of screening, which would be from the onset of clinical disease (without lead-time), to cancer death. In comparison of the survival of screen-detected and clinically detected cases, survival from hypothetical detection in absence of screening should be used to eliminate the lead-time bias, i.e. ensure comparability of information. However, the time when the disease would have been identified clinically is unobservable for screen-detected cases. This can be solved by applying stochastic modelling.

Furthermore, to adjust for length bias, the probability of being diagnosed with an interval cancer (typically with a short sojourn time) together with the probability of being diagnosed at screen (with a long sojourn time) was incorporated to obtain an unbiased estimate of the sojourn time. Besides, in order to further adjust for the higher proportion of slowly growing cancers at the first screen, the probability of asymptomatic cancer or normal finding at screening has to be conditional on time of surfacing to clinical phase > time to screen.

Accordingly, we defined a five-state stochastic process (figure 1) with the combination of the disease natural history model, based on screen-detected cases (long sojourn time) and interval cancer (short sojourn time), as well as disease outcome model, based on screen-detected cases

only. The details of the method for length bias adjustment have been addressed elsewhere [6].

In the model (figure 1), $I(\tau)$, $\lambda_1(\tau)$ and $\lambda_2(\tau)$ represent the pre-clinical incidence rate, the instantaneous transition rate from preclinical phase to clinical phase, and hazard of dying from cancer, respectively. The competing cause of other deaths was taken into account by λ_3. Based on the estimates of $\lambda_2(\tau)$, the cumulative survival curve after correcting lead-time and length bias can be calculated as

$$S(t) = \exp\left(\int_0^t -\lambda_2(s) ds \right).$$

Maximum likelihood approach will be applied to estimate the transition parameters and the cumulative survival adjusted for lead-time and length bias can be also obtained.

SAS Macro ADJUST

The SAS macro ADJUST which has fourteen components has been developed. The description for each components are as follows.

(1) data, the SAS data set to be analyzed; (2) dist1, dist2, and dist3, the distribution for transition from normal to preclinical detectable phase, from preclinical detectable phase to clinical phase, and from clinical phase to die from the cancer, respectively, and the choices of the distribution for each transition include exponential distribution, weibull distribution, log-logistic distribution, and gamma distribution; (3) mode, the variable name for identify the different detection mode; (4) fn, the coding of variable "mode" for normal at first screen; (5) fsd, the coding of variable "mode" for screen-detected cancer at first screen; (6) sn, the coding of variable "mode" for normal at subsequent screen; (7) ssd, the coding of variable "mode" for screen-detected cancer at subsequent screen; (8) psfun, the coding of variable "mode" for normal during post-screening follow-up; (9) ic, the coding of variable "mode" for interval cancer; (10) ocd, the coding of variable "mode" for other cause of deaths of screen-detected cases; (11) event, the coding of variable "mode" for event, i.e. dying from the disease, of screen-detected cases; (12) censor, the coding of variable "mode" for censoring of screen-detected cases; (13) init, the initial values of each relevant transition parameter; (14) upcon and lowcon, the values of upper constraints and lower constraints on each relevant transition parameters.

Example: prostate cancer screening

The Finnish population-based prostate cancer screening randomized trial was started in 1996 [7]. During 1996 to 1999, 80,458 men aged 55-67 years and resident in the metropolitan areas of Helsinki and Tampere were identified from the Population Registry of Finland as the study population. Of them, 32,000 men were randomly allocated to the screening arm and were invited to PSA screening for prostate cancer. The men were recruited and invited for the first screening round in 1996-1999, with the second screening round carried out in 2000-2003, i.e. with a 4-year screening interval. The remaining 48,458 men were assigned to the control arm and were not contacted.

Men in the screening arm with a serum PSA concentration of 4.0 ng/mL or higher were referred to diagnostic examinations, consisting of digital rectal examination (DRE), transrectal ultrasound, and prostate biopsy. Men with a PSA concentration of 3.0-3.9 ng/mL were offered a secondary screening test, which was initially (1996-98) a DRE by an urologist and since 1999 determination of the proportion of free PSA [7]. Prostate cancers diagnosed in 1996-2002 in both the screening and control arms were identified and followed up until death or until end of 2002. Causes of death were obtained from death certificates.

Example of SAS Macro ADJUST

%ADJUST(DATA=c.prostate, DIST1=weibull, DIST2=exponential, DIST3=weibull, MODE=type, FN=1, FSD=2, SN=3, SSD=4, PSFUN=5, IC=6, OCD=7, EVENT=8, CENSOR=9, INIT=0.0002 1.8 0.02 0.00001 2.3 0.02, LOWCON=0 0 0 0 0 0, UPCON=. . . . . .);

Results

The difference of survival between screen-detected cases and clinically detected cases has been heavily diminished after adjusting for lead-time bias and length bias. The unadjusted risk ratio of death for screen-detected cases against clinically detected cases was 0.17 (95% CI: 0.10-0.28). The risk ratio increased to 0.71 (95% CI: 0.51-1.00) after correcting for lead-time and length bias.

Conclusion

The program is very flexible and enables the user to specify homogeneous and non-homogeneous (i.e. Weibull distribution, log—logistic, etc.) Markov models for each transition. The program was successfully applied to an example of prostate cancer screening.

Effects of Genotype Error and Sample Error on Genome-wide SNP Analysis Using Pooled DNA

Siddharth Pratap[a], Scott M. Williams[c], Shawn E. Levy[a,b]

[b]*Department of Molecular Physiology and Biophysics, Vanderbilt University, USA*
[c]*Center for Human Genetics Research, Vanderbilt University, USA*

Abstract

A major obstacle in whole-genome association analysis is that the cost of individually genotyping hundreds of samples remains prohibitively expensive. One solution which addresses this is to pool genomic DNA of the cases and controls. However, pooling introduces an additional source of error, sampling error. In this study, we evaluate the effects of sampling error as well as genotyping error in pooled versus individual genotyping. Our results show that both genotype and sample error affect the significance of the results. Yet, sampling error has a larger overall effect.

Keywords:

single nucleotide polymorphism (SNP); pooled DNA; genome wide association

Introduction

In this study, we examine the feasibility of a pooling approach for genome wide association studies in the context of two types of experimental errors; genotyping error and sampling error. Genotyping error is present in both individual and pooled genotyping. Sampling error occurs in pooled genotyping when unequal amounts of genomic DNA are added to the pool, which can lead to incorrect allele frequency estimates for the pooled population.

Materials and methods

GenomeSIM simulation software was used to create a case/control population of one thousand individuals typed at ten thousand SNPs each. A three locus disease model with additive penetrance values was used. The final population consisted of 203 diseased individuals and 797 controls. Haploview was used for association testing of individuals. The Pooled DNA Analyzer (PDA) was employed for pooled association testing. Three levels of stringency were chosen with respect to the association testing chi square P-values. A low stringency cutoff (P-value <= $5E^{-2}$), a high stringency cutoff using Bonferonni correction (P-value <= $5E^{-6}$), and a middle stringency cutoff (P-value <= $5E^{-4}$).

Results and discussion

Although both genotype error and sample error had a significant effect, sampling error is much more influential. Overall, genotype error from 1% to 5% lowered the significance of P-values by a maximum of 1.6 fold across the entire range of individual or pooled genotyping. In contrast, sampling error from 1% to 5% in the pooled genotypes had a much more pronounced impact and lowered the significance of P-values by at least one order of magnitude across its range, with minimum of a 66 fold reduction in P-value significance (table 1). We conclude that if pooling is employed as a strategy for genome wide association analysis, great care must be taken to minimize the sampling error introduced while assembling the pools.

Abstract and objective

The management of information is a key aspect during microarray experiments analysis and results interpretation. The common use of this technique with clinical samples requires an adequate clinical annotation of those samples and the inclusion of that annotation into microarray information management systems. We present a module for clinical annotation of colon cancer samples for microarray experiments. This module has been developed to be integrated with a previously developed microarrays database (AMANDA). This new module stores information related with the clinical annotation of samples and patient information used during the experiments such as patient evolution, chemotherapy or surgical procedures. The module also includes information about the histological analysis of the samples used for gene expression analysis. The integration of this information into the microarray information system facilitates the processes of quality control and assessment of microarray experiments as well as further clinical interpretation of the results.

Keywords:

colonic neoplasm, microarray analysis, databases

Introduction

The recent advances in molecular biology and its techniques are being translated into medical applications and a better understanding of physio-pathological mechanisms underlying the disease states. One of those relevant techniques is microarray technologies, these techniques and their application for the study of pathological processes is becoming more and more frequent. Application of microarrays in medicine is mainly focused on the study of gene expression levels, and more specially on the correlation of those expression levels with relevant pathological states. Most of these works done with microarrays have been focused on the analysis of gene expression during cancer onset and development. Some examples of the aims pursued with these studies are the identification of relevant gene signatures for the prognosis of disease(1;2), differentiation and reclassification of disease(3) and others(1;4;5). This kind of experiments generate huge amounts of data that must be analyzed and correlated with relevant clinical data in order to facilitate their interpretation and extract the most of them. Therefore it's necessary to develop systems that can manage simultaneously both experimental data and clinical data for this purpose.

Methods

The design of the new module for the clinical annotation of samples used in microarray experiments was developed on AMANDA microarray database. AMANDA is a MIAME(6) compliant microarray database previously presented in Medinfo 2004.

The extension module has been developed in MS Access due to the familiarity of the user with this environment, continuing the philosophy of AMANDA database. This new module is composed of tables and forms in which the clinicians fill in all the selected fields.

The module was developed in collaboration with clinical oncologists who gave feed back of what information is relevant for their studies and will be required to correlate gene expression with the clinical outcomes of the disease. In the development of the extension module controlled vocabularies and terminologies as well as codes were used with the aim of standardizing the database as well as minimizing the mistyping errors during database filling processes.

The new module includes tables and forms related with:

- Patient data (AJCC defined stage group, ECOG scale level, whether the patient undergo surgery, what type of surgery, the therapies used and finally also a record for patient follow-up regarding disease state).
- Tumor data (aspects regarding tumor location in colon, Dukes' scale, metastasis degree, whether there are affected nodes and their number, and also a tumor extension scale).
- Sample Data: the data collected includes the reference to those histological preparations used for sample selection including aspects such as type of histology, % tumoral cells, % of necrosis or inflammation degree in that piece of tissue.

The forms for data input as well as some reports have been designed in order to present users with some of the most relevant data available in the database. For this purpose several queries have been especially done and formatted.

Results

A new customized version of AMANDA database has been generated by the inclusion of this new module. The use of a modular design had the benefit of using an already designed system that is compliant with microarray standards. With this new module it is possible to achieve a higher level of accuracy in the clinical annotation of samples, in a microarray environment.

During database design non standardized terminology was avoided as much as possible in order to facilitate further integration of the data with other systems. Where it was possible the use of standard terms and controlled vocabularies and codes was used. This extension module is focused on colon cancer and therefore some of the terminologies uploaded in the database are focused only on this particular disease (v.g. anatomical location), while other fields can be directly applied on any other type of cancer (v.g. metastasis degree).

The system has been developed using an user friendly interface with several forms to facilitate the user the uploading of data into the system in a environment that is well known (MS Access) for both clinicians and researchers. In this interface it's possible to find forms designed for data uploading. There are also customized reports based on queries presenting the data in the most demanded fields by the physicians as well as by the molecular biology researchers.

Conclusions

The annotation and management of all the processes undergone by the samples ensures the quality control of all these processes and it's very important in order to minimize the presence of experimental artifacts that may affect the final results of these experiments.

A remarkable aspect is that the interface must be easy to use and intuitive to ensure the participation of clinicians in filling the required fields. For this reason an MS access environment was selected, clinicians are already familiarized with this environment and they can use it immediately with few if any explanations about the system.

The use of a unified system for storage of both clinical and experimental data and information related with the microarray based analysis of clinical colon cancer samples facilitates the interpretation of these complex experiments.

Applying Features Selection to Optimise the Cost-Benefit of Diagnostic Classifiers

Frank Lin[1], Vitali Sintchenko[1,2], Fanrong Kong[2], Gwendolyn Gilbert[2], Enrico Coiera[1]

[1]Centre for Health Informatics, The University of New South Wales, Sydney, Australia
[2]Centre for Infectious Diseases and Microbiology, Institute of Clinical Pathology and Medical Research, Sydney West Area Health Service, Sydney, Australia

Abstract

BACKGROUND: Classification by supervised machine learning (SML) is increasingly used in clinical diagnosis. However, the benefits of feature selection (FS) prior to the construction of diagnostic classifier remain to be elucidated.

METHODS: Group B streptococcus (GBS) data were trained by SML to differentiate the invasive strains from the normal flora. Five feature ranking algorithms were used to rank the relative merits of 19 GBS features prior to classification. Areas under the ROC curve (AUC) using 10-fold cross-validation of 7 classifiers were obtained. The benefit of FS was measured by the minimum number of features (N_p) required to achieve the desired level of AUC (AUC_p).

RESULTS: For the same number of features, all classifiers achieved better AUCs under feature selection. At $AUC_{0.9}$ (90% relative to the best AUC), the median N_p achieved by FS was 4, compared to 13 using random selection and 18 under the worst scenario. The reduction of AUC from 0.724 to 0.702 was not statistically significant (p=0.21).

CONCLUSION: Feature selection algorithms have the potential to improve the cost-benefit of diagnostic classifiers through the elimination of the non-discriminatory features without compromising the overall classification performance.

Keywords:

machine learning; feature selection; diagnosis

Introduction

Individualised medicine based on genomic and proteomic data has a promising future in clinical medicine. To enable individualised medicine on a practical level, factors such as accuracy, cost, and clinical utility of the tests need to be carefully evaluated. With the current advances in biotechnology, large amount of biological data can be generated rapidly and accurately. Supervised machine learning (SML) classifiers are increasingly used in analysing complex correlations in reaching a clinical diagnosis or in predicting outcomes of various diseases [1]. The issue of cost, however, remains a potentially limitation, ranging from bench-side material to expert interpretations [2]. Excluding non-discriminatory features can lead to cost reduction and potentially faster turnover time. In addition, the inclusion of non-discriminatory features not only can increase the training burden (curse of dimensionality), it could also affect the overall classifier performance.

In this paper, the benefits of feature selection (FS) algorithms were studied by extracting a subset of discriminatory features from the original unselected dataset prior to the training of SML diagnostic classifier. Feature selection has been known to facilitate dimensionality reduction to optimise measurement, storage, and efficiency of supervised classifiers [3]. To determine the optimal subset of features, we presented a graphical method for determining the optimal cut-off.

The dataset studied in this paper was the serotypic and genotypic data of a Gram positive bacterium, group B streptococcus (GBS). GBS is an important genitourinary pathogen that frequently finds its carriage in pregnant women. It has a potential to cause serious infection in neonates including sepsis, pneumonia, and meningitis. The trained classifier aims to distinguish the invasive isolates from the normal colonising flora based on various bacterial features. The classification aims to assist clinicians in identifying the high risk patients, such that by instituting prompt antimicrobial prophylaxis, the risk of potential morbidity and mortality can be reduced.

Methods

The group B streptococcus (GBS) dataset was used to construct classifiers for predicting the virulence of bacteria based on its serotype and genotype. Eighteen genotypes were determined by multiplex PCR and reverse line blot, including molecular serotype (MS), protein genetic profile (PGP), mobile genetic elements (*GBSi1, ISSag1, ISSag2, ISSag4, IS1381, IS861,* and *IS1548*), and antibiotic-resistance genes (*tetM, int, tetO, ermB, ermTR, aph, aad, mre,* and *mef)* [4][5][6][7]. Together with the capsular serotype (CS), 19 bacterial features were selected from the database. A total of 778 GBS isolates were used for classifier training, including 590 invasive and 188 colonising isolates that were collected from clinical cultures and routine antenatal swabs.

Seven SML classifiers were used in this study, including naïve Bayes (NB), Id3 and J48 decision trees, support vector machine (SVM) trained by sequential minimal optimisation (SMO) algorithm, logistic regression (LR), and decision table (DT). The bacterial features were ranked according to their relative discriminatory power by variable ranking algorithms based on correlation criteria (symmetrical uncertainty, and Chi-squared attribute selection) or information-theoretic criteria (Information gain and gain ratio, and ReliefF). Classifiers were trained and evaluated by adding each bacterial feature incrementally in sequence as determined by each FS algorithm. The performance of classifiers was evaluated by area under the ROC curve (AUC) using 10-fold cross validation. The classification and evaluation were performed using Waikato Environment for Knowledge Analysis (WEKA) [8].

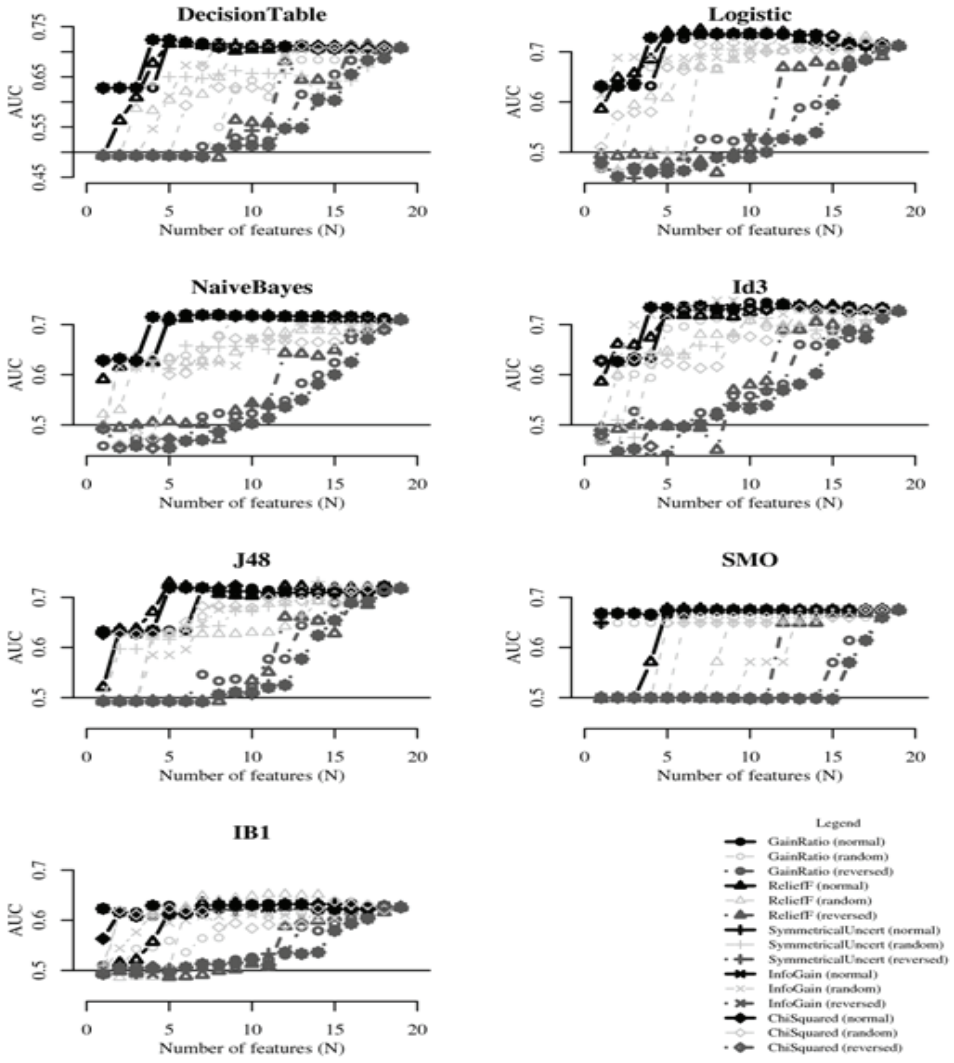

Figure 1 - AUC versus number of features (N) for 7 classifiers. (logistic: logistic regression; SMO: SVM trained by SMO algorithm; IB1: nearest-neighbour classifier)

To study the benefit conferred by the FS algorithms (normal), two extra feature selection schemes were performed. The theoretically "worst" ranking order was generated by reversing the normal rank produced by FS for each rank (reversed). In addition, the ranks were randomly shuffled to act as control, representing the

scenario where N features were selected by chance (random).

A cut-off value p (between 0.0 and 1.0) was defined to quantify the relative performance measured by AUC such that

$$AUC_p = 0.5 + p \times (AUC_{max} - 0.5)$$

In addition, N_p was defined as the minimum number of the first few features required to achieve AUC_p. The values of N_p were used to plot a cumulative gain chart for each classification scheme.

Results

The best AUC (AUC_{max}) achieved by FS using all 19 features under 10-fold classification were approximately 0.65-0.75 among the 7 classifiers (Table 1). At *N=19*, all AUC converged to the same point in all three studied ranking schemes (normal, random, and reversed). In general, the AUCs showed an increasing trend with more features involved in the classifier training. The AUCs for each classifier are shown in Figure 1.

The median N_p of the three ranking schemes across the classifiers were obtained and plotted in the cumulative gain chart as shown in Figure 2, which the ranking achieved AUC_p with less number of genes than the random and reversed set for all points. The median N_p at *p=0.90* for the 7 classifiers were 4, 13, and 18 for the normal, random, and reversed ranks respectively. The median reduction in AUC (from 0.724 to 0.702) was not considered statistically significant (p=0.21, two-tailed unpaired t-test). The top-4 features selected by FS algorithms are shown in Table 2. Features CS, PGP, *GBSil* and *ISSag2* were identified as top-4 by >50% of the selected algorithms.

Discussion

This paper evaluated the utility of feature selection algorithms in selecting a subset of features that best correlates bacterial informe random and reversed-FS ranking method for all number of features, suggesting the ability of FS algorithms in selecting the most discriminatory set of features for classification.

We used a graphical method in this paper for determining the optimal number of features to participate in the classifier training. For the desired level of AUC_p, the minimum number of features N_p can be determined by plotting a cumulative gain chart of the relative best AUC (p) that enables the visual representation of features-performance trade-off. Subsequently the corresponding N_p can be used

to select a discriminative set of features from the rank produced by FS algorithms given a desired level of classifier performance. This technique may be useful in data with larger dimensions to determine the optimal number of features, as the lengthy list generated by FS may not be immediately obvious for processing.

The benefit of FS in diagnostic classifiers can be demonstrated in Table 1 with *p=0.90*. By reducing the average number of features from 19 to 4, there was a potential reduction of over 75% on the cost of material given a <10% of relative AUC trade-off. The decrease in AUC did not represent a statistically significant decrease in performance. For our GBS classification task, the cost of the "unhelpful" PCR primers and hybridisation probes can be eliminated from the final product. According to Wilson's criteria, the cost-benefit is an important consideration in a diagnostic screening test [9]. Compared with the classifier trained with full set of features, the FS-optimised classifier potentially increased its acceptability as a screening tool, in which the cost of material was reduced through the elimination of the need non-discriminatory features where the benefits is preserved as measured by AUC.

Conclusion

Feature selection algorithms have the ability to optimise the cost-benefit of diagnostic classifiers by eliminating non-discriminatory features without compromising the overall classifier performance. This paper demonstrated that feature selection should be an integral part in the construction of machine learning-based diagnostic classifiers.

Phenotype Analysis for Insights into Complex Inheritance Diseases: a Case Study

Yunli Wang[a], Jesse Li-Ling[b]

[a]*Institute for Information Technology, National Research Council, Canada*
[b]*Department of Medical Genetics, China Medical University, China*

Abstract

Systematic analysis of phenotypic data may provide important clues for delineating developmental mechanisms as well as functional genetic networks. In this study, 68 entries involving congenital pancreatic abnormalities were selected from OMIM. Clinical synopses data were extracted and standardized. Data mining of processed data has suggested that, anatomically, major features of syndromes involving pancreatic defects seems to congregate along the midline of the human body, which conforms to John Opitz's theorem of developmental field defects. We conclude that utilization of phenotypic data can facilitate delineation of developmental as well as genetic mechanisms underlying various types of congenital anomalies.

Keywords:

pancreas; syndrome; phenotype; data mining

Methods

Phenotypic data could be used for obtaining insights into complex diseases. Various phenotypes have usually been considered as isolated features, and studies on high-level phenotypes were rare. Cantor and Lussier (2004) had attempted to use self-organizing maps and hierarchical clustering for clinical phenotypes in order to achieve better understanding for genotypes. However, since the original categories provided in the OMIM entries were not rationalized, it is difficult to judge the usefulness of clustering results. More recently, van Driel et al. proposed an approach for measuring similarities between phenotypes, and demonstrated they are correlated with the protein sequence, protein motifs, and functional annotation. Although this result appears to be promising, meaningful patterns for a particular syndrome still cannot be obtained.

In this study, we explored using data mining techniques for analyzing clinical data derived from congenital syndromes involving pancreatic malformations. 68 pancreatic malformations entries were retrieved from OMIM (as by Nov 1st 2005). After removal of those that are non-congenital in nature, 23 entries were derived. The listed clinical synopses of these entries were converted into 55 categories manually.

The correlation between individual phenotypes among pancreatic malformations was analyzed using statistically significant association rules [3]. The results were also compared with hierarchical clustering and K-means clustering.

Results

Correlations between phenotypes were obtained, among them, kidney and liver has the strongest correlation. This result was consistent with results from hierarchical clustering and k-means clustering. Correlation of the common features among the selected syndromes seems to suggest that, developmentally, pancreas has a close relation with adjacent organs such as the kidney and the liver, whilst the overall pattern of above syndromes conforms to John M Opitz's theorem on the developmental field defect, that the midline structure of the body are most frequently involved among congenital syndromes.

Conclusion

Phenotype analysis may facilitate functional genomics and delineation of genotype ~ phenotype correlations. Data mining for a particular feature can be used for inferring closeness between genes and delineating genetic networks. Our future work will include development of a system that can automatically translate retrieved data into a comparable format, as well as utilization of laboratory experiment to validate the derived results.[1]

Proposal of Efficient Clinical Trials by using the Genomic Information

Wataru Ohashi [a], Hiroshi Mizushima [a], Hiroshi Tanaka [a]

[a] *Tokyo Medical and Dental University, Information Center for Medical Science*

Abstract

Under current clinical trials, a new drug could be authorized when a patient has no effect ("non-responder") on an existing drug. This leads to unnecessary adverse effect and high medication cost. Recently, it has become possible to change the patient's treatment depending on their genomic information, which is called "personalized medicine". It has a big benefit to patients by efficient treatment and lower cost, however, pharmaceutical companies hesitate to pursue personalized medicine, because of large development cost with very little market size, and not a matured methodology. In this paper, we will describe an efficient clinical trial, which will have a benefit to pharmaceutical companies by decreasing the cost for clinical trial, and early approval of the drug, with less adverse effect.

We will begin by describing a small size clinical trial, within a short period of study, using the patient's genomic information. We calculated the statistically required numbers of subjects and compared the cost for the current big clinical trials and the small clinical trials, excluding non-responder, by genomic information by simulation.

Keywords:

clinical trials, SNPs, personalized medicine, development cost

1. Introduction

Recently, the importance of "personalized medicine" is emphasized when a suitable treatment is selected according to the "constitution" of each patient. In the near future, it is expected that the drug and dose can be determined based on the genetic information including SNPs (single nucleotide polymorphisms) of each patient.

When personalized medicine becomes more available, unnecessary administration of drugs to non-responders can be avoided, and dose can be optimized. Also, medical expense in general can be reduced, and unexpected adverse effect can be avoided. These advantages are beneficial not only to the patients concerned, but also to the society as a whole.

However, the pharmaceutical companies are not actively engaged in the development of "personalized medicine" because they are afraid of lost revenue, and other drugs would not be prescribed to non-responders. Furthermore, the procedure for handling genetic information is not fully established yet.

The purpose of this study is to clarify the benefit and loss for the pharmaceutical companies when they adopt "personalized medicine", that is, when they take advantage of genetic information in their clinical trials. Particularly, the benefit for the pharmaceutical companies in terms of following two points will be analyzed. 1. Development cost of new drug and period of clinical trial can be reduced because a clinical trial needs less subjects, 2. The new drug can be placed on the market earlier because the development period can be shortened.

2. Methods

1) Principle of sample size estimation

Generally, the sample size of a clinical trial is calculated according to an equation as follows, for example.[1][2][3]

$$n = \frac{\left\{ Z_\alpha \sqrt{2\bar{P}(1-\bar{P})} + Z_\beta \sqrt{P_1(1-P_1)+P_2(1-P_2)} \right\}^2}{(P_1-P_2)^2}$$

$$where \quad \bar{P} = \frac{P_1+P_2}{2}$$

（In case of chi-square test for the difference in ratio between two groups）

N: Number of necessary samples

P_1: Response rate in investigational drug group

P_2: Response rate in control drug group

Z: Value calculated from significance level (generally 1.96 at 5%)

Z: Value calculated from power (generally 0.84 at 80%)

For example, when the response rate in the investigational drug group is estimated to be 70% and that in the control group is estimated to be 60%, the sample size of each group is n=356 according to above equation. Similarly, when the response rate in the investigational drug group is 90% and that in the control group is 60%, then n=32. That is, if there is a large difference in response rates, thus small sample size will be sufficient. The size is calculated based on significance level (typically =0.05) and power (typically =0.80) specified in the protocol, and estimated drug

response rate and difference between the groups. The calculation differs depending on the test method used.

3. Result

1) Enhancement of response rate using specific SNPs (Investigational drug group vs. control drug group)

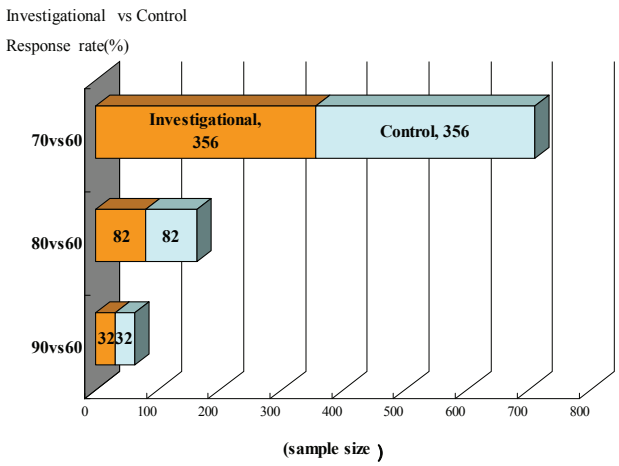

Figure 1 - Response rate and necessary sample size

By extracting and excluding non-responders based on SNPs information, the response rate of the investigational drug can be raised by 10%, e.g., from 70% to 80%. Then, the sample size of each group can be cut by 274 (356 to 82). In total, this means 548 cases will be unnecessary. This effect is more apparent when the response rate is low. Thus, this approach is highly useful in clinical trials in which only little difference in response rate is estimated between groups such as clinical trials of psychotropic drugs. In the approach above, additional cost may be necessary for a genetic testing before the clinical trial. Therefore, the total cost will be initially higher. However, if the sample size can be reduced by 548 in total, the cost as a whole will be less than the trial according to existing method. Furthermore, the cost of genetic testing is decreasing and the databases of genetic information are expanding day by day. In this circumstance, the genetic testing can be carried out at low cost in the near future.

2) Reduction of risk of adverse events

When any known adverse event (AEs) is anticipated due to causative gene, the patients concerned can be excluded from the investigational drug group. Thus, the risk of adverse events can be reduced.

Besides the safety enhanced by avoidance of an adverse event, the treatment for adverse event can be avoided. For the society in general, medical expense can be reduced, and for the pharmaceutical companies, compensation or indemnification cost can be avoided. In U.S, more than 2 million patients forced to be hospitalized because of the adverse effects in every year, hundred thousand people dies, and more than 70 billion health care cost wasted.

4. Conclusion

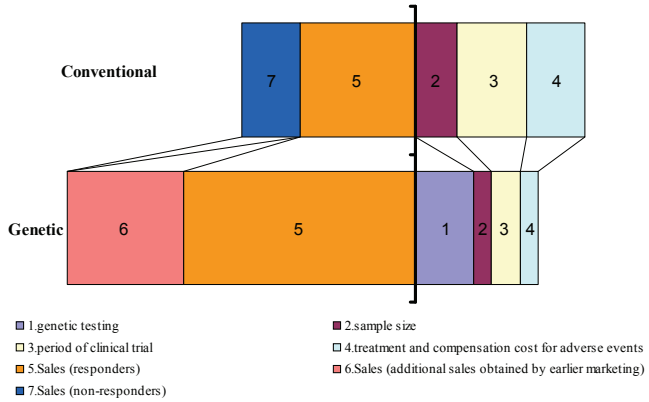

Figure 2 - Profit-cost structure in conventional clinical trial and clinical trial based on genetic information

Based on the discussion above, the profit-cost structure of a conventional clinical trial and a clinical trial based on genetic information can be estimated as Figure 2. According to our estimation, a clinical trial that takes advantage of genetic information is superior to a conventional clinical trial in terms of cost and profit. For example, the above shows, the development cost can be reduced by 5.5 million US dollar (10 thousand dollar /sample)[4]. Furthermore, the development period can be shortened by about 120 for 548 samples[4]. But, on the other hand, the sale for non-responders will be lost. However, because the drug can be marketed a120 days earlier than usual, the projected sales for the 120 days should be factored. In addition, risk of adverse events can be mitigated by screening patients based on genetic information such as SNPs. Reduction in compensation and indemnification cost, and reduction in medical expenses will be beneficial to the patients, the pharmaceutical companies, and the society as a whole. In a clinical trial using genetic information, temporary increase in process and cost may be inevitable. But, when genetic testing comes to be widely used, the cost will drop. Additionally, as the databases of genetic information are growing, it is apparent that the genetic testing will be simplified.

In view of the many benefits stated above, we expect the pharmaceutical companies to aggressively take advantage of genetic information in their clinical trials. We are now

planning profit simulation based on a clinical trial that was actually conducted.

Proposal of Efficient Clinical Trials by using the Genomic Information

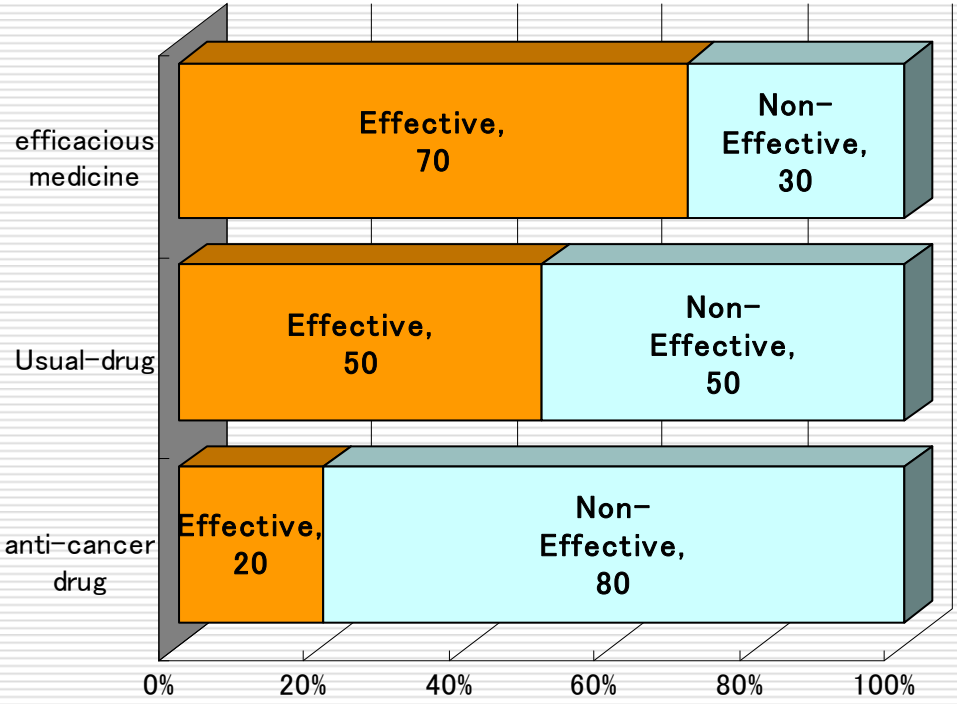
Wataru Ohashi [a] , Hiroshi Mizushima [a] , Hiroshi Tanaka [a]

a) Tokyo Medical and Dental University, Information Center for Medical Science

1. What does Efficacious medicine mean?



In a new drug's clinical trial, it is approved and allowed to be marketed if it can successfully show statistically significant effect compared to a placebo, a control drug (existing treatment) or a usual drug.

Even if it effects only 20% of patients like the anti-cancer drug.

The difference between responders and non-responders is often explained in terms of difference in subjects' profile. When the subjects have largely similar profiles, the difference is explained by a term called "constitution".

2. Personalized Medicine

- It is expected that the drug and dose can be determined based on the genetic information including SNPs (single nucleotide polymorphisms) of each patient.
- When personalized medicine becomes more available, unnecessary administration of drugs to non-responders can be avoided, and dose can be optimized.
- Also, medical expense in general can be reduced, and unexpected adverse effect can be avoided.

These advantages are beneficial not only to the patients concerned, but also to the society as a whole.

3.Comparison of clinical trials

Design / *Trials*	***Determination of usage and dose***	***Determination of the number and profile of subjects to be enrolled***	***Medical expenses***	***Risk of Adverse Events***
Current	Effect and adverse effect are determined based on the average.	Determined using sample size estimation equation	Rises due to unnecessary administration to non-responders	Unknown adverse event
Personalized	Can be optimized for each patient according to the patient's capacity of drug metabolizing enzyme (e.g., CYP2C29, CYP2D6)	Can be selected and response rate can be improved based on relevant genetic information	Can be cut because unnecessary administration to non-responder can be avoided	Can be minimized based on information on causative gene and minimization of drug doze.

4.Purpose

The pharmaceutical companies are not actively engaged in the development of “personalized medicine” because ･･･

1. they are afraid of lost revenue, and other drugs would not be prescribed to non-responders.
2. the procedure for handling genetic information is not fully established yet.

The purpose of this study is to clarify the benefit and loss for the pharmaceutical companies when they adopt "personalized medicine", that is, when they take advantage of genetic information in their clinical trials. Particularly, the benefit for the pharmaceutical companies in terms of following two points will be analyzed.

1. ***Development cost of new drug and period of clinical trial can be reduced because a clinical trial needs less subjects,***
2. ***The new drug can be placed on the market earlier because the development period can be shortened***

5.Methods

Generally, the sample size of a clinical trial is calculated according to an equation as follows, for example.[1][2][3]

$$n = \frac{\left\{ Z_{\alpha}\sqrt{2\bar{P}(1-\bar{P})} + Z_{\beta}\sqrt{P_1(1-P_1)+P_2(1-P_2)} \right\}^2}{(P_1 - P_2)^2}$$

$$where \quad \bar{P} = \frac{P_1 + P_2}{2}$$

(In case of chi-square test for the difference in ratio between two groups)

N: Number of necessary samples
P_1: Response rate in investigational drug group
P_2: Response rate in control drug group
Z_{α}: Value calculated from significance level (generally 1.96 at 5%)
Z_{β}: Value calculated from power (generally 0.84 at 80%)

5.Methods(2) Power Curve

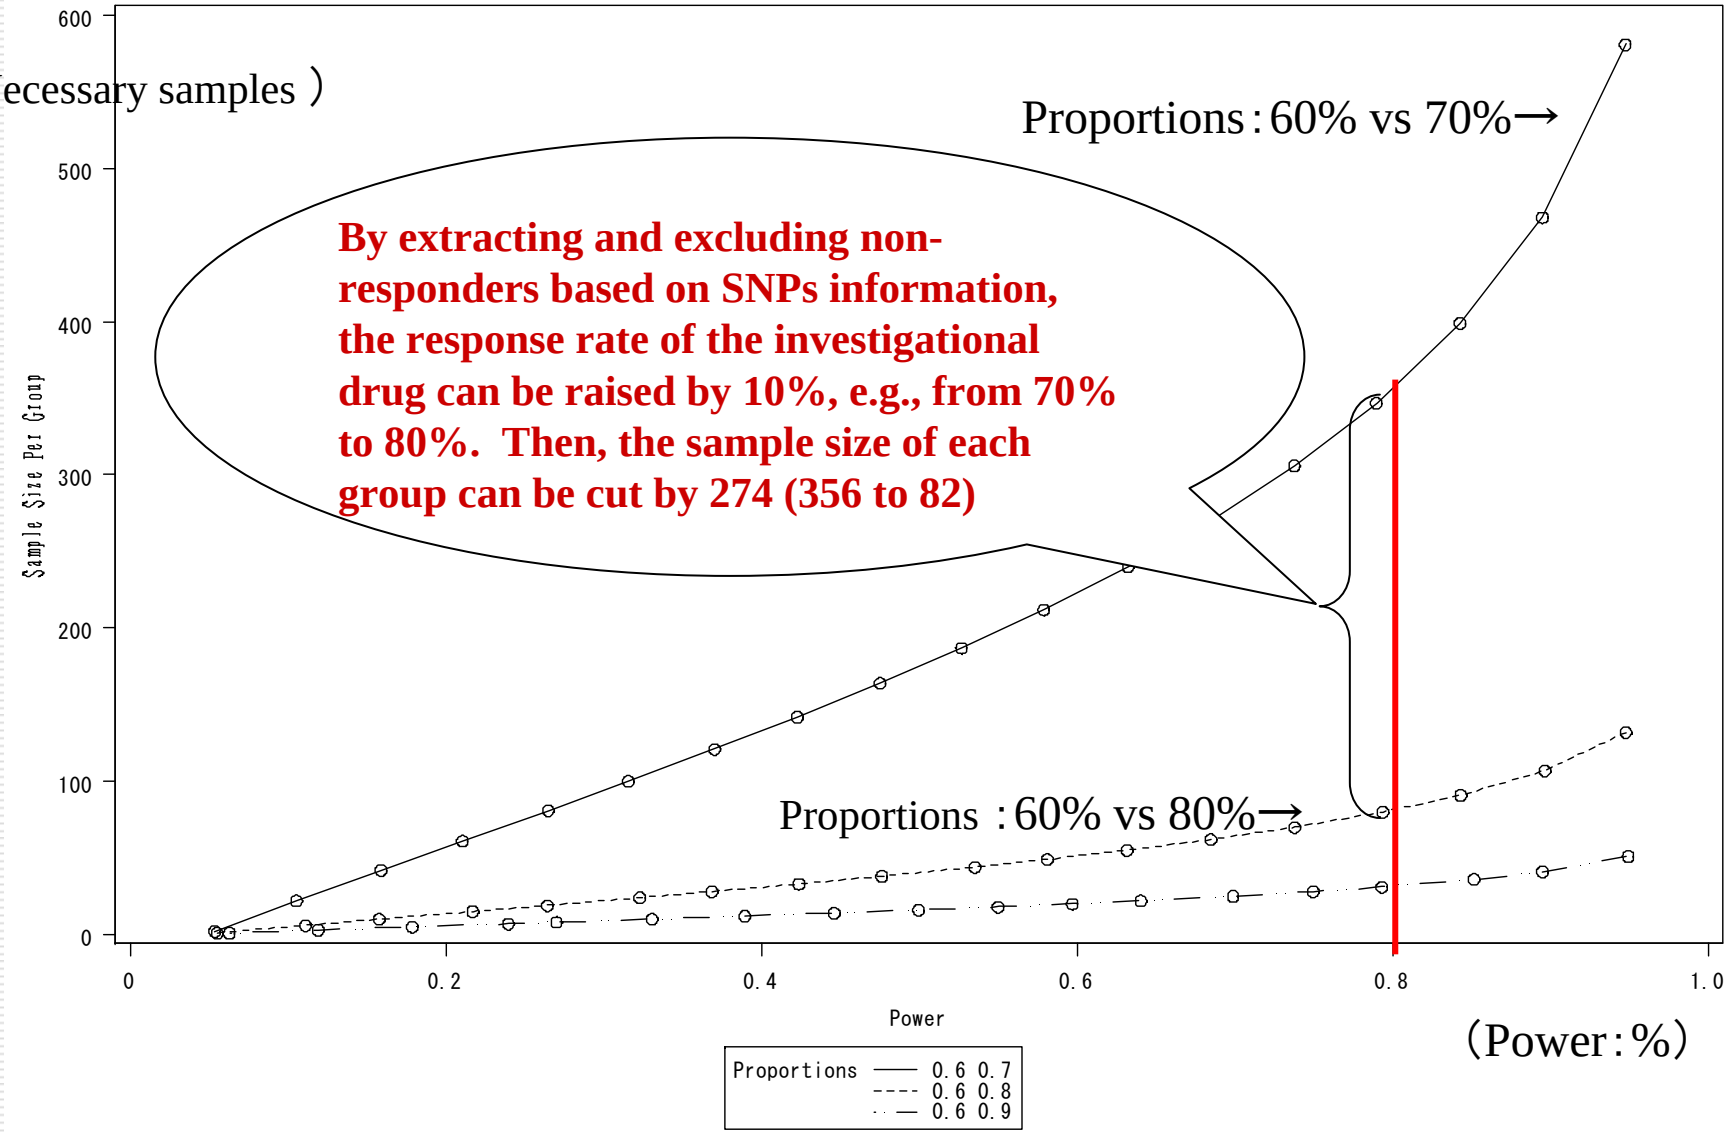


Fig. 1 Response rate and necessary sample size

6.Results

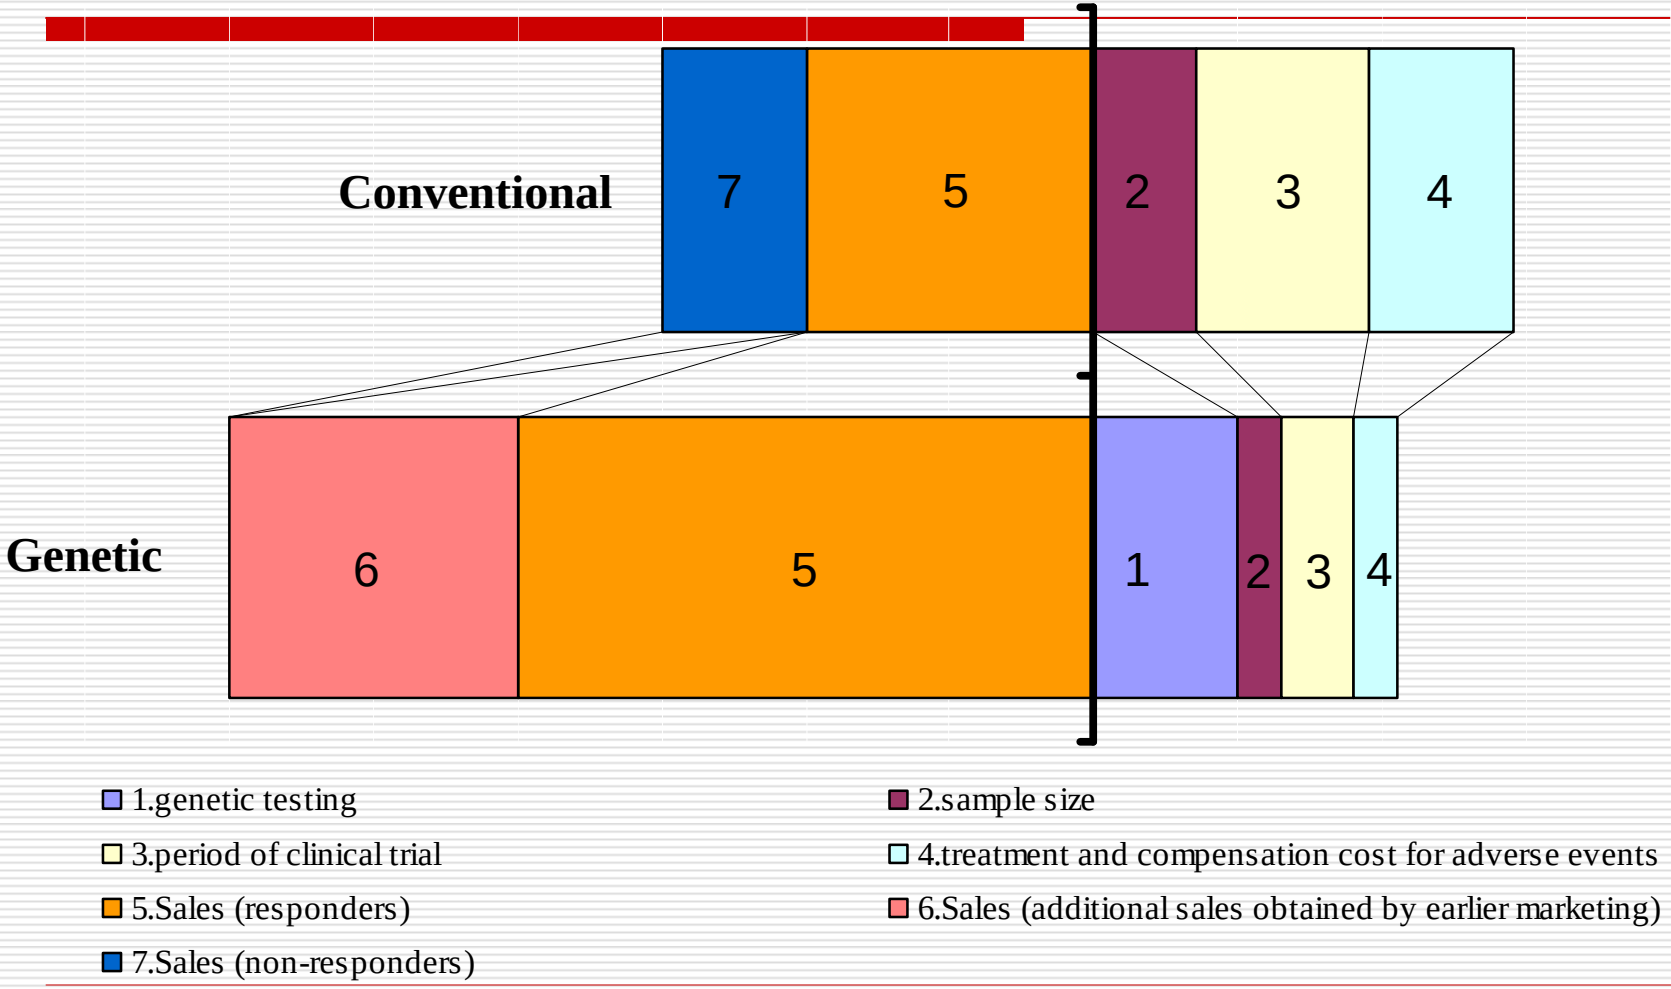
- In total, this means 548(274 per each group) cases will be unnecessary.
- This effect is more apparent when the response rate is low.
- When any known adverse event (AEs) is anticipated due to causative gene, the patients concerned can be excluded from the investigational drug group.
- Besides the safety enhanced by avoidance of an adverse event, the treatment for adverse event can be avoided.

For the society in general, medical expense can be reduced, and for the pharmaceutical companies, compensation or indemnification cost can be avoided.

(ex. In U.S, more than 2 million patients forced to be hospitalized because of the adverse effects in every year, hundred thousand people dies, and more than 70 billion health care cost wasted.)

7. Conclusion

Fig2 Profit-cost structure in conventional clinical trial and clinical trial based on genetic information



7. **Conclusion** (2)

According to our estimation, a clinical trial that takes advantage of genetic information is superior to a conventional clinical trial in terms of cost and profit.

1. **The development cost can be reduced by 5.5 million US dollar (10 thousand dollar /sample)[4].**
2. **Furthermore, the development period can be shortened by about 120 for 548 samples[4].**
3. **But, on the other hand, the sale for non-responders will be lost. However, because the drug can be marketed a120 days earlier than usual, the projected sales for the 120 days should be factored.**
4. **In addition, risk of adverse events can be mitigated by screening patients based on genetic information such as SNPs.**

Development of the Home-Based Multimedia System for Mental Health Management in Adolescents via Information Superhighway

Jeongyee Bae

Department of Nursing, Inje University, Korea

Abstract

The purpose of this study was to develop a web-based multimedia system for mental health management in adolescents using principals of user centered design. Research process includes needs assessment, needs analysis, design, development/testing, and application release. With this computerized system, adolescents can improved their mental health states. In addition, adolescents who have minor mental health problems can manage it by oneself.

Keywords:

mental health, information system, internet, adolescents

Introduction

World Health Organization's warning last year that the fastest-growing mental health problem in the world, and particularly in the developed world, was among adolescents. According to the rapid socio environmental change In Korea, many adolescents suffer from their identity confusion. Most of Korean adolescents are under pressure to study hard for an examination. The failure to examine the possible causes of rising levels of mental ill health amongst adolescents provoked much critical commentary, even from those who welcomed efforts to draw attention to the problem. One of the solutions to this problem can be a web based intervention.

Worldwide, about 4.5% of all Internet searches are for health-related information [1]. Several Internet interventions have emerged in recent years to treat mental and behavioral health problems. Computers and Internet-based programs have great potential to make psychological assessment and treatment more cost-effective [2]. In Korea, the Internet has become a most favored source to find health information. About 44.5% of all Internet searches are for health-related information [3]. Thus this project was conducted to develop a health information service system for mental health care in adolescents via internet.

Methods

This study used user-centered design model including needs assessment needs analysis, design, development/ testing, and application release.

To identify users' information needs, the investigator will conduct a descriptive study by performing surveys, interviews, and workshops in major cities in Korea. 3487 Korean adolescents participated in this study.

Investigator attempted to meet the needs of population who have various backgrounds including age, education, and knowledge in computer and mental health. The target population was identified as Korean adolescents between 13-18 years old. Minimum hardware requirements were determined to be Pentium III 1.0 GHz computer, 128mb of RAM, sound card, and a network card. Minimum software requirements were a browser capable of supporting Macromedia Flash and JavaScript; Microsoft Internet Explorer and other popular browsers support these two requirements. Task requirements were determined to be: ability to access web site, explore each intervention, read and post messages on the discussion board, enter self-assessment data, and understand tailored advice.

As we created the storyboards, we tried to make it engaging, accessible, interactive, and informative. First, we focused on the most effective and interesting way to deliver the information based on issues found through our preliminary research.

Results

The web site was released using the URL: http://www.baejy.com/youth. This system will go through individual data and will be utilized to screen those who have mental health problems. In addition, this system includes intervention programs to relieve mental health problems such as education, exercise, relaxation, visualization, music therapy, family therapy and counseling with researcher or psychiatrist. Using this system, every adolescent who has minor mental health problems can manage it by oneself.

Figure 1 - Main page

Discussion and conclusion

This research interested in the telemedicine and developing home-based multimedia system for management of the adolescent's mental health problems. Therefore, through these system adolescents can save time and cost. And it could be adequately applied to assessing mental health problems and as an intervention strategy for not only adolescents who have mental health problems but also normal adolescents. It is expected that this management system will contribute to the mental health promotion as well as community for the mental health related researchers, professionals and experts to share information on the adolescent's mental health.

We will revise this web site through these research results and through the continuous feedback that we have received from users. The second phase of this project will evaluate the effectiveness of this web intervention for further development of the program.

This research interested in the telehealth, especially information service system for more efficient psychiatric mental health care. Therefore, this system will be a new way of nursing intervention and contribute to the psychiatric mental health promotion in adolescents.

Analyzing User Satisfaction with the System in Useprior to the Implementation of a New Electronic Inpatient Record

Claude Sicotte[a], Guy Paré[b], Marie-Pierre Moreault[a], Luc Valiquette[c], Jeffrey Barkun[d], Anne Lemay[ac]

[a] *Interdisciplinary Research Group in Health, University of Montreal, Canada*

[c] *Montreal University Hospital Centre, Canada*
[d] *McGill University Health Centre, Canada*

Abstract

This research focuses on the users' attitudes in the pre-implementation stage of a new electronic clinical information system. Contrary to most of the research in this domain, we focused on the clinical information system in use rather than on the attitudes toward the new system. The current system was analyzed as a hybrid system composed of both paper-based and electronic records. We conducted a survey with nurses and physicians in two teaching hospitals to assess user satisfaction with the current – to be replaced – hybrid system. The results showed significant differences between the two groups according to several system attributes. It highlights that a successful implementation strategy should be tailored to take into account differences among various groups of users. This approach is promising in terms of its implications for how the electronic inpatient record can be more effectively framed to facilitate user acceptance.

Keywords:

electronic patient record, clinical information system implementation, user satisfaction

Introduction

User acceptance is generally seen as a crucial factor determining the success or failure for the implementation of new information technology [1]. It is especially true in the case of the electronic inpatient record. This system is not only used as the repository for all clinical information relevant to the care of a patient but also as the main communication tool for patient-related information among clinicians. This system is thus at the core of delivery of care and is critical for teamwork productivity and quality of care. It is thus normal that the implementation of such new system monopolizes a great deal of attention. Frequently, however, little interest is left to evaluate user acceptance of the replaced system. This attitude is far from ideal given its potential impact upon the implementation strategy for the new system. Indeed the level of satisfaction or dissatisfaction with the current system affects the users' propensity to change. This oversight leaves out the first and critical stage of Lewin's field theory of organizational change that consists of three phases: (a) unfreezing old patterns, (b) moving and experimenting with new behaviors and (c) refreezing, so that new behavior becomes part of every-day business processes that are then considered normal [2]. We think that the period prior to go-live implementation is worthy of research attention because of its role in shaping users' attitudes toward the new system. Thus, similar to many models [3], this paper focuses on the users' attitudes or predispositions in the pre-implementation stage as possible significant determinants of implementation behavior. However, contrary to most of the research in this domain, we focused on the system in use rather than the attitudes toward the new system. This approach is original and promising in terms of its implications for how the electronic inpatient record can be more effectively framed to facilitate user acceptance.

Furthermore, the current patient record system is interesting to analyze because it is a hybrid system composed of both paper-based and electronic records. Although, more and more healthcare organizations are adopting electronic health records (EHRs) to overcome the weaknesses of the traditional paper-based record, we are still reproducing a dual workplace environment. We are still far from able to fully replace the paper-based record. Rather, electronic clinical documentation is usually used in addition to paper-based records. The "new" system remains a hybrid one that can be plagued with the problems of the "old" system. Earlier research suggests that the parallel use of electronic and paper-based patient records resulted in inconsistencies between the systems [4-5]. These inconsistencies can lead to significant problems for the healthcare staff in daily care. Understanding the strengths and weaknesses of the old system thus remains crucial to being able to better manage the system's transition and to ensure the successful implementation of the new system.

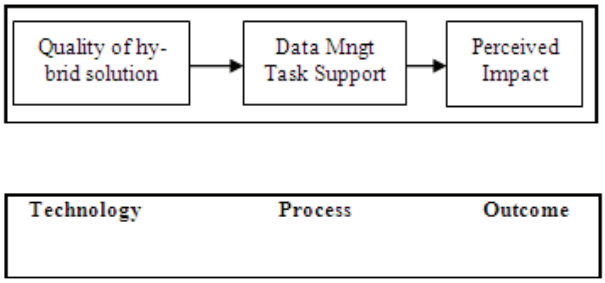

Figure 1 – Analytical framework

Within this context, our study uses a survey to pursue three objectives: (1) to assess user satisfaction with the "quality attributes" of the current – to be replaced – inpatient record system; (2) to evaluate user satisfaction with the capability of the current system to support the task of clinical data management; and (3) to measure the users' appraisal of the impact of the current system on quality of care. The sequential relationship between these 3 objectives is illustrated in Figure 1.

Materials and methods

Settings and study design

The study was conducted at the two main teaching hospitals in the province of Quebec which is the second largest healthcare jurisdiction in Canada with 7.5 million inhabitants. Both hospitals are multi-site organizations (three and five-sites), each employing approximately 10 000 employees and 1 000 physicians. The two hospitals jointly purchased the same electronic inpatient record system in 2004 and are pursuing a collaborative implementation strategy. In May 2006, a first wave of six medical and surgical services, three in each hospital, started using the new system: paediatric general surgery, internal medicine, urology/nephrology, two services of neurology and a transplantation unit.

Between November 2005 and April 2006, prior to go-live of the new inpatient record system, a cross-sectional survey with all of the nurses and physicians of these six services was conducted. At that time, the physicians and nurses had access to a complete paper-based record. However, they were also currently using electronic systems to read the results of laboratory tests and radiology exams. In two of the services, the electronic systems even allowed the ordering of lab tests and radiology exams. Electronic systems were currently used in parallel with the paper-based record by both the nurses and physicians. As shown in Table 1, the self-reported usage of electronic systems was 7.3 for nurses and 8.8 for physicians on a ten-point scale (1 indicating a low level; 10, a high level).

Three hundred and forty six (346) questionnaires were distributed to the nurses and physicians working in the six medical and surgical services. Physician questionnaires were sent out to all 150 physicians and 196 nurse questionnaires were sent out to all regular nursing personnel (24hours/7days). Questionnaires were anonymous but marked so personal reminders could be sent to those individuals who did not respond. Survey responses were confidential. The appropriate institutional review boards approved the study.

Survey instrument

The survey instrument was designed to measure users' satisfaction according to the three research objectives. The survey included the following:

- Objective 1: four "quality attributes" (ease of use, usability, data quality and record accessibility) for respectively evaluating the paper-based and electronic record systems and two additional attributes (system reliability and response-time) specifically designed for the electronic record system.
- Objective 2: approximately 20 attributes to measure the capability of the inpatient record system to supporting clinical data management. Due to task differences between nurses and physicians, two different sets of items were used: 21 items for physicians and 19 for nurses.
- Objective 3: 16 items to assess the impact of the inpatient record system in terms of quality of care.

All survey questions were answered with 10-point likert scales, rating the above-mentioned attributes of the system. With regard to objective 1, variables such as ease of use, usability, quality of information were defined in line with the DeLone & McLean Model of Information Systems success [6-7]. Table 2 shows the psychometric qualities of these measures. Their reliability (internal consistency), measured with Cronbach's alpha, indicate that all of the measures surpass the usual 0.70 threshold of statistical significance. In relation with the second objective, we used a task-oriented questionnaire developed for evaluating electronic medical record systems [8]. The questionnaire has successfully been tested in terms of criterion validity and reliability. The key feature of this evaluation tool is a list of 21 general clinical tasks that are applicable to physicians of most specialties and that covers essential parts of their information-oriented work. We have adapted the questionnaire for nurses while maintaining its structure. The nurses' questionnaire included 19 tasks related to clinical data management. Lastly, for the third objective, a 16-item scale was developed for the specific needs of this study. The scale was aimed at assessing the outcomes with positive items such as quality of care, continuity of care, accuracy of clinical decisions and negative

ones such as transcription errors and delays in patient care.

Analysis

SPSS software was used for all statistical analyses. Alpha levels of 0.01, 0.05 and 0.10 were used to test the significance of all Chi-square and t-test comparisons. Factor analyses were performed to create factors in relation to objectives 2 and 3. The variable reliability was assessed with Cronbach alpha tests.

Results

Survey response & characteristics of respondents

Questionnaires were received from 219 (63%) of 346 eligible respondents, including 123 (63%) nurses and 96 (64%) physicians.

As shown in Table 1, significant differences were observed between the nurses and physicians in terms of gender, age and experience with computers. Also, the use of the current electronic inpatient record system was significantly different between the two groups. On a ten-point scale (1 indicating a low level; 10, a high level), the nurses' use mean rating of the electronic record system was lower (7.3) than the physicians' rating (8.8). But still, both groups showed a high level of electronic systems use.

		RNs (n = 123)	MDs (n = 96)	
Gender	Male Female	12% 88%	74% 26%	$X^2 = 87.1$ (p<.000)
Age	≤ 30 31-40 41-50 51-60 61 & +	27% 23% 36% 14% 0%	10% 23% 33% 21% 13%	$X^2 = 24.1$ (p<.000)
Users' Experience with computers	A little 2 3 4 A lot	10% 32% 27% 21% 10%	2% 4% 25% 43% 26%	$X^2 = 42.7$ (p<.000)
Electronic inpatient records Use (Scale 1 – 10)	Mean (sd)	7.3 (2.3)	8.8 (1.9)	t-test p=0.000***

Table 1 – Distribution of survey respondents

User satisfaction with the inpatient record system

As shown in Table 2, the users were more satisfied with the electronic record. The global index of satisfaction for the electronic patient record reached a score of 6.8 while the paper-based record was just above the mid-point (5.7) of the 10-point scale. The electronic record system reached its highest scores for "ease of use" (7.7) and "data quality" (7.7) while the paper-based record reached its highest score for "usability" (6.3) and "ease of use" (6.2). "Data quality" was the attribute for which the electronic record showed the greatest difference (7.7 for the electronic record vs. 5.7 for the paper-based record). In both systems the least satisfactory attribute was "file accessibility" (4.2 for the paper-based record vs. 4.7 for the electronic one). The electronic record's unexpected low score was mainly attributed to the small number of PC stations available in each service.

Quality attributes of the record system	Nb of items	Cronbach Alpha	Mean	SD
Paper record				
Ease of Use	3	.93	6.2	2.2
File Access	2	.65	4.2	2.2
Usability	3	.91	6.3	2.0
Data Quality	7	.87	5.7	1.6
Total Mean	15	.91	5.7	1.5
Electronic record				
Ease of Use	3	.86	7.7	1.7
File Access	3	.87	4.7	2.3
System reliability	2	.77	6.5	2.1
Response time	1	--	6.9	2.4
Usability	2	.83	7.1	2.0
Data Quality	4	.73	7.7	1.5
Total Mean	15	.84	6.8	1.2

Table 2 – User satisfaction

Ratings of the systems' attributes varied by user group (Table 3). The nurses were more satisfied than the physicians with all attributes of the paper-based record (p=0.000) with the exception of "file accessibility" that was poorly rated by both groups. The physicians were more satisfied with the electronic record (7.2 vs. 6.5; p=0.000). Four attributes were significantly different between the 2 groups: "ease of use", "file accessibility", "usability" and "information quality".

Quality Attributes of the Record System	RNs (n=123) *Mean(sd)*	MDs (n=96) *Mean(sd)*	*t-test*
Paper Record			
Ease of Use	7.0 (1.8)	5.1 (2.3)	p=0.000***
File Accessibility	4.2 (2.2)	4.3 (2.2)	p=0.742
Usability	6.9 (1.7)	5.5 (2.1)	p=0.000***
Data Quality	6.1 (1.5)	5.3 (1.6)	p=0.000***
Total Mean	6.2 (1.3)	5.2 (1.6)	p=0.000***
Electronic Record			
Ease of Use	7.3 (1.8)	8.2 (1.4)	p=0.000***

Table 3 – Comparison of User Satisfaction between Groups

Task-oriented evaluation of the Inpatient record system

The second aim of the survey was to evaluate the users' satisfaction with the capability of the record systems to support clinical data management tasks. Because it would have been difficult to distinguish the specific contribution of the paper-based record from the electronic one, their joint effect was assessed. A detailed survey instrument was developed to fulfill this objective [8].

Factor analyses[1] were conducted to be able to group the tasks together in larger domains of activities. For the physicians, the analysis of the initial 21 items generated 4 factors with eigenvalues greater than 1.0. These 4 factors were composed of 15 items that all presented loading scores greater than 0.5, a clear evidence of the discriminate validity of the measures used (Table 4). Taken together, the 4 factors explained 67% of the variance. For the nurses, the factor analysis generated 3 factors with eigenvalues greater than 1.0. The 17 items associated with these factors also presented loading scores greater than 0.5 (Table 4). Taken together, the 3 factors explained 66% of the variance. In both cases, these factors portrayed an interesting typology for identifying the main activities of clinical data management. As shown in Table 4, the composite reliability coefficients (Cronbach alpha) of all the factors were very good, varying from 0.77 to 0.96.

As shown in Table 4, the assessment scores were rather low, reaching a maximum of 6.4 on a ten-point scale (1 indicating a low level of "task usability"; 10 indicating a high level of "task usability"). The nurses rated "task usability" higher (6.4) than the physicians (5.9), a significant difference (p = 0.023). The only exception was for a similar factor, "physicians' results monitoring" and "nurses' results management" that reached a higher score of 7.8 in both groups.

Data Mngt Task Support	Nb of items	Cronbach Alpha	Mean	SD
Physician Tasks				
Medical Ordering	5	.93	5.1	2.5
Results Monitoring	4	.86	7.8	1.7
Pts' Status Monitoring	3	.79	6.3	2.0
Patient Discharge	3	.82	4.4	2.2
Summative Measure	15	.88	5.9	1.5
Factor Analysis = 67,2% explained variance				
Nurses Tasks				
Pts' Data Management	10	.96	6.2	2.1
Results Management	2	.77	7.8	1.7
Pts' Status Monitoring	5	.84	6.4	1.7
Summative Measure	17	.94	6.4	1.7
Factor Analysis = 66,4% explained variance				

Table 4 – Task-oriented evaluation

Impact evaluation of the inpatient record system

The third objective of the survey was to assess the impact of the inpatient record system. Here also, the joint effect of both the paper-based and electronic records was assessed with a ten-point scale (1 indicating a very negative impact; 10, a very positive impact).

Inpatient Record System	Nb of Items	Cronbach Alpha	Mean	SD
Impact				
Quality of care	7	.92	6.2	1.5
Data Mismanagement	5	.93	5.2	22.0
Factor Analysis = 67,5% explained variance				

Table 5 – Dimensions of impact evaluation

We also proceeded with a factor analysis[2] to identify the dimensions of impact present among our 16-item scale. The analysis generated 2 factors with eigenvalues greater than 1.0. The composite reliability coefficients (Cronbach alpha) of both factors were excellent reaching over 0.9 (Table 5). All of the 12 items associated with these variables presented loading scores greater than 0.5. Taken together, both factors explained 67.5% of the variance.

1 Principal axis factor analysis with oblimin rotation. The detail of the factor analyses is not shown here.

2 Principal axis factor analysis with oblimin rotation. The detail of the factor analyses is not shown here.

The first factor referred to positive items associated with the quality of care while the second one included negative items associated with the mismanagement of clinical data.

As shown in Table 5, the two scores were near the middle of the ten-point scale. Thus, respondents did not perceive that the record system had a negative impact on the quality of care and the occurrence of data management errors. At the same time, the contribution of the record system to the quality of care is weak. The only significant difference between the two clinician groups was with respect to the "quality of care" which received a higher rating by the nurses (6.4 vs. 6.0; p=0.054).

Inpatient Record System	RNs n=122 *Mean(sd)*	MDs n=95 *Mean(sd)*	*t-test*
Impact			
Quality of Care	6.4 (1.4)	6.0 (1.8)	p=0.054*
Data Mismanagement	5.1 (2.0)	5.3 (2.1)	p=0.423
*p<.10			

Table 6 – Comparison of Impact Evaluation between Groups

Discussion

The main results of the study are summarized in this section. A first positive result is that the electronic record was rated higher than the paper-based one. The positive ratings are congruent with other studies evaluating user satisfaction toward other electronic clinical systems [9-11]. This situation should facilitate the implementation of the electronic inpatient system. However, it is also important to note that physicians and nurses had rated the two record systems differently. The nurses rated the "quality attributes" of the paper-based record higher than the electronic system. This highlights the need to consider both perspectives when implementing a new system. This lesson is important for developing a successful implementation strategy in the domain of electronic clinical information systems. It means that the management of users' expectations should be tailored to take into account differences among various groups of users. In other words, the readiness to adopt a new system varies between user groups. In Lewin's terms, the unfreezing challenge may be different between user groups and requires different implementation strategies. It underscores the importance of specifically targeting different user groups in the implementation of a new system. The unfreezing strategy used to encourage users to give up the paper-based record should be narrowly framed according to the positive and negative attributes associated with it. We note that for the present case, "data quality" and "ease of use" were attributes showing the greatest differential in favor to the electronic record over the paper-based system. This finding is congruent with the importance given to these attributes in the research conducted with the renowned DeLone & McLean model of information system success [6-7].

Further, we also note that the presence of a hybrid record system, necessitating a joint usage of paper-based and electronic records, was poorly appraised. Indeed, the task-oriented evaluation of the hybrid record system was rather low remaining under a 6.5 level on a ten-point scale. These results are congruent with previous studies that have shown that the parallel use of electronic and paper-based patient records can result in inconsistencies between both systems that lead to significant problems for the healthcare staff in daily care [4-5]. It is thus of the utmost importance to take special care to reduce the possible impact of this conflict when implementing a new electronic clinical system. It is important to note that even if most healthcare organizations are in the process of increasing the use of electronic systems to manage their clinical data, the paper-based record is still present.

Similarly, the results also show that the impact of the hybrid record system was halfheartedly received as demonstrated by the users' ratings which remained near the mid-point of the scale. Here again, it is thus important to take supplementary efforts to conceive the means by which the new system can correct the weaknesses of the system in place.

Prior to concluding, limitations must be acknowledged. First, the response rate (63%) could have been higher even if it can be considered satisfactory in comparison with similar studies which vary between 56% and 85% [9-11]. It will also be important to replicate the study with other medical specialties and organizational contexts. We also acknowledge the usual limitations and generalizations associated with the cross-sectional nature of the study. However, we intend to use this survey as a baseline and we plan to pursue user satisfaction assessments during the new system implementation.

In conclusion, the results presented in this paper have implications for both nurse and physician information technology adoption theory development and practice. With regard to theoretical development, it would be useful to analyze in greater depth the relationship between user satisfaction with the current system, their consequent readiness to change and the latter adoption of a new system. Our results can also guide clinical information system project managers whose objectives are to further use among clinicians in their organizations. In this respect, our results suggest that users' expectations with the new system should be carefully framed in relation to their current experience with the system in place.

Acknowledgments

The authors thank all of the nurses and physicians who have taken the time to complete this survey and have made this paper possible. As well, the Canadian Institutes of Health Research and the Social Sciences and Humanities Research Council of Canada are gratefully acknowledged for providing financial support for this research project.

Introduction

User acceptance is generally seen as a crucial factor determining the success or failure for the implementation of new information technology [1]. It is especially true in the case of the electronic inpatient record. This system is not only used as the repository for all clinical information relevant to the care of a patient but also as the main communication tool for patient-related information among clinicians. This system is thus at the core of delivery of care and is critical for teamwork productivity, patient safety and quality of care. It is thus normal that the implementation of such new system monopolizes a great deal of attention. Frequently, however, little interest is left to evaluate user acceptance of the replaced system. This attitude is far from ideal given its potential impact upon the implementation strategy for the new system. Indeed the level of satisfaction or dissatisfaction with the current system affects the users' propensity to change and to efficiently use the new system. This oversight leaves out the first and critical stage of Lewin's field theory of organizational change that consists of three phases: (a) unfreezing old patterns, (b) moving and experimenting with new behaviors and (c) refreezing, so that new behavior becomes part of every-day business processes that are then considered normal [2]. We think that the period prior to go-live implementation is worthy of research attention because of its role in shaping users' attitudes toward the new system. Thus, similar to many models [3], this paper focuses on the users' attitudes or predispositions in the pre-implementation stage as possible significant determinants of implementation behavior. However, contrary to most of the research in this domain, we focused on the system in use rather than the attitudes toward the new system. This approach is original and promising in terms of its implications for how the electronic inpatient record can be more effectively framed to facilitate user acceptance.

Furthermore, the current patient record system is interesting to analyze because it is a hybrid system composed of both paper-based and electronic records. Although, more and more healthcare organizations are adopting electronic health records (EHRs) to overcome the weaknesses of the traditional paper-based record, we are still reproducing a dual workplace environment. We are still far from able to fully replace the paper-based record. Rather, electronic clinical documentation is usually used in addition to paper-based records. The "new" system remains a hybrid one that can be plagued with the problems of the "old" system. Earlier research suggests that the parallel use of electronic and paper-based patient records resulted in inconsistencies between the systems [4-5]. These inconsistencies can lead to significant problems for the healthcare staff in daily care. Understanding the strengths and weaknesses of the old system thus remains crucial to being able to better manage the system's transition and to ensure the successful implementation of the new system.

Objectives

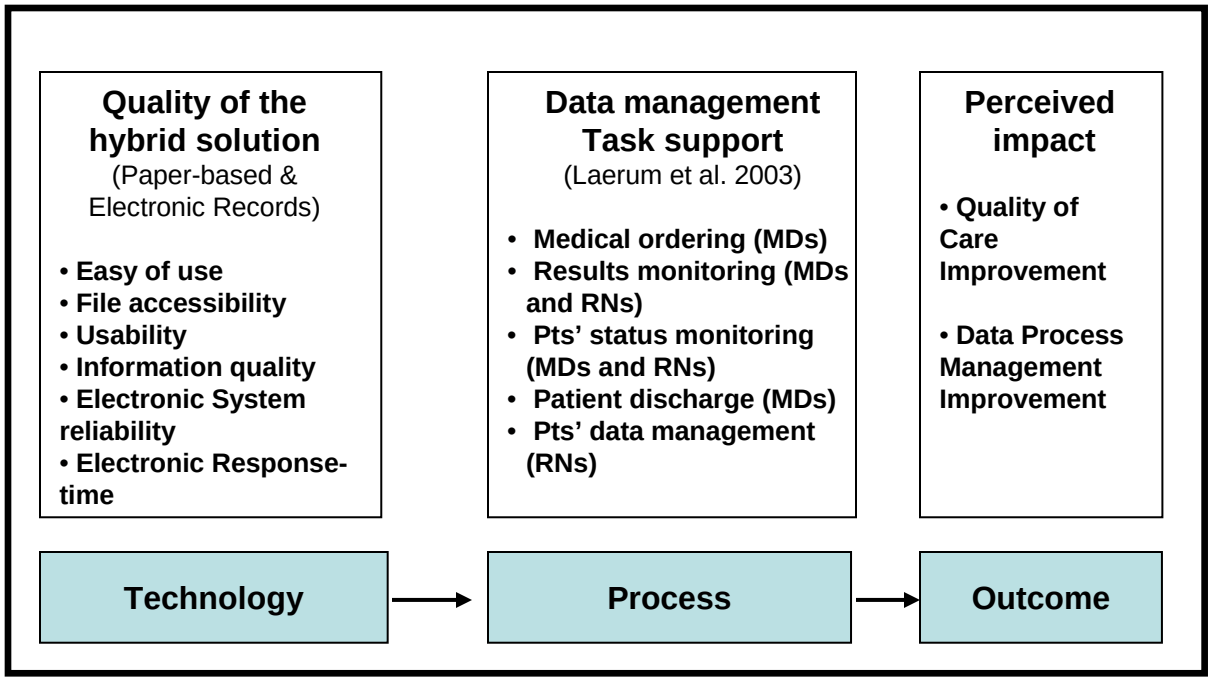
The study uses a survey to pursue three objectives:

1- to assess user satisfaction with the "quality attributes" of the current – to be replaced – inpatient record system;

2- to evaluate user satisfaction with the capability of the current system to support the task of clinical data management; and

3- to measure the users' appraisal of the impact of the current system on quality of care. The sequential relationship between these 3 objectives is illustrated in Figure 1.

Figure 1 – Analytical Framework



Methods

The study was conducted at the two main teaching hospitals in the province of Quebec which is the second largest healthcare jurisdiction in Canada with 7.5 million inhabitants. Both hospitals are multi-site organizations (three and five-sites), each employing approximately 10 000 employees and 1 000 physicians. The two hospitals jointly purchased the same electronic inpatient record system in 2004 and are pursuing a collaborative implementation strategy. In May 2006, a first wave of six medical and surgical services, three in each hospital, started using the new system: paediatric general surgery, internal medicine, urology/nephrology, two services of neurology and a transplantation unit.

Between November 2005 and April 2006, prior to go-live of the new inpatient record system, a cross-sectional survey with all of the nurses and physicians of these six services was conducted. At that time, the physicians and nurses had access to a complete paper-based record. However, they were also currently using electronic systems to read the results of laboratory tests and radiology exams and to consult PACS images. In two of the services, the electronic systems even allowed the ordering of lab tests and radiology exams. Electronic systems were currently used in parallel with the paper-based record by both the nurses and physicians. As shown in Table 1, the self-reported usage of electronic systems was 7.3 for nurses and 8.8 for physicians on a ten-point scale (1 indicating a low level; 10, a high level).

Three hundred and forty six (346) questionnaires were distributed to the nurses and physicians working in the six medical and surgical services. Physician questionnaires were sent out to all 150 physicians and 196 nurse questionnaires were sent out to all regular nursing personnel (24hours/7days). Questionnaires were anonymous but marked so personal reminders could be sent to those individuals who did not respond. Survey responses were confidential. The appropriate institutional review boards approved the study.

Survey instrument

The survey instrument was designed to measure users' satisfaction according to the three research objectives. The survey included the following:

• Objective 1**: Four "quality attributes" (ease of use, usability, data quality and record accessibility) for respectively evaluating the paper-based and electronic record systems and two additional attributes (system reliability and response-time) specifically designed for the electronic record system.**

• Objective 2: **Approximately 20 attributes to measure the capability of the inpatient record system to supporting clinical data management. Due to task differences between nurses and physicians, two different sets of items were used: 21 items for physicians and 19 for nurses.**

• Objective 3: **Seize items to assess the impact of the inpatient record system in terms of quality of care.**

All survey questions were answered with 10-point likert scales, rating the above-mentioned attributes of the system. With regard to objective 1, variables such as ease of use, usability, quality of information were defined in line with the DeLone & McLean Model of Information Systems success [6-7]. Table 2 shows the psychometric qualities of these measures. Their reliability (internal consistency), measured with Cronbach's alpha, indicate that all of the measures surpass the usual 0.70 threshold of statistical significance. In relation with the second objective, we used a task-oriented questionnaire developed for evaluating electronic medical record systems [8]. The questionnaire has successfully been tested in terms of criterion validity and reliability. The key feature of this evaluation tool is a list of 21 general clinical tasks that are applicable to physicians of most specialties and that covers essential parts of their information-oriented work. We have adapted the questionnaire for nurses while maintaining its structure. The nurses' questionnaire included 19 tasks related to clinical data management. Lastly, for the third objective, a 16-item scale was developed for the specific needs of this study. The scale was aimed at assessing the outcomes with positive items such as quality of care, continuity of care, accuracy of clinical decisions and negative ones such as transcription errors and delays in patient care.

Users' Experience with Computers	**A little** **2** **3** **4** **A lot**	10% 32% 27% 21% 10%	2% 4% 25% 43% 26%	X^2 = 42.7 (p<.000)
Electronic Inpatient Records Use (Scale 1 – 10)	**Mean** **(sd)**	7.3 (2.3)	8.8 (1.9)	t-test p=0.000***

Questionnaires were received from 219 (63%) of 346 eligible respondents, including 123 (63%) nurses and 96 (64%) physicians.

As shown in Table 1, significant differences were observed between the nurses and physicians in terms of gender, age and experience with computers. Also, the use of the current electronic inpatient record system was significantly different between the two groups. On a ten-point scale (1 indicating a low level; 10, a high level), the nurses' use mean rating of the electronic record system was lower (7.3) than the physicians' rating (8.8). But still, both groups showed a high level of electronic systems use.

Results

User satisfaction with the Inpatient System

Table 2 – User Satisfaction

Quality attributes of the record system	Nb of items	Cronbach Alpha	Mean	SD
Paper Record				
Ease of Use	3	.93	6.2	2.2
File Access	2	.65	4.2	2.2
Usability	3	91	6.3	2.0
Data Quality	7	.87	5.7	1.6
Total Mean	15	.91	5.7	1.5
Electronic Record				
Ease of Use	3	.86	7.7	1.7
File Access	3	.87	4.7	2.3
System reliability	2	.77	6.5	2.1
Response time	1	- -	6.9	2.4
Usability	2	.83	7.1	2.0
Data Quality	4	.73	7.7	1.5
Total Mean	15	.84	6.8	1.2

As shown in Table 2, the users were more satisfied with the electronic record. The global index of satisfaction for the electronic patient record reached a score of 6.8 while the paper-based record was just above the mid-point (5.7) of the 10-point scale. The electronic record system reached its highest scores for "ease of use" (7.7) and "data quality" (7.7) while the paper-based record reached its highest score for "usability" (6.3) and "ease of use" (6.2). "Data quality" was the attribute for which the electronic record showed the greatest difference (7.7 for the electronic record vs. 5.7 for the paper-based record). In both systems the least satisfactory attribute was "file accessibility" (4.2 for the paper-based record vs. 4.7 for the electronic one). The electronic record's unexpected low score was mainly attributed to the small number of PC stations available in each service.

Results

User satisfaction with the Inpatient System

Table 3 – Comparison of User Satisfaction between Groups

Quality Attributes of the Record System	RNs (n=123) *Mean(sd)*	MDs (n=96) *Mean(sd)*	*t-test*
Paper Record			
Ease of Use	7.0 (1.8)	5.1 (2.3)	p=0.000***
File Accessibility	4.2 (2.2)	4.3 (2.2)	p=0.742
Usability	6.9 (1.7)	5.5 (2.1)	p=0.000***
Data Quality	6.1 (1.5)	5.3 (1.6)	p=0.000***
Total Mean	6.2 (1.3)	5.2 (1.6)	p=0.000***
Electronic Record			
Ease of Use	7.3 (1.8)	8.2 (1.4)	p=0.000***
File Accessibility	4.3 (2.3)	5.1 (2.3)	p=0.027**
System Reliability	6.4 (2.2)	6.7 (1.9)	p=0.244
Response Time	6.9 (2.6)	7.0 (2.3)	p=0.814
Usability	6.5 (2.0)	7.9 (1.7)	p=0.000***
Information Quality	7.5 (1.7)	7.9 (1.1)	p=0.068*
Total Mean	6.5 (1.3)	7.2 (1.0)	p=0.000***

*** p<.001; ** p<.05; * p<.10

Ratings of the systems' attributes varied by user group. The nurses were more satisfied than the physicians with all attributes of the paper-based record (p=0.000) with the exception of "file accessibility" that was poorly rated by both groups. The physicians were more satisfied with the electronic record (7.2 vs. 6.5; p=0.000). Four attributes were significantly different between the two groups: "ease of use", "file accessibility", "usability" and "information quality".

Results

Task-oriented Evaluation of the Inpatient Record System

Table 4 – Task-oriented Evaluation

Data Mngt Task Support	Nb of items	Cronbach Alpha	Mean	SD
Physician Tasks				
Medical Ordering	5	.93	5.1	2.5
Results Monitoring	4	.86	7.8	1.7
Pts' Status Monitoring	3	.79	6.3	2.0
Patient Discharge	3	.82	4.4	2.2
Summative Measure	15	.88	5.9	1.5
Factor Analysis = **67,2% explained variance**. Principal axis factor analysis with oblimin rotation. The detail of the factor analyses is not shown here.				
Nurses Tasks				
Pts' Data Management	10	.96	6.2	2.1
Results Management	2	.77	7.8	1.7
Pts' Status Monitoring	5	.84	6.4	1.7
Summative Measure	17	.94	6.4	1.7
Factor Analysis = **66,4% explained variance**. Principal axis factor analysis with oblimin rotation. The detail of the factor analyses is not shown here.				

The second aim of the survey was to evaluate the users' satisfaction with the capability of the record systems to support clinical data management tasks. Because it would have been difficult to distinguish the specific contribution of the paper-based record from the electronic one, their joint effect was assessed. A detailed survey instrument was developed to fulfill this objective [8].

Factor analyses were conducted to be able to group the tasks together in larger domains of activities. For the physicians, the analysis of the initial 21 items generated 4 factors with eigenvalues greater than 1.0. These 4 factors were composed of 15 items that all presented loading scores greater than 0.5, a clear evidence of the discriminate validity of the measures used (Table 4). Taken together, the 4 factors explained 67% of the variance.

For the nurses, the factor analysis generated 3 factors with eigenvalues greater than 1.0. The 17 items associated with these factors also presented loading scores greater than 0.5. Taken together, the 3 factors explained 66% of the variance. In both cases, these factors portrayed an interesting typology for identifying the main activities of clinical data management. The composite reliability coefficients (Cronbach alpha) of all the factors were very good, varying from 0.77 to 0.96.

The assessment scores were rather low, reaching a maximum of 6.4 on a ten-point scale (1 indicating a low level of "task usability"; 10 indicating a high level of "task usability"). The nurses rated "task usability" higher (6.4) than the physicians (5.9), a significant difference (p = 0.023). The only exception was for a similar factor, "physicians' results monitoring" and "nurses' results management" that reached a higher score of 7.8 in both groups.

Results

Impact Evaluation of the Inpatient Record System

The third objective of the survey was to assess the impact of the inpatient record system. Here also, the joint effect of both the paper-based and electronic records was assessed with a ten-point scale (1 indicating a very negative impact; 10, a very positive impact).

Table 5 – Dimensions of Impact Evaluation

Inpatient Record System	Nb of Items	Cronbach Alpha	Mean	SD
Impact				
Quality of care	7	.92	6.2	1.5
Data Mismanagement	5	.93	5.2	2.0
Factor Analysis = **67,5% explained variance.** Principal axis factor analysis with oblimin rotation. The detail of the factor analyses is not shown here.				

We also proceeded with a factor analysis to identify the dimensions of impact present among our 16-item scale. The analysis generated 2 factors with eigenvalues greater than 1.0. The composite reliability coefficients (Cronbach alpha) of both factors were excellent reaching over 0.9 (Table 5). All of the 12 items associated with these variables presented loading scores greater than 0.5. Taken together, both factors explained 67.5% of the variance. The first factor referred to positive items associated with the quality of care while the second one included negative items associated with the mismanagement of clinical data.

As shown in Table 5, the two scores were near the middle of the ten-point scale. Thus, respondents did not perceive that the record system had a negative impact on the quality of care and the occurrence of data management errors. At the same time, the contribution of the record system to the quality of care is weak. The only significant difference between the two clinician groups was with respect to the "quality of care" which received a higher rating by the nurses (6.4 vs. 6.0; p=0.054).

Table 6 – Comparison of Impact Evaluation between Groups

Inpatient Record System	**RNs** n=122 *Mean(sd)*	**MDs** n=95 *Mean(sd)*	***t-test*** * p<.10
Impact			
Quality of Care	6.4 (1.4)	6.0 (1.8)	p=0.054*
Data Mismanagement	5.1 (2.0)	5.3 (2.1)	p=0.423

Discussion and Conclusion

The main results of the study are summarized in this section. A first positive result is that the electronic record was rated higher than the paper-based one. The positive ratings are congruent with other studies evaluating user satisfaction toward other electronic clinical systems [9-11]. This situation should facilitate the implementation of the electronic inpatient system. However, it is also important to note that physicians and nurses had rated the two record systems differently. The nurses rated the "quality attributes" of the paper-based record higher than the electronic system. This highlights the need to consider both perspectives when implementing a new system. This lesson is important for developing a successful implementation strategy in the domain of electronic clinical information systems. It means that the management of users' expectations should be tailored to take into account differences among various groups of users. In other words, the readiness to adopt a new system varies between user groups. In Lewin's terms, the unfreezing challenge may be different between user groups and requires different implementation strategies. It underscores the importance of specifically targeting different user groups in the implementation of a new system. The unfreezing strategy used to encourage users to give up the paper-based record should be narrowly framed according to the positive and negative attributes associated with it. We note that for the present case, "data quality" and "ease of use" were attributes showing the greatest differential in favor to the electronic record over the paper-based system. This finding is congruent with the importance given to these attributes in the research conducted with the renowned DeLone & McLean model of information system success [6-7].

Further, we also note that the presence of a hybrid record system, necessitating a joint usage of paper-based and electronic records, was poorly appraised. Indeed, the task-oriented evaluation of the hybrid record system was rather low remaining under a 6.5 level on a ten-point scale. These results are congruent with previous studies that have shown that the parallel use of electronic and paper-based patient records can result in inconsistencies between both systems that lead to significant problems for the healthcare staff in daily care [4-5]. It is thus of the utmost importance to take special care to reduce the possible impact of this conflict when implementing a new electronic clinical system. It is important to note that even if most healthcare organizations are in the process of increasing the use of electronic systems to manage their clinical data, the paper-based record is still present.

Similarly, the results also show that the impact of the hybrid record system was halfheartedly received as demonstrated by the users' ratings which remained near the mid-point of the scale. Here again, it is thus important to take supplementary efforts to conceive the means by which the new system can correct the weaknesses of the system in place.

Prior to concluding, limitations must be acknowledged. First, the response rate (63%) could have been higher even if it can be considered satisfactory in comparison with similar studies which vary between 56% and 85% [9-11]. It will also be important to replicate the study with other medical specialties and organizational contexts. We also acknowledge the usual limitations and generalizations associated with the cross-sectional nature of the study. However, we intend to use this survey as a baseline and we plan to pursue user satisfaction assessments during the new system implementation.

In conclusion, the results presented in this paper have implications for both nurse and physician information technology adoption theory development and practice. With regard to theoretical development, it would be useful to analyze in greater depth the relationship between user satisfaction with the current system, their consequent readiness to change and the latter adoption of a new system. Our results can also guide clinical information system project managers whose objectives are to further use among clinicians in their organizations. In this respect, our results suggest that users' expectations with the new system should be carefully framed in relation to their current experience with the system in place.

Acknowledgments and References

The authors thank all of the nurses and physicians who have taken the time to complete this survey and have made this paper possible. As well, the Canadian Institutes of Health Research and the Social Sciences and Humanities Research Council of Canada are gratefully acknowledged for providing financial support for this research project.

Information Technology for Clinical Decision Support in Primary Health Care Practices

Judith M. Engelbrecht, Inga M. Hunter, Richard J. Whiddett

Department of Information Systems, Massey University, Palmerston North, New Zealand

Abstract

- This study of New Zealand General Practitioner (GP) practices demonstrates that those surveyed are generally well equipped with information technology (IT), suggesting there is the potential for them to be able to utilize levels of clinical decision support (CDS) similar to each other. However,
- three commonly available technologies used by 80% or more of practices were all found to be used by fewer practices for CDS. This suggests that
- barriers other than the availability of technologies are important inhibitors to the utilization of IT for CDS.

Introduction

- International and Australasian health care organizations are seeking to improve the use of computerised clinical decision support (CDS) in health care[1;2;3].
- New Zealand's primary health care sector is now structured around not-for-profit Primary Health Organisations (PHOs)[4].
- Knowledge of IT infrastructure and its usage by PHO practices would enable their management organisations to formulate appropriate strategies to encourage better use of technologies, and the decision support capabilities they provide.
- This presentation gives preliminary results regarding the IT supporting patient care in primary care GP practices.

Study area

- Where?
  - Medium sized New Zealand Primary Health Organisations (PHOs)
    - PHO Management Services Organisations
    - Contributing General Practitioner practices
- Who?
  - PHO Management Services Organisation
    - Staff
    - Contract holders
  - Contributing General Practitioner practice
    - Doctors
    - Practice nurses
    - Practice administrators
- What?
  - What information technologies (IT) are available in the organisations
  - How the organisations use IT in the support of clinical decision making

Methodology

- A multiple case study of medium sized PHOs was undertaken, consisting of
  - a pilot case study, and
  - two other case study organisations.
- Triangulation[5] was achieved by
  - the use of face-to-face interviews,
  - a postal questionnaire survey of GP practices and
  - the collection of documentation at each case study organisation.

Results 1: Practice use of technologies

Technology	% Practices using technology
Practice Management Systems (PMS)	100
Fax. Machine	100
Printer	100
PCs	100
Healthlink[1] connection	100
Word processing software	100
The Internet/external websites or databases	90
Internal messaging system	90
Spreadsheet	90
Extranet application (e.g. ACC logging)	80
e-mail	80

[1] Secure network for health sector electronic messaging

The table shown here shows the most popular technologies identified as used in the support of patient care by the responding practices.

Results 2: Individual PHO GP practice use of technologies supporting patient care

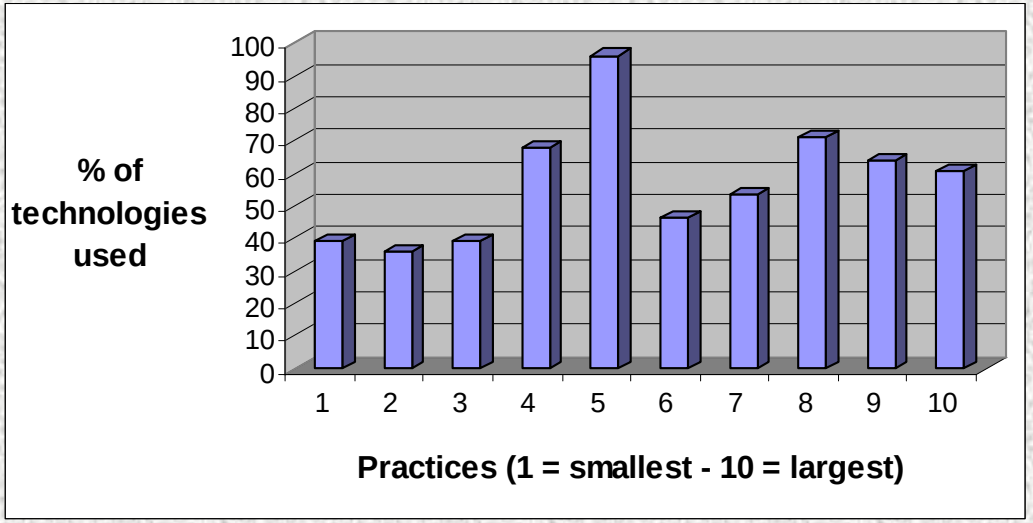

Figure 1, above, illustrates that

- individual practices used between 35.7% and 96.4% of the technologies identified as being present in similar practices belonging to their PHO, and
- all but the three smallest practices used more than 40% of the technologies, but otherwise there appeared to be little evidence that increasing practice size corresponded to increased technology infrastructure.

Results 3: Practice use of three technologies

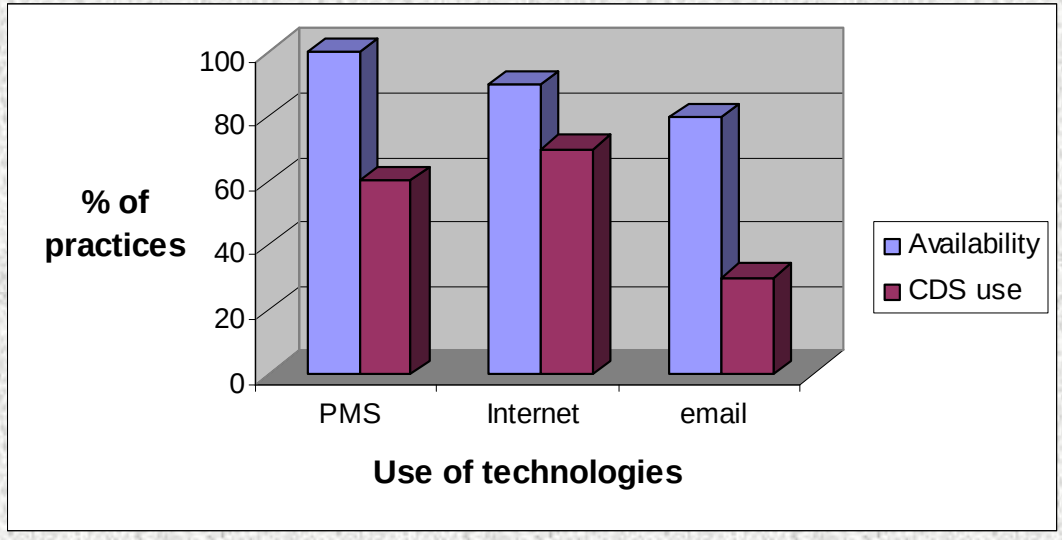

Figure 2, above, illustrates that

- practice management systems (PMSs), the Internet/external websites or databases, and e-mail were used by 100%, 90% and 80% of practices respectively. However,
- when asked about their use of the same systems in the support of clinical decision making when caring for their patients, the percentage of practices found to use the systems in that way was smaller.

Discussion

- This study shows that the respondent practices are using a wide range of available IT technologies. However,
- three of these technologies (the PMS, the Internet and e-mail) which were used by a high proportion of practices were found to be utilised by fewer practices for CDS. This suggests that
- beyond a certain point IT infrastructure ceases to have as much influence on systems use than other factors, i.e. once technology saturation is reached, other factors become responsible as barriers to adopting the technology for CDS.
- Such additional barriers may include resource and clinical issues such as time, cost, training, credibility, and skills in using CDS programmes, and less importantly, technical and systems considerations[6;7;8].
- These findings are re-enforced by this study which also illustrates that
- actually having access to popular technologies within an organisation or even within one practice does not necessarily guarantee either their general use, or use for CDS.

Conclusions

- The results demonstrate that within one organisation, GP practices can have similarly high levels of IT in some areas which should enable them to achieve similar levels of CDS to each other, by utilising available technologies. However, there is evidence to the contrary.
- In order for primary health care managers and practices to improve CDS a detailed knowledge of practice IT infrastructure and how it is used, together with a clarification of barriers to the use of available technologies for CDS, would be beneficial.

Introduction

International and Australasian health care organisations are seeking to improve the use of computerised clinical decision support (CDS) in health care [1;2;3]. New Zealand's primary health care sector is now structured around not-for-profit Primary Health Organisations (PHOs) [4]. Knowledge of IT infrastructure and its usage by PHO practices would enable their management organisations to formulate appropriate strategies to encourage better use of technologies, and the decision support capabilities they provide. This paper presents preliminary results regarding the IT supporting patient care in primary care General Practitioner (GP) practices.

Methods

A multiple case study of medium sized PHOs, consisting of a pilot and two other case study organisations, was undertaken. Triangulation [5] was achieved by the use of face-to-face interviews, a postal questionnaire survey of GP practices and the collection of documentation at each case study organisation.

Results

A response rate of 43.5% was received from 10 completed questionnaires. Table 1 shows the most popular technologies identified as used in the support of patient care by the responding practices.

Figure 1 illustrates that individual practices used between 35.7% and 96.4% of the technologies identified as being present in similar practices belonging to their PHO. All but the three smallest practices used more than 40% of the technologies, but otherwise there appeared to be little evidence that increasing practice size corresponded to increased technology infrastructure. Figure 2 shows that PMSs, the Internet/external websites or databases, and e-mail were used by 100%, 90% and 80% of practices respectively. However, when asked about their use of the same systems in the support of clinical decision making when caring for their patients, the percentage of practices found to use the systems in that way was smaller.

Attitudes PEP HIV/AIDS Health Care Workers' (HCW) for Implementation of Electronic Health Record: A study at AIIMS, New Delhi, INDIA

Sushil K. Meher[a], A. Biswas[b]

[a] *Department of Computer Facility, All India Institute of Medical Sciences, New Delhi, INDIA*
[b] *Department of Medicine, All India Institute of Medical Sciences, New Delhi, INDIA*

Introduction

India is having 3.97 million people living with HIV/AIDS, which is 2nd height in the world next to South Africa. The first case of HIV in India was detected in Tamil Nadu in 1986. Over 38% of those living with HIV in India in 2006 are women, most from regular partners who were infected during paid sex and blood transfusion. For treating HIV/ AIDS patients, health care worker (HCW) need protection and management. So there is a lot of health worker has got infected during treatment or care to the patients. PEP means Post-exposer prophylaxis means taking antiviral medications as soon as possible after exposure to HIV so that the exposure will not result in HIV infection. These medications are only available with a prescription. PEP should begin within as soon as possible after exposure to HIV but certainly within 72 hours. Treatment with 2 or 3 antiviral drugs should continue for 4 weeks, if tolerated. To analysis the information that in what time and place and what type of health worker are getting infected. Occupational exposures to HIV should be considered urgent medical concerns to ensure timely post exposure management and administration. To keep their record of these Health Care Workers and monitoring them regular whether they got infected or not and further their treatment and management it requires a proper EHR (Electronic Health Record).

Keywards:

PEP, EHR, Health Care Worker (HCW)

Objective

To identify the attitude of i. Health Care Worker' (HCW) interested to keep their health record electronically or not. ii the attitudes among Health worker (Doctors, Nurses, Paramedical staff) to use of computers in their clinical information/Investigation of their health and other health worker. iii. Is their electronic record to be monitor by other physician without permission from the health workers? iv. Is their health will be monitored by management or not.

Methods

A self-completed, 35 questions questionnaire were distributed to 750 randomly selected Health Care Workers (HCW). The questionnaire focused on details of the Health Care Workers (HCW) practice; actual computerization of or intention to computerize clinical and administrative functions of Health Care Workers; attitudes towards computerization; self-perceived computer ability and knowledge; and demographic information of HCW. The attitude statements were grouped under four themes according to a factor analysis. HCW Electronic Health Record (EHR) to be monitor by other physician without permission from the health worker. Can their EHR to be used for the administrative Purpose.

Results

The survey was completed by 750 physicians. Only 24% physicians, 2 % Para-medical staff and 12% Nurse were interested for computerisation of HCW EHR. 87 % HCW are in interested to share their record with their friends and colleagues. Only 27 % are interested to use their EHR for administrative purpose. If you will consider age group above 50 years, 34 % physician are interested to share their EHR with their colleagues. Those 54% physician less then 50 years of age interested to share their EHR with their colleagues. The 26% less 25 years old nurses are interested in favor of HCW EHR. Non-clinical users were older and had fewer specialist qualifications. Although there was strong support for the attitude statements among both groups with regard to the benefit of computerization (EHR) to HCW, there was much less support from medical records personnel. Non-clinical users were concerned about the potentially negative impact of computerization on the clinical encounter for HCW.

Discussion

1. The attitudes among current clinical users and non-users (HCW) were substantially different. They need proper training and exposer to the technology.

2.It needs proper policy in the hospital administration level that the HCW's data to be stored and shareable with the following community

3 Policy to be framed to start this type of program.

4. Govt and NGOs should be involved.

5. Motivate the people for the technology

6.Continuous training to be continued and be in touch with people

7.Continuous monitor is required for each hospital

8. This type of program to be introduced at the time of education/course. If attitude of HCW change then EHR for HCW can be implemented in thoroughly.

Abstract

Application of tele-ophthalmology to community-based screening for diabetic retinopathy with one-stage or two-stage design in remote area has been hardly addressed. Digital image data underpinning this architecture were transferred for sending images to a retinal specialist for diagnosis. The clinical burden of diagnosis and confirmatory should be taken into account even though applying the tele-ophthalmology screening in rural area. In this circumstance, one needs to screen general population on the basis of predictive model to ascertain high-risk subjects that in turn receive confirmatory diagnosis at second stage. The balance between cost and effectiveness for different screen regimes was worthy of being investigated. A Monte Carlo computer simulation approach has been employed to simulate the disease natural history of diabetic retinopathy for a hypothetical population. The model generates a hypothetical population with the make-up of demographic features identical to that of Matsu population in 2004. Economic evaluation of different screening regimes was performed by TreeAge. All strategies dominated over no screening according to incremental cost-utility ratios. The incremental C/U ratio for two-stage design versus no screening (US 218) was not substantially different from that for tele-ophthalmology (US 220). The optimal inter-screening interval was two years for tele-ophthalmology and two-stage design.Time-dependent predictive model was developed for two-stage design with tele-ophthalmology. Economic evaluation found biennial screen regime dominates over other screening regimes because it elicits less cost but more benefit.

Keyword:

tele-ophthalmology, retinopathy screening, cost-effectiveness analysis

Introduction

The application of teleophthalmology to population-based screening for eye-related diseases in remote areas with scare ophthalmologists has been developed through a population-based multiple disease screening for ocular diseases among residents aged 40 years or older in Tungyin, one of townships in Matsu, Taiwan. Digital image data underpinning this architecture were transferred to a conventional personal computer via the Internet[1].

Data from clinical trials have shown that timely intervention with retinal photocoagulation prevents vision loss due to diabetic retinopathy. Because the condition is often asymptomatic in its early phase, regular evaluation is critical to clinical management of diabetic retinopathy. Numerous studies have demonstrated an overall cost effectiveness of retinopathy detection for type 2 diabetic patients. Although tele-ophthalmology has been recognized as a tool in providing health care for rural community[1], the clinical effectiveness and economic value of telemedicine has been poorly understood. From the viewpoint of evidence-based medicine, decision on whether such a diabetic retinopathy screening is worthwhile is dependent on a series of factors, including screen tools, disease natural history, cost, effectiveness of screening and inter-screening, interval. The balance between cost and effectiveness was worthy of being investigated. The aim of this study is to perform economic evaluation for the assessment of tele-ophthalmology and screening regime for diabetic retinopathy.

Methods

Participants would then be consecutively imaged using a store-and-forward telemedicine system. Digital 350 color fundus images were obtained with the non-mydriatic digital fundus camera. Two-field dilated digital images would be taken per eye. As screening for DR with direct method and fundus image check in general population may be costly two-stage design was therefore proposal to identify high-risk group for further referral to undergo examinations. To ascertain high-risk group, one may require predictive model on the basis of inexpensive and routine biochemical variables, time-dependent Cox regression model was proposed to build up adequate predictive model.

The five-state Markov model was used to model the disease natural history of diabetic retinopathy following the proliferative pathway to blindness was delineated follows NDR->BDR->PPDR->PDR->blindness. Through screening, asymptomatic stages were detected and received intervention in order to reduce blindness. Markov decision

tree was applied as the basis of the decision on policy of screening for diabetic retinopathy regarding tele-ophthalmology.

The base-case parameters estimated including probability of disease progress, sensitivity, specificity, attendant rate, utilization value and discount rate. The costs for tele-ophthalmology include direct costs for devices, training, and overhead expenses. The cost without tele-ophthalmology for screening and treatment were based on current health insurance programme for an ophthalmology visit with a dilated eye examination. A Monte Carlo computer simulation approach has been applied to simulating the disease natural history of colorectal cancer for a hypothetical population with the make-up of demographic features identical to that of Matsu population. Micro-simulation using Tree-Age software was performed to calculate cost in dollars, effectiveness expressed by the remaining vision after 50 years of follow-up of subjects who are screened from 30 years of age

Results

Average baseline values were also used to derive average QALYs for each strategy. Base-case analyses resulted in 18.39 of average QALYs with the tele-ophthalmology strategy , 18.35 of average QALYs using two-stage design and 18.28 of average QALYs with no screening strategy. The average cost effectiveness ratio was US 220 per QALY for the tele-ophthalmology , US 218 for two-stage design, and NTD 262 for no screening strategy. Again, all strategies dominate over no screening. The incremental C/E ratio for two-stage design was not substantially different from that for tele-ophthalmology. Incremental cost for reducing one unit of QALY was UD 1,595 for tele-ophthalmology against two-stage design. The optimal inter-screening interval was two years for tele-ophthalmology and two-stage design for sensitivity-analysis.

Discussion

Two screening decisions, including tele-ophthalmology, and tele-ophthalmology with two-stage design, opposed to no screening were considered in the current study. It is very interesting to note that tele-ophthalmology elicits more cost but also more effectiveness in reducing blindness. On the other hand, two-stage tele-ophthalmology may reduce cost but lead to smaller benefit because of false negative cases compared to tele-ophthalmology. This suggests that one may make use of two-stage design with the application rather than the administration of tele-ophthalmology to the entire population. As far as inter-screening interval, biennial screen regime dominates over other screening regimes.

In conclusion, tele-ophthalmology with or without two-stage design was demonstrated to be feasible in community-based screening for DR in remote area. Economic evaluation found two-stage tele-ophthalmology with time-dependent model almost as cost-effective as the application of tele-ophthalmology to the whole population.

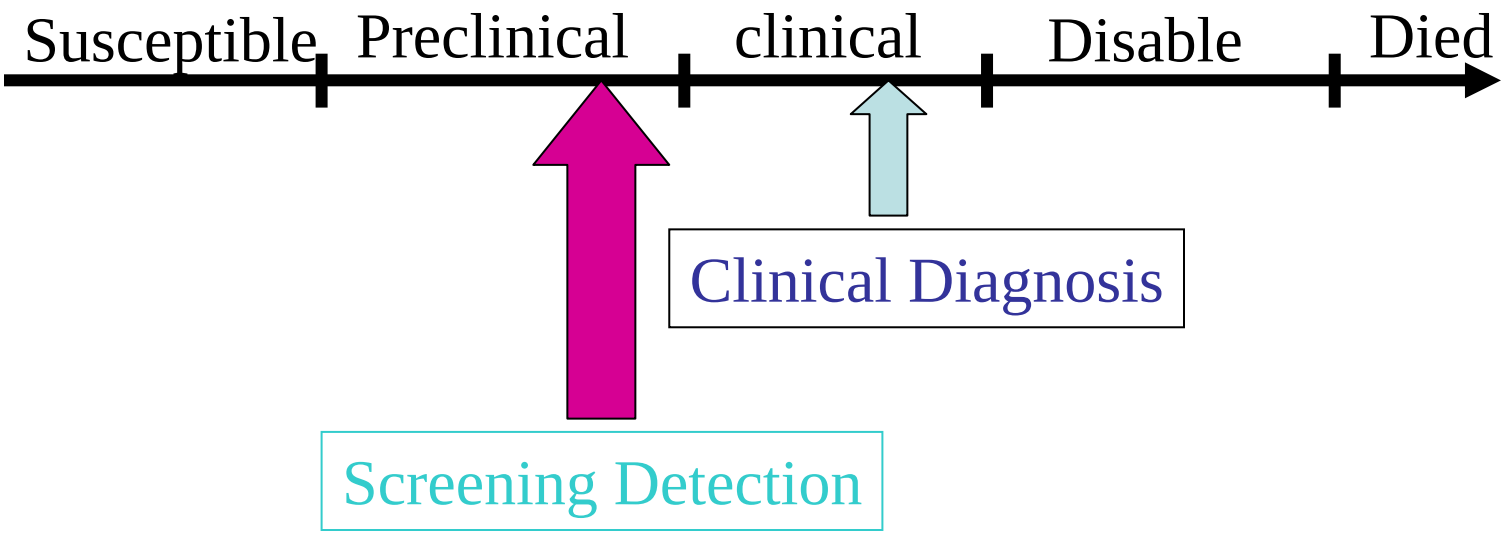
Why Tele-ophthalmology

- Scarce resource in Ophthalmologist in remote area
- Visual loss problem
  - Between 2000 and 2020, the prevalence of blindness is expected to double
  - Major causes of low vision and blindness
    - diabetic retinopathy, macular degeneration, cataracts, and glaucoma
- Diabetic retinopathy incidence increase
  - Diabetes is expected to increase worldwide from 135 million to 300 million people between 1995 and 2025(Mokdad ,2000)
- Tele-ophthalmology has been recognized as a tool in providing health care for rural community (Chen et al. 2004)



The disease natural history of diabetic retinopathy

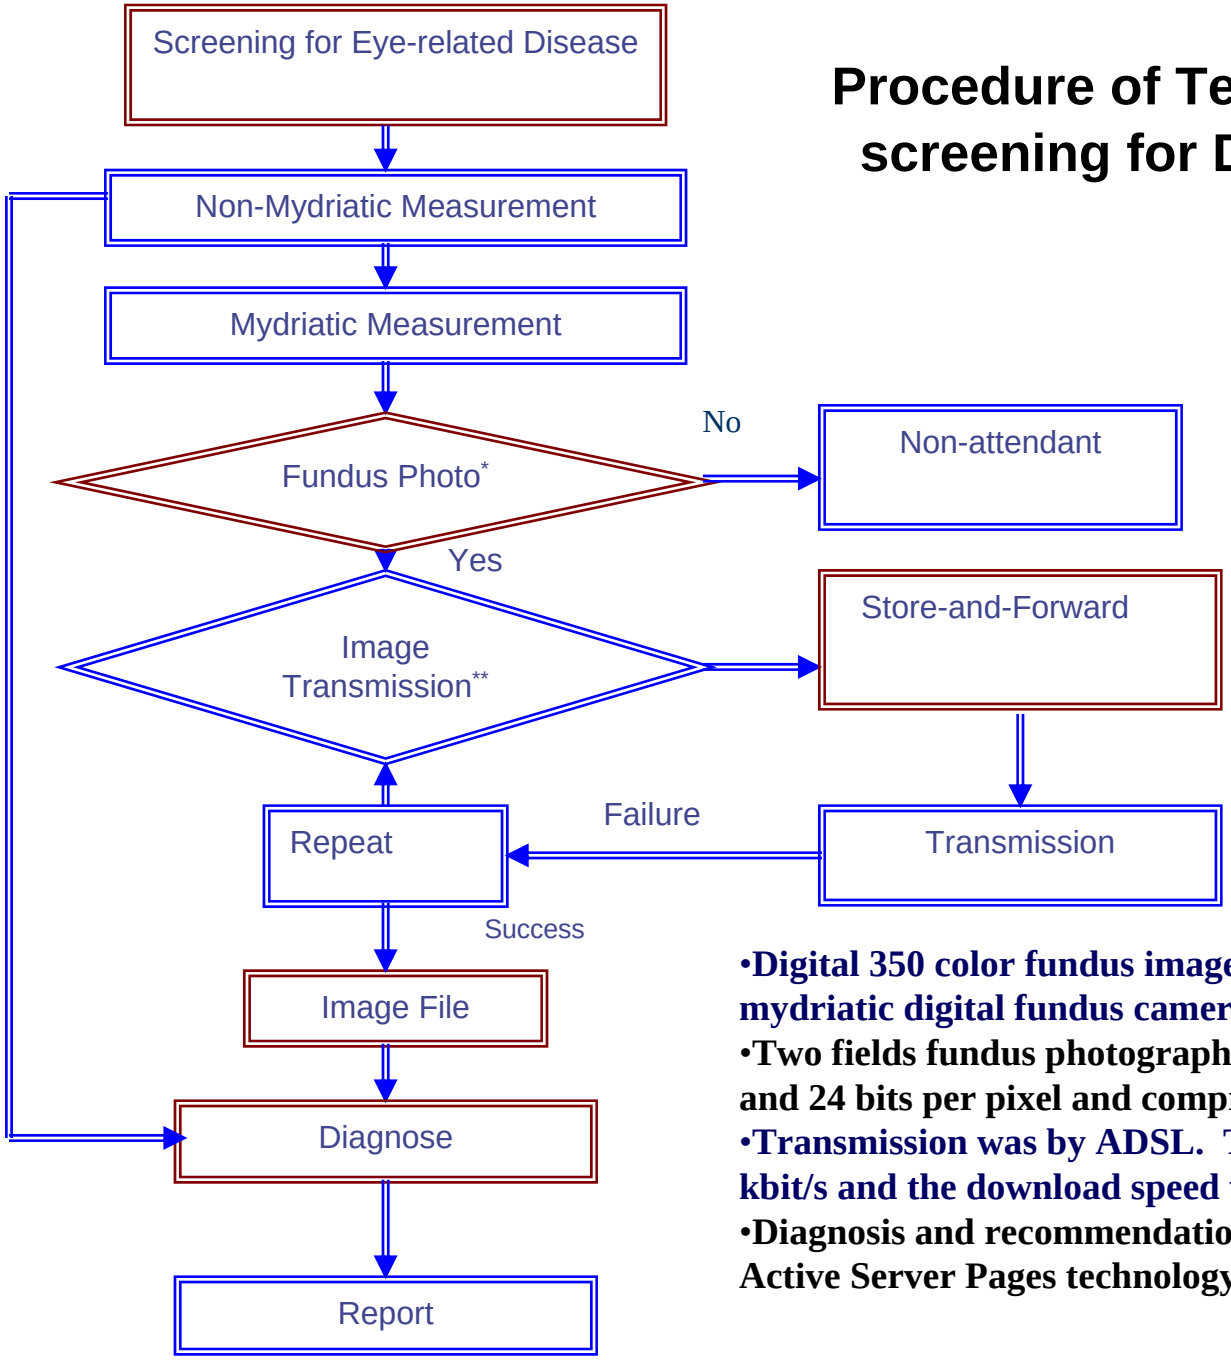
NDR (1) $\xrightarrow{\lambda_1}$ BDR (2) $\xrightarrow{\lambda_2}$ PPDR (3) $\xrightarrow{\lambda_3}$ PDR (4) $\xrightarrow{\lambda_4}$ Blindness (5)

Annual transition rates

λ_1 (NDR→BDR):	0.11	λ_2 (BDR→PPDR):	0.07
λ_3 (PPDR→PDR)	0.24	λ_4 (PDR→Blindness) :	0.20

NDR: No diabetic retinopathy BDR: Background diabetic retinopathy
PPDR: Preproliferative diabetic retinopathy PDR: Proliferative diabetic retinopathy

Procedure of Tele-ophthalmology for screening for Diabetic Retinopathy



- **Digital 350 color fundus images were obtained with a non-mydriatic digital fundus camera**
- **Two fields fundus photographs consisted of 2048 x 1360 pixels and 24 bits per pixel and compressed to 1:20 before sending**
- **Transmission was by ADSL. The lowest upload speed was 64 kbit/s and the download speed was 512 kbit/s**
- **Diagnosis and recommendations in a server was based on the Active Server Pages technology and SQL-SERVER database**

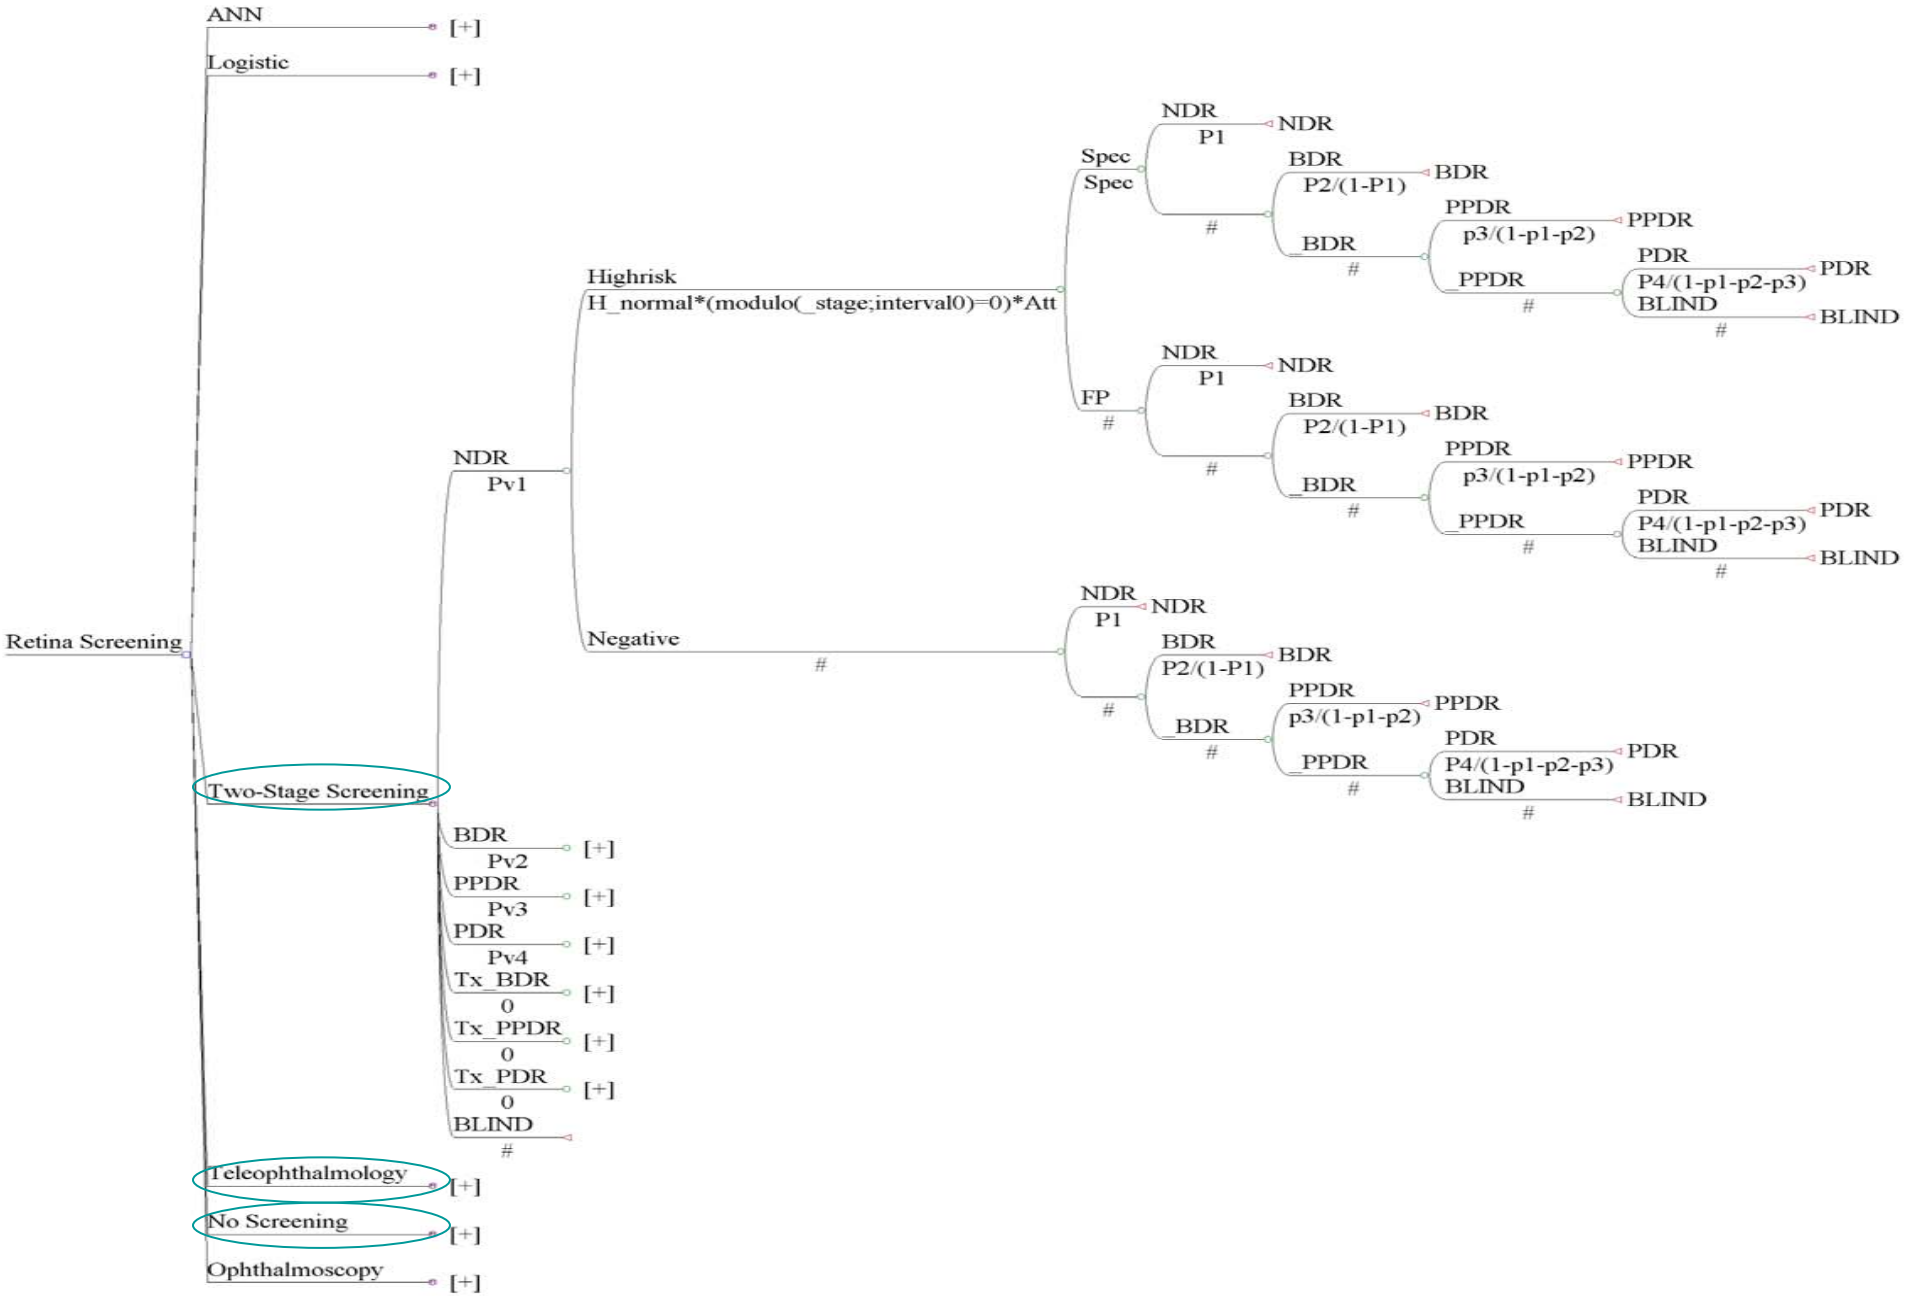
Rationale

- Natural History Model of Diabetic Retinopathy
- Markov Decision Analysis
- Data source and base-case probability
- Utility measurement
- Cost data
- Monte Carlo Computer Simulation
- Implementation of computer simulation
- TreeAge 4.0 used

Decision Tree for diabetic retinopathy screening



Base-Case Estimates

- Annual transition rates
  - NDR to BDR 0.11
  - BDR to PPDR 0.07
  - PPDR to PDR 0.24
  - PDR to Blindness 0.20

(Liu et al , Diabet Med, 2003)

- Screening test characteristics
  - Ophthalmoscopy
    - Sensitivity% 0.75(0.33-0.86)
    - Specificity% 0.86(0.75-0.99)
  - Teleophthalmology
    - Sensitivity% 0.88(0.72-0.98)
    - Specificity% 0.9(0.75-1)

Base-Case Estimates

- Attendance rate 0.5(0.25-0.7)
- Attendance rate on site 0.9(0.5-0.95)
- Utilization Value 0.92(0.91-0.93)
- Discount rate % 5%
- Year of repeat screening 4(2~8)

Cost Estimated

- Teleophthalmology
  - Fundus photograph evaluation — US:5
  - Initial Cost — US:20000
- Nonteleophthalmology
  - Examination Cost — US:6
  - Transportation — US:90
- Confirmatory Cost
  - Fluorescein angiography — US:30
  - Transportation — US:90
- Cost of treatment
  - Clinic visit — US. 120
  - Transportation Fee — US. 300
  - Operation Fee — US. 400
  - Transportation Fee — US. 160
- Cost of Blindness care
  - Age < 65 years — US. 2000
  - Age ≥ 65 years — US. 30

Blindness Incidence Case-55 years follow up

- No screening strategy : 265 blindness
- Teleophthalmology strategy: 218 blindness
  - Compare no screening: 15.7% blindness reduction
- Two-stage Design strategy: 236 blindness
  - Compare no screening: 9.5% blindness reduction

Cost-Utility for each screening regime

Two-stage Design v.s No Screening

ICUR: $\frac{3{,}992 - 4{,}781}{18.350 - 18.276} = (10{,}658)$ dominate

Tele-ophthalmology v.s No Screening

ICUR: $\frac{4{,}051 - 4{,}781}{18.387 - 18.276} = (6{,}573)$ dominate

Cost-Utility for each screening regime

Two-stage Design v.s Tele-ophthalmology

ICUR: $\dfrac{3{,}992 - 4{,}051}{18.387 - 18.350} = 1{,}595$

Screening interval for each screening regime

	Screening interval	Two-stage Design	Tele-ophthalmology
Cost		3,773	3,581
Qalys	2	18.43	18.51
C/E		204.7	193.4
Cost		3,992	4,051
Qalys	4	18.35	18.39
C/E		217.5	220.3
Cost		4,025	4,112
Qalys	6	18.32	18.35
C/E		219.6	224.1
Cost		4,032	4,125
Qalys	8	18.31	18.33
C/E		220.2	225.1

Economic Evaluation

- Tele-ophthalmology elicits more cost but also more effectiveness in reducing blindness
- Two-stage tele-ophthalmology may reduce cost but lead to smaller benefit because of false negative cases compared to tele-ophthalmology
- Cost per one Qalys gained was US 1,595
- Biennial screen regime dominates over other screening regimes because it elicits less cost but more benefit

Conclusion

- Tele-ophthalmology with or without two-stage design was demonstrated to be feasible in community-based screening for DR in remote area
- Cost per one Qalys gained was US 1,595

[c] *Clinical Trial Management Center, Kanazawa University Hospital, Japan*
[d] *University hospital Medical Information Network (UMIN) Center, the University of Tokyo Hospital, Japan*

Abstract and objective

The number of pharmaceutical safety reports from medical institutions to the government is about 5,000 annually and only one fifth comparing to industry in Japan. In order to facilitate such reporting, and enhance early detection or prevention of adverse drug reactions (ADRs), we have developed a pharmaceutical safety reporting system on University hospital Medical Information Network (UMIN). UMIN is the largest and most versatile academic network information center for biomedical sciences in the world, and considered as indispensable information infrastructure for the Japanese medical community.

The major benefits of this system are as follows; user-friendly interface to make reports, easy management of reports, and immediate sharing information on suspect ADRs among medical institutions. In the future, it will be more beneficial for reporters if the government accepts pharmaceutical safety reports directly through UMIN.

Keywords:

adverse drug reaction reporting systems, internet, safety management

Introduction

Based upon national or international agreements, rules, and regulations, individual case safety reports (ICSR) of ADRs need to be transmitted. The International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) is a project that brings together the regulatory authorities of Europe, Japan and the United States and experts from the pharmaceutical industry in the three regions to discuss scientific and technical aspects of medicinal products. E2b is one of the expert working groups (EWG) in ICH for harmonization of Data Elements for Transmission of ICSRs. This group published E2b guideline in 1997. Due to the advantage of information technology, the Specification for the electronic message of ICSR was released in 2001 by ICH M2. M2 is a Multi-disciplinary Group 2 EWG in ICH and discusses Electronic Standards for the Transfer of Regulatory Information (ESTRI) that will meet the requirements of the pharmaceutical companies and regulatory authorities. After this development of specification, each region implemented electronic ICSR system. Since October 2003, electronic ICSRs have been accepted for industry by the Ministry of Health, Labor and Welfare (MHLW). However, most medical institutions need to report ICSRs to the government as paper form. The number of ICSRs from medical institutions to the government is currently about 5,000 annually and only one fifth comparing to industry in Japan.

In order to facilitate such reporting from medical institutions to the government, and enhance early detection or prevention of ADRs, we have developed a pharmaceutical safety reporting system on University hospital Medical Information Network (UMIN). UMIN is the largest and most versatile academic network information center for biomedical sciences in the world, and considered as indispensable information infrastructure for the Japanese medical community.

Methods

The system was designed as web-based in Japanese. Although the form is based upon paper which is currently used for safety reporting from medical institutions to the government, each element reflects the global standard which ICH E2b/M2 produced. There are two steps to create a report. The form 1 is designed as the first step for capturing minimum data which should include at least one identifiable patient, one identifiable reporter, one reaction/event, and one suspect drug. If any of such data is missing or wrong, a reporter can't register it. The form 2 is the second step appearing as the next page to the form 1 and designed for entering other detailed information as optional. These optional data are for example, relevant medical history and concurrent conditions, and results of laboratory tests, etc. Our system also provides the function to search a drug by product name or substance name.

There are three classes for users; administrator, responsible user, and reporter. An administrator is usually a representative of a medical institution. This administrator assigns a responsible user in the same institution who has right to approve reports to be open to outside or not. A reporter is a person creating a report and usually a health professional.

There are three repository statuses of reporting, “temporary saving”, “waiting for approval”, and “approved reports”. The reports which are temporary saving or waiting for approval, are reviewable only within the same institution. The approved reports are open to outside the institution, but privacy information such as reporter’s name or patient’s name is anonymous. A reporter can receive a question via e-mail from an identifiable reviewer, and this reporter can answer anonymously.

Results

The system has been developed successfully. The first page of ICSR system has two parts; the upper section is for reporting, the lower section is for the administrative function. A reporter is likely to belong to two or more institutions. Therefore a reporter should define at which institution an ADR occurred.

The reporting function has three sections mainly; the first is for creating or amending reports, the second is for reviewing reports, and the third is for setting up reporter’s information. For the first time to use this system, a report needs to fill out reporter’s information. Once a reporter has completed this section, it is not required to fill out any more.

In order to create a new ICSR, a reporter is required to enter patient’s age and select gender. After that, identification number is assigned to each case automatically. Then the form 1 appears. The top section is to enter an adverse event. A reporter can enter several events. Then, the next column is for a suspect drug. There are two ways; one is to enter a substance name, and the other is to enter a product name. If you enter some characters for either of them, applicable drug names appear. Then a reporter can select intended drug name. There is also descriptive section about details of adverse reactions or events. After clicking the button “next” and no missing data on the form 1, the page can move to the form2. If there is any missing data, this system indicates which information is missing.

In the top section of the form 2, patient’s gender and age are placed automatically. A reporter can enter more information regarding a patient such as height, weight, pregnancy, if needed. As the next section, a reporter can enter relevant medical history and concurrent conditions. Also, there are some sections to capture some information, such as smoking, alcohol consumption, allergy, etc. The next section is for adverse reactions/events, and the major adverse reaction/event which was entered in the form 1 is placed in the top. And if necessary, a reporter can add more reactions/events. Also a reporter can enter the outcomes about ADRs, such as recovered, not recovered, fatal, etc. Also a reporter can enter the information about severity and concomitant drugs. And the next to them, a reporter can put results of laboratory tests. Also a reporter can enter descriptive information regarding ADRs. A reporter can stop the process any time and the entered data can be stored temporary and restart anytime.

Discussion

The two-step data entering prioritizes the information according to its importance, and contributes user-friendly interface. Archiving reports by three statuses helps to count how many ADRs occurred inside/outside the institution. Therefore, the system brings us easy management of reports. If lots of reports are stored, we can apply data mining to detect a signal of a real ADR. Furthermore, the numbers of suspect ADRs inside one institution is limited. Our system has the function to know the similar suspect ADRs outside and contact the reporter by e-mail to get the detail information immediately. This is helpful to evaluate ADRs and prevent more cases.

Since the government hasn’t approved our system yet, reporters need to print out and send ICSRs by surface mail or fax to the government. If the government accepts reports directly through UMIN, it is actually more beneficial for them. Created report can be exported as a Microsoft Word format, this format is acceptable through e-government portal gateway. Therefore our system is useful to adapt a report to this e-government. However, in order to send a report through this e-government portal gateway, a reporter should get an electronic certification from any certificate authority. This process of obtaining an electronic certification is difficult and complicated. If UMIN can take a role of a certificate authority; a reporter would not need to obtain an electronic certification from any other certificate authority.

The Pharmaceuticals and Medical Devices Agency (PMDA) was established in 2004 based on the law for the incorporated administrative agency. This agency started to open ICSRs which were submitted from pharmaceutical companies to the government. But there is about one-year time lag from reporting to disclosure because of evaluation process. Our system on UMIN has no such time lag. In addition, our system has a detail searching function which PMDA doesn’t provide.

Another benefit of our system is that it can be useful for data mining. FDA and WHO have already started to use data mining methods to detect suspect ADRs. These methods are probably applied to our system.

The strong proof of feasibility is necessary to get permission from the government. There is a plan to carry out a feasibility test of it in the near future.

Conclusion

In order to facilitate pharmaceutical safety reporting from medical institutions, and enhance early detection or prevention of ADRs, we have developed a system on UMIN successfully. The major benefits of this system are user-friendly interface, easy management of reports, and immediate sharing information on suspect ADRs among medical institutions. The feasibility test of it is necessary in the near future.

Pharmaceutical Safety Reporting System on UMIN

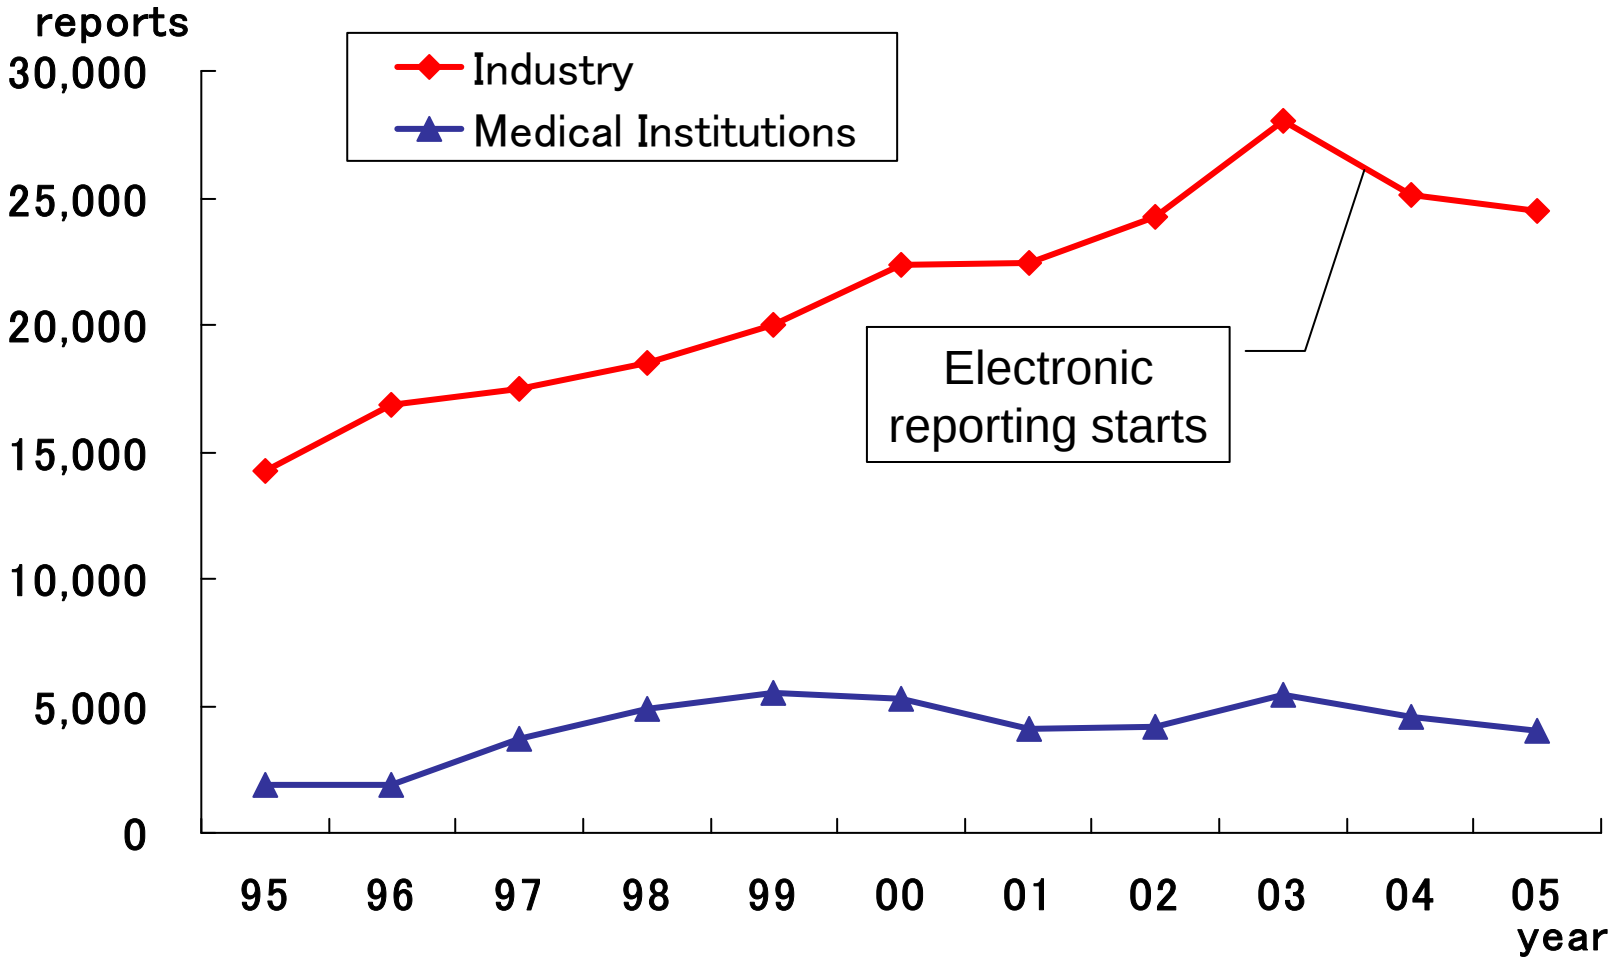
Introduction

- ICSRs of ADRs need to be transmitted nationally and Internationally.
- ICH E2b/M2 guidelines provide standardized data elements for transmission of ICSRs.
- Since Oct. 2003, electronic ICSRs have been accepted for industry by MHLW in Japan.
- However, most medical institutions still need to report ICSRs to the government as paper form.

ICSR : Individual Case Safety Report / ADR : Adverse Drug Reaction
ICH : International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use

The number of pharmaceutical safety reports to the government in Japan



Purpose

- Facilitate pharmaceutical safety reporting from medical institutions to the government.
- Enhance early detection or prevention of ADRs.

A pharmaceutical safety reporting system should be developed on UMIN

UMIN : University hospital Medical Information Network in Japan

Methods 1 cont.

- Web system based on paper form.
- Each element reflects the ICH E2b/M2 guideline.
- Two-step creation
  - Form 1:minimum data (mandatory)
    - identifiable patient, identifiable reporter, reaction/event, and suspect drug.
  - Form 2:detail data (optional)
    - relevant medical history and concurrent conditions, and results of laboratory tests, etc.

Methods 2

- User class
  - Administrator
    - Representative of a medical institution
  - Responsible user
    - An administrator assigns a responsible user who has right to approve reports to be open or not.
  - Reporter
    - Health professional
- Repository status
  - Temporary saving
  - Waiting for approval

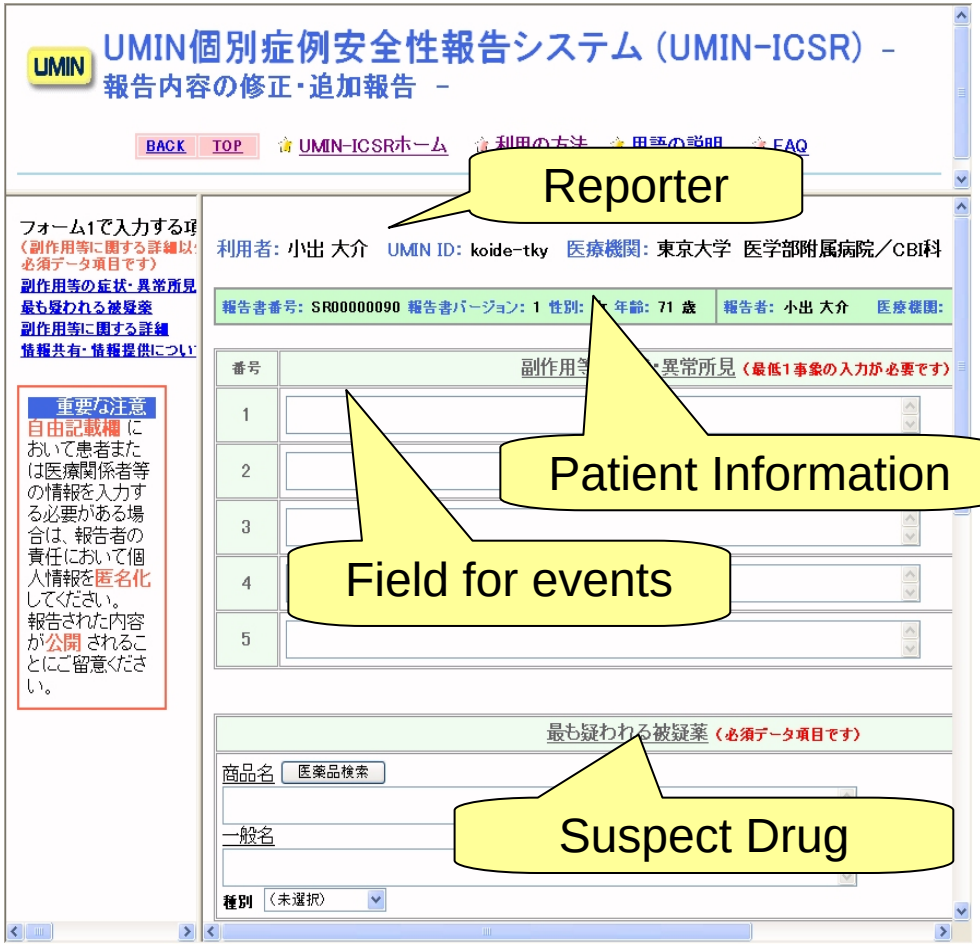
  } Reviewable only within the same institution.
  - Approved report— Open to outside a institution

Results 1 cont.

- The system has been developed successfully.
- The right figure is the top page of this system.

Results 2 cont.

Form1



Form2

Discussion

- The two-step data entering prioritizes the information according to its importance.
  - This contributes user-friendly interface.
- Archiving reports by three statuses helps to count how many ADRs occurred inside/outside the institution.
  - The system enables easy management of reports.
- If lots of reports are stored, data mining can be applicable to detect signals of ADRs.

Conclusion

- The pharmaceutical safety reporting system has been developed successfully on UMIN.
- The major benefits of this system are;
  - user-friendly interface,
  - easy management of reports,
  - immediate sharing information on suspect ADRs among medical institutions.
- The feasibility test is necessary.

Understandable Logical Design Specifications for HL7 CDA Interoperability

Tim Benson[a], Ayegül Avc[b], Fatih Boy[c], eref Arkan[d], Alp Timurhan Çevik[b]

[a]Abies Ltd and UCL CHIME, London, England,
[b]DataSel, Ankara, Turkey,
[c]Birim Bilgi Tek. Tic. A.S., Izmir, Turkey,
[d]Middle East Technical University, Ankara, Turkey

Abstract

This paper describes the approach adopted by the Turkish National Health Information System to build a national Data Warehouse, covering more than 50 Data Sets, specified by the Ministry of Health, and an EHR for each citizen.

The messages are first specified using a UML logical design model, which is understandable to all stakeholders. These specifications are then mapped to HL7 CDA Release 2 to produce the wire format specifications, xsd's and java classes.

Each message is assembled from stand-alone Data Sets, which populate the Data Warehouse, and Sections which are used to create the EHR.

Keywords:

systems integration, computerized medical record, logical design specification

Introduction

The Turkish National Health Information System is to provide a national Data Warehouse, based on more than 50 Data Sets, and an EHR for each member of the population of almost 80 million people. Data is submitted by hospital clinics and family physicians.

The project is being implemented by a consortium, which includes Datasel, Birim and Sun Microsystems. Interoperability uses HL7 V3 CDA Release 2, with nationally-defined coding schemes and identifiers.

The challenges include the development and implementation of a large number of messages, involving multiple suppliers in a short period, as well as reconciling the central requirements of the Ministry for data analysis and the users expectation of having a useful EHR.

Method

The messages have been designed using a common structure, shown in Figure 1 as a UML diagram. Each Message includes a Header and one or more Data Sets. Each Data Set contains one or more Sections and each Section contains may contain various Data Elements. The Header, Data Sets and Sections include default Context data. This maps to HL7 CDA Release 2 [1] in a straightforward way.

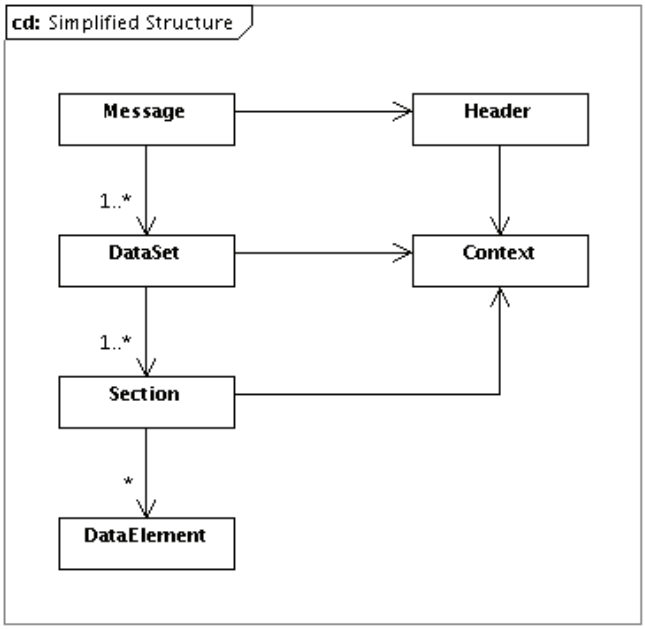

Figure 1 - Simplified logical design of messages

Context data

Each Message concerns one patient (who about), has a specific date (when), a single location (where) and author (who by). This is referred to as Context data and provides the default values of patient ID, date, location, clinic type (e,g, Cardiology) and user (health care party), which apply to all parts of the message, unless more specific data is provided.

Header

In addition to Context data, the Header for each message contains standard metadata, such as unique identifier, time of creation (to the nearest second), name, type and version of the message, realm (e.g Turkey), processing status (e.g. live or test) and confidentiality level.

Data set

The main body of the message contains one or more Data Sets, specified by the Ministry of Health. Examples of Data Sets include patient referrals, discharges, births and deaths. Each Data Set has its own unique identifier and specific version identifier (template ID) and includes Context data. Each Data Set is composed from a number of Sections.

Section

A Section is a standalone data object, which is reusable in different Data Sets. For example the Diagnosis Section (figure 2) may occur in several Data Sets. Other examples include procedure, medication and allergies. Each Section contains a unique identifier, type code, version (template ID) and a human readable free text statement of what it contains (text). It also includes default Context data, as well as its own data elements. Note that some Sections may only contain text and as a result have no additional data elements.

These Sections correspond to HL7 CDA Sections. In CDA the sharing of default Context in Data Sets and Sections is achieved by setting a Context Conduction Indicator to "true".

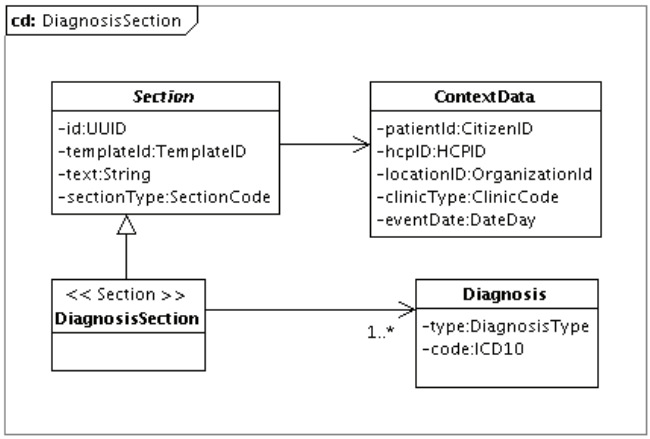

Figure 2 - An example of a section - diagnosis section

Design method

The number of Data Sets and their content will evolve over time, while the header, context and Section definitions are likely to be much more stable.

The data content used throughout the whole system is specified in a single UML model. Each message, Data Set and Section is one view into the model. This provides a comprehensive and consistent specification, written at the logical level, which understood by both users and developers [2]. The UML model is also computer-readable, generating an XML output (XMI).

It is straightforward to map the logical design specifications to HL7 CDA R2 as well as to the applications software used at both the sending and receiving ends. Each Section is mapped to build a library of HL7 templates, CMETs, xsd and Java classes, which can be assembled to build, check and process Data Sets and complete messages, just like putting Lego bricks together.

This method could be used to build a new set of tools, which may simplify development of CDA R2 based messaging solutions. HL7 already has tools for various purposes, but the method employed in this project is simple, flexible and powerful. Such a tool, based on the Eclipse platform, has the potential to boost adoption of HL7 CDA R2 by simplifying the production of stringent HL7 CDA specifications and interfaces.

System architecture

Messages are generated in hospitals, clinics and general practices and then sent to the Ministry of Health. On receipt and after validation, the information is directed as follows:

(a) Data Sets, in an anonymous form, are sent to the Data Warehouse as a resource for management and research.

(b) Sections are submitted to the EHR portal. Persons with a need to know may submit searches to the EHR portal to retrieve views into each patients record according to date (when), clinic (where), author (who) and the type of information required (what); this might be all data or a subset such as medications, allergies, diagnoses etc. The EHR portal returns the appropriate sections, and the human-readable text may be displayed on a web-browser.

The overall system is SOA-based and uses a layered approach, whereby each separate layer only interacts with the layer below the current step, and the lower layer not in any way interacting with the upper one, maintaining system changeability and extensibility, resulting in the layers having distributed responsibility.

Discussion

Some aspects of this project are comparable with the approach recently adopted by the NHS National Programme for IT in England with two main differences. First, the architecture (and scope) is much simpler and, secondly, a logical design specification is used to specify exactly what is required.

The UML-based logical design specification has been invaluable at all stages of the project. It has allowed discussions to focus on the critical issues of what is to be done, rather than on the constraints of representing this using HL7 artefacts. It has greatly facilitated communication between all members of the project, analysts, message

architects, software developers, managers and user representatives, who could not understand detailed HL7 specifications.

Opportunities for Error in CPOE Alert Responses

Amy Chused, MD[a,b]

Peter Stetson MD, MA[a,b]

[a] Department of Biomedical Informatics, Columbia University

[b] Department of Medicine, Columbia University

Ways Alerts Could Promote Error

- Erroneous Overrides [1]
  - Drug safety alerts override rates: 49-96%
  - May be due to alert fatigue, incorrect information, or clinician time shortage
- Errors of Commission [2]
  - Alert instructions may be followed contrary to clinical knowledge due to unwarranted trust in computer authority
- Errors of Distraction [3]
  - High cognitive complexity in CPOE systems can lead to missed steps when responding to alerts

Overall Alert Categorization

- Types
  - **Informational:** give timely information that may change patient care
  - **System Data Request:** collect information needed by electronic medical record and CPOE systems
  - **Critique:** detect a possible error in an order and request the clinician to change or confirm the order
  - **Suggestion:** anticipate an order and attempt to streamline the order process and/or ensure order correctness
- Features
  - Interruptive / Non-interruptive
  - Synchronous / Asynchronous
  - Enforced / Not Enforced
  - Triggered by Order Entry / Data Entry / User Interface

Current focus: Critique Alerts

- Usually Interruptive
  - Must break into clinical workflow
- Synchronous
  - Logic trigger = Display trigger
- Triggered by order entry
- Often Enforced
  - To continue with workflow, clinician must satisfy alert condition

Solution: "Offered Choices" [4]

- Selectable items from the alert which enable the clinician to specify their desired response
- Preconfigured to include most probable clinical choices
- Common options include
  - Write a new order (specified by alert)
  - Override the alert
  - Defer warning for later
  - Cancel pre-existing or current order
  - Edit pre-existing or current order

Possible Advantages of *Offered Choices*

- Rapid selection of desired alert response
  - → less clinician time pressure
  - → fewer incorrect alert overrides
- Explicit display of *Offered Choices*
  - → less perception of alert as decision maker
  - → fewer errors of commission
- Decreased cognitive load for alert responses
  - → fewer errors of distraction

Clinical Example with *Offered Choices*

Dr. Bright has decided to order paroxetine.

An alert notifies her that the patient is already receiving fluoxetine, which is the same class of drug as paroxetine.

Dr. Bright decides to cancel the previous order of fluoxetine and continue her current order for paroxetine.

Task Analysis With *Offered Choices*

1. Using *Offered Choices*, Dr. Bright selects “Cancel pre-existing order” and continues with her work.

Task Analysis Without *Offered Choices*

Option 1

Select “Go Back”

Save constructed but unsubmitted order for paroxetine

Find pre-existing order for fluoxetine in long list of current orders

Cancel fluoxetine order

Recall saved order for paroxetine

Submit order for paroxetine

Option 2

Select “Proceed”

Submit new order for paroxetine

Find pre-existing order for fluoxetine in long list of current orders

Cancel fluoxetine order

Task Analysis Comparison

- With *Offered Choices*
  - 1-step process
  - Less clinician time consumption
  - Less cognitive complexity
  - Explicit choices available
- Without *Offered Choices*
  - Either 4-step or 6-step process
  - Increased clinician time consumption
  - Increased cognitive complexity renders alert responses vulnerable to Error of Distraction
    - “Proceed” path → both drugs received
    - “Go Back” path → neither drug received

Further Advantages of *Offered Choices*

- Without *Offered Choices*, override rates are difficult to measure
  - "Go Back" vs. "Proceed" selection insufficient to determine whether alert advice was followed
  - Must laboriously examine order sets following alert triggering
- With *Offered Choices*, explicit selection allows clear determination whether alert advice was followed

Conclusions

Several types of errors are associated with clinical alerts, as demonstrated by our analysis of critique alerts.

Offered Choices, as a feature of critique alerts, provide significant theoretical potential for decreasing alert-related errors.

Further study is needed to evaluate improvements in alert efficacy and usability after implementation of *Offered Choices*.

Opportunities for Error in CPOE Alert Responses

Amy E Chused[a,b], Peter D Stetson[a, b]

[a] *Department of Biomedical Informatics, Columbia University, New York, USA*
[b] *Department of Medicine, Columbia University, New York, USA*

Abstract

The default alert response options in a commercial Computerized Physician Order Entry (CPOE) system are markedly different from the clinical cognitive model. This difference can contribute to alert fatigue, incorrect alert overrides, and increased errors in patient treatment. By examining an interruptive, overridable alert from the perspective of both cognitive and workflow analyses, this paper presents insights into potential errors and proposes a novel testable model for alert conflict resolution.

Keywords:

CPOE, user computer interface

Introduction

CPOE systems have been shown to both prevent errors and open opportunities for new types of errors. Overriding alerts is a serious and common problem, with 49-96% of all alerts being overridden.(1) Many alerts are interruptive. They stop the clinician's workflow until the alert receives a response. When encountering this type of alert, clinicians are more likely to respond, rather than automatically overriding it, if they are provided with a reasonable set of alternative actions.(2)

Clinical cognitive model vs. workflow constraints

Consider the scenario in which the clinician is presented with an alert of the form "Item A conflicts with Item B". There are three possible responses to this alert form: delete or modify Item A; delete or modify Item B, or override the alert. The specific implementations vary depending on what A and B are. Drugs can be canceled or modified. Allergies can be marked as inaccurate, or narrowed in scope, if the patient had tolerated a related substance. Lab values could be marked as unreliable.

In a currently implemented commercial system, the two response options for this type of alert are *Go Back* and *Proceed,* as in Figure 1. Pre-existing orders (Item A) cannot be modified until the new orders are submitted or cancelled.

Opportunities for error

Tracking Errors: (a) The alert is logged as cancelled, but the user did change their orders. (b) The alert is logged as overridden, but user changed orders in a separate session.

Patient Care Errors: Without the ability to immediately modify Item A, the user is forced to recall the conflict state for later correction. This imposes an unnecessary cognitive workload which is vulnerable to interruption and error.

Hypothesis and implications for future studies

We hypothesize that the ability to change both preexisting and new items when responding to alerts is both desired by clinicians and necessary to reduce errors. To confirm this, alerts of the form "A conflicts with B" will be presented to clinicians who will be asked about their possible responses. Then they will be asked to respond to these alerts while unable to modify any pre-existing items in the same order session.

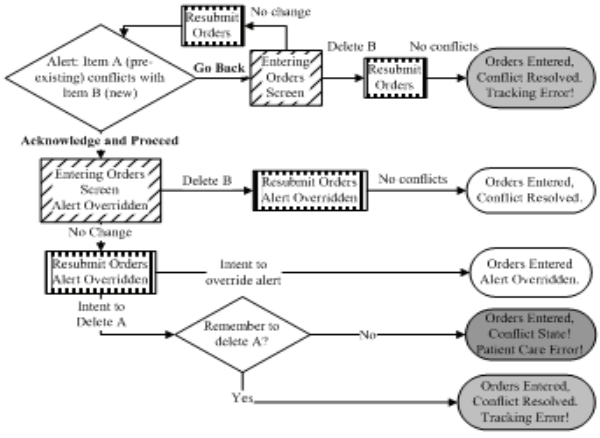

Figure 1 – Alert response task flow

Elements of CPOE Style: A Guide to Formatting Text for Clinician Users

R. Clayton Musser, James E. Tcheng

Department of Medicine & Duke Health Technology Solutions, Duke University, North Carolina, USA

Abstract

We present our methodology for formatting the text of medical information to clinicians in the context of computerized physician/provider order entry (CPOE). Well-formatted text improves usability, and ease of use is not just a nicety: systems that are easy to use will be adopted more readily and, more importantly, will be used more accurately and thus more safely. In our experience of CPOE implementation, text formatting can be most helpful for two key goals: helping the user find the desired information, and adding meaning beyond the literal words. Specific principles are presented here verbally, and visual examples of better and worse text formatting are shown on the poster.

Keywords:

Medical Order Entry Systems, CPOE, Usability

Introduction

Computerized Physician/Provider Order Entry (CPOE) systems have the audacious job of presenting vast amounts of material to clinicians, most of whom experience the volatile combination of being both very busy and under high pressure to perform well and almost all of whom express a desire for more simplicity (e.g. fewer clicks, fewer words). In our experience of CPOE implementation, we have encountered both a general under-appreciation of the importance of carefully crafting the on-screen text encountered by clinician users and a demand for an easy-to-follow style guide for clinical content creation. Here we lay out several design principles which have evolved and proven helpful throughout our CPOE implementation – in all levels of content, from individual orderable items to ordersets to complicated pop-up advisors – and on the poster we display several examples of formatting, both better and worse.

Principles of text formatting in CPOE

Help users find their target

Focus on keyword(s) – Starting each item's name with the key concept maximizes visibility for the scanning user and gives similar items parallel structure.

  Complicated Urinary Tract Infection (Peds)

  AFTER

  Urinary Tract Infection: Complicated (Peds)

- Use standard English conventions and familiar (or at least logical) abbreviations – The need to convey the most meaning in the most concise fashion developed in the paper-based world, but it is arguably even *more* important in the digital one. Ideally, present an abbreviated version to the prescriber (input) but a more explicit version for the nurse (output).

- BEFORE

  6. nurse: complete diabetic flowsheet with each glucose measurement
  + nurse: teach patient and family to check blood sugars, draw insulin, and give insulin
  + teach family signs & symptoms of hypoglycemia, and treatment of hypoglycemia
  + nurse: teach family how to administer intramuscular injection (glucagon prn)

  AFTER

  6. record each glucose measurement on diabetic flowsheet
  + teach checking glucose & giving subq insulin
  + teach s/sx & tx of hypoglycemia & giving im glucagon

- BEFORE

  17. nursing: collect aliquot (10-20 ml) of each void and label with time. if frank hematuria is present, notify h.o.

  AFTER

  17. collect & label aliquot each void; notify if hematuria

- Organize text with concise headers and assure the visual alignment reflects logical hierarchy – Subdivide long lists into logical groups so users can go straight for what they want and be less intimidated along the way. Do not let line-wrapping interfere. Concise use of ALL CAPS helps draw the eyes to important categories.

BETA-BLOCKERS

Increase meaning using visual relationships

- Consistency of format – In some ways, it is more important than the format itself… but "proper" formatting (eliminating typos and adhering to conventions of spelling and grammar) creates the professional appearance clinicians expect and engenders trust in the accuracy of the clinical contents. Note that difference of structure implies difference of meaning, even when there is no such difference.

- BEFORE

RADIOLOGY

18. pediatric general surgery consult

AFTER

CONSULTS
If immunocompromised, allergic & needing alternative antibiotics, comorbid conditions, clinical treatment failure after 48 hrs:
17. pediatric infectious disease consult
If parapneumonic effusion, necrotizing pneumonia, abscess:
18. pediatric general surgery consult

Conclusion

The human eye and mind are remarkably facile at recognizing patterns and inferring meaning from them; in the never-ending quest to make CPOE both faster and safer, optimal formatting of text can help guide them to their targets. Meaning occurs in layers beyond the literal words themselves: how the words are formatted can say as much as the words themselves. The central challenge is balancing the need for clarity (for the sake of quality and accuracy) against the demand for conciseness (for the sake of speed and efficiency); achieving the optimal balance requires an understanding of the information-processing needs of clinicians. Conveying the same information with fewer words (or symbols) improves the signal-to-noise ratio and is thus favorable in almost all cases. Good text formatting can go a long way toward increasing usability, which is a necessary (but not sufficient) step toward craft-

ing information systems than can help meet the many challenges faced by our struggling healthcare system.

Contact R. Clayton Musser at Cay.Musser@Duke.edu.

Elements of CPOE Style: A Guide to Formatting Text for Clinician Users

R. Clayton Musser MD MS
James E. Tcheng MD

Duke University Medical Center
Duke Health Technology Solutions

Setting & Challenge

- CPOE becoming more common → rapidly-increasing prescriber “face-time” with computers
- Increasing recognition of unintended consequences of CPOE (Ash, 2007)
  - More or new work for prescribers
  - Workflow mismatches
  - New kinds of errors
- We believe well-formatted text can → improve usability & ease-of-use

  → improve adoption

  → accuracy → safety

Under-Appreciation of Formatting

- Pressure to install CPOE
  - Basic performance (e.g. software, hardware) & functionality given higher priority
- CPOE often installed/configured by non-prescribers
  → Less familiar with prescribers' mental processes
  - Filtering of information (What needs to be shown? What does NOT need to be shown?)
  - Language / jargon
  - Time pressure / urgency to find information
    - High value of fewer words, fewer clicks
- Lack of style guide

Goals & Principles

- Lofty goals: extra care in text formatting can actually…
  1. Help user find desired information
  2. Add meaning beyond literal words
- Design principles
  - Applicable to all levels of text in CPOE
    - From individual orderables
    - To complicated pop-up advisors
  - Evolved and proven helpful throughout our CPOE experience (Duke Univ. Hospital, North Carolina, USA)

Help User Find Desired Information

- Focus on keywords
  - Favor bringing keyword to the margin
  - Creates natural organization

BEFORE	AFTER
VENTILATOR 8. pc/ps mechanical ventilation + emergency (fio2 100%) backup mechanical ventilation 9. qam compliance study by rt	VENTILATOR 8. mechanical ventilation: pc/ps mode + mechanical ventilation: emergency (fio2 100%) backup 9. compliance study by rt qam
Complicated Urinary Tract Infection (Peds)	Urinary Tract Infection: Complicated (Peds)

Help User Find Desired Information (Cont'd)

- Take advantage of conventions & abbrev'ns
  - Ideal if prescriber can select abbrev'ed version (input) but nurse receives more explicit version (output)
  - As used profusely in written charts (for good reasons, mostly)
  - Choose standard English conventions: avoid IT jargon
  - Choose familiar (or at least logical) abbrev'ns

BEFORE	AFTER
6. nurse: complete diabetic flowsheet with each glucose measurement + nurse: teach patient and family to check blood sugars, draw insulin, and give insulin + teach family signs & symptoms of hypoglycemia, and treatment of hypoglycemia + nurse: teach family how to administer intramuscular injection (glucagon prn)	6. record each glucose measurement on diabetic flowsheet + teach checking glucose & giving subq insulin + teach s/sx & tx of hypoglycemia & giving im glucagon
17. nursing: collect aliquot (10-20 ml) of each void and label with time. if frank hematuria is present, notify h.o.	17. collect & label aliquot each void; notify if hematuria

Help User Find Desired Information (Cont'd)

- Visual alignment must reflect hierarchy of info
  - Essential for quick navigation to information sought
  - Beware line wrapping
  - Assume user looking for visual patterns more than reading literal text
- Organize text with brief headers
  - Concise use of ALL CAPS can help navigation

BEFORE

Nitrates
17. nitroglycerin 2% oint [nitro-bid] topical ntg x28 days off from midnight to 0600
18. nitroglycerin infusion (100mg/250ml) iv cont now x5 days
-titrate
up until chest pain relieved or systolic bp <100 mmhg; requires stepdown status
19. nitroglycerin sublingual [nitrostat] 0.4 mg subling q5mprn prn x28 d for chest pain per chest pain protocol

20. all formulary nitrates >>
BETA-BLOCKERS

Add Meaning Beyond Literal Words

- Consistency of format
  - Different format implies different meaning (even when not true)
  - Internal/local (especially within field of vision) consistency more important than

BEFORE	AFTER
Non-cardiac: 17. cefuroxime inj [zinacef] 50 mg/kg/dose iv q8h x2d + gentamicin inj [garamycin] 3.5 mg/kg/dose iv q24h x99d Cardiac closed chest: 18. cefuroxime inj [zinacef] 50 mg/kg/dose iv q8h x 2 days	Non-cardiac: 17. cefuroxime inj [zinacef] 50 mg/kg/dose iv q8h x2d + gentamicin inj [garamycin] 3.5 mg/kg/dose iv q24h x99d Cardiac closed chest: 18. cefuroxime inj [zinacef] 50 mg/kg/dose iv q8h x2d
RADIOLOGY (if fluctuant) ultrasound of affected area (if history of trauma) plain radiograph	RADIOLOGY (if fluctuant) ultrasound (if history of trauma) plain radiograph
23. expressed breast milk (no adds) po 24. expressed breast milk (with additives)	23. expressed breast milk (no additives) 24. expressed breast milk (with additives)

Add Meaning Beyond Literal Words (Cont'd)

- Structure conveys relationships
  - Similar structure implies similar meaning (thus words are not needed to state the relationship)

BEFORE	AFTER
Consider Pediatric Infectious Diseases consult if: **Immunocompromised patient, alternative antibiotics needed for allergies, comorbid conditions, clinical failure after 48 hrs of treatment** **17. pediatric infectious disease consult** **Consider Pediatric General Surgery consult if:** **Parapneumonic effusion, necrotizing pneumonia, abcess** **18. pediatric general surgery consult**	**CONSULTS** **If immunocompromised, allergic & needing alternative antibiotics, comorbid conditions, clinical treatment failure after 48 hrs:** **17. pediatric infectious disease consult** **If parapneumonic effusion, necrotizing pneumonia, abscess:** **18. pediatric general surgery consult**

Add Meaning Beyond Literal Words (Cont'd)

- Align common text
  - Highlights differences
  - Natural pattern recognition brings the choices into focus

BEFORE	AFTER
1. peds hem-onc admission (if not already done) >> 2. peds line draw (if not already done) 3. enter bsa (if not already done) 4. enter dosing weight (if not already done)	1. (if not already done) peds hem-onc admission >> 2. (if not already done) peds line draw 3. (if not already done) enter bsa 4. (if not already done) enter dosing weight
3. weight: obtain on admission (in kg) 4. weight (kg): estimate only & defer measurement	3. weight (kg): obtain on admission 4. weight (kg): estimate only & defer measurement
43. nutrition consult for evaluation of intake 44. nutrition education consult 45. nutrition evaluation consult	43. nutrition consult: evaluation of intake 44. nutrition consult: education 45. nutrition consult: evaluation

Conclusion

- The human eye and mind can recognize (& infer meaning from) patterns readily. Take advantage of that.
- Present information in the way that it is expected → Less interpretation → Less cognitive load → More safety & satisfaction
- Saying the same thing with fewer words improves signal-to-noise ratio.
- Well-formatted text can make a difference.

SCHOOL OF HEALTH INFORMATION SCIENCES

Background

- **User Interface Engineering (UIE)** is the process of designing the interfaces for the interactions of a human (user) and a machine
- UIE focuses on the way the user inputs and retrieves information, and efficiently navigates the system
- This is the foundation of HCDID
- **Health information management** was a challenge during the **relief efforts** of U.S. hurricanes Katrina and Rita
- Multiple systems, both electronic and paper, were implemented in an effort to collect, distribute and share information about the victims

THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON
SCHOOL OF HEALTH INFORMATION SCIENCES

Background

- The integration of these systems was impossible due to the lack of standards and inconsistencies in the data
- In response to the information challenges, The UT-School of Health Information Sciences developed a web-based system to assist during major Disaster's Relief Efforts: **HIMS-DRE**
- HIMS-DRE allows the creation and use of web-based forms
- An interviewer is the HIMS-DRE user who utilizes such forms to enter data into the system

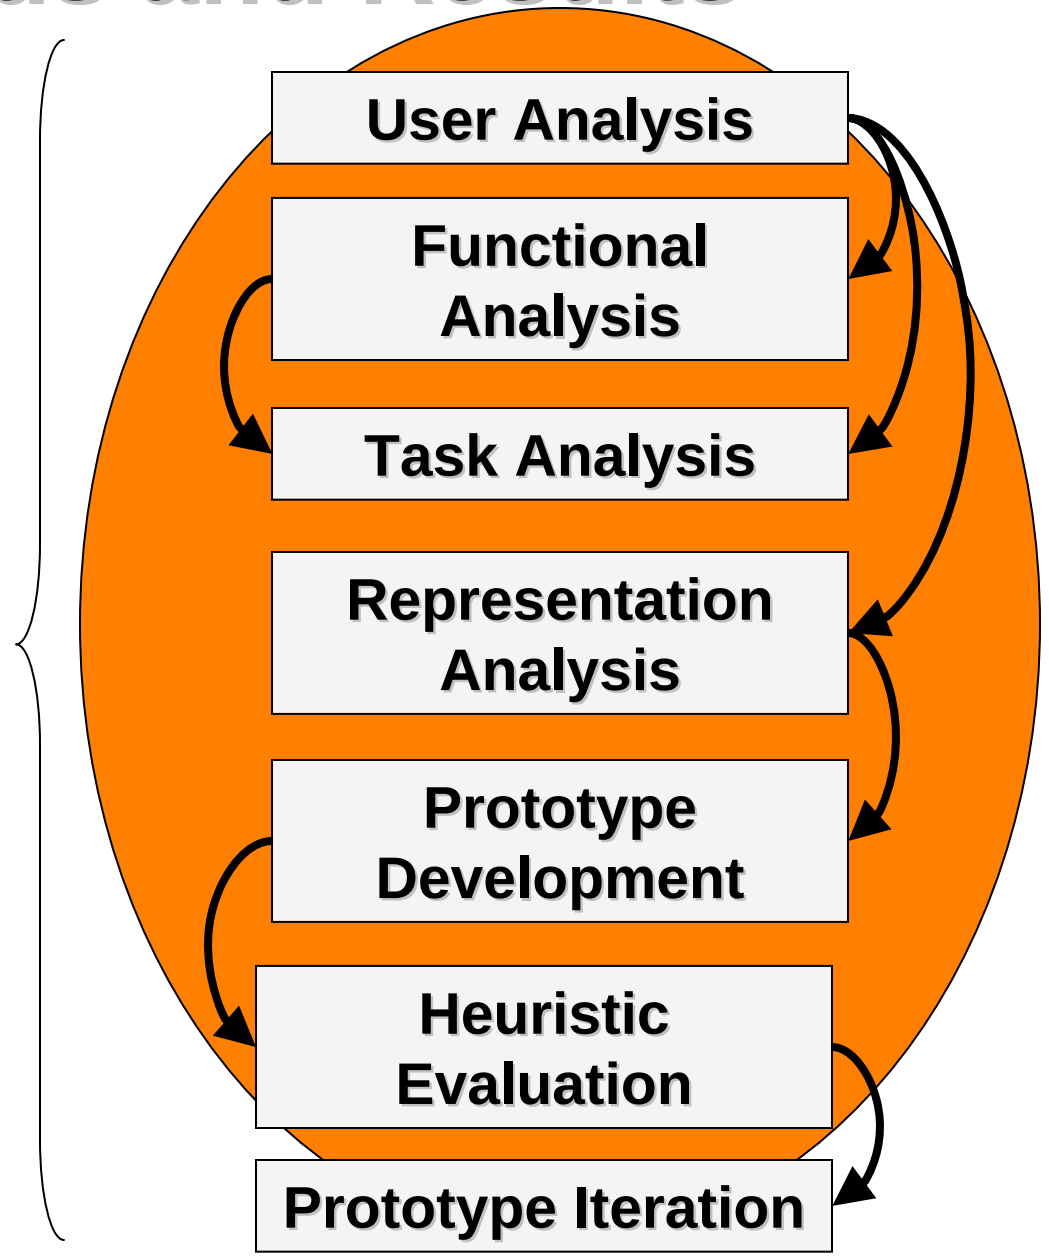
Methods and Results

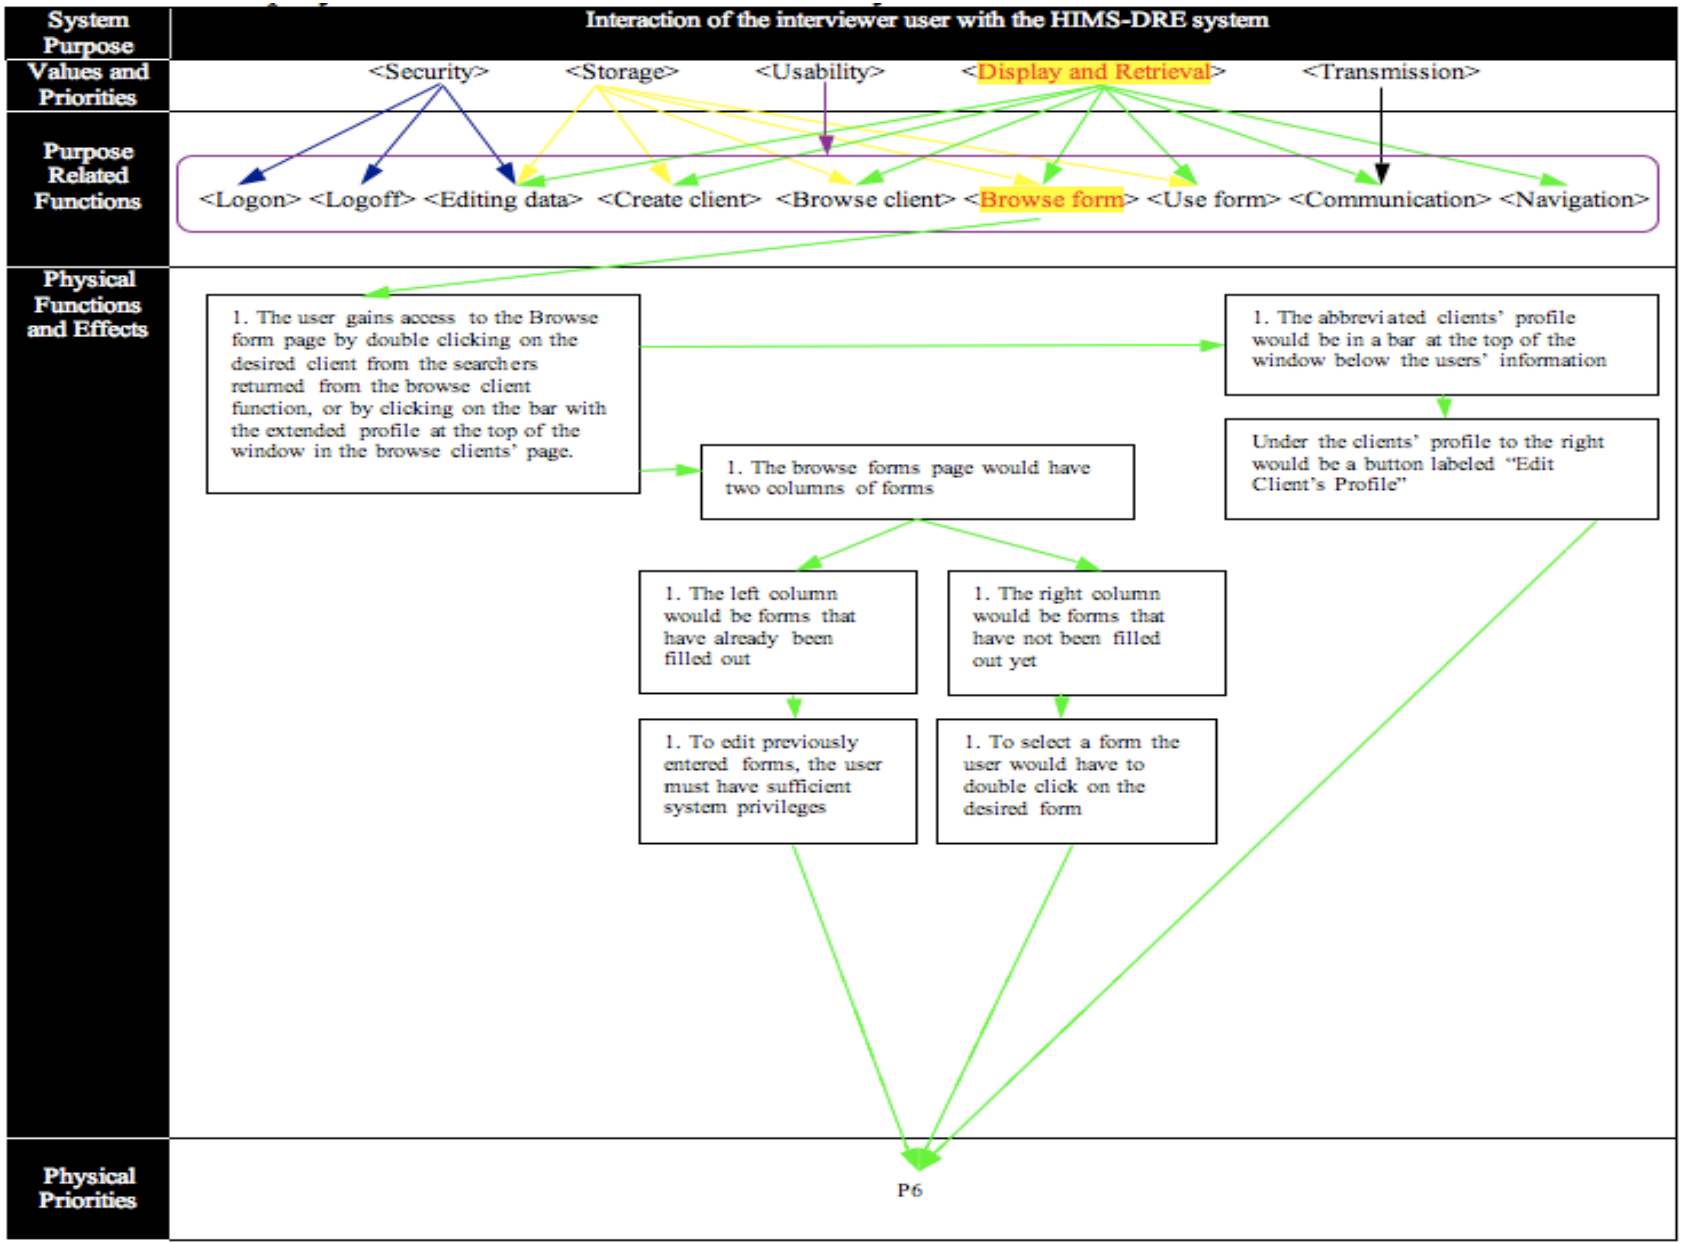
HCDID
Multiple Levels of Analysis



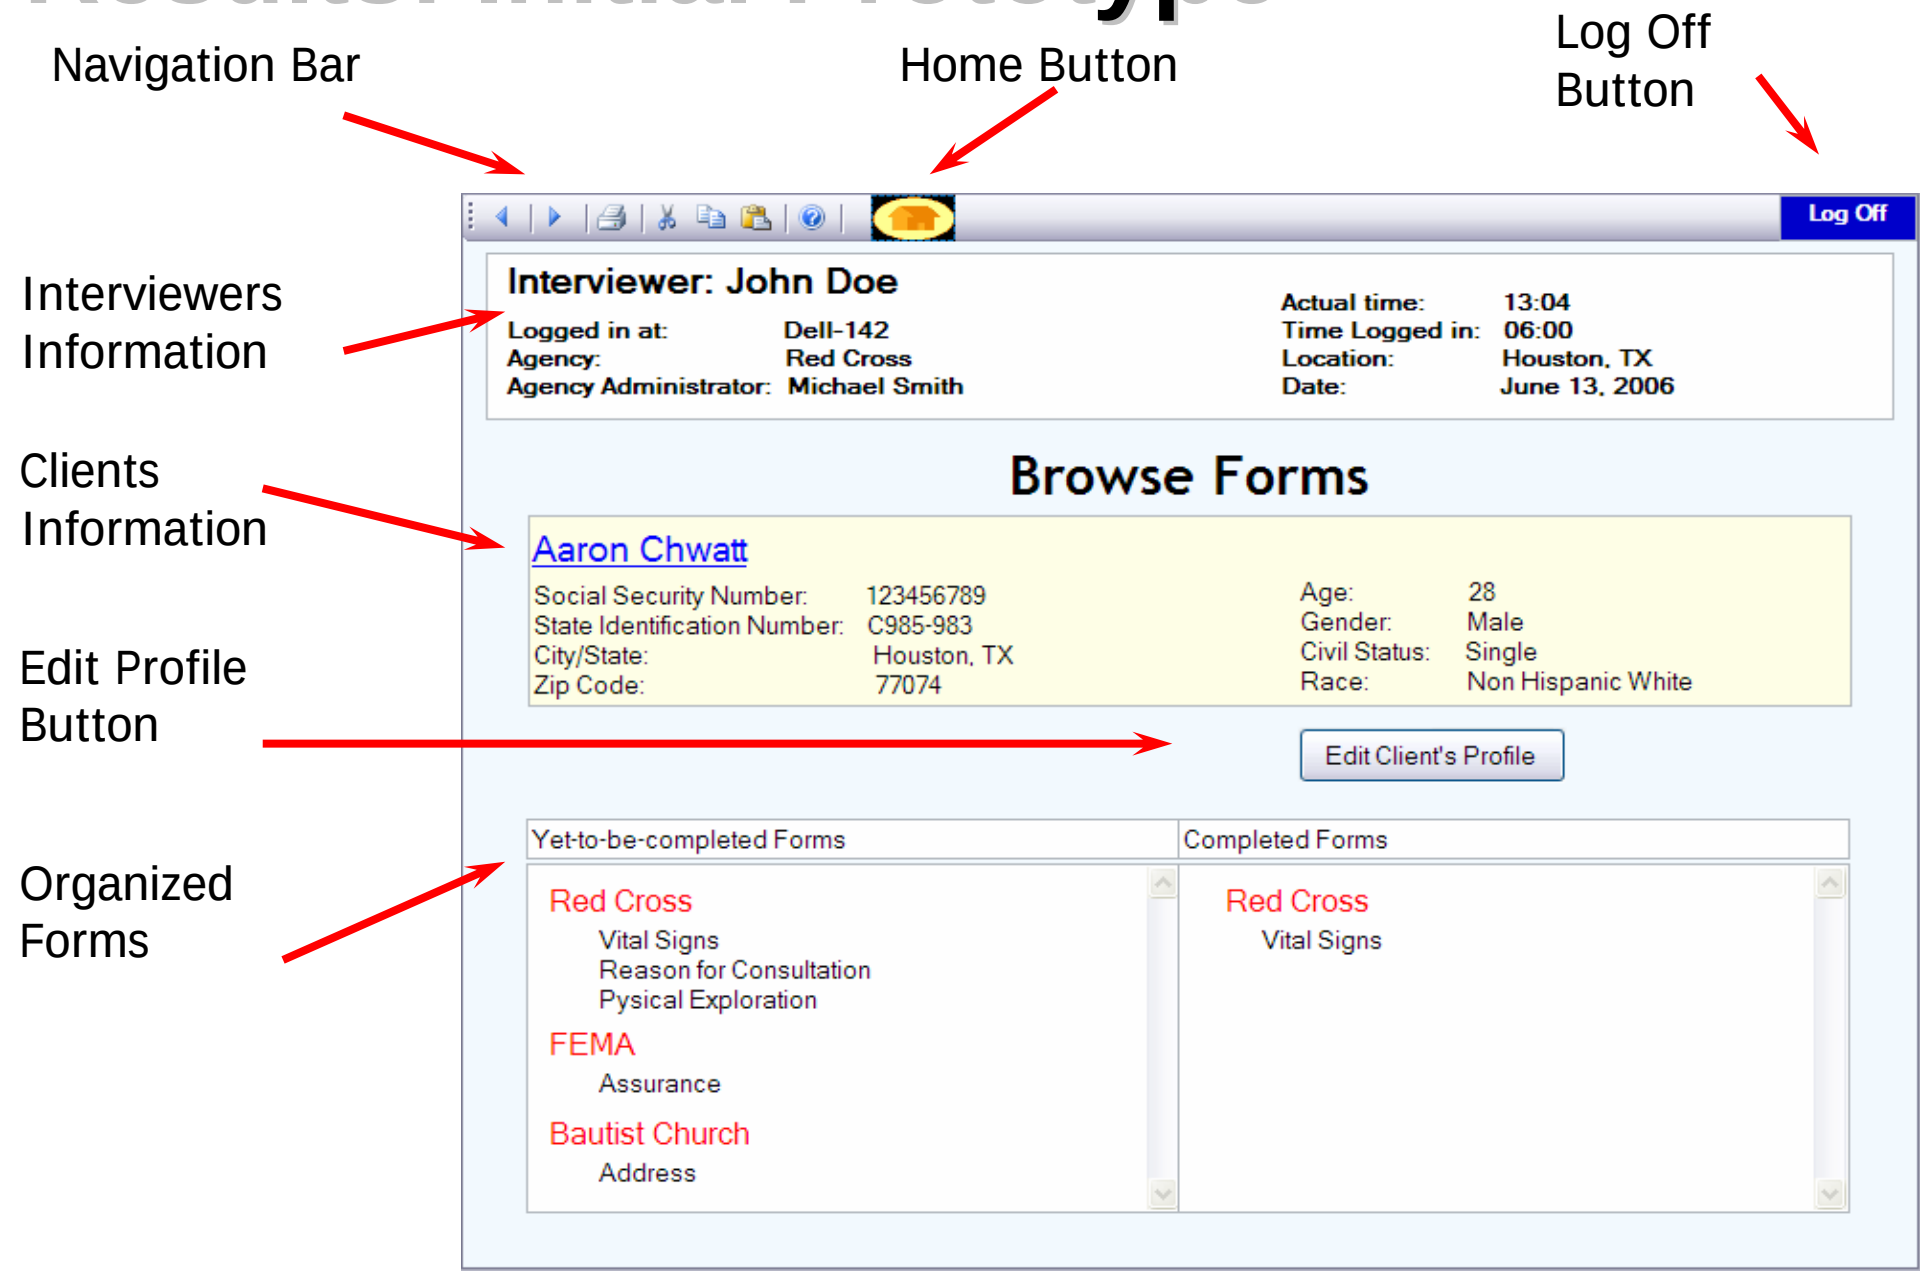
Results: User Analysis

User	Location Profession Life Style	Education	Gender	Expertise	Age	Skills	Physical Abilities
Interviewer	Any	High School at minimum	Either	Basic Word Processing	18 Until not physically able	Interview	Motor control
							Speech
							Vision
						Able to work under pressure	Not depend on medications
							Cognitive awareness
				Basic Web Browsing		Language	Mobility
							Extended time outdoors

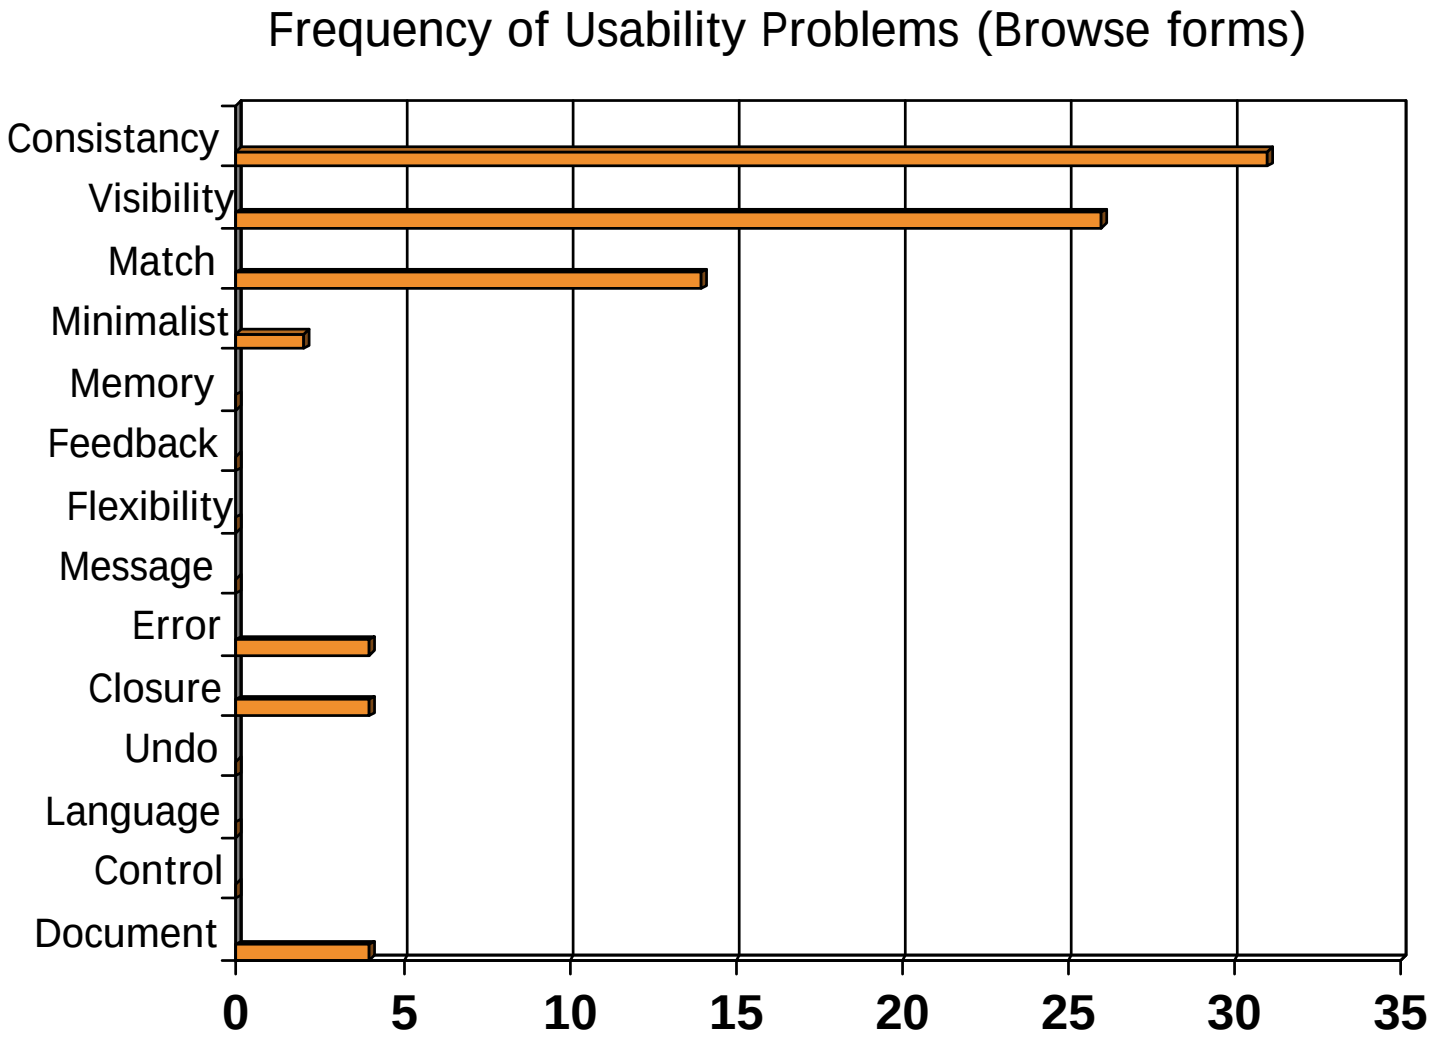
Results: Functional/Task Analysis



Results: Initial Prototype



Results: Usability Violations



Results: Improved Prototype

Notification of Entry to System

Event Name

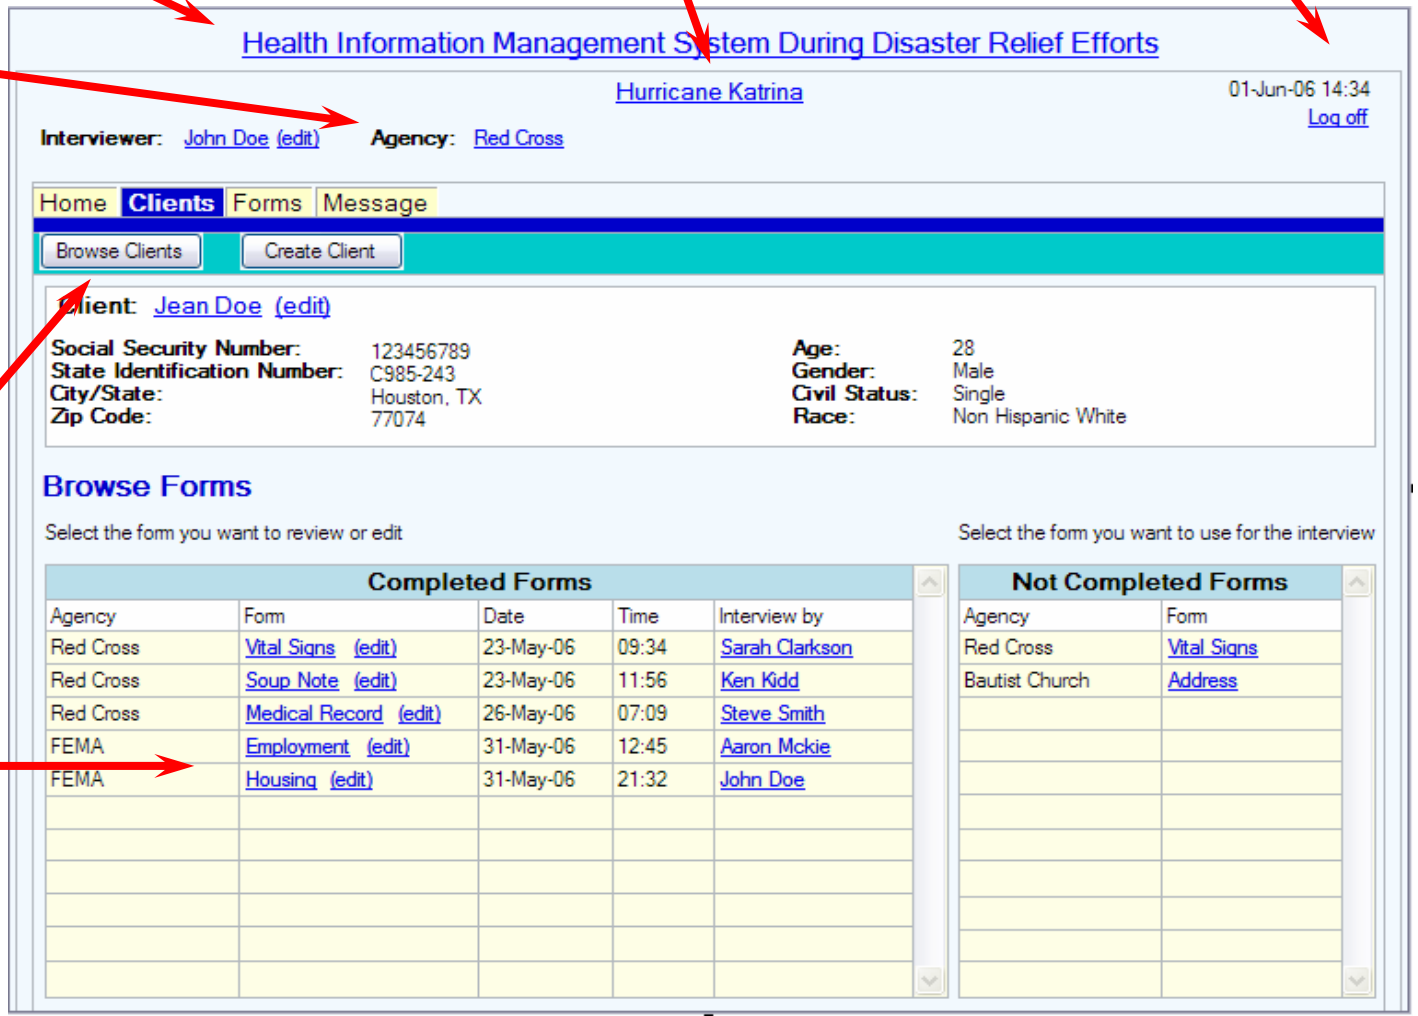
Standardized Dates

Agency Name

Tabbed Browsing

Buttons for Functions

Links for Navigation



THE UNIVERSITY of TEXAS
HEALTH SCIENCE CENTER AT HOUSTON
SCHOOL OF HEALTH INFORMATION SCIENCES

Conclusions

- HCDID was a useful methodology in determining the structure of our user analyses and to construct a framework for our interface development.
- WDA greatly assisted in the interface design process. It helped identify the purpose, priorities, values, functions, and it drew connections between them that facilitated the graphical representation of our interface.
- Heuristics evaluation was an effective and time-efficient method of evaluating user interface prototypes.
- During every step of the design it was important to focus on the users' needs rather than on the system's developers so that the final product would be based on the users.

Abstract and objective

This project used the Human-Centered Distributed Information Design Methodology (HCDID) to develop a series of interfaces for a Health Information Management System. HCDID employs several levels of analysis including an analysis of the user, a functional and task analysis, a representational analysis, then prototype development, a heuristic evaluation, and finally prototype iteration. Based on the user, functional, task and representational analyses, an initial prototype was developed and then evaluated using a heuristics worksheet. Using the information from the heuristic evaluation, an improved prototype was created that addressed the problems of the original prototype. HCDID was an effective methodology for analysis of interfaces of a Health Information Management System. During the design phase, the focus was on the users' needs rather than the system's developers so that the final product would meet the users' requirements.

Keywords:

User interface engineering, health information management, heuristics, work domain analysis

Introduction

This project used the Human-Centered Distributed Information Design Methodology (HCDID) to develop a series of interfaces for a Health Information Management System. HCDID is based on User Interface Engineering (UIE), a process of designing interfaces for human interactions between a human (user) and a machine focusing on the way the user inputs and retrieves information, and how effectively users navigate the system.

Health information management was a challenge during the relief efforts of last year's U.S. Gulf Coast hurricanes Katrina and Rita. Multiple systems, both electronic and paper, were implemented in an effort to collect, distribute and share information about the victims. The integration of these systems failed due to the lack of standards and inconsistencies in data.

In response to the information challenges during the gulf coast disasters, The UT-School of Health Information Sciences developed a web-based system to assist during major disaster's relief efforts, the Health Information Management System -Disaster Relief Efforts. (HIMS-DRE) This HIMS-DRE allows the creation and use of web-based forms by an interviewer, who utilizes them to enter data into the system.

Methods

HCDID employs several levels of analysis including an analysis of the user, a functional and task analysis, a representational analysis, then prototype development, a heuristic evaluation, and finally prototype iteration. [1]

User analysis

User analysis is a method that allowed us to identify and classify the most important attributes of potential users that will directly affect how the user interacts with the system. The information about the users of the system was acquired by performing interviews, site visits, surveys, and a review of the literature. The user's own definition of their role was also an important factor to consider when designing the system.

Functional analysis

We used functional analysis to describe the main user's goals, and task analysis to identify the information, processes, and expected outcomes needed to achieve those goals. We used Work Domain Analysis (WDA) to identify the functional properties of the system.

Representational analysis

We constructed Abstraction Decomposition Maps (ADM) to graphically represent the WDA. The representational analysis consists of a graphical analysis of the interaction between a system and its user, taking into account the previously completed user analysis and the functional and task analysis. Representational analysis also utilizes several design principles including layout, type face, color, language, and structure.

Heuristic evalution

Heuristic Evaluation is a type of usability inspection method in which evaluators examine an interface for usability issues. In our case, three independent users evaluated the user interface using heuristics to identify usability problems, grade the severity of the problems, and propose solutions. There were 14 heuristics in the evalua-

tion including the following: consistency and standards, visibility of system state, match between system and world, minimalist, good error messages, prevent errors, clear closure, and help and documentation.

Results

User analysis

Based on techniques such as job description and interviews with the system's designers we designed a basic profile for the interviewer user. The focus was on several aspects of the interviewer that are flexible and several that have more rigid requirements. The more flexible characteristics of the interviewer user include the user's location, profession, lifestyle, and gender, because these characteristics would have less influence on the user's interaction with the system. Other aspects were less flexible and had more requirements. For example, the education level of the user, a minimum of high school, would have to include basic reading and writing skills. The user's technical expertise would have to consist of at least basic computer use (e.g. word processor and internet browser use) because the interface would have similar features to these programs. The minimum age of the user would be 18 years old age, because some agencies involved in the aftermath of hurricane Katrina, preferred to have volunteers that were older. The upper age limit is not definite because it would depend on the physical and mental abilities needed to complete the tasks required. Being physically and mentally competent means the ability to talk freely without impediment, have no trouble seeing or reading, have motor control of the hands, have the ability to hear without aid, have medications that do not require refrigeration, to work outdoors, and have cognitive awareness. These are all basic factors needed to be able to conduct an interview and interact with the system's interface. It is possible that the user could be of limited mobility, and still be able to perform the tasks, as long as the location allowed the user access. The user would have to possess certain skills, for example, the ability to perform an interview, to work in stressful situations, and be proficient in the victims' language. These skills are important because the user must be able to work in crisis situations. The user would also be required to have affiliation with an organization granted access to the system. These conditions should be considered when looking for qualified users.

Functional/task analysis

We identified several high-level interviewer functions and interaction with the system. Based on the WDA that was conducted, security, storage, display and retrieval, transmission, and usability were priorities because these values were important and they encapsulated all of the tasks that the interviewer-user would perform. These values also influence all of the user's interactions with the system. The purpose-related functions that related to security included logon, logoff, and editing already entered data. These functions would allow structured access and interaction with the system as well as provide a safe environment for both the user and the information that is being stored, displayed, retrieved, and transmitted. The values of storage, display and retrieval share relations with many of the same purpose related functions including browse clients, edit already entered data, create clients, browse forms, and use forms for interview. These functions are the ones that will have the greater impact on how the user interacts with the system. In addition, the display and retrieval values also include the navigation function and shares the communication function with the transmission value. These last two functions are important to the user because they are the functions that provide routing through the system and support for the user when it is needed.

Heuristic analysis and prototype development

Based on the user, functional, task and representational analyses, we developed an initial prototype and then evaluated it using a heuristics worksheet. In just one prototype screen, there were 75 heuristics violations. 14 were minor (0-2 on the rating chart) and 61 were rated as major violations (3-4). We catalogued all of the heuristics evaluations along with information about the description of the problem, the heuristic that was being evaluated, the severity of the problem, and the recommended solution. Using the information gathered, we created an improved prototype that addressed the problems of the original prototype.

Conclusion

We used HCDID based on UIE to develop interfaces of the HIMS-DRE. WDA greatly assisted us in the interface design process. It helped us identify the purpose, priorities, values, functions, and draw connections that facilitated the graphical representation of our interface. Heuristics evaluation was an effective and time-efficient method of evaluating user interface prototypes. During the design phase, we focused on the users' needs rather than the system's developers so that the final product would meet the users' requirements.

Evolving a Second Opinion Software to Web 2.0

Marcello R. Mello[a,b], Magdala A. Novaes[a,c]

[a] *NUTES - Telehealth Center, Federal University of Pernambuco, Brazil*
[b] *Informatics' Center, Federal University of Pernambuco, Brazil*
[c] *Department of Internal Medicine, Federal University of Pernambuco, Brazil*

Abstract

This article describes the evolution needs of a second opinion software (HealthNet), which uses Java language with Web pages. The HealthNet was deployed in April 2004 and only a few clinical cases were started since then. In conclusion, besides the barriers to acquire technology in a poor region of an under development country, cultural barriers have to be undertaken by health professionals and a whole new set of functionalities has to be developed to achieve full potential of the HealthNet. This facts and the approach of the Web 2.0 made a second version necessary using new concepts such as communication and facilitating community.

Keywords:

telemedicine, family practice, medical second opinion

Introduction

HealthNet is a web based information system designed to support the evaluation of clinical cases, family practice professionals and reduce referrals to the Clinics Hospital (HC), of the Federal University of Pernambuco (UFPE), which admits around 1,000 inpatients and provides assistance to 13,000 outpatients per month [1], leading to faster and better care of high complexity level medical cases. Through the HealthNet, health professionals that are located in health basic assistance units can ask for support in diagnosis and therapeutically conducts to health professionals from Reference Centers.

The idea of constructing a Telehealth system occurred in 1999 within the ATM (Asynchronous Transfer Mode) Recife Network Project. From this period until nowadays, some prototypes were developed. Based on these experiences, a review from literature and meetings with health professionals from primary care, the initial requirements of a health information system to support the Family Health Program (FHP, a national program implementing family practice, started in 1994 [2]) in the state of Pernambuco were established and implemented. The first version of HealthNet system was constructed and implanted in Pernambuco Telehealh Network, in Recife city and its metropolitan area, in April 2004.

Despite of the good appearance evaluation made by the users themselves [3], the usability (easiness, errors and flaws) is the worse thing found in the current version of the system, and lacks of a better way of using.

Now, it is possible to improve the use of the HealthNet by making advantage of the Web 2.0 concept and its keywords such as: freeing of data, building of virtual applications, user participative, work for the user, modular, sharing, communication and facilitating community, remix, smart [4].

Materials and methods

HealthNet was constructed with Java language, using Servltes technology and structured in layers. Due to its design, HealthNet can be expanded to support the most of medical specialties. It uses a database server (MySQL), a Web and application server (Tomcat).

After development of the system, Health Units and professionals were recorded. A main telehealth center (NUTES-HC) coordinates the telehealth network maintaining the users' registers (solicitant and consultant), the Health Units and their relationship.

The pilot health areas considered were medical clinic, pediatrics, cardiology and nursing. There were training in the HC with nurses and doctors from this hospital as well as technicians from FHP units that are participating in this project. The technicians are trained in Loco, the doctors and nurses from their localities. After training process, the system was putted under utilization.

Based on a store-and-forward concept the users can type the information in almost any Web browser and it is planned to don't need a broadband connection – it is possible to have good use even with a dial-up connection.

Results

There was observed a low rate of utilization. Since its deployment there were submitted twenty eight clinical cases to be evaluated by specialists. Some factors are highlighted as contributions to this low usage: (i) Health professionals from primary care are not used to electronic information system, this fact can induce resistance to its

usage. Many of them think information systems can overload their already busy work routine. (ii) The nearness of the basic health units and Reference Centers motivate to a non alteration of the leading processes already established for many years. (iii) Fragility of telecommunication infrastructure between FHP units and specialized center. Besides, as part of the evaluation process of the system, there were pointed some functionalities and technological limitation.

Discussion and conclusion

Because of the problems found, planning to overcome the difficulties is to be adopted in a second version. About technological and functionality points, new requirements were identified and the system was redesigned. For the Web 2.0 interface it is intended to permit the development of a wide health cooperation network bringing notorious resources found in communication's software such as Windows Live Messenger [5]. Below are listed some highlights: synchronous (on-line) and asynchronous (off-line) communication; multimedia communication (text, sound and image) allowing users wish association; handling free use of its desktop, dragging components/ services; modular components/services allowing future evolutions without program code need.

The second version of Healthnet is already under development.

"To tell or not to tell?" :Incorporating Disclosure and Privacy Requirements In Web Portal Design for Malaysian Cancer Patients

Nasriah Zakaria

Universiti Sains Malaysia, Penang MALAYSIA

Abstract

Cancer patients need to disclose their health information to their disclosure network: a group of people who patients disclose sensitive health information. The disclosure process can be done using oral as well as communication technologies like telephone and the Internet. In this paper, I propose a research agenda to get requirements from cancer patients and their disclosure network to build a web portal for cancer information management. A web portal is conceptualized as a website set up by healthcare providers whereby patients have the ability to import necessary information (monitored and verified by healthcare providers) from their electronic medical record to disclose information to their disclosure network. Patients need to make active decision who and when to disclose as well the depth and level of information to share with others. This paper will outline the importance of the research, the methodology and expected outcomes from this research.

Keywords:

Web Portal, Disclosure, Privacy, Cancer Information

Introduction: health disclosure

Self-disclosure is defined as "any message about self that one communicates to another" [6]. In this paper, I will use the term self-disclosure and disclosure interchangbly. The topic has attracted scholars from diverse fields – communications, information studies, social psychology, sociology, and psychology. Northouse and Northouse (1998) presented five variables in health communication, where disclosure is one of the central variables that determine the effectiveness of communication. The authors discussed disclosure as a variable since the presence (or absence) of disclosure facilitates (or impedes) effective health communication among patients and medical teams.

Numerous studies have examined disclosure of health information. These studies looked at the content, frequency and consequences of self-disclosure in different medical situations and raised different issues of disclosure, but frequently ignored the balance between disclosure and privacy issues (Cozby, 1973; 17]. Wiener et al. (1996) explored the process of disclosure and consequences among HIV patients and their support network. It examined the caregiver-patient dyad it did not discriminate between the different roles of caregivers during the coping period, thus we are unable to conclude what specific roles are crucial for effective communication with the dyad. Another study [1] explored how family and caregivers cope with cerebral palsy, and found that support network members were dissatisfied with the information disclosure activities. That study also determined that factors such as the age of the child, the timing of diagnosis and the severity of physical disability influenced information disclosure. At the end, the study suggested "best practice" guidelines for disclosing the diagnosis of an illness to the support network. Contro et al. (2002) showed that some family members such as siblings were often not included during the information disclosure process; this in turn caused the siblings to feel "left out" of the coping process.

A few studies pointed out the lack of empirical work in understanding self-disclosure among medical teams and family in chronic illness situations [2, 5]. Families also made it clear that they wanted more information from the medical teams in order to be able to provide the appropriate support for the patient [2,9]. Other recent research on self-disclosure in healthcare examined different situations, contexts and issues as well as the nature of relationships. Topics examined include the process of disclosure (e.g. content and frequency) and its consequences [9], the dyad relationship during disclosure[14,22], practices for disclosing illness [1], disclosure of chronic illnesses [2,5] functional perspectives on health disclosure [7], privacy and disclosure [21], and the influence of illness, relationship and information-seeking on disclosure [4]. Recently, self-disclosure research in healthcare has begun to pay attention to the larger group of people involved in patient care – friends, employers, spiritual groups and self-help groups. Petronio and her colleagues (2004) explored the role of these "informal advocates" by examining the self-disclosure behavior of family and friends when they were present during a patient's visits with the physician and/or medical team.

All the empirical work mentioned above informs the question of self-disclosure in various medical situations. However, it is clear that little work has been done on the disclosure of health information using Information and Communication Technology (ICT) , specifically using web portal. Thus it is a good candidate for exploration using grounded theory, when little is known about a topic.

ICT for health disclosure

There are numerous of health websites resided in the World Wide Web today. Most of them provide health information on specific illness, treatment, drugs and rehabilitation. Websites like WEBMD(http://www.webmd.com/) and Ask Dr. Greene (http://www.drgreene.com/) are moderated by healthcare professionals and they are endorsed as one of the most reliable and trustworthy health websites. There are also many social support type websites that provide emotional support and information sharing among patients and family members. In addition, there are also new research developments for health web portal. There are many different elements that go into the web portal. For an example, a group of researcher designed and developed a diabetes web portal where patients are able to import "diabetes care plan" from their electronic medical record. Patients were able to use this information from the portal to make decisions on their own diabetes care management [8].

The focus of this research is to explore the possibility of using health web portal for health communication. The web portal has to have the ability to import medical record so that patients can use the technology to disclose information to others. The uniqueness of this research is to explore the disclosure and privacy requirements for the web portal design.

The Malaysian Government, under the Multimedia Supercorridor (MSC), has invested billions in ICT infrastructure to support Telehealth(http://www.telehealth.com.my/portals/myhealth/) projects around of the country. One of the main projects is to develop a website called Telehealth to provide credible and trustworthy health information in Malaysia context. The mission of the web portal is to enhance the quality of health among Malaysians. However, there is no cancer-specific web portal has been developed for patient communication. Thus, the outcome of this research can merge with the existing initiatives in MSC.

Methods

There are two stages for this research; the first one is to get the requirements on disclosure and privacy from patients. The technique proposed in this stage is using face to face interviews and grounded theory analysis. In the second stage, I propose to conduct software prototyping to evaluate the usability of such portal. This involves the development of desired prototype and a think aloud technique to capture user satisfaction on using the prototype.

Stage 1: interview with patients

An interview is defined as a construction of knowledge [10] or as a "purposeful conversation, usually between two people but sometimes involving more" [13, page 93]. "Purposeful conversation" here means that interviewers have chosen a specific topic that both interviewer and interviewee can explore and discuss at length. An interview is a tool with which to elicit information from a participant, to find out his or her perceptions, meanings and construct of reality [16]; its purpose is to gather what people say about their perceptions, feelings and behaviors.; its purpose is to gather what people say about their perceptions, feelings and behaviors.

As part of my preparation, I reviewed literature pertaining to conducting interviews. From several previous research projects, I had prior experience conducting interviews with patients, family members and medical personnel in a hospital setting as well as with undergraduate students and these experiences enhanced my confidence in my ability to conduct interview-based research.

This study employed face-to-face semi-structured interviews. Interviews will be conducted wherever the subject feels comfortable. With the subject's permission, I will record the interview session using an audiotape recorder. If respondent refuse to be taped, I will take notes during the interview.

Interview protocol

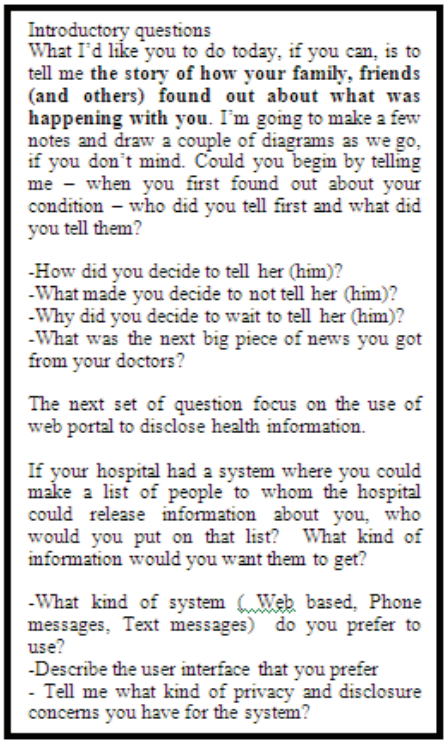
I have developed an interview protocol to start up interviews with cancer patients. I designed a protocol with a background question that asks patient's disclosure behavior when dealing with cancer. Then, I created some questions to elicit the requirements for the future web portal (Figure 1). These questions will be modified based on the feedback by the subjects.

Sampling

Research subjects comprised of medical patients in Malaysia. I will select patient with any types of cancer illness. I chose cancer illness because it is one of the leading illness in Malaysia [11]. The annual incidence of cancer was 30,000 in the year of 2000. Cancer illness has a predictable prognosis where patients have some flexibility in planning either their treatment, recovery or facing end of life situations. With this existing factual in Malaysia, it is appropriate to explore how to build a cancer specific web portal for cancer patients and their disclosure network.

Research subjects will be selected using a convenient snowball-sampling technique. The technique is convenient in the sense that respondents are recruited based on whoever who meet the criteria and was available for the interview. Using the snowball sampling technique, I will identify research volunteers based on others' recommendations [3]. Many patients who would have been reluctant to discuss their illness with a stranger were more open and willing to talk when approached by someone with whom they were comfortable. A snowball-sampling technique

takes advantage of the natural human tendency to extend trust through social relationships, since the interviewer is implicitly endorsed as trustworthy by the participant who provides the referral.



Introductory questions
What I'd like you to do today, if you can, is to tell me **the story of how your family, friends (and others) found out about what was happening with you**. I'm going to make a few notes and draw a couple of diagrams as we go, if you don't mind. Could you begin by telling me – when you first found out about your condition – who did you tell first and what did you tell them?

-How did you decide to tell her (him)?
-What made you decide to not tell her (him)?
-Why did you decide to wait to tell her (him)?
-What was the next big piece of news you got from your doctors?

The next set of question focus on the use of web portal to disclose health information.

If your hospital had a system where you could make a list of people to whom the hospital could release information about you, who would you put on that list? What kind of information would you want them to get?

-What kind of system (Web based, Phone messages, Text messages) do you prefer to use?
-Describe the user interface that you prefer
- Tell me what kind of privacy and disclosure concerns you have for the system?

Figure 1 - Interview protocol

Data analysis

Grounded Theory is a qualitative data analysis technique that serves several purposes [20, page 24]: immersion in the real world situation to gain a deeper understanding of the research phenomena, formation of a theoretical framework that arises from the data itself, and comprehension of the process of change in real situations.

Analysis and coding will begin as soon as the first interview ends and continues until the last interview is completed and coded. Grounded theory recommends that data analysis take place in parallel with data collection [12] so that the researcher is able to make ongoing adjustments to the existing data collection process. For example, analysis of subjects' responses in the first few interviews may suggest new dimensions and directions for subsequent interviews. Ongoing data analysis in parallel with data collection also encourages the early discovery of new insights rather than waiting until the end of the entire data collection process.

Stage 2 study

In the second phase, the main research goal is to expose users to a web portal prototype and to evaluate user acceptance. The focus will be on user interface for the portal where I will explore factors that influence patient to use web portal to disclose sensitive information. Since there is no specific web portal exists yet for patient to communicate and disclose sensitive information with their disclosure network, I would like to employ a socio-engineering approach. With this approach, I will develop a software prototype and refine the design iteratively by incorporating end user needs at every stage. An adaptation of a software engineering approach called rapid software prototyping [19] will be applied to my socio-engineering nature of work.

In creating a "universal" web portal that could be used by patients all over the world, no single theory that can inform the best web portal design for disclosure activities. This is because there are many technological, human, situational and institutional factors that could influence the final product. It is a very complex design and development process to create a "one for all" system, thus a qualitative combined with rapid software prototyping approach seem to be most suitable way to proceed. In this optimization approach, researcher will try to maximize the user acceptance into system design and development. The end goal of this research is to develop an appropriate ICT innovation that could enhance social interaction among cancer patients and their disclosure network. This ICT innovation could also be incorporated in the existing telehealth system in Malaysia.

Using the rapid software prototyping approach, the main research activity is to create an artifact based on a rough approximation. The artifact will be tested and refined according to user feedback. For my research problem, I will develop the first version of the web portal using the effective web design guide. In each stage or version, I will carefully observe and document users' perception on multiple outcome variables like sense of privacy, usefulness and ease of use of the web portal. One possible way to capture users' perceptions is by using a "think aloud" technique. We can also use a technique called "aggregation" to quantify the system outcome. After each data collection, I will incorporate the users' suggestions and make necessary changes in next version of the program. I will then repeat the data collection process with end users until I find their suggestions reach saturation. I will need to observe all the outcome variables over time. The proposed duration of this prototyping process is between six to nine months. The key of this methodology is the iterative refinement process based on users' needs when they want to disclose sensitive health information over the web portal.

Expected outcomes

This research will be conducted over the duration of 24 months beginning of January 2007. It is fully funded by the Malaysia Cancer Council (MAKNA) as part of its annual cancer research award. The expected outcomes are the following:

1. a list of requirements addressing the disclosure and privacy concerns on cancer-specific web portal.
2. a web portal prototyping processes with user feed-back.
3. a well developed web portal prototype.

Acknowledgement

This research work is funded by Malaysia Cancer Council (MAKNA) to facilitate the understanding of health communication through the use web portal among cancer patients and their network in Malaysia. I would also like to acknowledge Dr. Jeffrey Stanton from School of Information Studies, Syracuse University for his guidance in Information Privacy issues in health care setting.

Using An Electronic Prescribing Tool As a System for Chronic Disease Management

Laurel Taylor [a], Sara Ahmed [a], Lise Poissant [a], David Buckeridge [a], Gillian Bartlett [a], Nancy Winslade [a], Yuko Kawasumi [a], Roland Grad [b], Martin Dawes [b], Pierre Ernst [c], Allen Huang[c], Robyn Tamblyn[a]

[b] *Dept of Family Medicine, McGill University, Montreal, Canada*
[c] *McGill University Health Centre, Montreal, Canada*

Abstract

Electronic prescribing tools are gaining popularity because they promote best prescribing practices. We have previously shown that the MOXXI electronic prescribing solution is used frequently to help manage patients with complex medication problems. We have now begun to investigate the utility of using the MOXXI system to improve management of asthma in the primary care setting. If a decision support system targeted at improving chronic disease management is to be effective, it must be used often. In addition to traditional clinician user feedback we discovered that the analysis of system audit trails yielded information useful in modeling physicians' behaviours and contributed to improved software design. We have implemented these improvements and await observational data.

Keywords:

electronic prescribing, medical informatics applications, computer assisted decision-making, disease management

Introduction

Clinical software that is well designed and integrated into the clinical workflow along with providing relevant recommendations has the best chance of being frequently used. The Medical Office of the XXIst century (MOXXI) project is an electronic prescribing solution that was developed for use by primary care physicians in community-based practice. In previous work [1] we showed that this system is preferentially used by busy clinicians to manage their complex cases. Our group has now focused on asthma management since it is a chronic condition with substantial morbidity, involves significant healthcare costs, and has effective therapeutic options that can reduce those costs if disease management is optimized. Our objectives were to determine if computerized decision-support and timely home-monitoring of asthma severity that are integrated into the MOXXI system can improve asthma management and treatment outcomes for those patients.

Methods

A new custom-designed module was integrated into the MOXXI system to provide recommendations and action plans to optimize care for patients older than 5-years with asthma. Clinical content was based on the Canadian Asthma management guidelines. Information relevant to asthma control were presented and treatment options were directly integrated into the electronic prescription tool. During the iteration of the module design we analyzed the system audit trails and discovered that certain fields or screens were avoided. This information, along with feedback from test physicians resulted in a greatly improved module design that is now deployed among 85 family physicians in Montreal and Quebec City.

Conclusion

Consistent use of information technologies in primary care leads to an opportunity to assist in the optimal management of chronic diseases. We are exploring the utility of using an electronic prescribing solution to improve management of asthma in primary care. Future candidate conditions include: hypertension, diabetes, and cardiovascular diseases. The eventual addition of lab results management to this system would create a 'light' electronic medical record, with perhaps similar impacts on quality of care improvements as hospital-based clinical information systems.

Tracking Children for the Newborn Hearing Screening in Northern Germany

Roland Linder[a], Josef Ingenerf[a], Alexander Katalinic[b], Ute Thyen[c], Rainer Schönweiler[d]

[a] *Institute of Medical Informatics, University of Lübeck, Germany*
[b] *Institute of Social Medicine, University of Lübeck, Germany*
[c] *Clinic of Pediatrics , University of Lübeck, Germany*
[d] *Department of Phoniatrics & Pediatric Audiology, University of Lübeck, Germany*

Abstract and objective

The Newborn Hearing Screening (NHS) in Schleswig-Holstein (northern Germany) covers about 23,000 newborns a year. In Germany NHS has not yet become "universal" for the state but has voluntary activities in many of its federal countries, predominately based on private sponsorship. In Schleswig-Holstein, a multidisciplinary screening program ("UNHS-SH") was started in December of 2003 involving the departments of pediatric audiology, otolaryngology, pediatrics, obstretrics, social medicine, education, medical informatics, and a quality management group supported by the Schleswig-Holstein-division of the German Medical Association. We aimed to fulfil all claims of the international consensus in regard of screening procedures, quality management, tracking, follow-up, and timing. All of the 28 birth hospitals participate in the screening. In 2005, the mean participation rate was 81.6 %, while seven hospitals reached over 90 %. Lost to follow-up was 1.5% and 16 hard hearing newborns (of the statistically expected 23) were discovered by the UNHS-SH. UNHS-SH shows that an internet tracking with intensive feedback to screeners and parents is a candidate to overcome the potential drawbacks of a voluntary screening.

Keywords:

tracking, newborn hearing screening, hardness of Hearing

Introduction

As a voluntary approach, an Universal Newborn Hearing Screening was started in Schleswig-Holstein (northern Germany) in December 2003 ("UNHS-SH"). The multidisciplinary screening program is arranged in a highly multidisciplinary fashion including the departments of pediatric audiology, otolaryngology, pediatrics, social medicine, or medical informatics. Currently UNHS-SH serves for approximately 23,000 newborns a year in Schleswig-Holstein, further federal countries are joining.

Methods

Healthy newborns are screened bilaterally with a two-step-screening (otoacoustic emissions; OAE) and newborns at risk bilaterally with a one-step-screening (automated auditory brainstem response; AABR). If necessary, an immediate follow-up is performed in the university hospitals (Fig. 1).

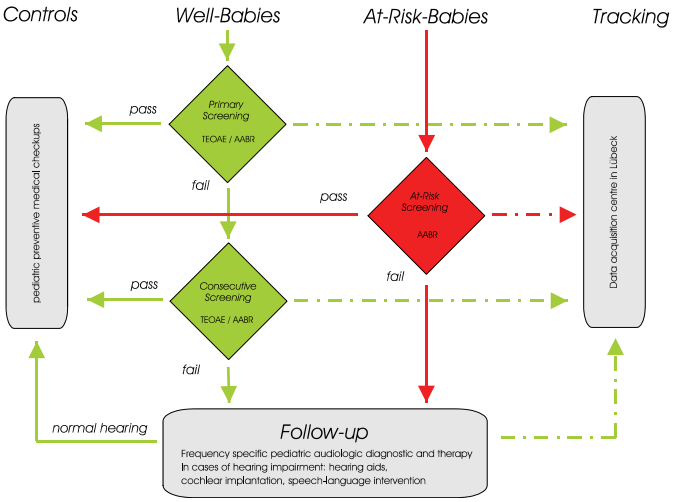

Figure 1 - Timing chart of the UNHS-SH: At-Risk-Babies are obligatory screened using AABR technique. Well-Babies undergo a primary screening (mostly by OAE) and if necessary a consecutive screening.

Results are noted in paediatric development protocol and also send to the data acquisition centre in Lübeck via the internet or email-attachment using special software for data acquisition (Fig. 2).

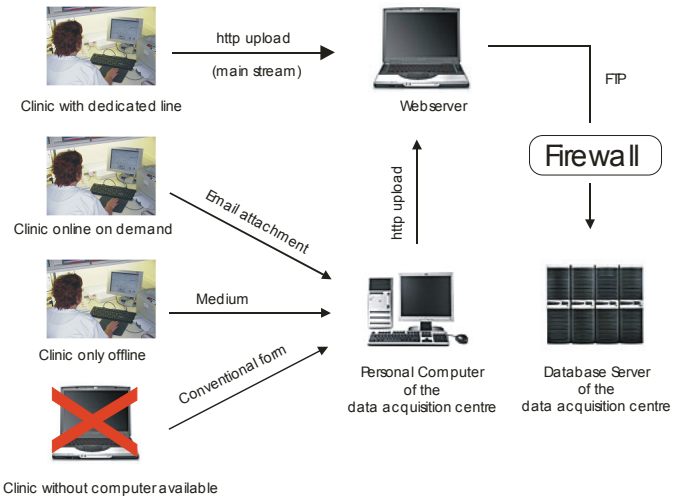

Figure 2 - Data flow of the UNHS-SH: Data are mainly transferred using http upload but some nurses have no access to the internet

Needs for 2nd step screenings or a follow-up are automatically recognized by the software in the data acquisition centre in Lübeck. Parents are then informed by automatically generated letters (up to three times if necessary, afterwards telephone call). If they changed their addresses, local authorities are involved to find them. The tracking software used supports the above mentioned activities by providing to-do lists (Fig. 3).

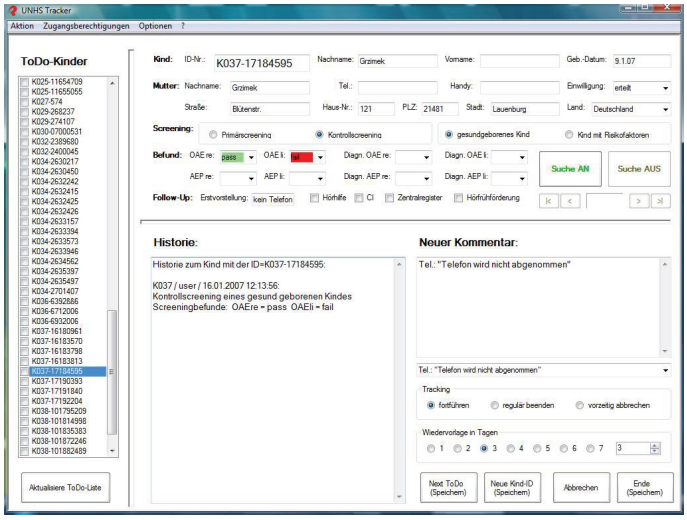

Figure 3 - Screenshot of the tracking software. Picking a child of the to-do list on the left hand side displays all corresponding information like address data or history. Dummy patient

Moreover, the tracking software provides statistics as a feedback to the institutions involved. The statistics comprise rates as demonstrated in Tab. 1.

Rate	Meaning
Acquisition rate	Ratio of registered babies relating to total number of newborns
Screening rate	How many % of the registered babies have been screened in hospital?
Consent rate	How many % of the parents have given their consent for tracking?
Fail rate	How many % of the screened babies have been considered „fail“?

Table 1 - Some of the statistics provided by the tracking software of the UNHS-SH

Results

All of the 28 birth hospitals participate in the screening, while the biggest 25 hospitals participate in the tracking and three smaller ones are prepared to join soon. In 2005, the mean rate was 81.6 %, while seven hospitals reached over 90 %. All hospitals and practitioners are periodically informed about their statistics compared to the other in order to keep their motivation. In case of a rate below 60 %, a mobile service gives an on-site training session. In 2005, lost to follow-up was 1.5 % and 16 hard hearing newborns (of the statistically expected 23) were discovered by the UNHS-SH and fitted with hearing aids beyond the age of nine months (six months desired, of course).

Discussion and conclusion

In Germany, a voluntary screening instead of an obligate is going to be installed nationwide. Thus, acquisition rates and lost-to-follow up rates are problematic issues. The UNHS in northern Germany shows that a far-reaching automatic internet tracking with intensive feedback to screeners and parents is a candidate to overcome the potential drawbacks of a voluntary screening. Thus the UNHS-SH approach might be suited for other countries building up a NHS of their own.

UI Improvement Plan by Analyzing User Requirements at NICU for OCS in Korea - Focused on Laboratory Information System at Asan Medical Center in Seoul

[a] Nam-Hyun Kim [b] Keun-Ae Cho

[a] *Dept. of Medical Informatics, PhD.,University of Yonsei, Republic of Korea*
[b] *Dept. of Medical Informatics, M,S. in Information System.,University of Yonsei, Republic of Korea*

Abstract and objective

This study examines a way to improve UI by analyzing on-the-spot user's requirements, By making surveys and interviews with medical staffs at NICU and by my personal experience learned from using the Laboratory Information System while working at NICU for A general hospital Asan Medical Center in Korea. This study analyzes user's requirements on Laboratory Information System and seeks to improve UI of Laboratory Information System. Accordingly, this study aims for the current NICU users to perform NICU businesses easy and convenient, by redesigning display screen and procedure on Laboratory Information System of OCS. In addition, this study will further help achieve improvements of work environments for medical staffs and improvements of OCS efficiency.

Keywords:

OCS, user interface, LIS, NICU

Methods

User interface (UI) improvement plan is made reflecting user's requirements at NICU in a hospital, centered on Laboratory information system, in designing the actual display screen of OCS. This study examines a way to improve UI by analyzing on-the-spot user's requirements, By making surveys and interviews with medical staffs at NICU and by my personal experience learned from using the Laboratory Information System while working at NICU for A general hospital Asan Medical Center in Korea.

Results

This study re-composed a next generation OCS User Interface plan based on NICU (Neonatal Intensive Care Unit) User' s requirements From investigation results analysis on Laboratory Information System and improved User Interface of Laboratory Information System

Conclusion

Laboratory Information System from Order Communication System (OCS) is a computer system that is built for laboratory information processing. Laboratory Information System exists as a sub system of hospital information system or exists as an independent system. However, although it exists under the sub system of hospital information system, it has a high rate of use and has the largest volume of information in a hospital, except for image information.

However, according to the previous studies, database construction and studies on OCS medication information are done and made, But database construction and studies on Laboratory Information System are rare. In fact, Laboratory Information System is built based on clinical pathologic tests. However, it is believed that necessary measures need to be taken to reduce nurse's jobs according to doctor's order from a variety of actual clinical tests such as cranial nerve center test, radiation test, digestive organ center test, cardiac center test, nuclear medicine test, and respirator lab test.

This study analyzes user's requirements on Laboratory Information System and seeks to improve UI of Laboratory Information System. Accordingly, this study aims for the current NICU users to perform NICU businesses easy and convenient, by redesigning display screen and procedure on Laboratory Information System of OCS. Abstract

This study examines a way to improve UI by analyzing on-the-spot user's requirements, By making surveys and interviews with medical staffs at NICU and by my personal experience learned from using the Laboratory Information System while working at NICU for A general hospital Asan Medical Center in Korea.

This study analyzes user's requirements on Laboratory Information System and seeks to improve UI of Laboratory Information System. Accordingly, this study aims for the current NICU users to perform NICU businesses easy and convenient, by redesigning display screen and procedure on Laboratory Information System of OCS.

In addition, this study will further help achieve improvements of work environments for medical staffs and improvements of OCS efficiency.

Keywords[1]: OCS, User Interface, LIS, NICU

Introduction - (1)

Laboratory Information System from Order Communication System (OCS) is a computer system that is built for laboratory information processing.

Laboratory Information System exists as a sub system of hospital information system or exists as an independent system.

However, although it exists under the sub system of hospital information system, it has a high rate of use and has the largest volume of information in a hospital, except for image information.

Introduction – (2)

However, according to the previous studies, database construction and studies on OCS medication information are done and made, But database construction and studies on Laboratory Information System are rare.

In fact, Laboratory Information System is built based on clinical pathologic tests. However, it is believed that necessary measures need to be taken to reduce nurse's jobs according to doctor's order from a variety of actual clinical tests such as cranial nerve center test, radiation test, digestive organ center test, cardiac center test, nuclear medicine test, and respirator lab test.

Methods

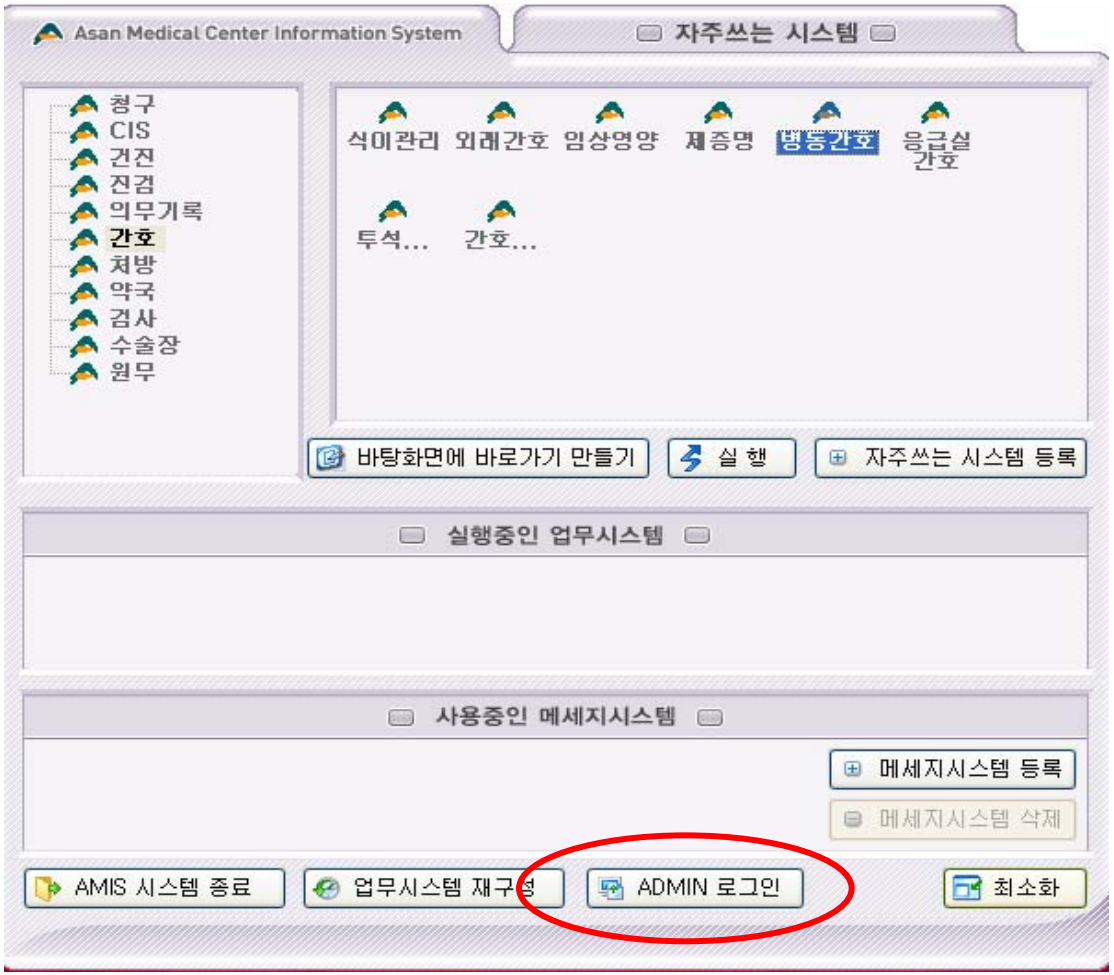
User Interface (UI) improvement plan is made reflecting user's requirements at NICU in a hospital, centered on Laboratory information system, in designing the actual display screen of OCS.

This study examines a way to improve UI by analyzing on-the-spot user's requirements, By making surveys and interviews with medical staffs at NICU and by my personal experience learned from using the Laboratory Information System while working at NICU for A general hospital Asan Medical Center in Korea.

Results - (1)

This study re-composed a next generation OCS User Interface plan based on NICU (Neonatal Intensive Care Unit) User' s requirements From investigation results analysis on Laboratory Information System and improved User Interface of Laboratory Information System

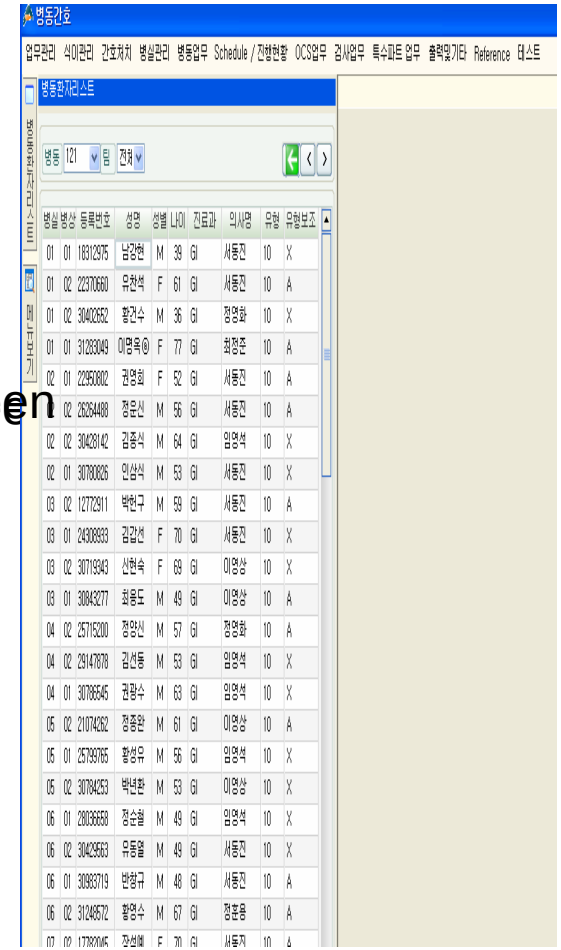
Results - (2)



The next generation OCS program which is 2005 May opened project of the Seoul subject matter A general hospital the user to existing login did in multi branch program and it did information confirmation, but from next generation OCS all programs at one login to integrate the screen which it does at one and to the program which the user in that writes frequently and [to seem system registration which it writes frequently] to register only necessary program in order to come, it planned.

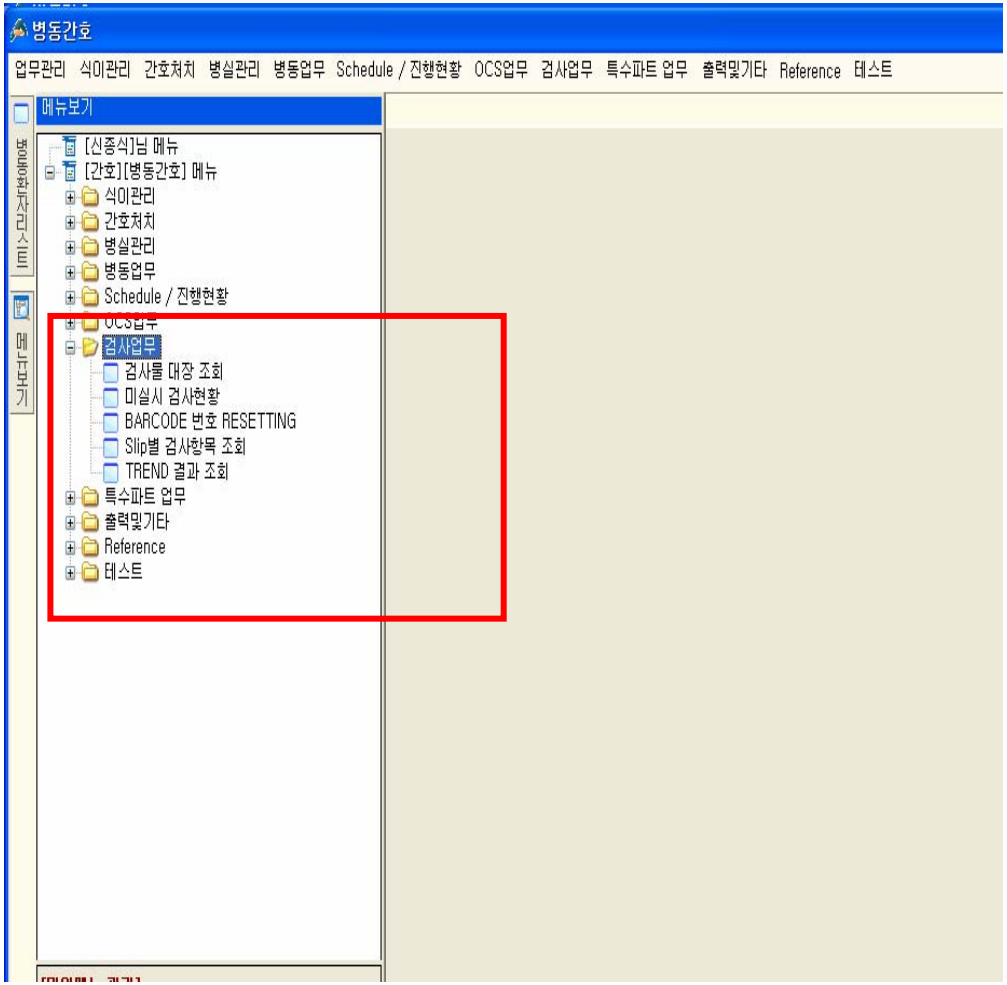
Results - (3)

Click the screen magnification



From the interface position of User Interface the ward patient list comes to seem has the Sub menu from existing OCS program to do, it is not and to do it is inconvenient, from next generation OCS in the left side the ward patient list is fixed in Tab height type and menu and click it appears and to do it disappears. When click it does and the patient list is expanded and there is a possibility of seeing information which is detailed against the patient. From program of existing registration number of the hazard patient who sees different information tie Ping there is a day when it does by the hand but it means like that day will lose from next generation OCS program.

Results - (4)

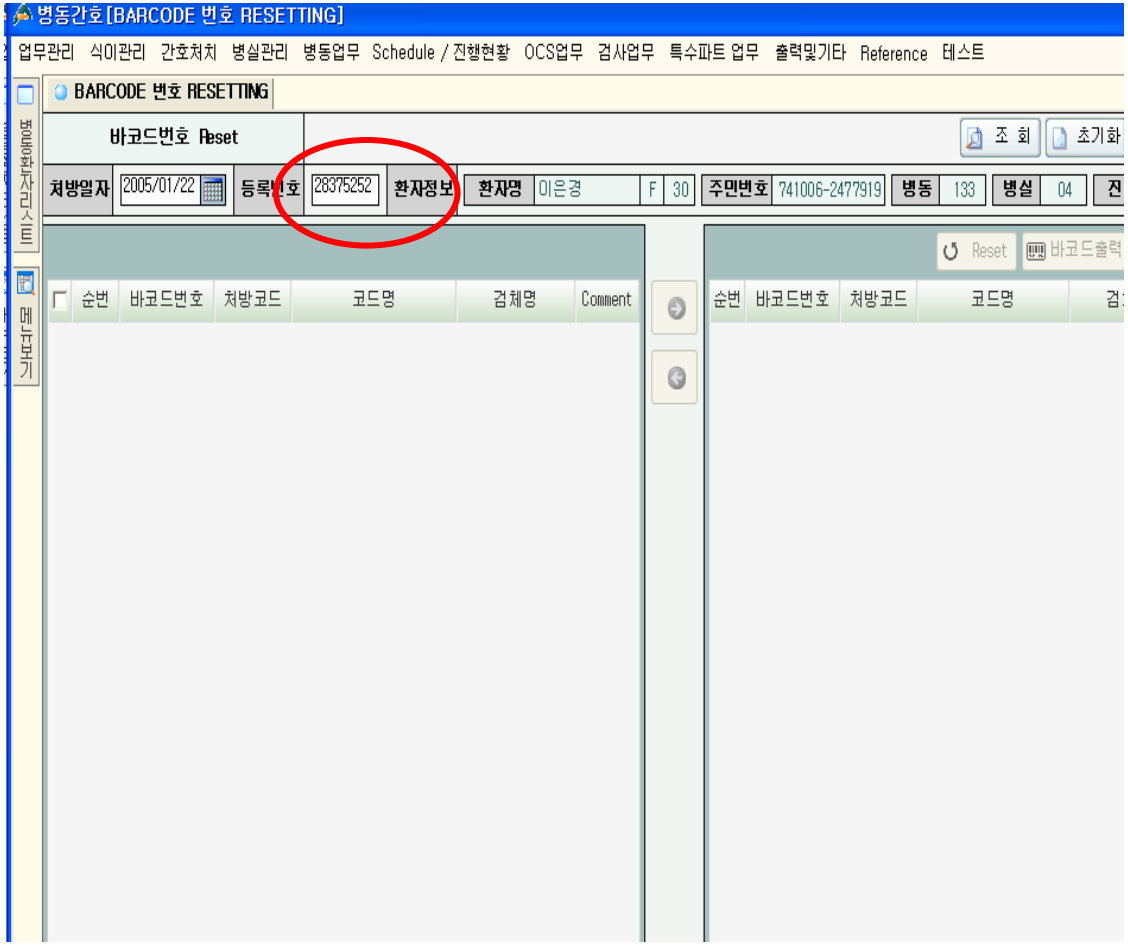


It considers that interface of User, the menu of Tab type it sees in that interface concept and the left side of User of width portion, it established, design it did that interface of User of length concept. User it will be able to select the interface which is convenient from that position in order, the menu which menu control chart oneself to do writes plentifully selection it will be able to manage in order.

Results - (5)

From laboratory Information System at the diagnosis test is named frequently with the L30, L32 , the possibility of seeing all items from more in order to be, Slip test item inquiry it planned the screen

Results - (6)



With program of existing differently by the hand tie Ping or it copied a patient registration number from the different place and it attached and a patient license number without and rightly percentage necessity ward patient list after click it had the possibility of coming in order to be, it planned.

Discussion and Conclusion

This study analyzes user's requirements on Laboratory Information System and seeks to improve UI of Laboratory Information System. Accordingly, this study aims for the current NICU users to perform NICU businesses easy and convenient, by redesigning display screen and procedure on Laboratory Information System of OCS. In addition, this study will further help achieve improvements of work environments for medical staffs and improvements of OCS efficiency.

Open Source Patient Data Management System for Intensive Care

Massaut J, Reper P, Hooghe L, Gottignies P

Surgical Intensive Care, Brugmann Hospital, Université Libre de Bruxelles

Abstract and objective

In Intensive Care Units, the amount of data to be processed for patients care, the turn over of the patients, the necessity for reliability and for review processes indicate the use of Patient Data Management System (PDMS). To respond to the needs of a Surgical Intensive Care Unit, we developed a PDMS based on open source software and components.

The software was designed as a client–server architecture running on the Linux operating system and powered by the PostgreSQl data base system. The client software was developed in C. The application offers the following functions: medical notes captures, observations and treatments, nursing charts with administration of medications and scoring systems functionalities. The PDMS was used to care more than two thousands patients with the expected reliability and functionalities.

Key words:

database management system, software, intensive care

Introduction

Patient Data Management Systems are mandatory in Intensive Care Unit in response to the amount of data to be processed, the turn over of the patients and the necessity for reliability and review processes. Open Source Software (OSS) by publishing source code allows sharing of software resources and experience. To respond to the needs of our unit and benefit of resources from OSS we developed a PDMS based on open source software and components.

Methods

The software was designed as a client-server architecture running on the Linux operating system (SUSE Linux Enterprise Server 8.0). It uses the PostgreSQL relational database (v 7.2). The client software was developed in C using the GTK interface library. Remote access from remote PCs is implemented by virtual network connections (VNC) : the use of VNC servers on linux servers and VNC viewers on Windows PCs.

The hardware consists in two Intel x86 servers with uninterrupted power supply, one master and one slave to assure the integrity of the database by replication, 14 medical grade panel PCs (Advantek PPC-153m) connected via RS232 medical bus to the patient's monitoring devices and to the servers via dedicated local Intranet network. The master server runs the postgreSQL database, the client-software and the VNC servers. The slave server is used for replication of the database by drdb (Distributed Replicated Block Device). The 14 medical grade panel PCs run the client software at the bedsides and acquire data from the monitoring devices.

The software, developed in C on the Linux platform, offers the following functions:

1. Medical notes captures with patient's history, observations and treatments,
2. Nursing charts for vital signs, IN-OUT balance, ventilation parameters and settings,
3. Functionalities for administration of medications,
4. Scoring system possibilities for patient's classification. (APACHE II, SAPS II, SOFA scores).
5. Reporting at the end of hospitalization in Intensive Care.

Interoperability between these modules is realized through access to the PostgreSQL database and not the use of local memory in the interface. The software was developed to be open source in all its components and is interfaced with Open Office for reporting..

Results

The PDMS was used in our unit from February 2004 for the care of more than two thousands patients. The system is accessible at every bed through panel PCs and at desks or offices through VNC viewers on windows PCs. Its design allowed an access to the database's functionalities with a high availability level (less than 5 hours of interruption over one year).

The use of open source resources was effective to customize the solution to ICU's request and contributed to the acceptability of the software. The use of the C language permitted to obtain small response times but limits the portability of the system and complicated the debugging process in this critical environment. For that reason, Valgrind software was used to systematically track runtimes errors. As pointed before, the system was well accepted locally, but was harder to interface with the information system of the hospital. The PostgreSQL data base largely

contributed to the overall efficacy and robustness of the system.

Discussion

We developed the present software to respond to the needs of our surgical unit, with the hope that this will enhance quality in our unit. In a review of Clinical Informatics in Critical Care, G. Daniel Martich describes several reasons to implement information system in intensive care.[1] The first one is that information systems could reduce medical errors and first of all medications errors. The second reason is that information overload is present at point of care in intensive care units. Clinical informatics at the bedside can help to better manage this load. Other reasons are described like necessity to achieve and assess compliance to guidelines and accreditation rules.

We decided to base our development work on OSS for tree main reasons, first to benefit of the large OSS library and resources, second to avoid to be locked into proprietary software and third to be able to adapt the software to the manual procedures preexisting in our unit. Economical reasons were also present. These reasons are similar to that described by Douglas Carnal. That author described in 2000 that open collaboration over the internet is changing development methods and that OSS will be a significant part of the Medical Software's Future. [2]

Intensive care environments require systems with high availability. The system described here was able to respond to these requirements by the use of dedicated and duplicated servers and the use of dedicated local network for communication between bedside Panel PCs and servers.

Software development and testing for Intensive Care need to achieve high reliability. The C language used to develop the software is unfortunately not by itself a safe language. For that reason, we systematically tested the software with Valgrind, a suite of simulation based debugging and profiling tools, to track run-time errors. The uses of static analysis of the C code with tools like Splint [3] early in the development process and before compilation, or the use of safer languages like Ada or SparkAda [4] are however a better solutions and are used to develop secure systems.

The lack of module specifically designed to communicate with other medical software and applications is a limitation of the system. Development of a communication module with ProGen/HL7 library (an implementation of HL7 in C++) or with Mirth (implemented in java 1.5) would greatly facilitate the integration of the PDMS with other medical software and the hospital's information system.

Conclusion

PDMS based on open source software components are effective and able to respond to the needs of the ICU environment, with a high availability level. The use of OSS allowed us to customize the software to the preexisting organization of the unit and contributed to the acceptability of the whole system. Better integration in the hospital's information system necessitates development of a module specifically designed to communicate with other medical software and applications.

Development of Case-based Medication Alerting and Recommender System:A New Approach to Prevention for Medication Error

Kengo Miyo[a], Yuki S. Nittami[a], Yoichiro Kitagawa[a], Kazuhiko Ohe[a]

[a] *Department of Planning, Information and Management, the University of Tokyo Hospital, Japan*

Abstract

The purpose of this study was to develop a new alerting and recommender system for preventing medication errors. In recent years, alerting systems have been widely implemented, but because these systems apply a same static threshold for all patients in all cases, they produce excessive alerts and subject physicians to "alert fatigue". We believe that the most commonly-written prescription for a patient's status is the safest one. From this standpoint, we developed a real-time case-based medication alerting and recommender system linked to a database of past prescriptions. When a physician issues his or her prescription, our system dynamically compares it with past ones for similar patients in the database. An analysis of the 10 most frequently-used drugs in the University of Tokyo Hospital revealed that our system reduced the number of false alerts compared to the traditional static alert method. Our system contributes to the creation of alerts that are appropriate for patients' clinical conditions and based on physicians' empirical discretion.

Keywords:

case-based alerting; decision support systems, clinical; medical order entry systems; medication errors; prescriptions, drug

Background

In recent years, computerized physician order entry (CPOE) systems have been introduced to health care institutions worldwide [1, 2]. In Japan, the use of CPOE systems for medication has become widespread [3], and their implementation rate in hospitals with 500 or more beds was 70% as of 2005 [4]. The use of CPOE system is expected to contribute to efficient health care delivery and reduce physicians' time costs [1, 3, 5].

CPOE systems also contribute to improvements in health care quality, particularly in regard to safety [6–8]. To decrease errors in medical treatments, several systems with real-time data input checks have been developed, for example, to detect inappropriate dosages or drug combinations. In these systems, as soon as a physician clicks the "issue prescription" button, the system compares input data on dose regimen and concomitant drugs to data on dosage limitations and contraindicated drugs stored in a master table file. If the prescription contains inappropriate data, the system displays an alert. Alert systems that use static threshold data stored in a master table file are called *static alert systems.*

Although static alert systems are generally useful, excessive alerts can be produced because the systems check off patient status and treatment policies. Excessive alerts cause physicians to pay less attention to the alerts [9], which then lose their effectiveness. In other words, the few important alerts are overlooked amid a lot of meaningless ones. Peterson et al. described physicians in this situation as being in a state of "alert fatigue" [7, 10]. Particularly in university hospitals, where doctors treat many patients whose cases run counter to standard treatment, the risk of overlooking alerts cannot be ignored.

Physicians need to receive appropriate alerts. In this paper, the term *appropriate alert* refers not to an alert generated based on whether the data match standards determined by drug notes, but rather to an alert generated based on whether the present treatment differs greatly from actual treatment records. Our purpose in this paper is to suggest a new approach for generating appropriate prescription alerts. We believe that most commonly written prescription is the safest one, and we considered past records stored in HIS as the gold standard. From this standpoint, we developed a real-time case-based system that alerts physicians when their prescription deviates from this gold standard.

System design

System structure

The overview of our system is shown in Figure 1. The system consists of existing HIS and a database of past prescription records, as well as an alert engine. MySQL version 5.0 was chosen as the database for our system. All prescription data from the University of Tokyo Hospital (UTH) for 2000 through 2005 were extracted from HIS and stored in the database. For the alert engine, both Perl version 5.8, PHP version 5.1, and Apache version 2.0 were used.

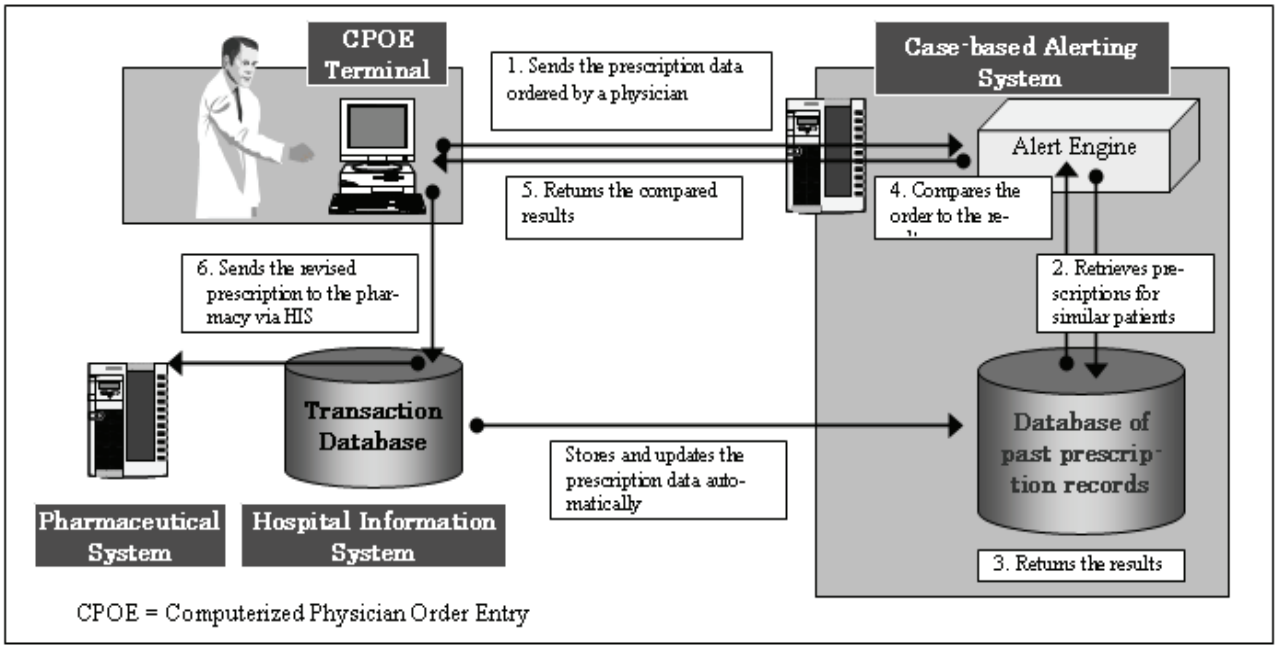

Figure 1- The structure and workflow of the case-based alert system

System feature

Our system has two major functions: alert function and decision support.

Alert function

The alert engine receives the prescription data entered by a physician before sending them to the pharmaceutical system. The alert engine compares these data to the statistical data for that same drug, compiled from past records in the database. If the alert engine finds that the entered data exceed the threshold described below, it sends an on-screen alert to the physician. Figure 2 presents an example of such a prescription alert. At present, the items that can trigger an alert are dosage, dose regimen, duration of drug administration, and concomitant drugs.

Figure 2 - A pop-up alert on the computerized physician's order entry terminal

Statistical data on past prescriptions (such as 95th percentile and standard deviation) serve as the alert threshold. Prescription data in the database are also linked to the patient in question and to his or her diseases. Therefore, the alert thresholds classified according to clinical department (specialty), disease, sex, and age can be also used.

Decision support function

The recommendation function shown in Figure 3 is used when a physician wants to know the appropriate dosage and duration of drug administration. This function pro-

vides the most frequently used value by analyzing a distribution of values of past records. The physician can reexamine his or her prescription with these recommendations in mind. As in the case of the alert function, the recommendation function takes the patient's attributes into consideration.

Interim system evaluation

The final evaluation of our system should be done by physicians who actually use it. The present system, however, is still in the prototype phase. Therefore, we here clarify some interesting aspects of our method by comparing it to traditional static alert systems. We used data on dosage for the evaluation.

Figure 3 - The window of the recommendation function

Evaluation method

We used the September 2006 the UTH prescription records for the system evaluation. We compared cases using our method to those using information about dosage limitation provided by drug notes. The alert function of our system used two thresholds. One was the 95th percentile threshold of each drug, and the other was the mean + 2. We analyzed the 10 most frequently prescribed drugs at the UTH.

Evaluation results

Results are shown in Table 1. Under both the mean + 2 and the 95th percentile thresholds, we found that the number of alerts declined for nearly one-third of the drugs compared to the existing static alert method. However, because the value of the mean + 2 for prednisolone is lower than the value described in the drug note, the number of alerts increased. The reason is that the range of prescribed dosages of prednisolone is broad (i.e., the maximum prescribed dosage was up to 120 mg, whereas the values of prescribed dosages were concentrated around 5 and 10 mg). Thus, our research showed that our system, based on physicians' empirical discretion, set different thresholds than the existing static alert methods.

Discussion

System evaluation

One advantage of our method is that the number of alerts distinctly decreased from that produced by traditional static alert methods because unlike these traditional methods, our thresholds have upper values (e.g., for drugs with high variance of dosage). Loxoprofen sodium and amlodipine are good examples. In the case of prednisolone and aspirin, the mean + 2 thresholds were lower than those described in the drug notes, which caused the increase in alerts. It is critical to warn physicians when they are about to prescribe drug dosages that they do not often prescribe, even if that dosage is within the normal range described in a drug note. This is another advantage of our case-based method. It is one of our key future tasks to determine which threshold to use: mean + 2 or 95th percentile.

Another advantage of our method is that it can issue alerts differently for each clinical department. Prednisolone, whose dosage varies greatly among departments, is a good example. Applying a threshold across the board as traditional methods do results in the production of unnecessary alerts in certain departments. Our system, however, avoids

this issue by issuing alerts based on department features, and on values such as disease, sex, and age, even for one drug. This ensures that alerts are appropriate for each patient's clinical conditions.

Although our system is in the prototype stage at present, we will start actual operation in 2007 and survey physicians' prescribing behavior and degree of satisfaction.

Availability of case-based approach

Master table maintenance is unnecessary

The traditional method, which keeps static descriptions of dosage limit and contraindicated drugs in master tables, requires a huge amount of work to maintain these tables. Our system, however, requires less maintenance because information on dosage limit and contraindicated drugs is dynamically created using already stored data. In addition, our method keeps up with medical advances. When dose regimens change, our method automatically updates the alert thresholds and consequently can issue alerts based on the current prescription trends.

Oriented to physicians' experiences

Our system promises to clarify various dose regimens in a way that is consistent with physicians' empirical discretion. By using past records, our system can alert physicians to drug combinations not empirically prescribed, even if the drugs are not described in drug notes as being contraindicated. In addition, our system can present information about recommended concomitant drugs, similar to the way interns receive advice from supervisors.

Drug	Total number of orders	Threshold from drug note	# of alerts	$M + 2\sigma$*	# of alerts	95th percentile*	# of alerts
Teprenone	3424	150 mg	14	202.3 mg	0	150 mg	14
Loxoprofen Sodium	2623	180 mg	27	244.8 mg	5	240 mg	5
Brotizolam	2666	0.25 mg	460	0.485 mg	447	0.5 mg	1
Famotidine	2238	40 mg	3	51.2 mg	3	40 mg	3
Prednisolone	2110	60 mg	32	41.9 mg	77	40 mg	77
Rebamipide	2094	300 mg	12	398 mg	12	300 mg	12
Amlodipine	1915	5 mg	392	10.2 mg	2	10 mg	2
Aspirin	1950	300 mg	0	125 mg	24	100 mg	24
Sennoside A·B	1820	48 mg	26	47.2 mg	154	48 mg	26
Mecobalamin	1849	1500 μg	1	1815 μg	1	1500 μg	1

*The system issues an alert when the dosage is greater than this value.

Table 1 - Results of interim evaluation

Possibility of graded alert

Our method provides distributions of various parameters such as dosage and dose period. As a result, our system can present graded alerts, such as 1: attention, 2: warning, and 3: prohibited. Gradings of how extensively prescription data diverge from past records enable the physician to quickly decide whether he or she should heed the message.

Limitations of our system

One limitation of our system is that it does not function well with an insufficient amount of past data. For drugs on which a hospital has few or no past records, it is necessary to combine our method with other existing techniques. Small hospitals that do not have a sufficient number of past records must import prescription data from authorized large-scale hospitals. Using data from other hospitals is equivalent to asking "In your hospital, how is this drug commonly used?"

Future direction

The alert and recommendation function can also be applied to laboratory test and radiological records. We are now considering how to make the system available for other medical practices.

Conclusions

We developed a real-time case-based medication alert system that alerts physicians when a prescription deviates from similar commonly written prescriptions in a database of stored records. We set past records stored in HIS as the gold standard. An analysis of the 10 most frequently prescribed drugs at the UTH revealed that our system reduced the number of unnecessary alerts compared to the traditional static alert method. Our easy-to-maintain system

creates alerts appropriate for patients' clinical conditions and alerts based on physicians' empirical discretion. In addition, it can provide more appropriate alerts than traditional methods, and as a result, will contribute to the prevention of errors in medical treatments.

Developing A Paper-Based Surviving Sepsis Campaign Guidelines Compliance Support and Outcome Predicted System

Ying-Che Huang[ab], Wen-Hsien Tseng[a], Polun Chang[a]

[a] *Institute of Health Informatics and Decision Making, National Yang-Ming University, Taipei, Taiwan*
[b] *Department of Anesthesiology and Critical Care, Veteran General Hospital Taipei, Taiwan*

Abstract

In 2003, 11 international organizations had a consensus committee created and published an evidence-based guidelines - Surviving Sepsis Campaign (SSC) guidelines- for the management of severe sepsis and septic shock.

Keywords:

sepsis, outcome, artificial neural network, intensive care Uuit, decision support system

Introduction

In 2003, 11 international organizations had a consensus committee created and published an evidence-based guidelines -Surviving Sepsis Campaign (SSC) guidelines- for the management of severe sepsis and septic shock. SSC had provided tools and website to help interested hospital and teams to improve to meet the standard care outlined in the guidelines. Meanwhile the product of computer industry, such like IBM® CDI (clinical decision intelligence) system, had tried to provide different solution. These methods are not fitted to every situation, either cost too much time (to audit whole care procedure) or too much money (to integrate the whole hospital computer system) and they also lacked for outcome (mortality) prediction system. Trying to resolve above problems, we have developed a Surviving Sepsis Campaign Guidelines Compliance Support and Outcome Predicted System especially for an Intensive Care Units (ICU) that has basic bedside monitoring machines but lacked for integrated clinical information system (CIS) and still paper-based working.

Method

A 22 beds surgical ICU, lacking for integrated clinical information system, still uses paper-based method to collect patient data. First step we transformed Surviving Sepsis Campaign guidelines into one-page document. There are checkboxes on this document represented the data we want to collect for helping treating the sepsis patient. This document will be scanned later in our OMR (Optical Mark Recognition) system. In second step we developed OMR system included three primary modules which are "Document Positioning Generator (DPG)", "Guideline Document Recognition Engine (GDRE)", and "Correction and Statistic Tools (CST)". The output of our system is in XML-format which makes the data easily transferable to customize designed SCC guidelines rule engine based decision support system. In the same time, XML-format data would be randomly allocated to either the training or validation set for constructing and validating artificial neural network (ANN) using a back-propagation algorithm which will be used to predict patient's outcome. (Figure 1 demonstrated our system architecture)

Results

Our results can be divided into three parts. First part is about error rate of document recognition. The error rate in preliminary study is 0.19% (1 error in 531 scanned checkboxes), after changing automatic scan documents to scan document one by one, the error rate can be reduced to 0.057%(1 error in 1754 scanned checkboxes). Second part is the raise of the rate that adherence to guideline-based care, from 25% to 54% (immediate adherence rate). The third part is mortality prediction. After collecting enough case number (near 200 cases), the prediction result will gain soon.

For the cost issue, the whole system hardware cost less than 6,000 US dollars. Compared to build integrated clinical information system in studied ICU, it cost more than 600,000 US dollars.

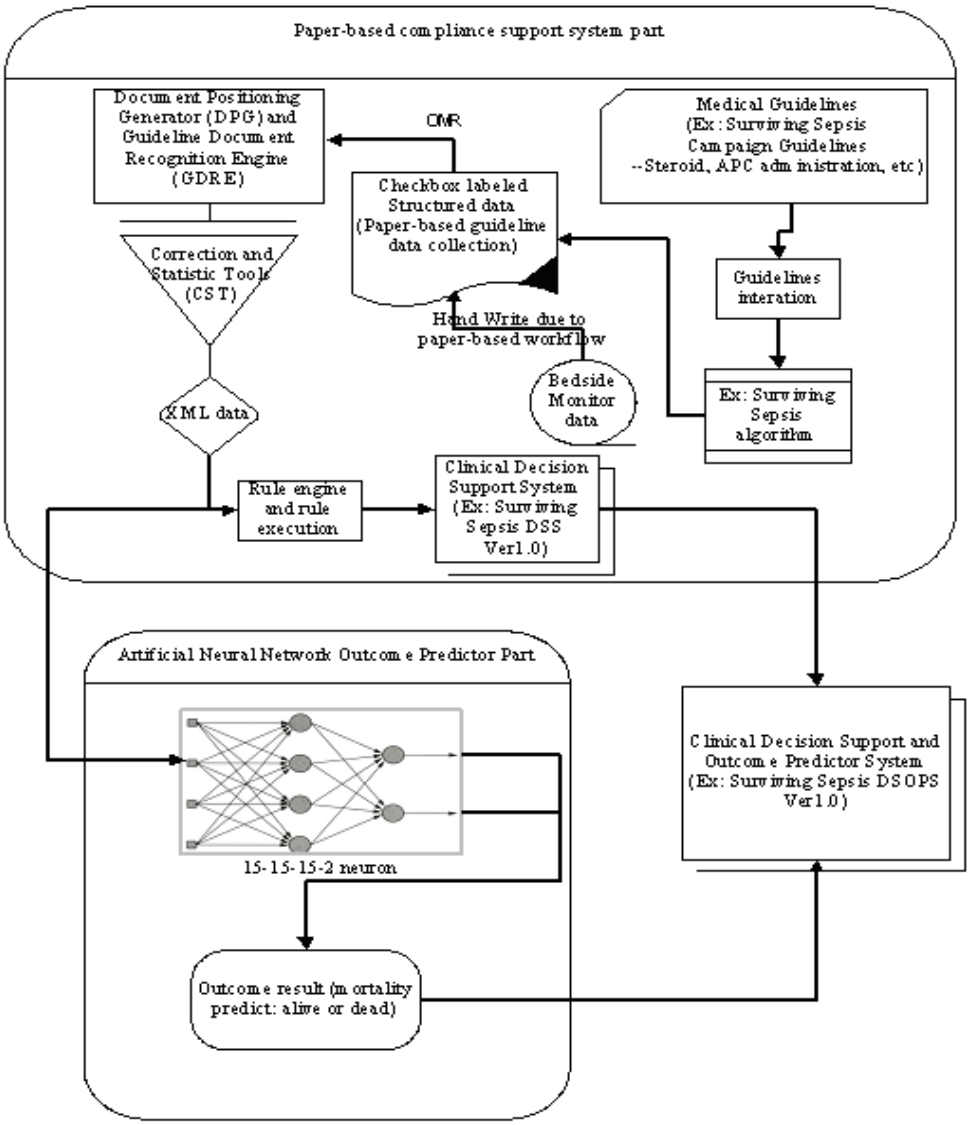

Figure 1 - System architecture

Conclusion

Not only the ICU owning the advanced and integrated CIS could take the advantage of guideline implementation and quality improvement, we proved that using our system has the chance to do the same thing; especially in the ICU that still using paper-based method to collect patient data and the cost of whole system could be minimized.

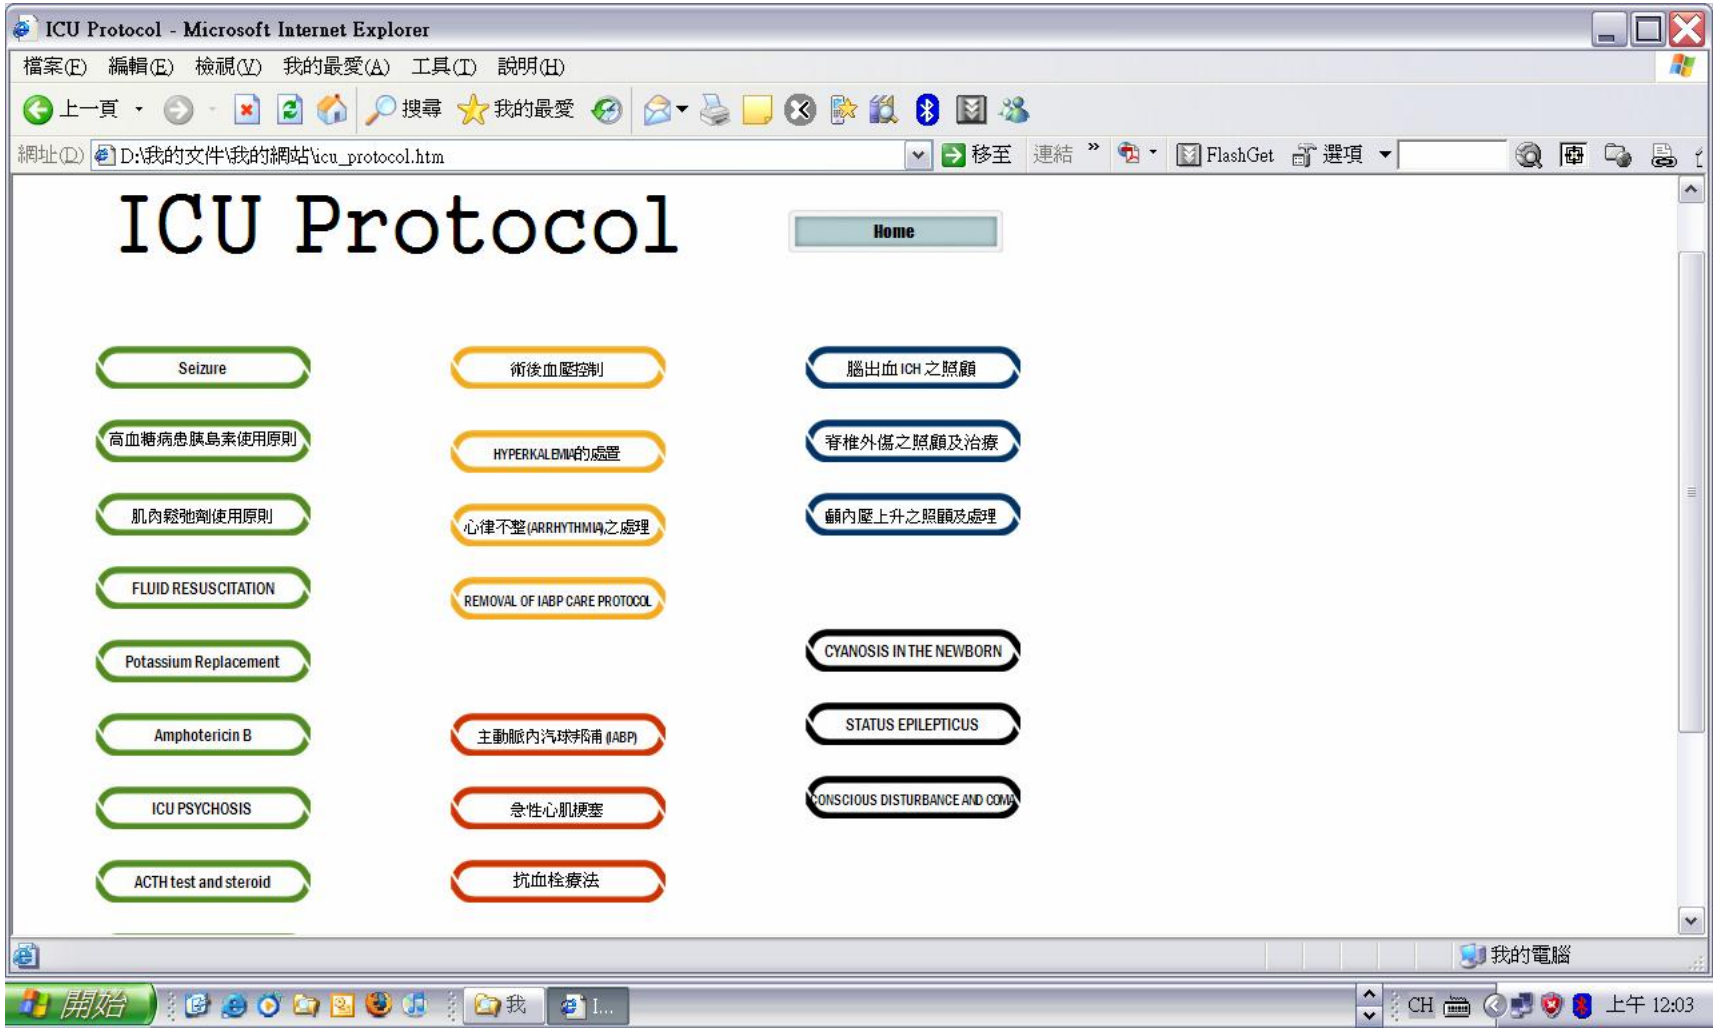
Embedded Rule Engine CDS



Results

- Error rate of document recognition: 0.19%
  - If scan document one by one, the error rate can be reduced to 0.057%
- Raise of the rate that adherence to guideline-based care: from 25% to 54%
- Mortality prediction: Need more data collection

Conclusion

- Cost saving : 6,000 us dollars versus 600,000 us dollars to setup CDS
- Organization that still paper-based working can take advantage of this CDS to improve guideline-based care

Identifying a Rare Mortal Risk Factor Using Full Text Search of an EMR

Joshua C. Denny[a,b], Frederick V. Arndt[b], William D. Dupont[c], and Eric G. Neilson[b]

Departments of [a]Biomedical Informatics, [b]Medicine, and [c]Biostatistics, Vanderbilt University Medical Center, USA

Abstract objective

Hippus, a rare physical exam finding, is a prominent, repetitive oscillation of the pupils. Through a full-text search of our electronic medical record, we identified hippus cases and matched controls. Hippus was associated with a 3-fold increase risk of 30-day mortality.

Keywords:

electronic medical records, text searching, clinical research, mortality

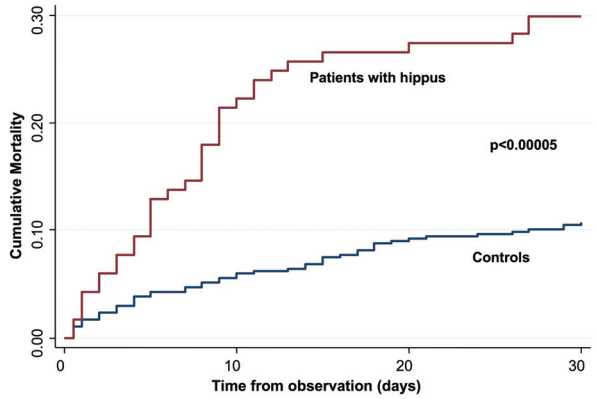

Figure 1 - Cumulative mortality of patients with hippus versus

We conducted a retrospective cohort study of hospitalized patients demonstrating hippus prominent enough to be noted in their electronic medical record (EMR). To identify cases of hippus, we did a full text search of greater than 60 million electronic records representing 1.3 million patients between 1995 and 2005 at one academic medical center. To mitigate observer bias, we used hospital billing records to select four controls for each case: two adjacent admissions by the same attending physician before and after each index case. We compared patients by past medical history, medications, and mental status. Chart abstraction was performed by two physicians, using a concept identifier to assist mapping this free text to standard terms[3]. Cases and controls were assessed for risk and mortality by univariable and multivariable logistic regression and Kaplan-Meier survival analysis.

Results

We found 147 cases of hippus in our search; 117 of these were inpatients. We identified 468 controls. There were no demographic differences between cases and controls. Patients with hippus were more likely to die within 30 days of observation ($p<0.00005$, see Figure). Independent risk factors for death by 30 days were altered mental status (OR 4.11; 95% CI 2.05 – 8.25, $p<0.001$), hippus (OR 2.99; 95% CI 1.46 – 6.11, $p=0.003$), renal disease ($p=0.054$), and cirrhosis ($p=0.029$); angiotensin-system inhibitors were protective ($p=0.012$). The presence of hippus on exam was associated with altered mental status (OR 11.23; 95% CI 6.27 – 20.09, $p<0.001$), a history of trauma (OR 3.76; 95% CI 1.65 – 8.59, $p=0.002$), cirrhosis ($p=0.038$), renal disease ($p=0.051$), and the use of iron ($p=0.016$).

Conclusions

Recognition of hippus in hospitalized patients is a clinically important predictor of early mortality. Hippus is associated with altered mental status, trauma, and cirrhosis. Full-text searching of a comprehensive EMR allowed fast identification of a large cohort demonstrating a rare finding and discovery of new clinical knowledge.

Artificial Neural Networks to Predict Patient's Length of Stay

Raj Gopalan, John P Kichak, Matthew Hager

University of North Carolina Hospital System, Chapel Hill, NC, USA

Abstract

Hospitals determine the anticipated length of stay (LOS) based on the national benchmarks data. Those benchmarks are based on admitting diagnosis, Diagnostic Related Groups (DRGs), patients' age, sex, and other comorbidities. Providers are reimbursed based on these LOS calculations, since patients with similar DRGs/LOS are supposed to utilize comparable amount of hospital services. But unfortunately every patient is unique and every hospital is unique and the anticipated length of stay is far from accurate. We used large amount of historical data on our patients, compared the length of stay against their demographics, vital statistics and lab results. We attempted to use artificial neural networks (ANN), as a predictive modeling tool to learn this historical data and predict the length of stay for a new patient. We found that the neural network was able to predict the LOS 95% of the time within one day of error. We believe that ANN can be used to reliably predict the LOS at the time of admission

Keywords:
length of stay, artificial neural networks, prediction model

Introduction

Artificial Neural Network (ANN) is a computer algorithm that is modeled after the brain neural cell network. Scientists believe that humans learn new patterns by association. The human brain constantly looks for patterns in the real world, and associates these patterns with the outcomes. The brain cell network makes changes to the connections to store these patterns. After learning these large number of patterns and outcomes for those patterns, the brain cells will be able to predict an outcome for a pattern that is unique, based on the past experience. Thus an ANN can be trained using a large number of examples, to learn the implicit relationships between the variables that influence an outcome. Thus a trained ANN can be used to predict an outcome based on a set of variables that it has not seen before. We have referenced a few works in the past that have used this technology to predict LOS [1,2.3]. We attempted to use this technology to learn the influence of patients' demographics, vitals signs, and lab results in the total LOS, then use a trained network to predict the LOS based on those influencing factors that are available at the time of admission

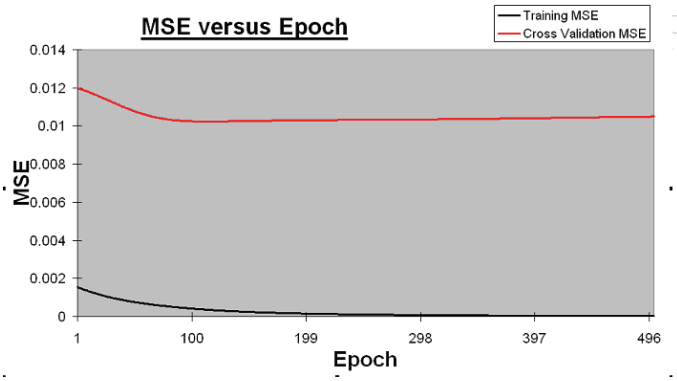
Materials and methods

We gathered the actual LOS data from our own patients, for the past 5 years. We tabulated these patients' demographics, such as age, gender, ethnicity, religion, city, state and active problems, vital statistics such as weight, height, blood pressure, respiration, pain score, and lab results such as chemeistry and hematology that are available at the time of admission. We were able to gather data from about 2000 patients without any missing elements. The population included all age groups from infants to all the way to the 90s and has a mix of all ethnic populations. We analyzed the data for any correlation between any of the above factors against the actual LOS.

We built a correlation matrix so that we will be able to filter any combination of the demographics components like city, gender, ethnicity etc, and visualize the effect of that on the LOS against any age groups.

We used the correlation model that was provided by the Neural solution plug-in for Microsoft excel. We couldn't find any consistent correlation using this tool.

Figure 1 - Shows the cross validation set with the MSE increasing after 100 epochs



We attempted to use artificial neural networks, as a predictive modeling tool to solve this problem. We were able to capitalize on the large amount of historical data available on our patients. We split the patient data into 3 parts, a training, validation a test set with 1000, 500, and 500 patients respectively. We tried different ANN architecture, learning parameters, and transfer function to determine the best architecture for this problem. We trained the network with the demographics data against the actual LOS on the training set and tested the accuracy of prediction by the

trained neural network on the test set. We found that the neural network was able to predict the LOS 95% of the time within one day of error. We are currently studying the value of feeding this anticipated LOS with additional parameters, like vital statistics and lab results to a series of trained networks, to fine tune the prediction accuracy.

Results

The artificial neural network learned demographic pattern to predict the LOS in the training set within 3000 epochs as shown in Figure 4 very accurately.

While training we used a cross validation set to compare the reduction in the mean square error (MSE) while learning, so as to stop the training when the MSE tend to increase in the cross validation set. That way the neural networks is prevented from over fitting the training set, but to make it more generalized so as to predict the test cases with a fair amount of accuracy.

Table 1 - The neural network learned the LOS very accurately as shown here within 3000 epochs. The LOS after 50, 250, 1000, and 3000 epochs are shown below

LOS	50	250	1000	3000
16	12.3	15.47	15.983	16.002
6	7.0	5.57	5.947	6.001
7	7.8	5.24	6.910	7.006
7	7.7	6.72	6.977	7.001
7	7.2	6.48	7.139	7.005
2	5.3	4.91	2.250	2.015
7	5.9	5.08	6.900	7.004
5	5.6	3.95	4.962	5.001
23	14.5	22.36	23.012	23.008
3	6.7	3.91	3.284	3.013
5	10.6	6.24	4.981	5.011
4	8.1	4.27	3.983	4.003
4	2.6	4.51	4.088	4.011
7	5.4	4.27	7.053	7.006
5	10.3	4.36	5.028	5.005
7	10.9	5.79	6.970	7.007
4	10.5	5.18	3.917	4.007
4	6.2	4.28	3.994	4.006
10	7.0	10.98	9.902	10.007
7	12.5	7.36	7.043	7.012
22	21.2	21.66	22.005	22.022
2	8.4	4.81	2.266	2.001

After the training we tried to use the trained neural network to predict LOS on a test set that the neural network has not seen before. The following table reflects the performance of the network.

The following table shows the prediction for LOS for all patients by trained network. The actual average LOS for all patients was 7.6 against the Neural Network that predicted the average to be 8.0. The current LOS prediction based on the national benchmarks data gives an average LOS value of 4.5. Thus the neural network prediction is very close to the actual since it is based on the local rather than the national aggregate data showing the value of local data in predicting the outcome since the local demographic mix and the local factors are more valuable.

Table 2 - Predicted Length of stay by NNW

	All		599pt
	LOS	Current	NN
Average=	7.6	4.5	8.0
Total=	4436	2607	4637

We were also able to train the NNW on a particular population of White Baptist, and then use the trained NNW to predict the LOS for that group. This will help us to predict outcomes even more accurately, if we have sufficient number of training data for that population.

Table 3 - Predicted LOS for White Baptist

	All		73pt
	LOS	Current	NN
Average=	7.2	5.1	7.7
Total=	512	361	545

We used the White Baptist since we had more patient data in that group than any other group.

Discussion

We believe that if a large number of historical data is available, an ANN can be used to reliably predict the LOS at the time of admission. Also as new evidence becomes available, like the vitals and lab results, those data could be used to continuously fine-tune the predicted length of stay. Once the care providers see the accuracy of predicted anticipated length of stay, and how it changes based on the accumulation of new evidence during the course of the patient stay, they would be able to fine tune their delivery of care to optimize the quality of the outcomes, enhance patient throughput and maximize reimbursement.

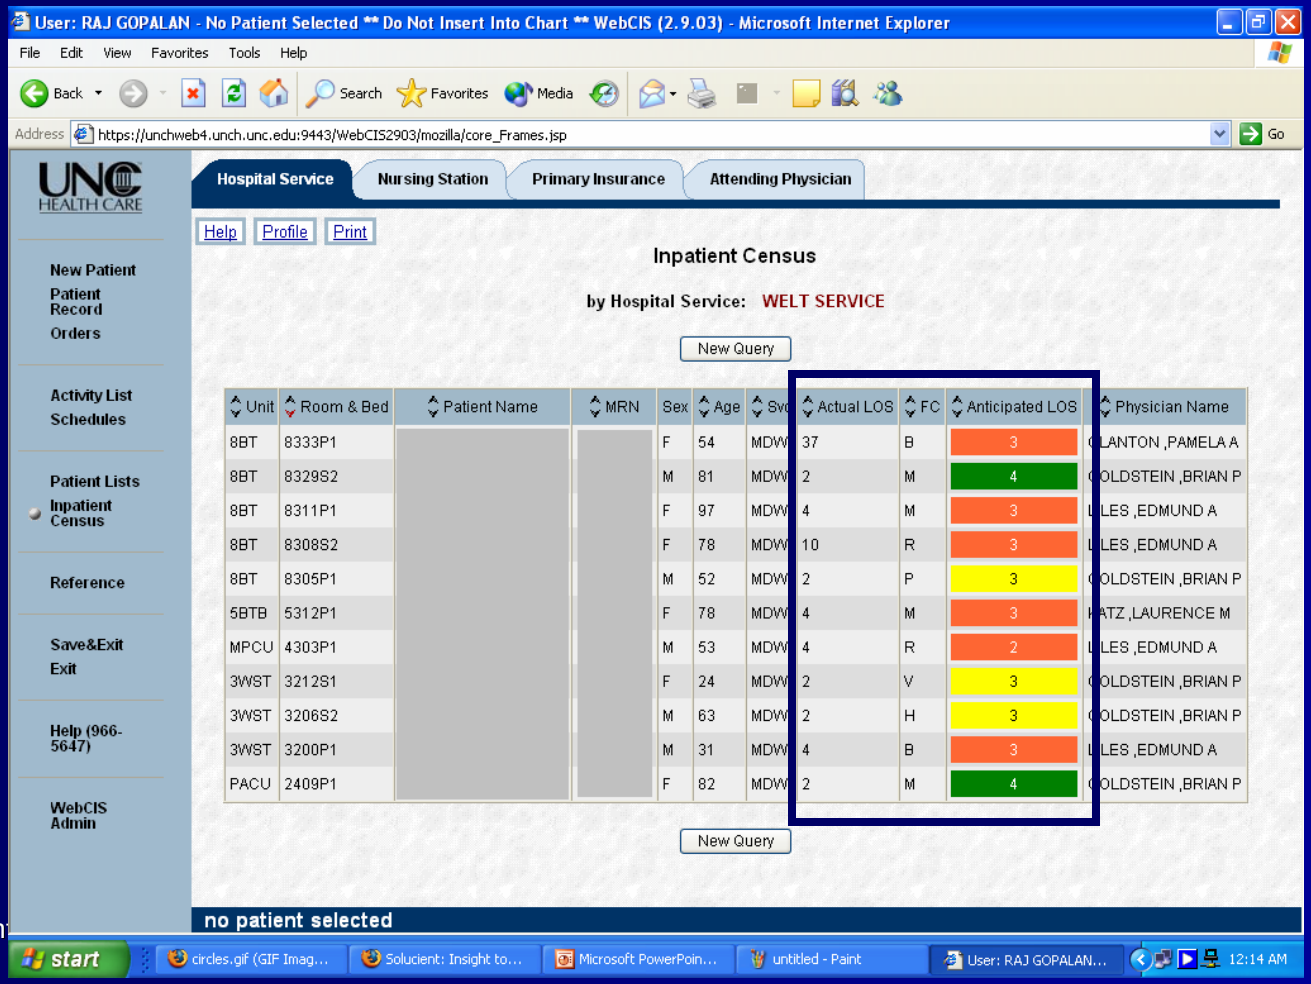
Why predict Length of Stay?

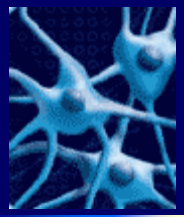
- Pre-admission authorization
- Bed-need assessment
- Concurrent review and discharge planning
- Reimbursement review and adjustment
- Identifying opportunities to reduce costs, save time and improve performance

- How computed today?
  - DRGs
  - ICD-9 codes
  - Insurance
  - Age groups

Traffic light Indicator in UNC EMR (WebCIS) census

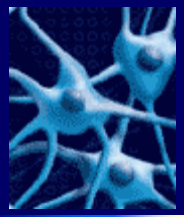


What do we know about a patient @ admission



- Age
- Gender
- Ethnicity
- Religion
- City
- Insurance Info
- Dept/Division

- Vitals
  - Ht, Wt, Pulse, BP, Resp, Pain Score
- Chemistry
  - Sodium, Potassium, Chloride, Bicarbonate Calcium, Urea, etc..
- Hematology
  - WBC, RBC, Platelets, Hg, MCV MCHC, etc..



Data gathering...

- *Analyzed Data from the past 5 years*
- *Selected Patients who has majority of these values*
- *Filtered by Labs & Vitals taken on the day or immediately before or after admission.*
- *Selected 2000 best representative patients...*

Our ANN Architecture

- *Single NNW*
  - *Not able to perform well*
- *Chain for NNW*

The Effect of Computer-assisted Prescription in Critical Care Unit

Authors: Dr. Humberto Fernán Mandirola Brieux, Fabián Korilen, Pablo Laguzzi & Sebastían Guillén

speaker: Dr. Humberto F. Mandirola Brieux

Email: hmandirola@biocom.com

BIOCOM

http://www.biocom.com

Objetive

In this work we propose to determine in what proportion computer-assisted prescription (CAP) reduces errors in medical indications if we compare it with hand-written medical prescription (HWP) in Intensive Care Unit (ICU) in Belgrano Hospital in Buenos Aires, Argentina.

Will determine if there are advantages between CAP and HWP. A retrospective analysis was used over an amount of 98 medical indications in ICU (intensive care unit) registered during the first quarter of 2006.

Introduction

- Advantages and benefit-cost which CAP enjoys at present are, in a way, affected by some legal aspects.
- There are existing contradictions between vanguard law and Digital Signature Law 25.506 and General Law of Medicine Exercise (law Nº 17132) which in its article 19 sub-sections 7 reads: “Prescriptions shall be hand-writing, in Spanish, dated and signed”. This fact at present complicates the situation of **physicians who use CAP** because they run the risk of being sanctioned.

Materials and Methods

we have chosen 43 traditional hand-written prescriptions and 55 computer-assisted ones to elaborate this study and to compare existing differences between them both.

Computer Program

It consists in an electronic form with the following fields:

drug /posology /doses /administration route/date of beginning and end of the treatment.

The output is the printing of a report with daily indications for each patient.

BIOCOM

Analyzed variables

- 1- **Incorrect information**: Information which is not relevant for patient treatment and which can lead to confusion. Indications which do not correspond to a patient and have been prescribed by mistake.
- 2- **Incorrect doses**: Doses calculated by mistake or indications wrongly transcribed.
- 3- **Omissions**: Lack of any of the elements in the indications, for example, when a transcription has not been made because somebody forgot to do it.
- 4- **Illegibility**: When two or more members from the committee cannot understand one or more words.

BIOCOM

Results

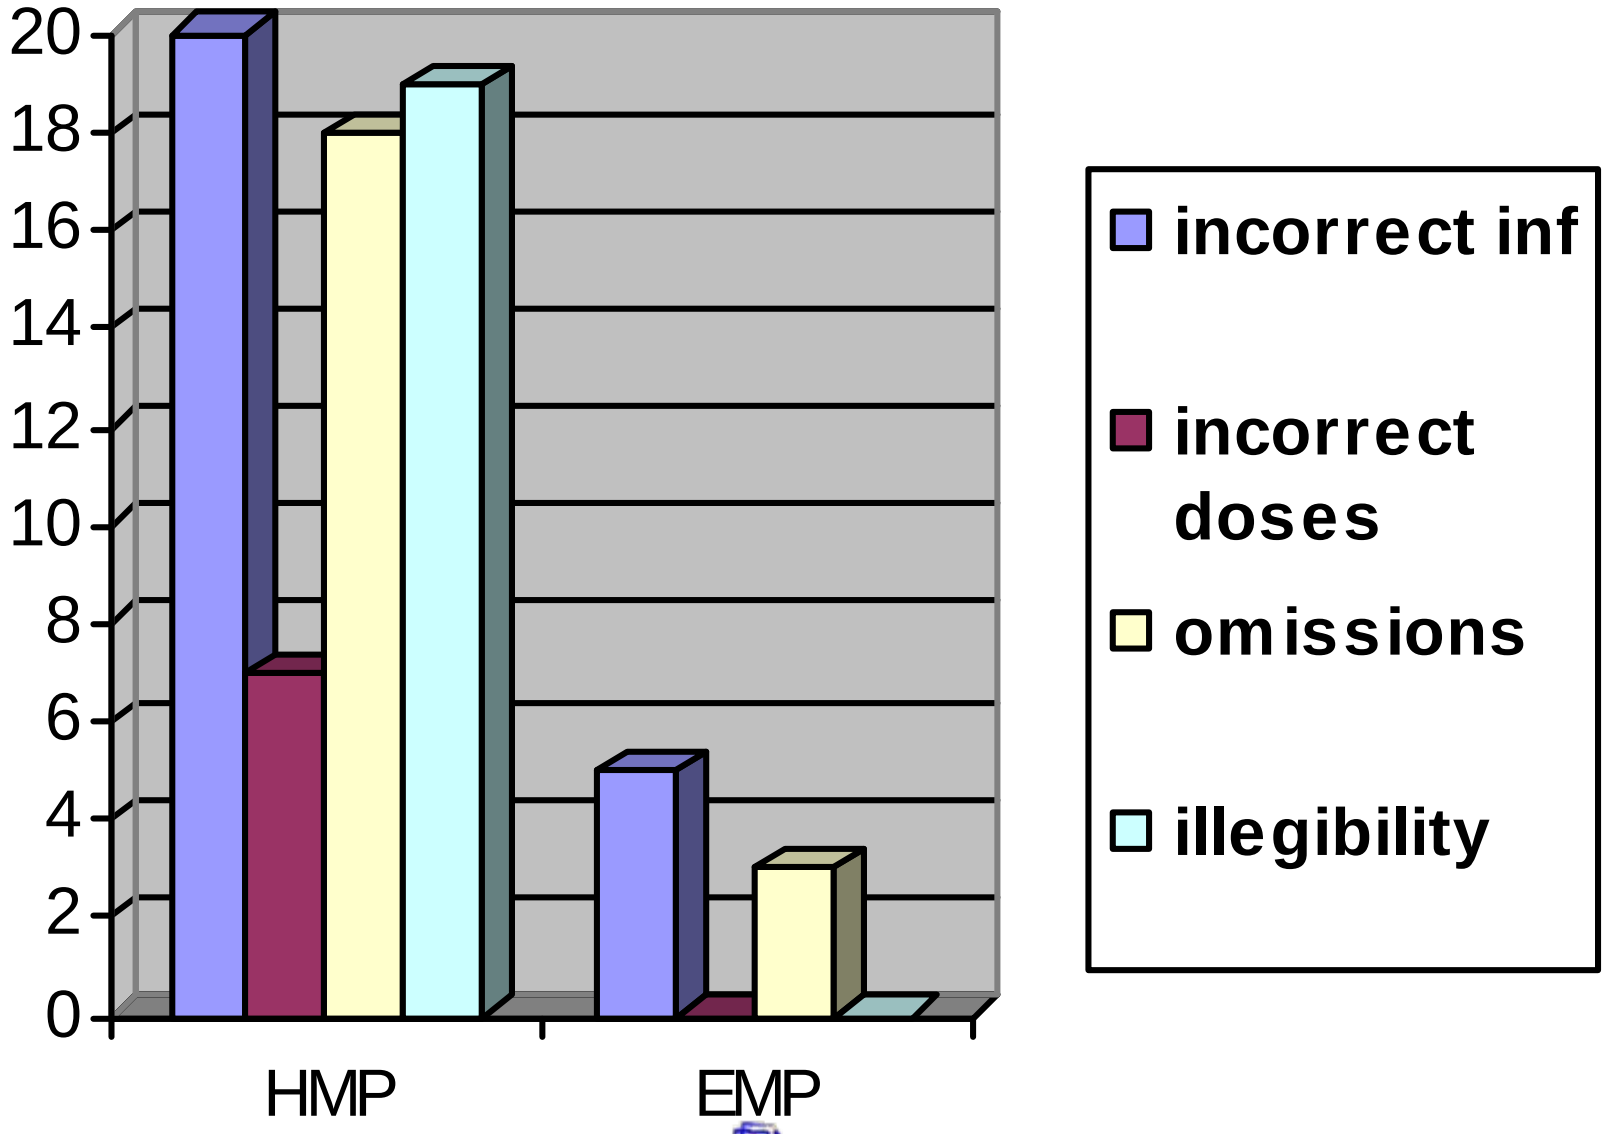
T otal of prescription mistakes (HWP) = 41,86 % (CAP)= 7,27%.

incorrect information
(HWP) = 20,93 %
(CAP) = 5,45%,

omissions
(HWP) = 18,60 %
(CAP)= 3,64%,

incorrect doses
(HWP) = 6,98 %
(CAP)= 0%,

illegibility
(HWP) = 18,60 %
(CAP)= 0%.



BIOCOM

http://www.biocom.com

Discussion

Results are eloquent:

41% of mistakes in HWP vs.

7% in CAP.

Main causes in this difference are illegibility problems and mistakes in transcription in daily indications.

Discussion

- It is important to consider that in many works it is indicated that Medical Error has an important incidence in morbidity and mortality of patients and longer permanence of patients in hospital so it has a high incidence in increase of health costs basically for bad administration and limitless resources use.

Conclusions

- To incorporate CAP to daily practice, it will be necessary to count with the digital signature of the physician; in this way it will be used as a legal proof tool. It is important to consider that a wrong manual indication could generate, for omission, illegibility, loss, damage or other, a medical mistake which produces a bad praxis with a morbidity and health cost easily avoidable if CAP is used.

The Effect of Computer-assisted Prescription on Critical Care Unit

Humberto Fernán Mandirola Brieux, Fabián Koliren, Sebastián Guillén and Pablo Laguzzi

Hospital General de Agudos Manuel Belgrano and
BIOCOM an Argentine Biocomputer Research Group

Abstract

Objective: To determine if computer-assisted prescription (CAP) reduces the frequency of prescription errors in the Intensive Care Unit (ICU) of Belgrano Hospital.
Method: A retrospective analysis was used to compare errors between computer-assisted and handwritten prescriptions (HWP) in 98 Medical indications: 43 handwritten and 55 Computer-assisted ones. Prescriptions were reviewed by expert staff. The items to be considered are: 1- incorrect information, 2- incorrect dose, 3- missing information, 4- illegibility.

Results:

1- Incorrect information HW=20,93% - CA=5, 45 %,

2- Incorrect dose HW=6, 98 % - CA=0%,

3- Missing information HW=18, 60% - CA=3, 64 %,

4- Illegibility HW=18, 60 % - CA=0 %.

Conclusions: Computer-assisted prescriptions sensibly reduce medical prescription errors compared to handwritten prescriptions. We found a total of 41, 86 % errors in handwritten medical prescriptions versus just 7, 27 % in computer- assisted ones.

Keywords:

prescription drugs; medication errors; computer-assisted medication systems

Introduction

In this work we propose to determine in what proportion computer-assisted prescription (CAP) reduces errors in medical indications if we compare it with hand-written medical prescription (HWP) in Intensive Care Unit (ICU) at Belgrano Hospital in Buenos Aires, Argentina.

Computer-assisted prescription (CAP) avoids main causes of medical errors at the moment of prescribing and/or making indications, because it basically avoids mechanical work of data transcription not only by doctors, who update indications given the previous days, but also by nurses' and pharmaceutics' work. CAP ends with discrepancies produced by data interpretation and transcription. It constitutes an indispensable election tool to improve quality in medical attention optimizing safety in patients and, in that way, diminishing expenses caused by medical errors.

CAP (computer-assisted prescription) integrated with CCH (computerized clinical history) not only optimizes processes and reduces mistakes in medication, but also constitutes a fundamental support for decision taking and allows detecting interaction between drugs-taking by patient.

Advantages and benefit-cost which CAP enjoys at present are, in a way, affected by some legal aspects. There are existing contradictions between vanguard law and Digital Signature Law 25.506 and General Law of medicine exercise (law Nº 17132) which in its article 19 sub-sections 7 reads: "Prescriptions shall be hand-writing, in Spanish, dated and signed". This fact at present complicates the situation of **physicians who use CAP** because they run the risk of being sanctioned.

With this work we hope to make a contribution so that legislators review this kind of impediment which constitutes an attempt against modernization and health and life of patients.

Materials and methods

Intensive care unit is formed by two bodies and a CAP system. Not all professionals use this system because of different reasons which go from lack of aptitude to accept these new information technologies to manifest criticism to CAP. So as to objectively determine if there are advantages between CAP and HWP, a retrospective analysis was used over an amount of 98 medical indications in ICU (intensive care unit) registered during the first quarter of 2006.

Analyzed variables are:

1- **Incorrect information:** information which is not relevant for patient treatment and which can lead to confusion or those indications which do not belong to a patient and have been prescribed by mistake.

2- **Incorrect doses:** Doses calculated by mistake or indications wrongly transcribed.

3- **Omissions:** Lack of any of the elements in the indications, for example, when forgetting to make a transcription.

4- **Illegibility:** When two or more members from the committee cannot understand one or more words.

Results

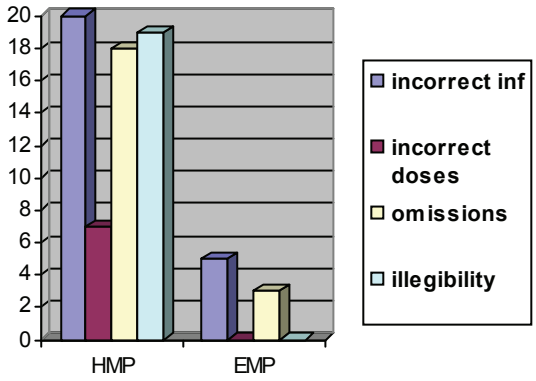
According to our controls, the results obtained are: incorrect information (HWP) = 20,93 % (CAP) = 5,45%, incorrect doses (HWP) = 6,98 % (CAP)= 0%,

Omissions (HWP) = 18,60 % (CAP)= 3,64%,

Ilegibility (HWP) = 18,60 % (CAP)= 0%.

Total of prescription mistakes (HWP) = 41,86 % (CAP)= 7,27%.

The difference between HWP and CAP is significant giving p <0,001



Discussion

Results are eloquent: 41% of mistakes in HWP vs. 7% in CAP. Main causes in this difference are illegibility problems and mistakes in transcription in daily indications. It is important to consider that in many works it is indicated that Medical Error has an important incidence in morbidity and mortality of patients and longer permanence of patients in hospital so it has a high incidence in increase of health costs basically for bad administration and limitless resources use.

Conclusions

To incorporate CAP to daily practice, it will be necessary to count with the digital signature of the physician; in this way it will be used as a legal proof tool. It is important to consider that a wrong manual indication could generate, for omission, illegibility, loss, damage or other, a medical mistake which produces a bad praxis with a morbidity and health cost easily avoidable if CAP is used.

Prospective Evaluation Strategy for Implementation of a Web-Based Care Planning and Communication System in General Practice

Svetla Gadzhanova, Richard Reed, Libby Kalucy

Department of General Practice, Flinders University, South Australia

Abstract

Global burden of chronic disease is increasing rapidly. E-health systems can play an active role to benefit the management of patients with chronic conditions.
HealthConnect SA is conducting a trial of a web-based care planning and communication system. The system is expected to facilitate the communication and collaboration between members of the primary health care team and to improve the health outcomes of the patients. A prospective evaluation methodology using mixed qualitative and quantitative techniques is designed to identify factors which influence the adoption of such a system in primary health care. The evaluation findings will inform the business needs and requirements for implementation of a state-wide online care planning and communication system.

Keywords:

internet, communication, care planning, general practice

Introduction

Global burden of chronic disease is increasing rapidly and is projected to account for 75% of all deaths by 2020 (World Health Organization 2004). Effective prevention and management of chronic conditions is a key policy objective of the Australian health system. It relies on coordinated care from a multidisciplinary team [1]. New chronic disease management items (GP Management Plan and Team Care Arrangement) were introduced as part of the National Chronic Disease Strategy in Australia to support General Practitioners (GPs) in providing care for patients with chronic medical conditions, including patients who need multidisciplinary care [2]. A care plan is a personalized management plan containing details of a patient's problems and needs. It outlines goals, treatment services and strategies to achieve those goals, and planned activities for monitoring progress and for reviewing the care plan. The care plan is developed between the patient, his/her family or nominated representative, and the health care provider (or provider team). The plan can relate to services from one or a number of health care providers or agencies [2].

E-health technologies and systems can play an active role to benefit health care providers and patients. Health*Connect* is an Australian national strategy to improve safety and quality in health care by establishing a range of standardised electronic health information products and services for health service providers and consumers. Health*Connect* South Australia is conducting a 12 month trial of a secure web-based system for communication and collaboration between health care providers involved in care planning. Flinders University is contracted to conduct a formal, independent evaluation of the trial.

Methods

Demonstrating a clear and unambiguous advantage for its users is a critical factor for adoption of an innovative electronic system into clinical practice [3, 4]. Implementing such a system requires attention to timing of events, acquisition and delivery of resources and development of human resource support structure [5].

The trialled web-based system (OzDocsOnline) enables health providers to work together to improve the management of chronic conditions. It is a tool enabling health care providers to create, share and store care plans on a secure server. Patients are able to access their care plans securely via the Internet.
A prospective, formative evaluation methodology using mixed qualitative and quantitative techniques was designed to determine the factors influencing the diffusion of the system in primary health care and to meet the main information needs of HealthConnect SA for the implementation of a state-wide care planning system after the end of the trial.

The evaluation methodology involves collecting data from the following information sources:

Surveys of adopting organizations (General Practices) to determine practice characteristics initial expectations and attitudes to the system towards the end of the trial.

Regular interviews with Division of General Practice liaison officers who disseminate the system to practices in their area to establish progress and issues arising during its implementation.

Case studies to provide in-depth understanding of the effects of implementation of the system in different contexts.

Focus groups with other health providers (allied health, specialists, pharmacists) and consumers to determine their erception of the effects of the system in care planning.

Monitoring Medicare item numbers relevant to care planning.

Monitoring the web-based system to determine extent of use.

The evaluation also aims to assess overall satisfaction and barriers in uptake of the system in different settings in order to make recommendations for improvements.

Results

The trial has been widely promoted and the current participants include three divisions of General Practice from South Australia, 35 general practices, 70 General Practitioners, 200 allied health providers (dietitians, physiotherapists, podiatrists, psychologists, social workers, occupation therapists, etc), 15 specialists / pharmacists and 45 patients with electronic care plans on the system.

Six month after the trial commenced the evaluation showed seven factors that influence the adoption of the innovative electronic care planning system in primary health care:

1/ **Proper timing of events** – implementation at the right moment and proper scheduling of the implementation steps;

2/ **Strong organizational structure** – strong personal relationships between the implementers and the adopters;

3/ **Effective implementation activities** – using wide and effective promotion methods (existing networks, information evenings, newsletters), dissemination of adequate communication/promotion materials;

4/ **Adequate resources** – proper IT equipment and secure broadband connection, prior computer knowledge, prior experience with EPC items, adequate training in the new system;

5/ **Comprehensive and timely support** – central helpdesk support, email address for enquiries, phone/mobile phone support, user manuals for the system;

6/ **Motivated adopters** – financial incentives in the training phase to encourage the uptake of the new system, secure broadband grants;

7/ **High-level system effectiveness** – the system has to:

- Be simple and highly integrated with existing clinical processes and systems (such as Medical Director);
- Be easy for all parties to learn and use;
- Facilitate the communication and collaboration between the health care team;

- Be accessible at each point of care;
- Secure and protective of medical information and patient privacy;
- Make a positive difference to time and revenue for health providers and to health outcomes for patients.

Discussion and conclusion

Adequate evaluation of health informatics initiatives is essential for efficiency and effectiveness of future initiatives [6]. The proposed evaluation methodology identified seven challenging factors in the uptake and use of a secure web-based system for electronic care planning. Addressing these aspects will enhance the likelihood of success of implementation and adoption of suchan innovative system for electronic care planning and communication in primary health care settings.

Prospective evaluation strategy for implementation of a web-based care planning and communication system in general practice

Introduction

♦ Global burden of chronic disease is increasing rapidly and is projected to account for 75% of all deaths by 2020 (World Health Organization 2004).

♦ Effective prevention and management of chronic disease is a key policy objective of the Australian health system. It relies on coordinated care from a multidisciplinary team [1].

♦ A personalized care plan which outlines goals, treatment services and care to achieve those goals make it easier for General Practitioners (GPs) to manage the care for patients with chronic medical conditions, including patients needing multidisciplinary care [2].

♦ E-health technologies and systems and a change in traditional business processes can play an active role to benefit health care providers and patients.

Introduction (2)

♦ Health*Connect* is a national strategy to improve safety and quality in health care by establishing a range of standardised electronic health information products and services for health service providers and consumers.

♦ Health*Connect* South Australia is conducting a 12 month trial of a web-based care planning and communication system for primary health care management of patients with chronic conditions.

♦ Department of General Practice at Flinders University is conducting a formal, independent evaluation on the trial to determine aspects that affect the implementation and uptake of such an innovative system in primary health care.

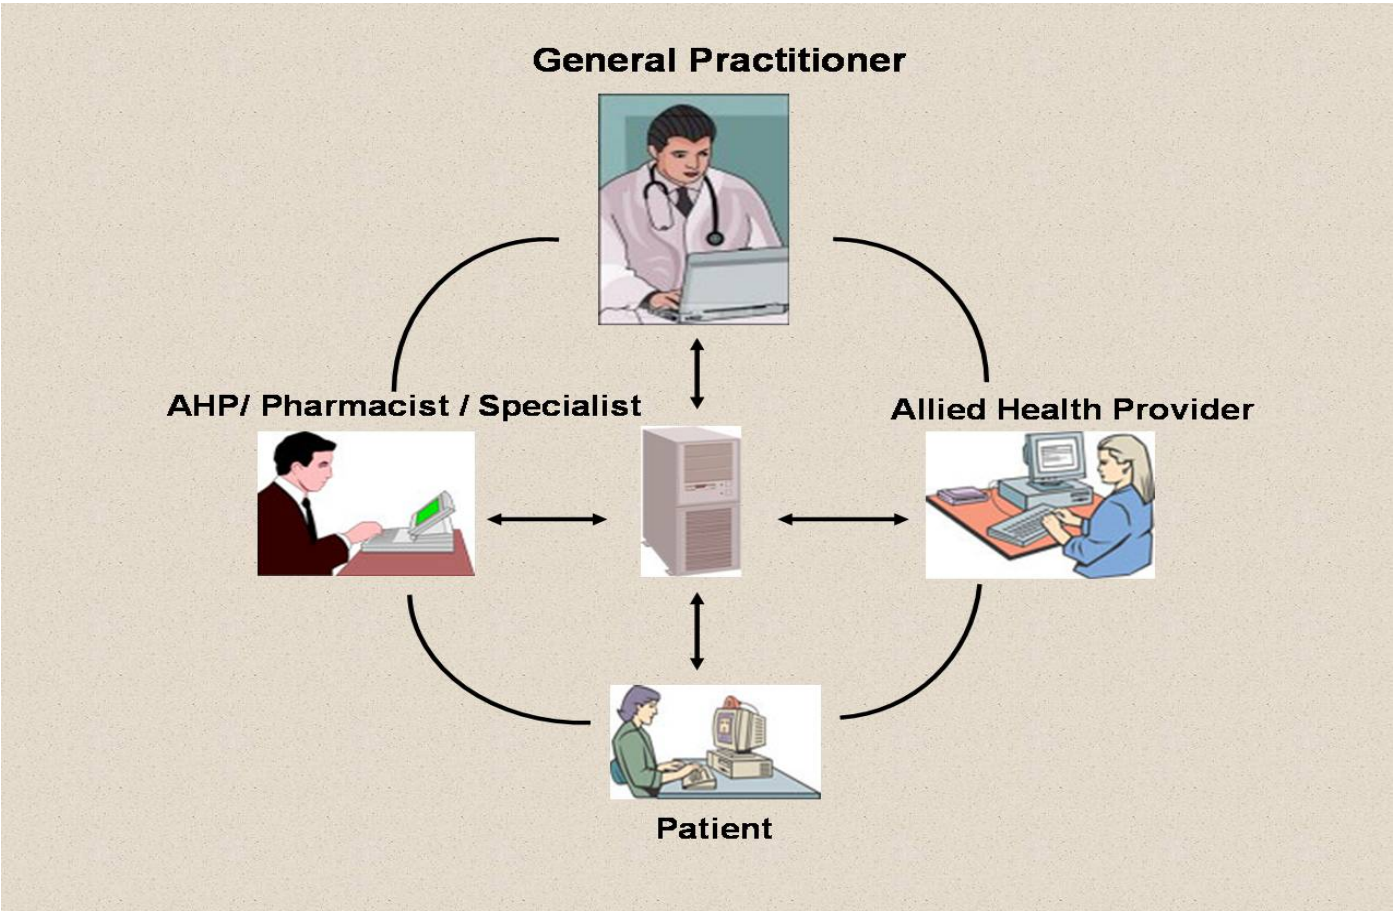
Innovative health systems

A critical factor for adoption of an innovative electronic system into clinical practice is to have a clear and unambiguous advantage for the users [3,4].

Issues such as timing of events, acquisition and delivery of resources, and development of human resource support structures [5] must be addressed to implement such as system.

The trialled web-based system (OzDocsOnline) enables health providers to work together to improve the management of chronic conditions. It is a tool enabling health care providers to create, share and store care plans (GPMPs and TCAs) on a secure server. Patients are able to access their care plans securely via the Internet.

The care planning system



Web-based care planning and communication system

Evaluation Methods

A prospective, formative evaluation methodology using mixed qualitative and quantitative techniques is designed to:

- determine the factors that influence the diffusion of an innovative system for electronic care planning in primary health care
- meet the information needs of Health*Connect* SA for implementation of a state-wide care planning system at the end of the trial (what makes an electronic care planning system effective for management of chronic conditions?)

Evaluation Methods (2)

Information sources	Purpose
Surveys of General Practices	Practice characteristics, expectations, attitudes
Interviews with Division liaison officers	Progress, implementation issues
Case studies	Effects in different contexts
Focus groups with health providers, consumers	Perception of system effects
Monitor Medicare item numbers, web based system	Extent of use

Participants

Current trial participants :

- Three divisions of General Practice in urban and rural South Australia
- 35 general practices
- 70 General Practitioners
- 200 allied health providers (dietitians, physiotherapists, podiatrists, psychologists, social workers, occupational therapists, etc)
- 15 specialists / pharmacists
- 45 patients with electronic care plans

Interim results at 6months

Factors which influence the adoption of an electronic care planning system in primary health care:

1. **Proper timing of events** – implementation at the right moment and proper scheduling of the implementation steps;
2. **Strong organizational structure** – strong personal relationships between the implementers and the adopters;
3. **Effective implementation activities** – effective promotion methods (existing networks, information evenings, newsletters), dissemination of adequate communication/promotion materials;
4. **Adequate resources** – proper IT equipment, secure broadband connection, prior computer knowledge, prior experience with EPC items, adequate training in the new system;

Interim results (2)

5. **Comprehensive and timely support** – central helpdesk support, email address for enquiries, phone/mobile phone support, user manuals for the system;
6. **Motivated adopters** – financial incentives in the training phase to encourage the uptake of the new system, broadband security grants;
7. **High-level system effectiveness – the system needs to be**
   - simple and fit with existing clinical systems (such as medical director) and processes,
   - easy to learn and use for all parties,
   - facilitate communication and collaboration in health care team,
   - accessible at point of care,
   - secure, protect medical information and patient privacy,
   - make a positive difference to time and revenue for health providers and to health outcomes for patients.

Discussion and Conclusions

- Adequate evaluation of health informatics initiatives is essential for efficiency and effectiveness of future initiatives [6].
- The proposed evaluation methodology identified seven factors which influence uptake and use of a secure web-based system.
- Addressing these factors will enhance the likelihood of successful implementation and adoption of electronic care planning and communication in primary health care settings.

GRHANITE™ - Sustainability in Data Collection, Information Sharing and Research

Douglas I.R. Boyle, Siaw-Teng Liaw

Department of Rural Health, University of Melbourne, Shepparton, Australia

Abstract

A prerequisite to quality medical research is access to high quality medical data. Australia has a strong record in medical research, but currently no Australian organization has the capability to link both primary and secondary care data on a large scale and in a sustainable manner. Issues are: ethics, consent, security and providing sustainable, on-going incentives for collaboration. The University of Melbourne is developing technologies designed to address these issues - GRHANITE™ - 'Generic Rural Health Academic Network Information Technology for the Enterprise'. GRHANITE™ provides participants with tools for managing consent, linking and extracting data from clinical repositories, extracting data only where consent is explicit and the secure uploading of data to a central repository in a de-identified, but linkable manner. Once linked, data can be used for research, but importantly, the data can contribute directly to clinical care processes in an ethical and secure manner. Any clinical use of the data is possible. As the capabilities of the clinical toolset increase, incentives for continued and further collaboration grow promoting long-term growth and sustainability.

Keywords:

medical record linkage, confidentiality, informed consent, automatic data processing, integrated advanced information management systems

Methods

The work of the author (Boyle D.I.R.), Morris A.D. et-al for the Diabetes Audit and Research in Tayside, Scotland project demonstrates that systems providing clinical benefits can grow from small research linkage projects to initiatives national in scope. This project now aggregates diabetes data daily from over 1,000 general practices and 50 hospital clinics without being mandated (diabetes pop 192,012, 3.97M user operations, >5,000 users – Nov 2006). Although data is primarily collected for clinical purposes, it has contributed greatly to the diabetes research capability of Dundee University as literature searches reveal. Australia is however different from the UK and different issues apply. What the Scottish experience demonstrates though, is that if the framework in which clinical systems function is cleverly managed, large collaborations can grow and comprehensive data for clinical research can result.

This broad methodology has been applied to the University of Melbourne, Rural Health Academic Network (RHAN) in its development of GRHANITE™ technologies designed to comprehensively link data across North-East Victoria, Australia. Each participating RHAN site (primary or secondary care) hosts a GRHANITE™ Consent Server. This server manages all issues of consent across the organization, the secure, de-identified extraction of data and communication with a central GRHANITE™ Repository. This repository performs deterministic record linkage and data aggregation for the purposes of clinical information sharing and decision support as well as providing anonymous data for research. All possible measures are taken to maximize the ease with which consent can be managed (opt-in or opt-out) in a highly secure and ethical environment. These same ease-of-use and security measures have the potential to grant clinicians immediate, context-sensitive ethical access to clinical data where consent for this has been granted by the patient.

Results

GRHANITE™ technologies are still under development. At this time (November 2006), pilot data extractions to a central GRHANITE™ Repository are under way. Collaborations with local general practices and the Goulburn Valley Hospital Diabetes Clinic are being utilized to build the initial decision support tools. These tools will demonstrate the capability of the system to support continuity of care and clinical functionality – in this case, for diabetes services between the hospital and primary care.

Conclusions

Although still under development, feedback from local clinical and healthcare IT professionals has been positive. It is unusual for consent to be managed by a specific consent application and GRHANITE™ is unusual in managing consent on behalf of whole organizations. A key facet of the GRHANITE™ Repository is its ability to link and provide clinical sharing capabilities without the central repository holding ANY person-identifiable information. It is early days for the GRHANITE™ technologies, but it is hoped that as the clinical utility of the

system grows, the incentives for the clinical community to collaborate will grow. If this development mirrors the experiences of Scotland, these further clinical incentives will lead to increased collaboration in an on-going and sustainable manner. The GRHANITE™ technologies are not limited in scope to Australia.

GRHANITE™ - Sustainability in Data Collection, Information Sharing and Research

GeneRic HeAlth Network Information Technology for the Enterprise

Dr Douglas I R Boyle*

Professor Siaw-Teng Liaw

University of Melbourne School of Rural Health, Shepparton, Australia

*** Douglas was formerly the Technical Architect (designer) for the DARTS / SCI-DC system in Scotland**

Background

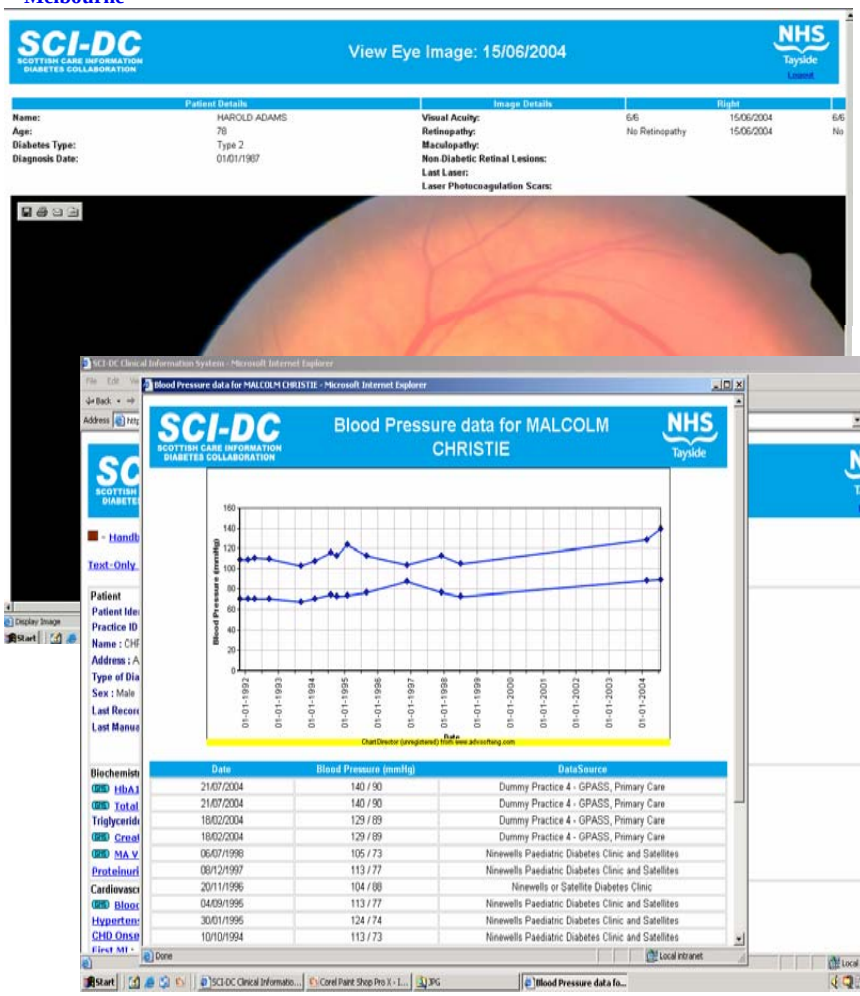
- HL7 and other messaging standards are at the heart of many national and international efforts to allow clinical information exchange. Such activities are effective, but costs are high, development timescales are long and interfaces are normally only developed between major clinical systems[1].
- Scotland has demonstrated another, pragmatic technique that can be used to link data for clinical care and research that is less dependent on messaging standard development. i.e. small systems can be linked as well as large ones [2].
- This Scottish system has proven itself through effectively providing an electronic health record for all patients in Scotland known to have diabetes [3],[4] (~190,000)

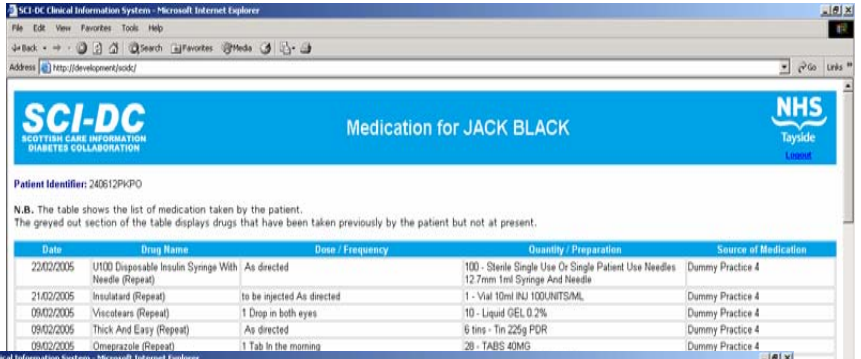
The Scottish Experience

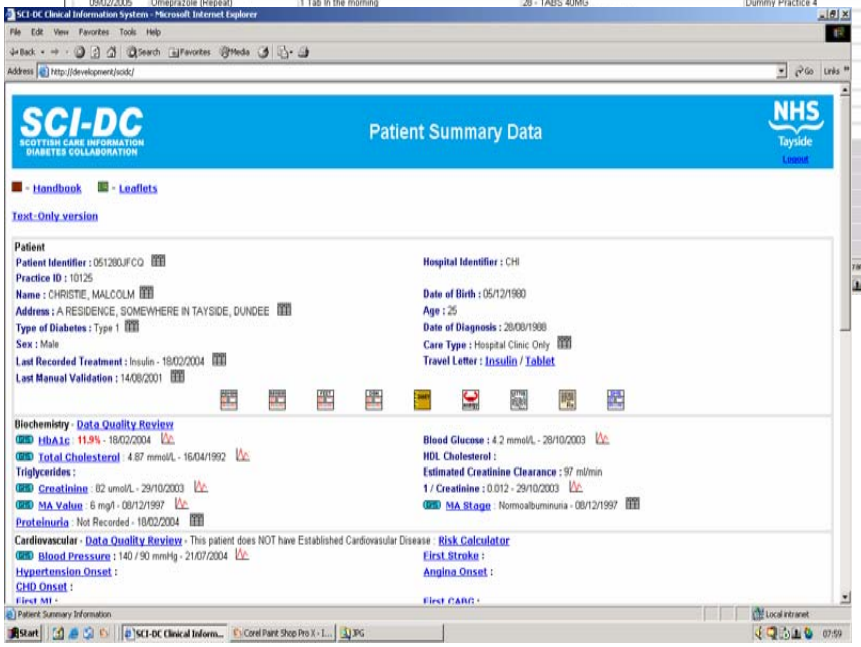
SCI-DC
SCOTTISH CARE INFORMATION DIABETES COLLABORATION

- Using a generic interface product developed by Dundee University (GENIE), data from any ODBC-compliant database can be extracted.
- This technology has been used to link data on a daily basis from over 1,000 general practice and hospital sites across Scotland.
- A central health record for diabetes (and cardiovascular disease) was constructed allowing patient care information to flow regardless of where the patient goes.
- This system is thought to provide the only fully population-based diabetes register (and care system) for a whole country in the world (Scottish population: ~5.1M).
- ~190,000 patient records are on the system, and there are >5,000 users spanning primary and secondary care (Nov 2006).
- Being a University of Dundee and National Health Service development, this system has achieved this for a total cost estimated to be around £10M – (~£10 (~$24 AUD) per patient with diabetes per year)
- Data from this system is at the core of Scottish Managed Clinical Networking for diabetes and underpins a wide variety of research programmes at the University of Dundee

SCI-DC Sample Screens



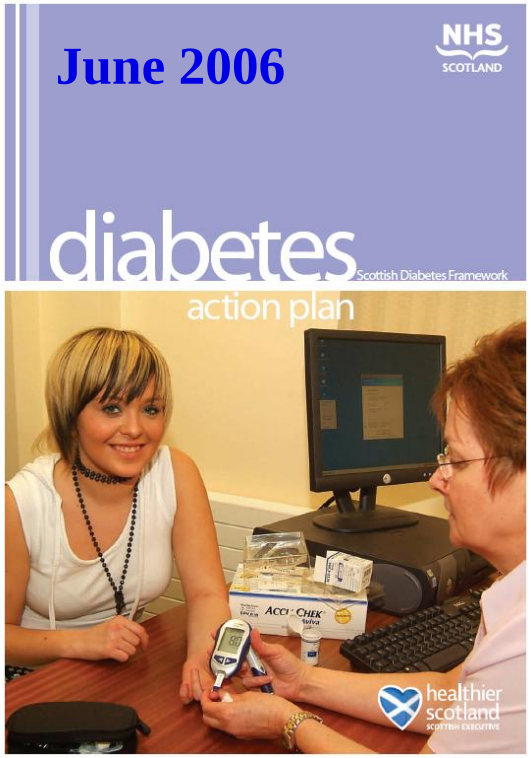


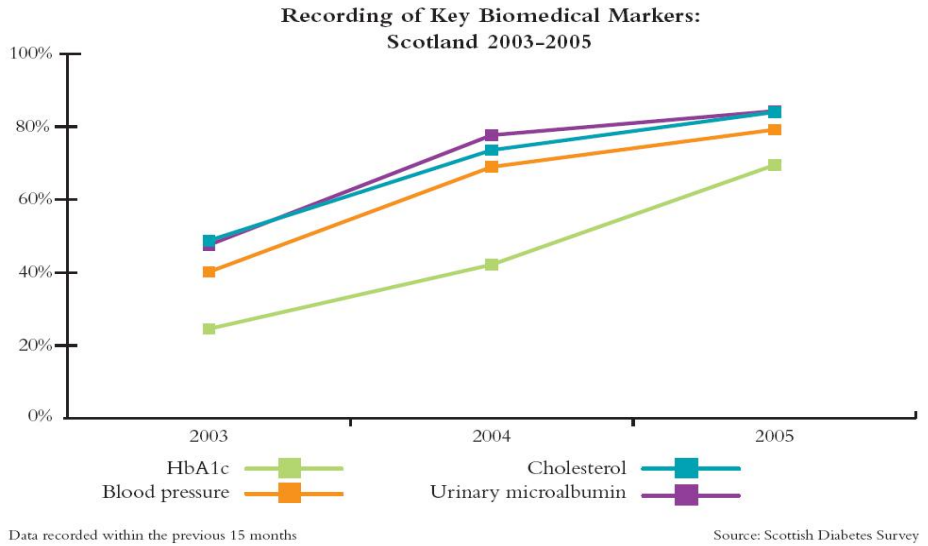


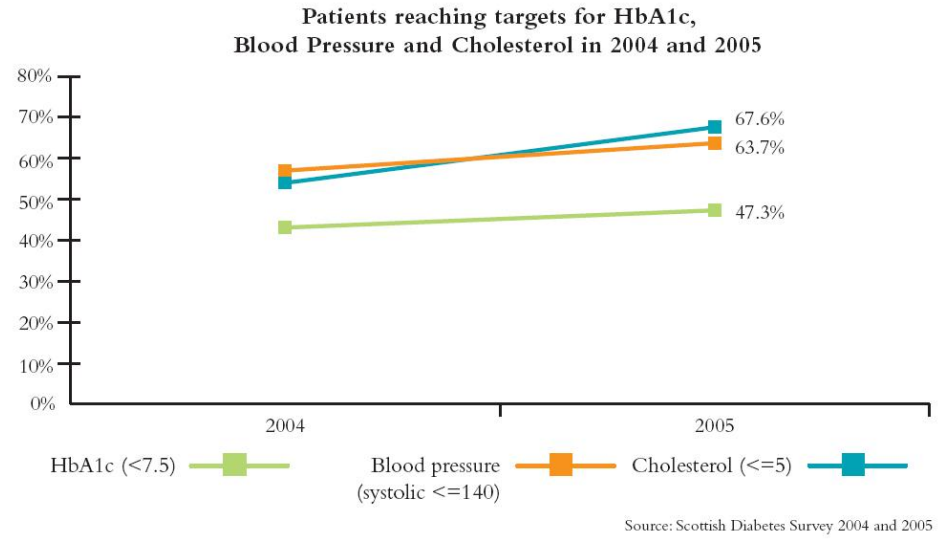
GRHANITE™ is still under development, but capabilities like these are one goal of GRHANITE™.
A demonstrator application is due for completion by November 2007

Evidence from Scotland demonstrates data quality improvement and improvements in patient outcome[4]

(People networks most important – IT underpins the network)







Australia - specific issues

Australia cannot implement strategies like those employed in Scotland without addressing the following issues:

- *No unique patient identifier (one is planned, but timescales are unknown)*
- *The divided commonwealth-state health financing system and the fee for service system discourages collaboration and shared-care systems*
- *Confidentiality, Ethics and Security are very public issues requiring the utmost respect with organisations such as the Australian Privacy Foundation carefully scrutinising activities in this area*
- *Information technology is a key enabler for improving communication, but improvements in patient outcome are a product of human intervention – effective collaboration across clinical communities is a necessity – as are structures that promote such collaboration*

Approaches to resolving the issues

There is no reason the methodologies employed in Scotland cannot be utilised in Australia but the problems specific to Australia must be addressed at a fundamental level

Identified prerequisites:

- **Managing the people issues – establishment of collaborative networks**
  - This ePoster is primarily about the technical aspects of supporting collaboration. Technology is a key enabler, but is ONLY an enabler.
- **Managing consent processes**
  - Comprehensive consent management at source
  - Flexible consent processes managing consent for research, clinical information sharing, even audit.
  - Consent processes that are opt-in or opt-out allowing operation in a variety of health environments based on advice from local ethics committees.
  - Consent processes that will work for any size of organisation – from a single-handed GP to a 1,000 bed hospital.
- **Managing record linkage**
  - For clinical information sharing, linkage must be performed. Given there is no Australian unique identifier, this process must use identifiers such as name, address, date of birth, even phone number to ensure linkage is accurate. Linkage errors when sharing health records must not happen.
  - Sharing personal identifiers is not good practice. Ideally, a linkage process that does not need to divulge personal identifiers would be preferable.
- **Managing security**
  - If clinical data is to be moved electronically, security mechanisms must be there to protect the rights of the individual.
  - All communications must be encrypted and secured against hacking.
  - All communications must be secured using reliable means of confirming user and client PC identity. This is usually established via user logins and digital certification.
  - Mechanisms must be established to ensure data can only be accessed by authorised individuals on a need-to-know basis.
  - Audit trails and auditing procedures must be present in all processes.

GRHANITE™ Technologies to resolve the fundamental issues

To-date, no application has been identified that can manage all the issues identified. GRHANITE™ technologies are being developed to fill this gap.

- GRHANITE™ has a generic interfacing capability that means it can link to any ODBC-compliant database. Users define the connection at install-time.
- It can use consent fields in a database, or can manage consent on behalf of the client database.
- It has a flexible (opt-in or opt-out) consent system that manages consent for whole organisations regardless of their scale.
- It manages consent for research, clinical and audit uses of data.
- No patient identifiers leave the organisation – non-reversible and dictionary attack-secured encrypted hashes are utilised for central linkage.
- The system manages its own X509 public and private key encryption processes to secure each site and each client PC connecting to the system – No need to purchase certificates. Techniques similar to Windows Activation are also utilised to guarantee the security of each connection.
- In addition to the above, messages are encrypted using constantly changing session encryption keys. Only publicly ratified and validated state-of-the-art encryption libraries are utilised.
- Code obfuscation is utilised.
- Approved health organisations only can install the product after the issuing of a passphrase-protected configuration file. Identified organisation administrators are responsible for allocating use accounts and user rights.
- GRHANITE™ performs a delta (Δ) data comparison to extract encrypted data changes each day or as otherwise scheduled – very small data quantities over the network.

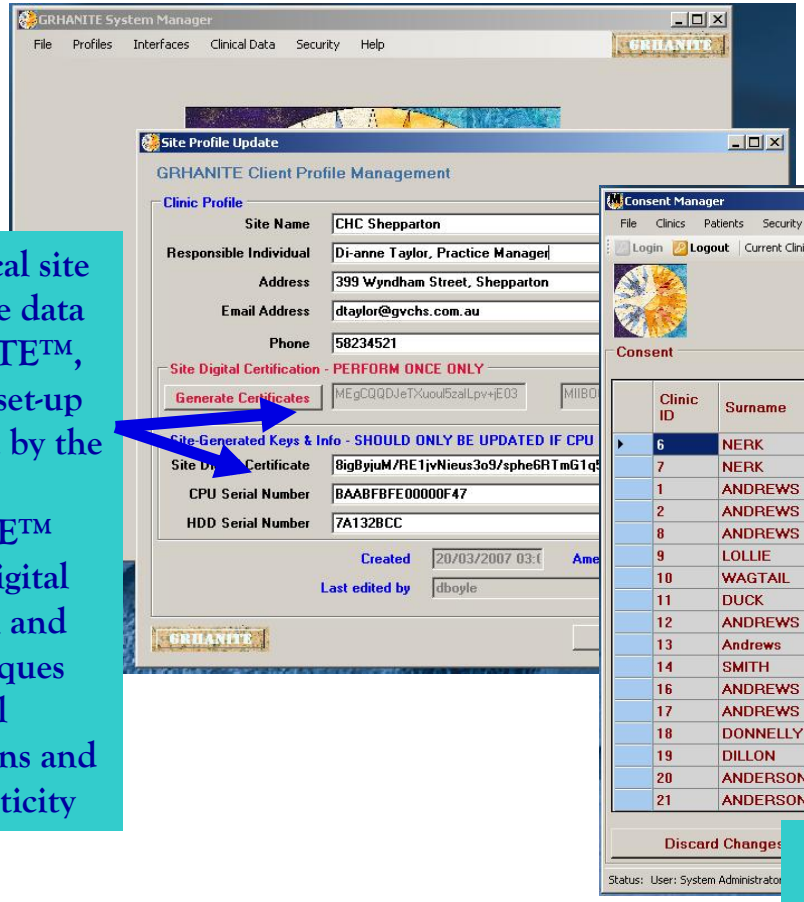
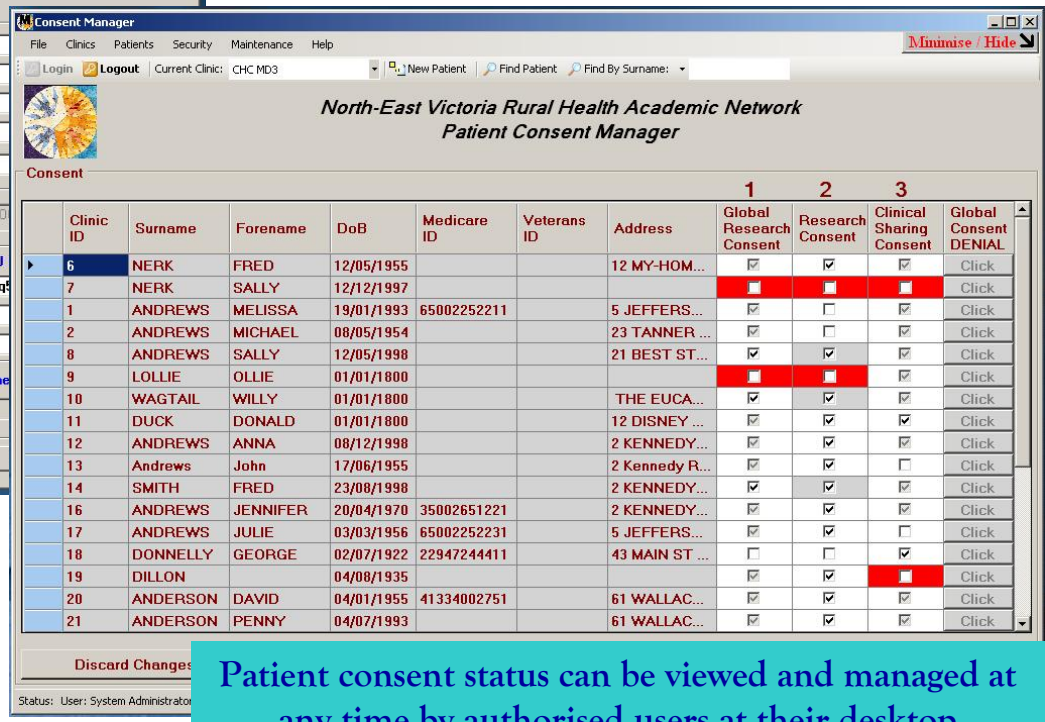
GRHANITE™





Before a clinical site can contribute data via GRHANITE™, they must be set-up and authorized by the central GRHANITE™ authority. Digital Certification and other techniques secure all communications and verify authenticity

Patient consent status can be viewed and managed at any time by authorised users at their desktop

- *GRHANITE™ is the technology underpinning the CONDUIT™ (Collaborative Networks Using Information Technology) project*
- *CONDUIT™ is the technical component of the North East Victoria Rural Health Academic Network (RHAN). This network has several goals, including managing the people aspects of establishing a Managed Health Network – initially for diabetes.*

Results and Conclusions

- GRHANITE™ has been developed to demonstrator status and is ethically managing de-identified, linked, consented data from Medical Director V3 and Practix V1.3.
- A generic interface is being finalised – this will allow connections to most modern healthcare database systems – including ad-hoc systems.
- Collaborations have been established with organisations to support large scale development, testing and implementation.
- Techniques as utilised in Scotland are being used to ensure the large-scale applicability of the system.
- Diabetes service provision across North-East Victoria, Australia will be the first example of the clinical utility of the system.
- A diabetes demonstrator website is planned for completion by October or early November this year.
- Because of the comprehensive management of consent and security, we hope that this technology can finally remove the barriers to clinical information sharing between primary and secondary care.
- Comprehensive research data for consented patients should be a valuable by-product of the system. Crucially, this includes primary care data that is a largely un-tapped research resource in Australia.
- As far as we are aware, this is the FIRST TIME a central databank holding live clinical data has been able to do so WITHOUT holding patient identifiers. If we can do it, shouldn't everyone?

HISA Ltd Australia

Information Technology Supported Clinical Handover - A Pilot Study

David G. Morris[a], Christopher C. Pearson[b], Murali Narayanan[b], Anna Baker[a], Eileen Hancock[a]

[a] *Clinical Governance Unit, Women's and Children's Hospital, North Adelaide SA*
[b] *Department of General Medicine, Women's and Children's Hospital, North Adelaida SA*

Abstract

Major improvements in the clinical handover process have been introduced to the Women's and Children's Hospital (WCH) in line with recently published Australian recommendations. The enhancement of this process by using the newly developed OACIS Clinical Handover module in a paediatric medicine setting is reported. The assessment included a pre-pilot survey questionnaire conducted to assess the medical staff opinions regarding the existing handover process with a follow up questionnaire after one week of using the OACIS computer augmented process. A further questionnaire will be conducted with the next rotation of medical staff.

Keywords:

continuity of patient care, medical errors, quality of health care, safety

Introduction

The implementation of Salaried Medical Practitioners' awards has changed the way healthcare personnel work in hospitals. No longer is a patient looked after by one doctor or only one team during an admission. Additionally, a doctor may have little or no day to day contact with a patient he/she is responsible for on a given shift. Also with increasing complexity of care, more and more patients now require care by multiple teams. Thus clear accurate and efficient communication is required to ensure optimal safe care.

In order to ensure good communication of relevant information about patients to all the team members, effective handovers are now deemed indispensable.

There has been a number of reports on clinical handover in recent years, particularly in Australia, ranging from descriptive to evaluative studies and suggestions for good practice[1-5]. While every format cannot be directly applicable in every clinical situation, most reports agree that the handover helps improve patient safety, aids medical education, improves patient confidence and fosters job satisfaction for the medical staff.

Recognition of the importance of the clinical handover process resulted in a Clinical Handover Improvement Project at the WCH in 2004. Prior to this paediatric medical handover was an informal process. The mission statement of that project was "that within six months 100% of paediatric evening and night trainee medical officers (TMOs) will follow a standard template of clinical handover." The implementation strategies and future plans resulting from the Improvement Project included the following:

- establishment of executive support and appropriate budget,
- to explore the possible roles for IT applications in handover,
- to address all issues pertaining to the morning handover.

At the time of the WCH handover improvement project, a clinical information system module to support clinical handover was being developed (OACIS system, careconnect.sa). . There are plans to introduce it to the integrated public hospital system in South Australia, providing the planned pilot study at the WCH and Royal Adelaide Hospitals does not display any major problems.

This study reports the pilot in the Department of General Medicine, WCH, including the utility of the new handover module and the criteria for assessment of key performance indicators.

Materials and methods

The Department of General Medicine (DGM) has a throughput of approx 3-3,500 patients each year. Three concurrent teams comprising a consultant, registrar and resident medical officer manage the patients during normal working hours. After hours, a single team of one registrar and two RMOs manage the patients until midnight; one registrar is on call from midnight until the following morning. There is a consultant on-call during these 2 shifts. The after hours team provides cover for all paediatric medicine inpatients both general and subspecialty.

At 08:00, the morning handover is held in a dedicated room. The Senior Registrar or one of the Consultants facilitates the meeting which is also attended by the nursing shift coordinator from the main medical ward and the Medical Emergency Team nurse who also contribute.

The general and subspecialty day teams handover to the after hours team at 16:30 -17:00. Both medical and nursing staff use the patient list summary reports (PLSRs) prepared from the careconnect.sa OACIS clinical information system.

OACIS is an Open Architecture Clinical Information System which is comprised of a series of integrated applications designed to deliver benefits to the public healthcare sector of South Australia via information technology. It is Australia's largest multi-hospital integrated real-time common clinical information system. The integrated modules available prior to the handover pilot included

- **Clinical display**, which provides a single point of access to the integrated online patient record. It includes demographics, encounters, outpatient appointments, medications, laboratory results, imaging reports, operating theatre procedures and emergency department attendances. This allows the clinician to view a comprehensive history in real time that charts and displays information and results without having to wait for paper records to be delivered.
- **Order Entry,** which is an electronic ordering system for diagnostic, therapeutic, pharmaceutical, medical and surgical patient services and incorporates best practice information into multi-disciplinary order sets. This enables clinicians to submit prescriptions, referral requests, restricted antibiotic approval requests and requests for diagnostic, medical, surgical and therapeutic services electronically.
- **Separation Summary,** which communicates information from the public hospitals to General Practitioners and other referring providers, thus ensuring continuity of ongoing healthcare. The summary gives a comprehensive account of the encounter, tests and continuing care requirements, and may be sent by hardcopy, electronically or by secure fax to the referring provider.
- **Clinical Reporting Repository (CRR)**, which provides the capability to query, analyse, and explore the substantial clinical data held across the patient population in the OACIS Data Repository (the data store for OACIS) to facilitate clinical decision making . The repository facilitates tracking of trends over time and leads to higher quality care. This allows research and reporting which has previously, not been possible.

The only changes to the established handover process needed prior to commencing the pilot were to provide the hardware for projection of the OACIS modules within the handover room and also to provide the individual training for the users.

The process was evaluated in two ways:

1. A pre implementation survey was done with all the staff attending the handover.. This was repeated one week after deployment of the handover module. The survey will be repeated with the next rotation of trainees.

Written feedback was also sought from the users of the system by means of a notebook left in the handover room. User comments were collated and acted upon and where necessary modifications made to the OACIS module or the handover process.

Results

The results indicated that all the staff were positive about the handover process.. The majority felt that the meetings started on time and that there were few distractions. There was universal agreement that the new electronic handover provided instant access to relevant investigations and past medical details (which were not easily available in the previous format).

In the one week post-implementation survey, several staff felt the new handover process took too long. Many of the respondents also gave valuable suggestions to improve the efficiency of this process. These changes have been introduced and the overall impact will be reassessed in the final survey.

Further benefits were noticed during the period of evaluation. Details of past admission and results of prior tests were instantly available at the time of handover. One could also access references online and this was helpful in planning the care for complex patients. The system has enabled the teams to recognize reportable incidents and provision has been made to insert reminders for these to be documented and reported.

Discussion

This paper describes the successful implementation of an IT supported handover module in a busy medical unit. It has been feasible to integrate the new format with existing patient management software and enhance the efficiency of the handover process.

The addition of the handover module to the handover process has obvious advantages:

- the ability to enter free text information,
- record jobs to do
- flag urgent issues into the database
- have the ability to print out customised lists (this was well received by the medical staff)
- allow the information to be accessed by all authorized staff involved in the care of a patient, thus ensuring continuity of care.

A list of patients is displayed prominently on the screen, thus enabling all the team members to be involved in the discussion.

Nursing staff were also very receptive to the introduction of the new module. Patient management plans can be accessed by ward staff (where authorised) thus keeping them informed of the medical plans.

The survey was limited by the small group of respondents (11 medical and nursing staff). Moreover, the medical unit already had an efficient handover process in place and so the introduction of the new handover module did not result in major improvements. It will be interesting to conduct this process in an environment where no pre-existing formal handover is established. We plan to continue assessing the impact of this module as it is introduced and taken up by other medical, surgical and allied health units in this hospital as well as the other South Australian public hospitals.

We believe there are exciting potential future advantages for this module. Preliminary work has already established that the OACIS system is enhanced with the availability of bedside computing through wireless or hard wired systems and this should improve the utility of the handover module. Communication with different teams will be more efficient and, therefore, safer.

The quality of the handover can be monitored by key performance indicators generated from the CRR and data collected at the time of the handover.

Conclusion

The addition of an IT module to an already established clinical handover has enhanced the quality of the information transfer between clinicians. It has improved the quality of patient care.

Illustration only. Not to scale

The rationale for Handover

- Major contributory factor in incident leading to harm to patients
- Changing patterns of medical staff rostering move to shifts
- Background in UK safe working hours European paper suggested IT to support Handover process

Handover via Oacis

- The public hospital clinical system used in 9 metro hospitals
- Established as the daily tool of junior medical staff
- Supporting an already established process

Basic requirements for Handover tool

- Sufficient and relevant information should be exchanged to ensure patient safety;
- Tasks not yet complete are clearly understood by the incoming team;
- Tasks should be prioritized;
- Plans for patient care are easily accessible; and
- The name and contact number of the doctor responsible for the care of the patient is easily accessible.

Viewing the Handover Screen

Roster column descriptions

- **H** indicates Handover note
- **U** indicates Urgent note
- **C** indicates Current note
- * indicates note from other discipline

OTHER NOTES: Patient is insulin diabetic Nurses/Medical Staff can see others's handover by changing Type via dropdown arrow. Information can be copied and pasted into the other clinical handover form. The correct permissions must be allocated for this to w	Stat

Benefits

- Access to Urgent and Cover rosters
- Can be viewed from any location within the Hospital
- Identifies patients most in need of review
- Improved Communications
- No longer working from memory

Benefits

- **Patient Safety Increased – as a result of improved, legibile information**
- **Continuity of Care – improved transfer of clinical information**
- **Decreased Repetition**
- **Handover notes available on Patient List Summary Report**

Evaluation

- The introduction of the Oacis Handover module was well received in the Unit. The greatest impact to the Unit was at the regular meetings at 8am each day. Due to the visibility of the patient list on the screen the order of patients being “handedover” became more structured.

- Access to clinical notes resulted in a more concise delivery of information. The inclusion of clinical notes on the Patient List Summary Report meant doctors could focus more on listening than each of them handwriting notes for themselves.

- Generally it was felt Handover had become more formalised, thorough and increased educational opportunities.

Drug Interactions During Three Decades

Emelie Åstrand[a], Bengt Åstrand[b], Karolina Antonov[c], Göran Petersson[d]

[a] *e-Health Institute, University of Kalmar, Kalmar, Sweden*
[b] *E-Health Services, Apoteket AB, and Department of Chemistry and Biomedical Sciences, University of Kalmar, Kalmar, Sweden*
[c] *National Board of Health and Welfare, Stockholm, Sweden*
[d] *E-Health Institute, University of Kalmar, Kalmar, Sweden*

Abstract

Physicians may inadvertently prescribe improper combinations of drugs. Changes in the epidemiological panorama of potential drug interactions were studied during three decades, from 1983 to 2003. During the study period polypharmacy increased with 61%. Overall, potential drug interactions increased (relative risk 1.177 95% confidence interval 1.104-1.256), although the more severe interactions decreased (relative risk 0.714 95% confidence interval 0.587-0.868). Potential drug interactions and polypharmacy among the elderly should be closely monitored.

Keywords:

community pharmacy services; decision making, computer-assisted; drug interactions

Introduction

As long as mankind has used plants, animals and inorganic substances to cure and alleviate health disorders, drugs have probably been used in combinations to potentiate their intended effects. It may be favourable to use a combination of drugs if the combination is well documented to enhance the effect or to reduce adverse effects. However, it has been shown that physicians may inadvertently prescribe improper combinations resulting in less effect or more adverse drug reactions [1]. The present study was conducted in order to make an analysis on changes in the epidemiological panorama of potential drug interactions during three decades, from 1983 to 2003.

Materials and methods

The prescriptions from all individuals (n=8,318; 8,726; 8,214) with two or more prescriptions during three periods of fifteen months, October to December 1983-84, 1993-94 and 2003-2004, were collected from an ongoing cohort study in the county of Jämtland [2]. The potential interactions were detected by a computerized system and classified according to clinical relevance (types A–D), type D being the most severe [3].

Results

The relative risk of receiving potentially interacting drugs increased for type C interactions (relative risk 1.177 95% confidence interval 1.104-1.256) and decreased for type D interactions (relative risk 0.714 95% confidence interval 0.587-0.868) from 1983-84 to 2003-04. The relative risk was positively correlated to the increase in polypharmacy and for the more severe type D interactions an exponential relationship was displayed. Polypharmacy for included subjects increased over time with 61%, from 9.05 filled prescriptions per subject in 1983-84 to 10.6 in 1993-94 and 14.6 in 2003-04.

Discussion

To avoid drug interactions and adverse drug reactions prescribers should regularly check the patient's list of medication, computerized or not. The patient's age and number of medications are significant predictors of medication discrepancy. The toxicity of drug combinations may sometimes be synergistic and be greater than the sum of the risks of toxicity of either agent used alone. Screening for drug interactions should include all medication, both for inpatients and outpatients, nursing homes included. To ensure effective partnership between different healthcare professionals and the patient, good communication is essential both technically and, not at least, personally [4].

The present study was conducted in year 2005, prior to the new Swedish legislation introducing two new national databases for which the Jämtland cohort has served as a model. The Swedish National Prescribed Drug Register is intended for statistical, epidemiological, and scientific purposes, whereby drug and disease associations and the risks, benefits, effectiveness, and health economical effects of drug use may be explored [5].

For clinical purposes the equivalent information is made available by the new Swedish National Pharmacy Register, which provides prescription dispensing information for the majority of the population with the objective to improve drug utilization. The medication history in the register may be accessed online by registered individuals, prescribers,

and pharmacists. Different systems for electronic health care records contain functionality for automated detection of drug interactions. These prescribing systems should be linked to the National Pharmacy Register in order to alert physicians at the point of care not to prescribe any inappropriate drugs (or duplicates) in combination with drugs already prescribed by other physicians and filled by the patient at pharmacy [6].

The advantages of the new databases compared to the Jämtland cohort are obvious; the new databases are mandatory, comprising all individuals filling prescriptions on a national level, probably constituting one of the largest and most comprehensive prescription databases in the world. To further develop these databases, exposure to drugs within hospitals and over-the-counter sales should be added. The Jämtland cohort may well be used for longitudinal studies, with its unique historical material [4].

Conclusion

Due to a pronounced increase in polypharmacy the reason for prescribers and pharmacists to be aware of drug interactions has grown over time. The risk of receiving potentially interacting drugs has increased for the type C interactions although it has decreased for the more severe type D interactions. This could be a result of changes in the market, more awareness among prescribers as well as introduced modules for interaction detection in electronic prescribing systems.

Aim of study

to evaluate the change in risk over time of receiving potentially interacting drugs, from 1983 to 2003

Materials and Methods

- Three periods of fifteen months;

  1983, 1993, 2003
- Prescriptions from all individuals

  (n=8,318; 8,726; 8,214) with two or more prescriptions
- Collected from an ongoing cohort study in the county of Jämtland, Sweden
- Computerized interaction detection system

Results

Polypharmacy increased with 62%, from 1983 to 2003

Study period	Filled prescriptions per subject
1983	9.05
1993	10.6
2003	14.6

Results

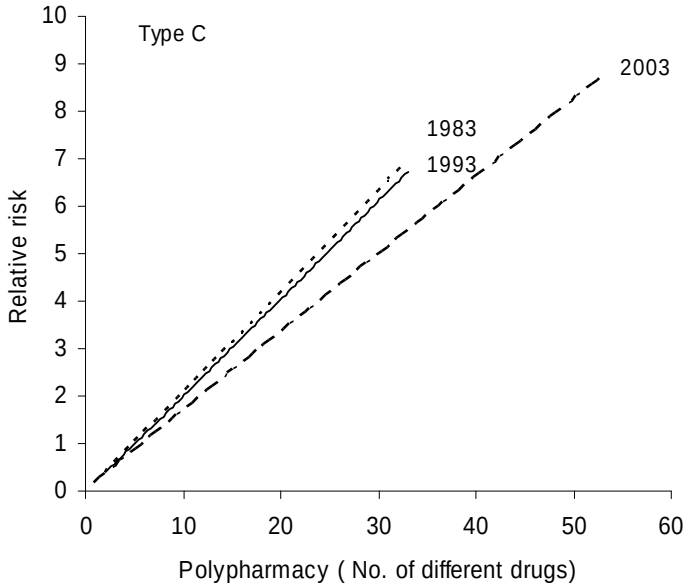
Relative risk of potentially interacting drugs

- *increased* for type C interactions
  relative risk 1.177 (95% C.I. 1.104-1.256)

- *decreased* for type D interactions
  relative risk 0.714 (95% C.I. 0.587-0.868)

Results

Relative risk positively correlated to
the pronounced increase in polypharmacy



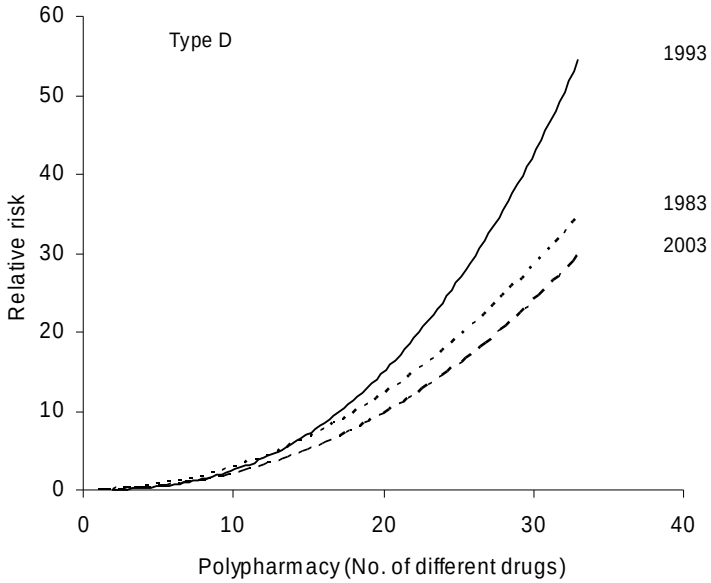


Fig. 1 Relative risk of potential interactions type C and D correlated to polypharmacy. 1983, 1993 and 2003 refer to the study periods Oct 1983 - Dec 1984, Oct 1993 - Dec 1994 and Oct 2003 - Dec 2004 respectively.

Conclusions

- pronounced increase in polypharmacy
- reason for prescribers and pharmacists to be aware that drug interactions has grown over time
- risk of receiving potentially interacting drugs

  has increased for the type C interactions,

  but decreased for the more severe type D interactions

The Efficiency of Applying Short Message Service for Surgical Patient's Families

Fan-Pin Huang[a,c], Shuo-Chi Liu[a,b], Su-Mei Shih,[c], Yao-Hua Tao,[c], Jeng-Yuan Wu[c], Shaw-Yeu Jeng[c], Po-lun Chang[a]

[a]Institute of Healthy Informatics and Decision Making, National Yang-Ming University, Taiwan
[b]Department of HealthCare Management, Yuanpei University of Science and Technology, Taiwan
[c]Armed Forces Taichung General Hospital, Taiwan

Abstract

This study was to build a web-based short message service (SMS) system in operating room. We approached the efficiency of SMS for patient's families during the time series of surgery process (pre-, intra-, and post-operation). In this study, 322 participants received 685 text messages. The findings show the usability of SMS applied to the clinical care, especially for reducing family's anxiety and improving their satisfaction. Therefore, it is suggested to exploit the effectiveness of personal medical care.

Keywords:

anxiety, surgical patient, short message service

Introduction

Patient's families usually appear stressful and helpless because of lacking information about the patient during the waiting time. The scholars also discovered high-level anxiety in both patient themselves and their family throughout the waiting period [1]. In order to achieve a good surgical patient management, it's possible to apply a novel technique for the communication between the hospital and patient/patient's family. Cellular phone is a well-established technology of communication in hospitals and commonly used with many benefits in patient care [2, 3, 4].

Materials and methods

We conducted the project in the OR that served about five hundred patients every month. The data was collected from HIS database, contents of storage text messaging, satisfaction questionnaires and anxiety scale. The investigators used available proprietary web-based software operating on Office 2003 Microsoft Windows personal computer to enter, edit, and store messages for delivery to the patients in the operation room (every8D.com, Taiwan). Outside of the operation room, mobile telephone and smart phone were considered as endorsement. The content of messages and exact time were recorded in the web database (figure1).

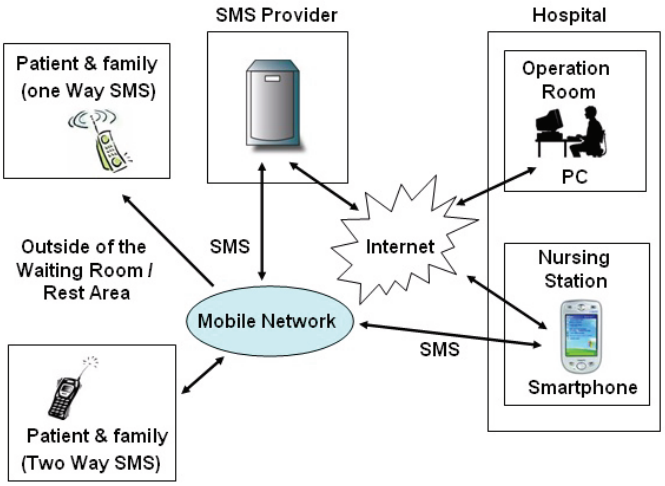

Figure 1 - The system architecture of web-based SMS system for surgical patient families

Results

The operation room totally served three hundred twenty-two participants who received 685 text messages and 283 participants answered satisfaction questionnaires (87.89) between August 20 and October19, 2005. The participants were sent 2 to 5 text messages. In all questionnaire items, the statistic data described phenomena that participants' satisfactions were high level (mean4.3, SD.69).The families reported that they were very anxiety during the waiting period when the patient in OR, the mean of anxiety score were 7.8, and 96.4% families reported the SMS could reduce their waiting anxiety(mean=2.3 ,SD=.12). About time management, 92% participants were strong agreed that the SMS provided an opportunity to arrange their time, and they did not always stay at the waiting area.

Medication reminder	4.5	.53

Conclusion

A web-based SMS build a general communication system between health delivery and people. Because the internet and cellular phone are universal, it's much easily and smoothly to develop a SMS system in hospital. It's believed that SMS is feasible to be applied in other situations such as outpatient department, medicine delivery and health information supplies.

Acknowledgments

This project was funded by the operation room at Armed Forces Taichung General Hospital, Taiwan. Thanks to all the members of 322 persons who consenting the SMS project and 283 persons answered the questionnaires. The SMS participants joined in it so well.

Discussion

- *this study captured self-reported anxiety, autonomy, and SMS demands.*
- *the automated paging system provided the advantage of personalized messages.*
- *the SMS system function is more convenience and excellent than before.*

Conclusion

- *The findings show the usability of SMS that applied to the clinical care, especially for reducing family anxiety, real time information, physician-patient communication, medical care processes and patient's safety.*

Abstract

This study presents the methodology of numerical simulation of two-phased flows (liquid melting – gas) with the separation interface specific for the filling process of the pattern for the framework of fixed partial dentures, as well as a series of numerical results for a typical geometry. Considering the presented issues, it is recommended to increase the revolution of the pouring table to 700 rotations / minute in the case of titan, creating similar conditions concerning the volume mass force between the two alloys.

Keywords:

numerical simuation, dental alloys casting, Fluent

Introduction

This study presents the methodology of numerical simulation of two-phased flows (liquid melting – gas) with the separation interface specific for the filling process of the pattern for the framework of fixed partial dentures, as well as a series of numerical results for a typical geometry.

The installation for melting and for pouring of titan - Titanplus (Seit Elettronica, Italy) is composed of a rotating table on which the pouring device is placed in dynamic balance.

The speed capacity of the pouring table is n = 500 rotations/minute, which corresponds to an angular speed of

$$\varpi = \frac{\pi n}{30} = 52.36\, rad / s$$

The heating and the melting of titan is accomplished with the help of high frequency currents. The metal pieces are placed in a crucible furnace that is set in position on the rotating table. When the melting temperature is reached, the rotating table, having the revolution n, the crucible furnace is sliding into position from where the melted metal is flowing into the pattern (the pouring shape). The flow of the melted metal into the pattern takes place especially due to the centrifugal force; the gravitational force can be neglected in this case [3].

Figures 1 and 2 present the field of analysis used to obtain the final study alternatives of the filling of the pouring cavity. Because of the great amount of calculations, two or three processors have been used at the same time as a calculating method. This method requires a partitioning of the main field into subfields, each sub domain being linked to one processor. The partitioning is made in such a way, so that the surface of the interfaces between the subfields has a minimal area and the number of junctions of the digitization network on the interfaces to be minimal. This condition is essential for the minimization (reduction) of data communications between the processors at every iteration of the solution algorithm.

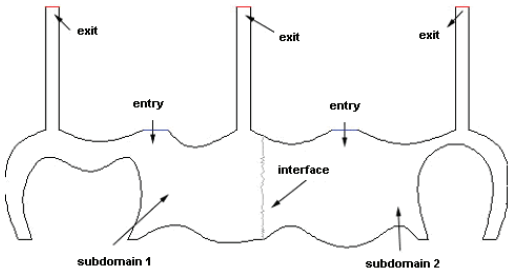

Figure 1 - The field of analysis, with the setting of the entrance/exit sections and partition into two subfields for parallel calculations on two processors

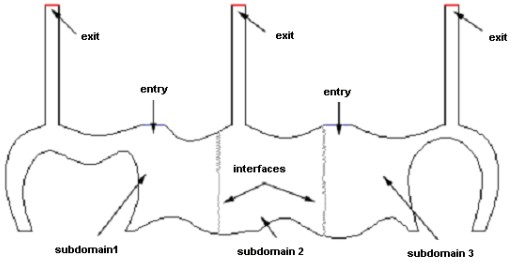

Figure 2 - The field of analysis with the setting of the entrance/exit sections and the partition into three subfields for parallel calculating on three processors

Figure 3 present the digitization network that has been used. In the details of figure 4, the used network of quadrilaterals can be observed in the neighborhood of the wall for a correct representation of the high speed gradients, with the triangulation from the inside (interior) which permits the covering of the fields with complicated geometry.

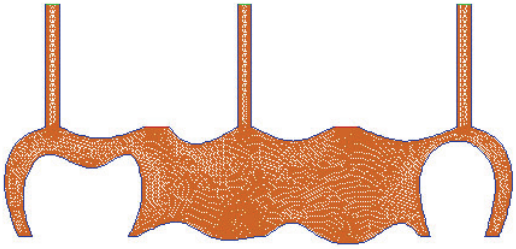

Figure 3 - The mixed digitization network of the field of analysis

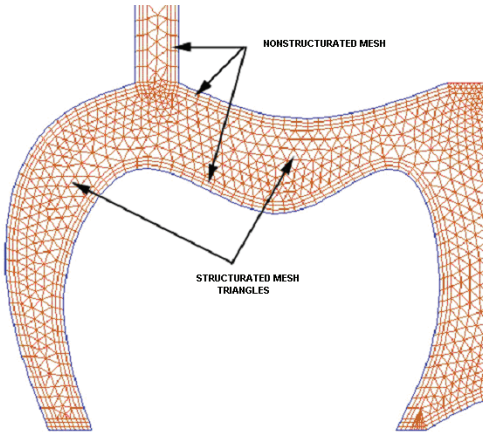

Figure 4 - Detail of the mixed digitization network

The final version for the configuration of the disposition of the ventilation channels, as well as the optimized digitization network represent some of the important accomplishments of the present study and guarantee the accuracy and the power of pointing out of the results obtained through the numerical simulation.

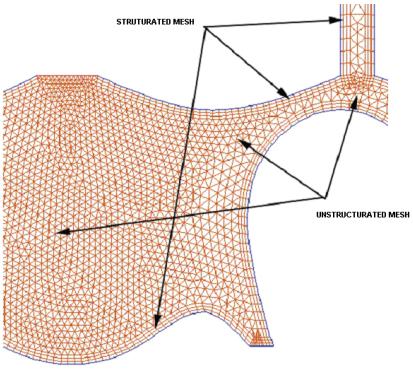

Figure 6 - Detail of the mixed digitization network. In the entrance section no quadrilateral elements are used. The layer of structured network embodies only the solid frontier, where the thick viscid fluid adheres to the wall

The local treatment of the ramifications (embranchments) is reduced to the study of the flow of the fluid into a "T"-type.

Coming back to the estimation of the entering speed of the melted metal into the cavity of the pattern,

with the hypothesis that $v_1 \cong 0$ and $v_2 \approx v$ (the medium speed in the hydraulic alimentation (supply) path) we have

$$v^2 = \frac{2}{1+\zeta}\left[\frac{\omega^2\left(r_2^2 - r_1^2\right)}{2} + \frac{p_1 - p_2}{\rho}\right]$$

In the initial stage – corresponding to the start of the flow, inside the pouring cavity the fall of the entrance/exit pressure is null and the entering speed of the melting is

$$v = \sqrt{\frac{52.36^2\left(0.14^2 - 0.1^2\right)}{2}} = 3.6\,m/s$$

After the crucible furnace has completely been emptied, due to the hydrodynamic resistance of the ventilation paths and because of the viscid chafe afferent to the flow into the pouring cavity, a difference of pressure of approximately 32000 Ps (in case of an Co- Cr alloy) appears between the entrance/exit and the speed decreases to the value of

$$v = \sqrt{\frac{52.36^2\left(0.14^2 - 0.13^2\right)}{2} - \frac{32000}{8700}} = 0.17\,m/s$$

The observation is made, that - during the filling process - the entrance speed of the melting into the cavity is consid-

erably decreasing onto the final [4]. This variation has been taken into consideration in the numerical simulation. Synthesizing the methodology of the numerical simulation, the calculation of the speed in the entrance section is made this way:

1 . first, calculation are made with a speed value of 3,6 m/s, according to the beginning of the emptying of the crucible furnace;

2. after the first interval of time, r_1 is recalculated corresponding to the liquid volume flown into the pouring form and the super- pressure p_2 is noted (p_1 is known as the atmospheric pressure);

3. the speed is recalculated in accordance with the previous relation;

4. the evolution in time continues for the new time span with the new speed value;

5. the time steps are calculated successively until the complete filling of the pouring cavity with melted metal [5].

Material and method

The numerical simulations have taken place at the Laboratory of Numerical Simulation and Parallel Calculation of the National Centre for System Engineering with Complex Fluids that functions at the University of Polytechnics of Timisoara.

The hardware infrastructure of the laboratory contains:

- 1 Linux Server, dual Pentium III, 1000 MHz, 2 GB RAM memory, 3xHDD 30 GB;
- 1 Windows Server, dual Pentium III, 1000 MHz, 2 GB RAM memory, 2xHDD 30 GB;
- 14 Working Stations, Pentium III, 1000 MHz, 1 GB RAM memory, 2xHDD 30 GB;
- Computer network infrastructure Linux /Windows, 2 Fast Ethernet Switch Allied Telesyn 24x100 Mbit, with management;
- Internet connection with optical fiber;
- uninterruptible tension sources;
- Network Printer Laser Jet HP 2200 DN, Printer Desk-Jet HP 1100C, Printer Laser XEROX P8 ex.

The software infrastructure of the laboratory is conceived to assure maximum of flexibility for the covering of a large scale of applications, in the educational field, as well as in the scientific performance research. Each working station is able to operate in Windows and Linux sub systems. The Fluent 5.5 program package is available in the Linux cluster configuration, which represents the world standard in the field of numerical simulation of fluid flow [1]. Fluent can be used in the multi-user mode (different problems are resolved simultaneously on different computers), but also in parallel calculation mode (a problem is solved simultaneously on several processors) [2]. In the Linux configuration, the network is used for the developing of parallel calculus algorithms utilizing the « Message Passing Interface » and the « Portable Extensible Toolkit for Scientific Computations » created at Argonne National Laboratory as information sources. In the Windows 2000 network, the whole usual Microsoft infrastructure is available (Visual Studio 6.0, MSDN Universal, Microsoft Office XP).

For the acquisition, processing and analysis of experimental data we use the graphic development tool LabVIEW (Laboratory Virtual Instrument Engineering Workbench). For post processing, analysis and interpretation of numerical data obtained from the simulation of the fluids flow phenomena, the Tecplot 8.0 program is available, together with its special CFD modules and the digitization network generator. A double investigation has taken place - for the titan melting and for the Co-Cr alloy. From the flowing point of view, the essential difference between the two situations is represented by the density of 4500 kg/m^3, respective 8700 kg/m^3. As the acceleration of the mass forces is determined by the rotation speed, its value remains the same in both situations. On the other hand, the mass force per fluid volume unit is equal to the product between density and centrifugal acceleration. The result shows that in case of the Co-Cr alloy, the mass force per volume unit is practically the double of that of the titan melting. This difference is responsible of the more rapid filling (and much more complete, in general) of the pouring form in the case of the Co-Cr alloy. The configurations are presented, in which the liquid phase is found at the following moments of time: 0.01 s, 0.06 s, 0.12 s, 0.25 s, 0.6 s, 1.4 s, 2.0 s and 3.0 s.

The first set of eight figures (tables 1-2) corresponds to the flow of the titan melting. It can be observed that the spurts of melted metal generated at the exit from the supply mouths are getting into contact with the inferior wall (in the following, we will be using the terms inferior/superior, although correctly it would be “at the little/large radius (beam)”, depending on the real disposition on the rotating pouring table) and are generating an ascendant spurt. At the 0.25 seconds moment this spurt enters the central ventilating channel. Subsequently, the filling of the left part of the pouring form starts, being almost filled at 0.6 s. The central area is filled in proportion of 75 % after 1.4 seconds and after 2 seconds approximately 50 % of the right part of the cavity will be filled. The almost complete filling of the cavity is accomplished in 3 seconds, with the visible existence of a few pouring imperfections afferent to the air bubbles trapped between the liquid mass and the solid walls near the supply mouths. We also appreciate the fact, that through the subsequent cover of these little imperfections with the ceramic layers, they will not have a

significant influence on the final quality of the prosthesis. The second set of seven figures (tables 3-4) present the succession of the filling phases with the Co-Cr melting. In the first filling phases, the evolution is almost identical to the titan melting; notable differences appear after 0.6 seconds. The mass force per volume unit is practically double in this case, encouraging a more uniform and complete filling of the pouring cavity. Practically, the pouring process can be considered finished after 2 seconds. The same little flaws or imperfections remain visible as in the case of the Co-Cr alloy.

The essential difference is that under the circumstances of maintaining of the same revolving of the rotating table - the titan pouring process lasts approximately 3 seconds, while for the Co-Cr alloy, there are only 2 seconds necessary to fill the form. Considering that titan is poured at a temperature over 1700 ºC and the Co-Cr alloy at 1300 ºC, the result shows, that the heat loss -and at the same time - the decrease of the temperature of the melting during the pouring process, is much smaller for Co-Cr. This is the main explanation for the different results obtained in practice with the two types of materials, in favor of the Co-Cr alloy.

Results

At first, a demonstration of the flow properties of titan, respective Co-Cr is presented; then, there is an explanation of the mathematic model that stands at the base of the FLUENT program that has been used for calculating. The capacity (the abilities) and limitations of this model are pointed out and the VOF type is found as proper for these particular investigations. The next step is represented by the analysis of the hydrodynamic of the supply path of the pouring form in order to evaluate the entrance speed of the melting into the cavity, as well as the variation in time of this speed.

For the numerical experiments, a typical geometry has been established for the fixed partial dentures and study versions have been carried out – with and without the taking into consideration of the embranchment of the supply channel, together with two versions of disposition of the ventilation channels. Initially, the field of analysis has been digitized with an unstructured network, this assuring the necessary flexibility for the approach of complex geometries. After that, a mixed network has been constructed, with quadrilateral elements near the solid wall and a triangulation inside the domain. This mixed network leads to the best numerical results.

The numerical simulations are the result of a great volume of calculations. As an example, the used time step (restricted because of stability considerations) is 10^{-4} seconds, which means that for a sequence of three seconds, $3x10^4$ time steps are needed. For every time step, the equation system that governs the two-phased flow is calculated iteratively, with a medium number of 3 iterations; this means a total of almost 10^5 iterations. The version of parallel calculation on three processors shows as a result a single iteration per second in its best shape, which gives us a rolling time of 10^5 seconds, which represent 28 hours. It must be said, that this version is the final result of multiple optimizations after more than 500 hours of pure calculation.

In the case of the version with a single processor (in our case PIII/GHz), one study version lasts three an a half days when optimized. Although this might seem an excessively large time span, the calculation effort is fully justified by the quality of the obtained results.

The preliminary numerical results have pointed out a series o problems of pure hydrodynamic origin, which may lead to the incomplete filling of the cavity of the pattern:

- The asymmetry of the embranchment of the supply channel, corroborated with the geometry of the cavity, may lead to a preferential filling of only one part of the cavity; this is why a careful execution of the distribution network of the melting to the cavity, with the best choice of the entrance angles into the cavity.
- even when assured of an even (uniform) repartition of the melting flow through the supply mouths of the cavity, there may appear difficulties caused by the improper disposition of the ventilation channels. This problem expresses the necessity of placing the ventilation channels on the same side with the supply mouths of the cavity.

As a result of these preliminary observations, an optimal disposition of the ventilation channels has been established (a number of three for the investigated case)- on the same side with the supply mouths. The calculation of the time variation of the effective flow supply permitted a realistic estimation of the length of the pouring process.

For titan three seconds are necessary, while for the Co-Cr alloy only two seconds are needed to accomplish a complete filling of the cavity. This difference is explainable by the significant difference of density (from simple to double).

Conclusion

Considering the presented issues, it is recommended to increase the revolution of the pouring table to 700 rotations / minute in the case of titan, creating similar conditions concerning the volume mass force between the two alloys.

The results presented in this study are no final solution for the problem of the geometric design of patterns for the pouring of frameworks for fixed partial dentures, but they

clearly point out the drawbacks that appear in practice and offer alternatives for eliminating them. We feel that these investigations must be extended and thoroughly analyzed, the numeric experiments being less costly and offering much more details about the intimacy of the pouring phenomena than physical experiments. The physical experiment should only be considered as a final validation of the results proposed by the numerical studies.

[2] University of Polytechnics of Timisoara

Abstract

The numerical simulation is a new method that allows evaluating the prognostic of some therapeutically solutions, in our case of the behavior of the prosthetic restorations such as fixed partial prostheses.

Materials and methods

The tool that is used is called MODELA and it can scan through contact, in successive steps, the shape of a solid object. The sum of the points identified as being solids is mathematically preceded and transformed in a virtual three-dimensional representation that is made according to the scanned solid surface. The scanning failure depends on the shape that is scanned and it can be of maximum 0.5 mm, equal to the rise of the needle scan.

Results

The maximum deformations were registered mainly at the fixed partial prostheses that are made of gold, the following were the ones made of ceramics, composite resin, titan, as for the minimum deformations were registered for Co-Cr alloys. A general characteristic was the existence of some maximum tensions at low temperatures (-100C) that reduced afterwards as the temperature increased. It is very important to point out this topic, as it explains the high fragility level of the fixed partial prostheses at low temperatures. This fragility is compensated by metal through its structure, but the ceramics, a material that has a low elasticity, can be broken when making similar trials.

Conclusions

The fixed partial prostheses made out of gold present a reduction of the maximum tensions recorded (at 500C) of 72.01% from the initial recorded value at -1000C, when using the same loading force. The fixed partial prostheses completely made out of ceramics presents a reduction of the initial values of 74.04%. The fixed partial prostheses that is made of composite resin gets to 81.14% of the initial values, while the Co-Cr fixed partial prostheses gets to 51.28%. The one made out of titan records a reduction of the tensions to 64.36% of the initial values. The lowest reductions were recorded in the cases of fixed partial prostheses made out of composite resin (18.86%), followed by ceramics (25.96%), gold (27.99%), titan (45.64%)and Co-Cr (48.72%)

Comparing Messages in an Online Communication Forum for Cancer Patients with Patients' Messages to a Clinical Nurse Specialist

Annette Jeneson, Trine Andersen, Cornelia Ruland

Center for Shared Decision Making and Nursing Research, Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway

Abstract

WebChoice is an online support system where cancer patients can exchange messages with other patients in an open communication forum as well as send personal e-mails to a clinical nurse specialist (CNS) who responds to their concerns. We compared the content of messages posted in the open forum with personal e-mail messages sent to the nurse. While patients were concerned with similar topics in both communication areas, there were differences in the types of messages sent. More patients actively used the patient-nurse email service compared to the forum, suggesting that nurses can play an important role in online systems supporting cancer patients over the Internet.

Keywords:

online systems, communication, nurse-patient relations, neoplasms

Introduction

Despite a growing interest in online support forums and patient-provider communication systems, knowledge of the relative use and benefits of these communication systems is still limited. In particular, there is little information about how patients' communications with care providers online differ from communications in discussion groups. Additionally, while a few studies have analyzed online messages between patients and physicians, online patient-nurse communication and the potential for nurses to support patients via the Internet is as of yet largely unexplored. The purpose of this study, therefore, was to compare the content of patient-nurse messages to messages posted on an online discussion forum for cancer patients. The study is part of a larger ongoing trial testing the effects of WebChoice, an internet support system for breast- and prostate cancer patients [1]. WebChoice includes tools for symptom monitoring, tailored information to support self-management, support forums for anonymous group discussion, as well as a more "private" communication area to exchange messages with a CNS specializing in cancer care.

Methods

We examined forum postings and e-mail messages by patients who logged on to WebChoice at least once from March - October 2006, resulting in a sample of 355 postings and 174 e-mails. Messages were coded according to the 'type' and 'topic' categories listed in Table 1 below. The 'type' categories are consistent with the coding schema of Klemm *et al* [2]. A message could belong to more than one category. An e-mail with questions about lymphedema and anxiety, for example, would be coded as *information seeking* for 'type', and *symptoms* and *feelings* for 'topic'. Messages were independently coded by two of the authors (AJ and TA) and 10% were coded by both to compare interrater agreement, established at 98 % for e-mail messages and 97 % for forum postings.

Results

Table 1 shows the percentages of e-mails and forum postings coded under the various 'type' and 'topic' categories.

Table 1 - Percentage of messages categorized by type and topic

		E-mails (*174 total*)	**Postings** (*355 total*)
TYPE	Personal experiences/ opinions	66	75
	Information giving	2	20
	Information seeking	62	20
	Encouragement / Support	0	17
	Thanks	22	8
TOPIC	Health personnel / institutions	21	20
	Treatment / Tests / Test results	63	59
	Symptoms / Side-effects	64	66
	Energy / Fatigue / Sleep	9	10
	Feelings	14	10
	Sexuality / Partner	3	7
	Family / Colleagues / Others	5	3
	Living with cancer / Lifestyle	22	23
	Metastasis / Relapse	7	8

The average number of topic categories per e-mail or posting was 2.4 (±1.5) and 2.3 (±1.3), respectively. As seen in Table 1, patients were concerned with largely the same topics in their e-mail messages and in their forum postings, but the type of message or posting varied, with e-mails being more 'information seeking' in nature and postings being more 'supportive' and 'information giving' to others.

There were also differences in use of the e-mail component of the WebChoice system compared to use of the discussion forum in terms of the number of participants actively using these two different components. 71% of participants given access to WebChoice logged on at least once in the data collection period (43 females and 31 males). Of these active WebChoice users, more patients used the patient-nurse communication area (n=45 or 61% of WebChoice users) compared to those submitting messages to the forum (n=34 or 46% of users). This holds true for breast cancer patients as well as prostate cancer patients. 72% of female users who logged on to the system at least once between March to October 2006 sent at least one e-mail to the nurse while 58% submitted at least one posting. 45% of active male users sent an e-mail to the nurse while 29% contributed to the forum. However, while more patients wrote e-mails to the nurse compared to the number of patients who submitted a posting in the forum, those patients actively participating in the discussion forum submitted on average more postings (10.4±10.5) compared to the average number of e-mails sent to the nurse (3.9 ± 4.6).

Discussion and conclusion

This sample of messages and forum postings, although small, provide useful information for health professionals interested in online communication systems. In a number of computer-based support systems for patients the communication areas are consistently highlighted as the most popular sections of the system, yet our knowledge about patients' use and benefits of different features within these communication areas is limited. A preliminary usage analysis of WebChoice suggest the forum is so far the most visited section in this support system [3], but the fact that more patients submit messages to the nurse via e-mail compared to the forum, and that the nature of messages in these two communication areas differ, suggest that opportunities for patient-nurse communication can provide valuable support for patients beyond that of support offered by participation in online discussion groups. Patients often experience multiple symptoms during treatment and rehabilitation, yet short hospital admissions allow little time for detecting and relieving these. Moreover, side-effects of certain treatments are often worst after the patients are discharged to home.

Therefore, patients could greatly benefit from support through an Internet based system, where they can communicate with a care provider independent of scheduled hospital or doctor appointments in an environment that is readily accessible and even anonymous. In this sample almost all of the questions patients asked via e-mail could be appropriately addressed by the CNS and did not require advice from a physician or other specialist. This suggests that online communication with a nurse may potentially reduce not only needless patient suffering and worrying but also the numbers of doctor's appointments scheduled. As cost concerns and shortages of health professionals continue to rise, online peer- and professional support provided by nurses could prove a viable health care supplement that can improve delivery of high quality patient care in the future [4].

Comparing Messages in an Online Communication Forum for Cancer Patients with Patients' Messages to a Clinical Nurse Specialist

Annette Jeneson MA, Trine Andersen RN, Cornelia M. Ruland RN, Ph.D
Center for Shared Decision Making and Nursing Research
Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway

Background

Despite a growing interest in online support forums and patient-provider communication systems, knowledge of the relative use and benefits of these communication systems is still limited. In particular, there is little information about online patient-nurse communication and the potential for nurses to support patients via the Internet.

Purpose

To compare the content of patient-nurse messages to messages posted on an online discussion forum for cancer patients as part of an ongoing trial testing the effects of WebChoice, an internet support system for breast- and prostate cancer patients.

About WebChoice

WebChoice is an internet support system for breast- and prostate cancer patients where

- **Patients can monitor symptoms over time.**
- **Patients have access to evidence-based self-management options tailored to their reported symptoms as well as general information about living with cancer.**
- **Patients can ask questions to a clinical nurse specialist via e-mail and exchange experiences with other patients in anonymous discussion groups.**

An ongoing randomized clinical trial evaluates effects of WebChoice on patient outcomes

Sample

- **71% of participants given access to WebChoice logged on at least once in the data collection period (43 females with breast cancer and 31 males with prostate cancer).**

- **We examined 355 forum postings and 174 e-mail messages submitted by patients who logged on to WebChoice at least once from March - October 2006.**

Method

- **Postings and messages were coded according to various ‘type’ and ‘topic’ categories as listed in Table 1 and 2 on the following slides. A message could be coded under more than one category.**

- **All messages were independently coded by two of the authors (AJ and TA) and 10% were coded by both to compare inter-rater agreement, established at 98 % for e-mails and 97 % for postings.**

Results

Table 1. Percentage of Messages Categorized by Type

	E-MAILS (174 total)	POSTINGS (355 total)
Personal experiences / opinions	66	75
Information giving	2	20
Information seeking	62	20
Encouragement / Support	0	17
Thanks	22	8

Results

Table 2. Percentage of Messages Categorized by Topic

	E-MAILS (174 total)	POSTINGS (355 total)
Health personnel /institutions	21	20
Treatment / Tests / Test results	63	59
Symptoms / Side-effects	64	66
Energy / Fatigue / Sleep	9	10
Feelings	14	10
Sexuality / Partner	3	7
Family / Colleagues / Others	5	3
Living with cancer / Lifestyle	22	23
Metastasis / Relapse	7	8
AVERAGE NUMBER OF TOPIC CATEGORIES	2.4 (±1.5)	2.3 (±1.3)

Results

- **More patients used the patient-nurse communication area (n=45 or 61% of WebChoice users) compared to those submitting postings to the forum (n=34 or 46%). This holds true for breast cancer patients as well as prostate cancer patients:**
- **72% of female users sent at least one e-mail to the nurse while 58% submitted at least one posting.**
- **45% of male users e-mailed the nurse while 29% contributed to the forum.**
- **However, patients submitted on average more postings (10.4±10.5) compared to the average number of e-mails sent to the nurse (3.9 ± 4.6).**

Discussion and Conclusion

The fact that more patients submitted messages to the nurse via e-mail compared to the forum and that the nature of messages in these two communication areas differ suggest that opportunities for patient-nurse communication can provide valuable support for patients beyond that of support offered by participation in online discussion groups.

Discussion and Conclusion

Most of the questions patients asked via e-mail could be appropriately addressed by the clinical nurse specialist and did not require advice from a physician or other specialist.

Online peer- and professional support provided by nurses could prove a viable health care supplement that can improve delivery of high quality patient care in the future.

Gender Differences in Online Messages Among Cancer Patients

Trine Andersen, Annette Jeneson, Cornelia M. Ruland

Center for Shared Decisionmaking and Nursing Research, Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway

Abstract

While previous research on online patient discussion groups has provided insights into patients' information and communication needs, we still know relatively little about whether women and men use online discussion groups differently and, if so, in what ways they differ. In this study we explored gender differences in messages submitted to online support groups in WebChoice, an internet support system for breast- and prostate cancer patients. Both men and women often shared personal illness experiences and they were equally supportive to each other, but women made use of online discussion groups considerably more frequently than men. Men were more information seeking and less information giving than women, and they were more thankful in their responses.

Keywords:

Online discussion groups, gender differences, cancer

Introduction

There is a widespread use of discussion groups for patients with different diseases on the Internet, and a few studies have analyzed information needs and message types posted in online support groups. However, little is still known about gender differences in the use of online discussion groups. Therefore, the purpose of this study was to explore gender differences in messages submitted to online support groups that are part of the WebChoice application, an online support system for breast- and prostate cancer patients [1]. WebChoice allows patients to monitor symptoms over time, and provides access to evidence-based self-management options tailored to their reported symptoms. It also provides a communication area where patients can ask questions to a clinical nurse specialist and exchange experiences with other cancer patients in anonymous discussion groups. This study is part of a larger ongoing randomized clinical trial that evaluates effects of WebChoice access on patient outcomes. Each participant is followed up for one year. The experimental group in the trial has unlimited access to a disease specific support group as well as a mixed support group for both breast- and prostate cancer patients.

Methods

We examined all forum postings from 43 women and 31 men undergoing treatment for breast- or prostate cancer who logged on to WebChoice at least once between March - October 2006 (constituting 71% of study participants in the experimental group with access to WebChoice). There were 355 forum postings that were coded according to response categories in Klemm et al's coding scheme [2] as listed in Table 2. Each posting was coded under one to three response categories, dependent on the number of category types within the same posting (e.g. the participant was sharing personal experiences as well as seeking information). All postings were coded independently by two of the authors (AJ and TA) with an inter-rater agreement of 98%. Uncertainties were resolved through discussion.

Results

Participation in the online support groups

As seen in Table 1 below, more women made use of the internet support system compared to men. Women also participated considerably more in the online support groups than men, and they submitted more postings.

Table 1: Gender differences in number of forum postings

	Male	Female
Subjects logged on to *WebChoice*	31 (42%)	43 (58%)
Total and average # of postings	66	289
# of subjects submitting posting(s)	9 (29%)	25 (58%)
Average # of postings pr subject who submitted postings	7,44	11,52

Type of messages in the forum postings

Table 2 shows that personal experiences, such as telling about their illness and treatment history, was the most frequently used message type for both men and women, which is consistent with other studies [2]. Contrary to findings reported by Klemm et. al [2], women in our study were more information giving (e.g. sharing personal knowledge with others and giving advice) than men, while men were more information seeking (e.g. asking others

about their experiences). Both gender groups were equally supportive of each other, but men were more often thankful in their responses than women.

Table 2 - Gender Differences in Response categories

	Male	Female
Personal experiences	46 (70%)	220 (76%)
Information giving	8 (12%)	64 (22%)
Information seeking	19 (29%)	53 (18%)
Support	12 (18%)	49 (17%)
Thanks	14 (21%)	16 (6%)

Discussion and conclusion

This study revealed interesting gender differences in messages submitted by breast cancer patients compared to prostate cancer patients. Considering that breast cancer treatment is more standardized than treatment for prostate cancer, however, the finding that men were more information seeking and less information giving than women might be related to the diagnosis as well as potential gender differences in communication style. More research on online communication among patients with less gender specific diagnoses is needed to explore this further.

Further research is also needed to explore the extent to which men and women passively participate in the online support groups by 'lurking' i.e. reading the postings but not actively participating themselves.

Another important issue to address in future research is to look at which topics patients bring up for discussion in different types of communication arenas, for example online support groups versus traditional support groups. Since online discussion groups allow anonymity, participants might address concerns that are important to them but too embarrassing to discuss face to face with others. Not only can participation in an online discussion group provide opportunities for discussion of more sensitive issues, it can also allow participants to distance themselves more to certain participants or topics than what is "socially acceptable" in traditional, face to face support group discussions, where it is expected that all participants share and listen to other participants' experiences and fears.

While certain barriers to participate in discussion networks might be fewer and the availability provided by the Internet better compared to traditional support groups, many patients no doubt prefer talking to someone face to face. One reason for our interest in exploring gender differences in messages submitted in the WebChoice system is to increase our knowledge about and awareness of who participates in these discussion groups, who don't, and for what reasons. If our goal is to provide systems for communication about health related problems that are useful for everyone, we should be attentive to differences in preferences and aim to offer a wide enough variety of options for communication in order that it can be tailored to the needs of each patient. It is obvious that these types of research goals require a broader investigation than the current exploration, and some logical next steps in this research area would be to ask why fewer men participate in online discussion groups compared to women and whether the differences observed here are true also of communication/ participation in traditional support groups.

Acknowledgments

We thank Laura Slaughter and Gro Hjelmeland Grimsbø for useful discussions.

BioHealth – Encouraging the Use of eHealth Security and Identity Management Standards

Claudia Hildebrand, Hans Demski,

GSF – National Research Centre for Environment and Health, Neuherberg, Germany

Abstract

Shared care and cross-border interactions require a reliable and stable framework based on the application of standardised solutions. These are often not sufficiently known, diffused and not implemented. The EC funded project BioHealth aims to raise awareness on eHealth standardisation, to inform on security standards and to facilitate their practical implementation. It also evaluates socio-economic and cultural aspects concerning eHealth with particular reference to the introduction of emerging technologies such as biometrics and RFID.

Keywords:

eHealth, security, standardisation, id management, biometrics

Introduction

Major social and economic changes are presently taking place in Europe. Thus the mobility of the citizens poses a major challenge on a continent which is still divided into many different regions with differing individual healthcare solutions, reimbursement systems and legal and ethical backgrounds. In many European countries the traditional social services are being linked to health services. Technological advances offered by new approaches, e.g. telemedicine, ask for new -international- solutions. The increased accessibility provided by eHealth solutions implies a growing need for security. Facilitating patient mobility -one of the goals of the Lisbon strategy Communication to the Spring European Council: "Working together for Growth and Jobs: A new Start for the Lisbon Strategy", Brussels, 2 February 2005, COM (2005) 24.- asks for standardisation. Security standards are high on the agenda. Identity management (IdM) and biometrics are to support the current deployment of reliable and interoperable security solutions. However, the acceptance, use and implementation of standards do not meet expectations.

Methods

Standardisation initiatives in eHealth

eHealth systems must be secure and privacy compliant at all times. They have to be based on trustworthy and reliable communication and application security services and they have to be failsafe and available at all times Blobel B: Analysis, Design and Implementation of Secure and Interoperable Distributed Health Information Systems. Series "Studies in Health Technology and Informatics" Vol. 89. IOS Press, Amsterdam 2002.. Cross-border solutions must make sure that the technical solutions are interoperable, but comply -at the same time- with the national legal and cultural requirements. The privacy and data of those involved needs to be protected. Standards facilitate interoperable solutions. However, almost each European country has its own national standardisation body issuing national standards.

The European Commission has been supporting standardisation activities for many years. CEN, the European Committee for Standardisation, was founded in 1961. The major activities of CEN/TC 251 -responsible for Health Informatics- standardisation are currently directed to "EHR communication" and to updating "Secure User Identification - Strong Authentication Using Micro-processor Cards". CEN/ISSS provides market players with a comprehensive range of standardisation services and products. Focus Groups report on the current standards' environment in a particular area of public interest to provide recommendations on necessary standardisation work for the future. CEN/ISSS eHealth Standardisation Focus Group investigated standards' requirements in the area of eHealth in support of "eEurope 2005 Action Plan". Presently main priorities of the European standardisation activities are the harmonisation of identification and authentication of the European citizen. Other important Standards Developing Organisations (SDOs) are -amongst others- ITU (International Telecommunication Union) and ETSI (European Telecommunications Standards Institute).

In some countries, international standards range first, followed by national ones. Established in 1998, ISO/TC 215 - Technical Committee Health Informatics of the International Standards Developing Organisation ISO- has been focusing on eHealth-related standards activities. Some important standardisation activities are currently "Privilege Management and Access Control" and "Public Key Infrastructure". ISO/TC 215 liaises with several other organisations like CEN or DICOM. ISO/IEC JTC1/SC17 - Joint Technical Committee on Biometrics- hosts working groups on ePassport, driver license and health. For other international organisations and more details see BioHealth

Consortium: Deliverable 2.1: Guidelines on the standardisation activities, their implementation and how to gain maximum benefit – available after registration at http://biohealth.gsf.de..

Challenges

eHealth with its many stakeholder groups strongly requires standards which procure tangible benefits in order to be accepted by the users. This, however, asks for those most affected -citizens, patients and healthcare employees- to increase their influence on the SDOs. Therefore, awareness -achieved by a respective level of information, education and training measures- are vital. Standards or even information thereof are mostly difficult to access; users are often not aware of their existence. Decision makers as well as Small and Medium Enterprises, however, depend on this information for writing tenders, or for developing interoperable systems. The varying and often competing standards at the different levels pose an additional problem. Missing legal regulations at European level hinder well proven national initiatives to successfully being transferred to European level.

BioHealth

BioHealth (Security and Identity Management Standards in eHealth including Biometrics) aims at promoting, in a European framework, the diffusion, knowledge and understanding of security standards in the area of eHealth. It especially emphasizes privacy rules, id management and implementation of biometrics as a Privacy Enhancement Technology.

Many people consider information about their health to be highly sensitive and to deserve strong protection. In shared care several health professionals may be sharing one patient record across differing health systems in different institutions and even across borders. Information associated with identities may change over a period of time. Adequate IdM and systems that interact with other information systems are required. Biometric technologies are a key technology for secure identification and for personal verification. Emerging technologies like radio frequency identification (RFID) hold the promise of improving patient care. Via RFID chips medical drugs in hospitals can be tracked. They can be used to follow up a patient in an emergency setting or to monitor a person and enable him/her to continue living at home. Tagging and biometrics raise a number of significant legal and ethical questions. Differing legal regulations cause additional problems. BioHealth addresses these issues.

BioHealth aims to raise awareness, confidence and acceptance among the users of security technologies by providing information on standardisation activities, standards and related subjects. The BioHealth portal serves for information exchange, coordination and community-building. It is open to contributions from the various stakeholder groups. Policy makers are contacted to advance convergence of the standardisation policies in eHealth on a European level. Presently, eHealth security standards are being analysed and optimised for use by the stakeholders.

Discussion

Changes caused by the introduction of a new system have often been underestimated. eHealth requires the support of those involved. Systems have to be secure and reliable at all levels and at all times. This will decrease perplexities and build the necessary trust to accept and support eHealth. Standardised and interoperable solutions are a necessity. Strong authentication methods have to ensure that the information can only be accessed by the entitled person. New technologies like biometrics or RFID are on the verge of being introduced. Their relation with privacy issues is a very delicate issue and any objection raised in terms of threatening data protection has to be taken seriously. Standards, on the other hand, have to be known, they have to be understood, they have to be appropriate and affordable.

Conclusion

eHealth provides solutions to 21st century healthcare. Interoperability is a necessity. This is facilitated by standards. Though significant work has been done on the required standardisation in recent years, many of the results are not known to the user nor has the standards' usability been fully evaluated. BioHealth informs users on security related standardisation in eHealth. The project's work focuses on standards' analysis, the security of data and identity management, and the legal, societal and ethical issues concerning IdM, biometrics and the new technologies related to eHealth security. BioHealth will support the implementation of standards by setting up guidelines. A website [http://biohealth.gsf.de] is available as a first step to an open platform for those interested this topic. Thus BioHealth intends to make a sounding contribution to eHealth in Europe.

Acknowledgment

The authors would like to thank the European Commission for funding the BioHealth project.

BioHealth is supported by the European Commission under the Europe INNOVA initiative

European Healthcare 2006

- Europe's health sector employs 9.3% of the EC's workforce.
- Europe's health sector is worth over 8.5% of its gross domestic product. The estimated size of the European eHealth market is €20 billion.

- 50,000 people die each year of healthcare-related infections in the EC.
- The EC estimates the costs of healthcare-related infections at £1 billion a year in the UK alone.

Healthcare becoming eHealth necessitates changes

- Care
  - Patient - Doctor treatment -> shared / collaborative care
  - Acute care -> preventive care
  - Cooperation with other domains (bio-informatics, public health, social care)
  - Increased communication
  - Administrative changes
- Role of the citizen
  - Access to health related information
  - Educate the citizen
  - Personalised electronic health care records

Need for EHR, Data Protection and Privacy, Identity Management

New Developments and Requirements to be met

- Technological Advances
  - Telemedicine (e.g. tele-consultation, home-monitoring)
  - Paper-based records -> digitalised electronic health record (EHR)
  - New technologies (e.g. wireless, multimedia, RFID)
- European Challenges
  - Increased movement of citizens
  - Diverse healthcare systems
  - Healthcare systems at differing development stages
  - Multitude of languages, cultures and ethics
  - Contradictory laws

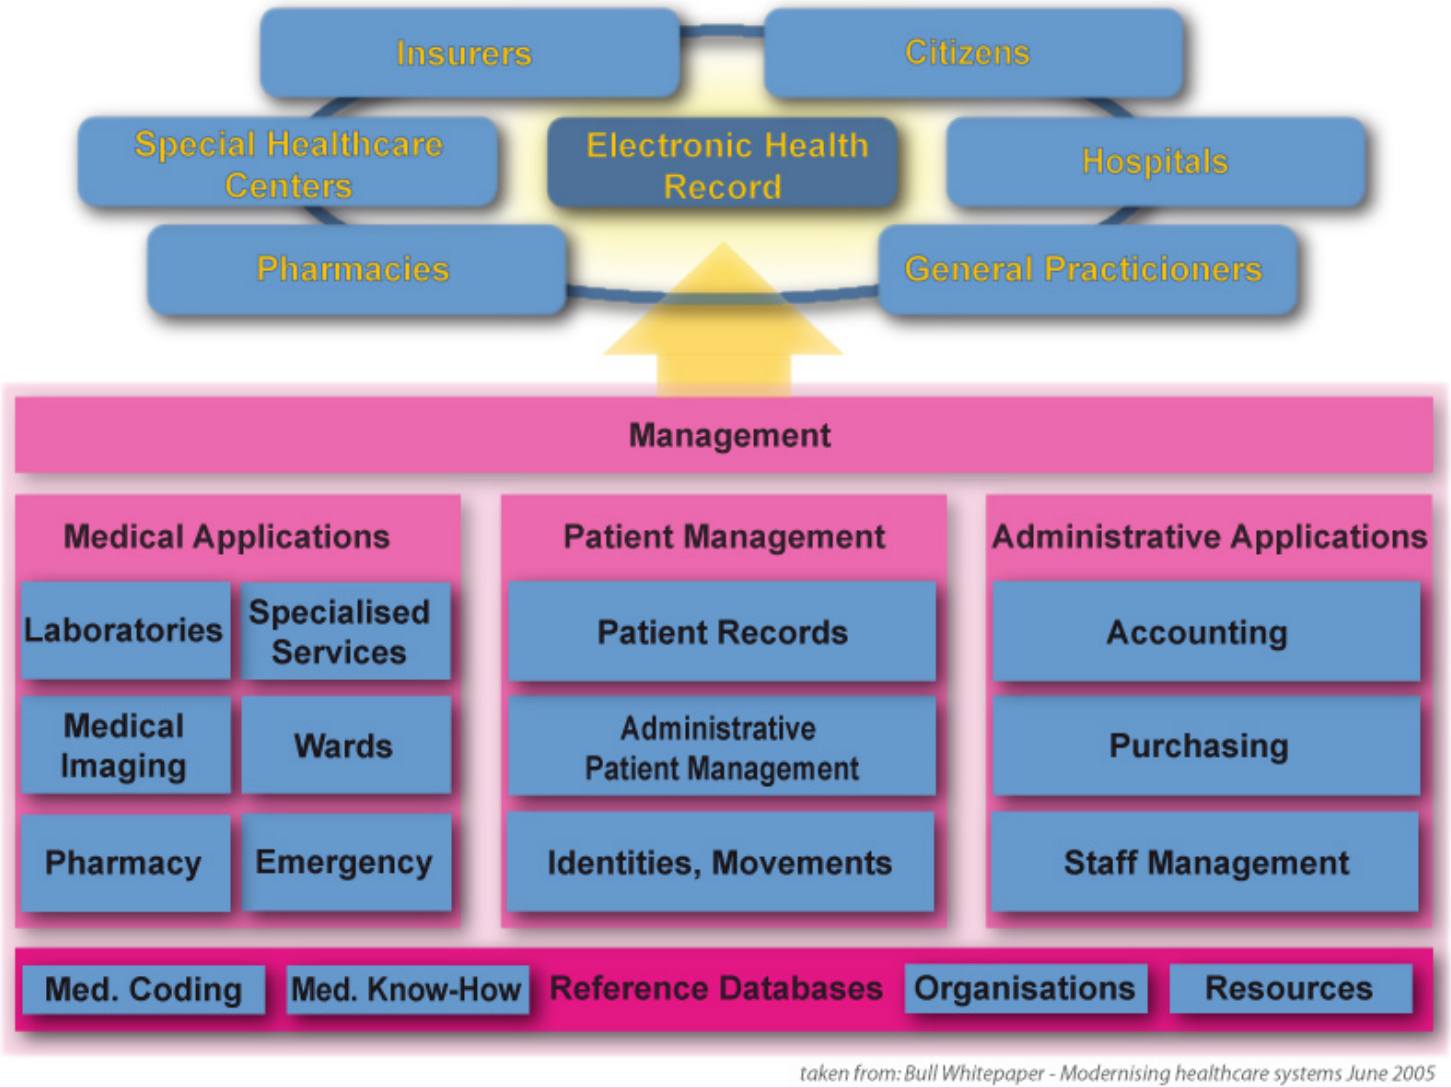
This requires secure, reliable, interoperable and standardised solutions

The BioHealth Project

- Creates awareness and acceptance on security, data protection, id management and related issues
- Informs on
  - eHealth Security Standards presenting the results of existing standardisation efforts
  - Security and Identity management pointing out special European requirements in eHealth
  - Identity management and new technologies and on critical issues connected to these
- Provides information and expert advice on standardisation related to eHealth security and facilitates the practical implementation
- Demonstrates the competitive advantages gained when applying standards
- Facilitates European and cross-boarder solutions

Thus it enforces the use of security related standards in eHealth

Security concerns all areas of healthcare



taken from: Bull Whitepaper - Modernising healthcare systems June 2005

eHealth Security requires

- **Data protection** "the implementation of administrative, technical, or physical measures to guard against the unauthorized access to data" [1]
- **Data safety** "the protection of data from unauthorized (accidental or intentional) modification, destruction, or disclosure" [1]
- **Privacy** "the subjective condition a person experiences when he or she has the power to control information about him-/herself and when he or she must exercise that control consistent with his/her interests and values" [1]
- **Safe and reliable communication**
  - Confidentiality
  - Data Integrity
  - Authenticity
  - Accountability
- **Failsafe and full-time available systems**

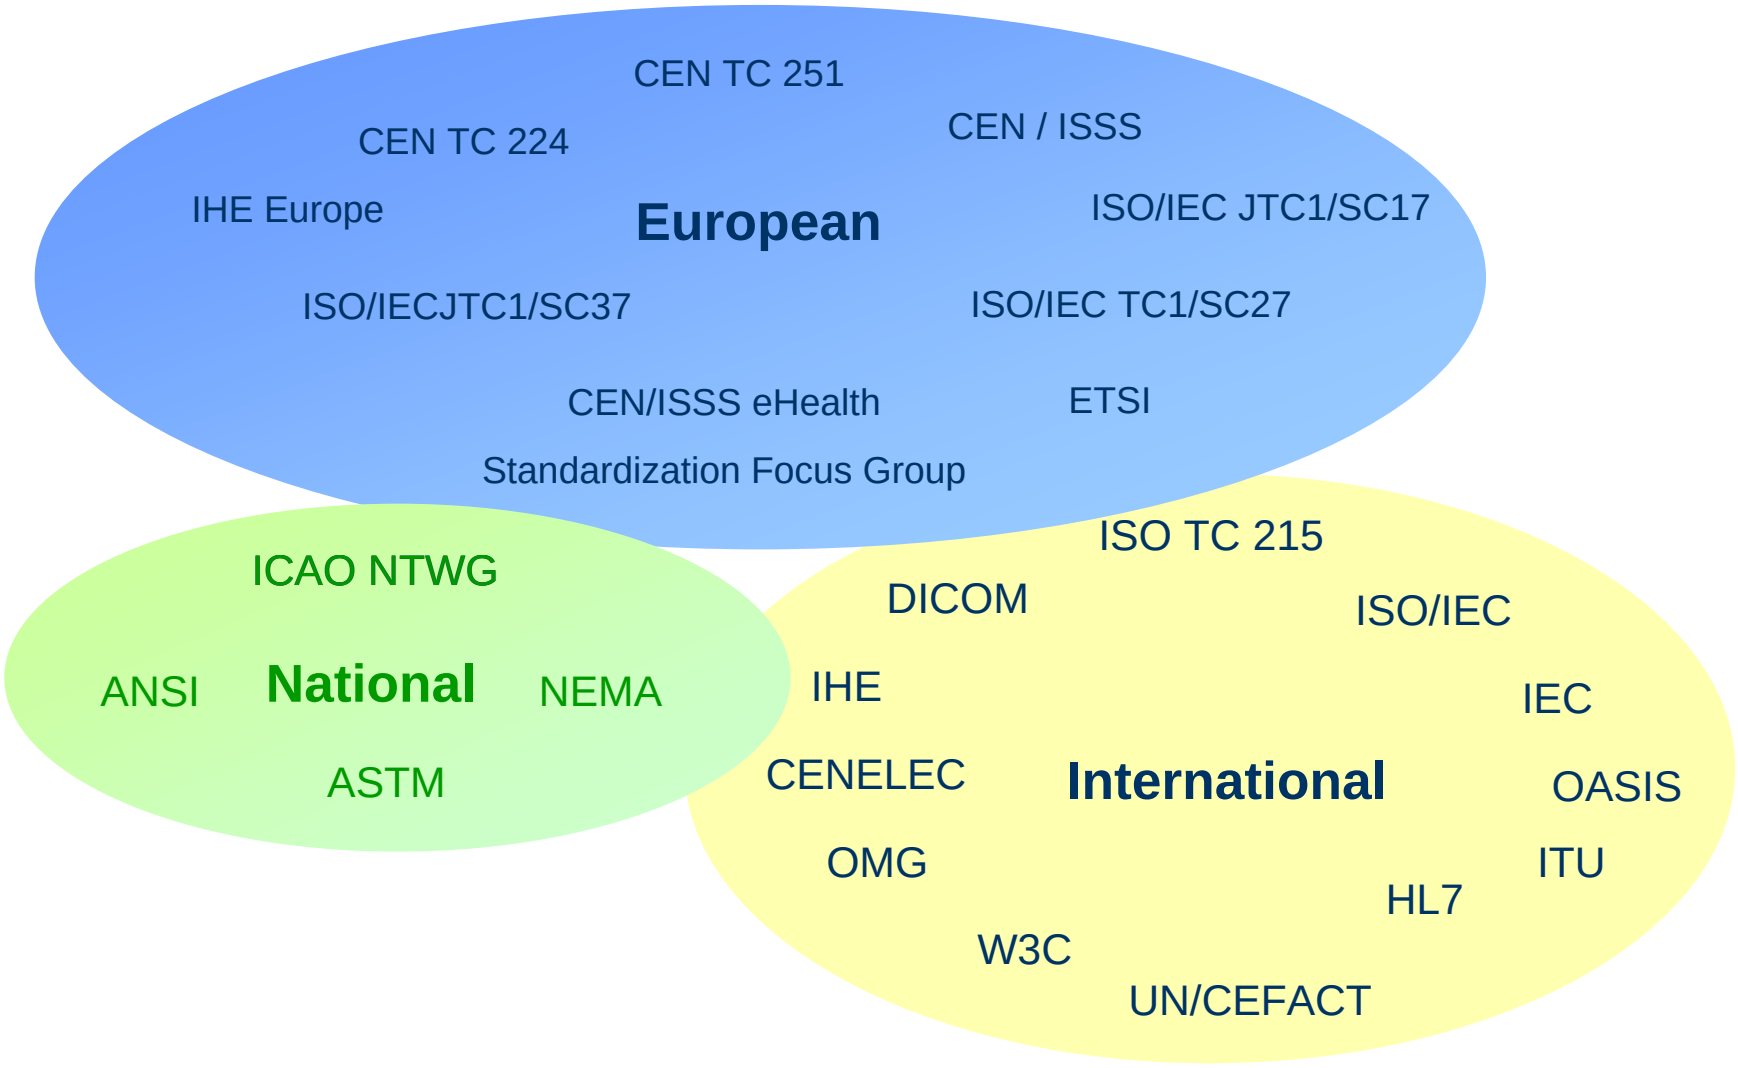
http://www.atis.org -accessed: 01-06-2007

BioHealth deals with the following aspects/technologies

- ***Standardisation***
  - Legal
  - Ethical
  - Technological
  - Organisational
  - Financial
  - Regional and National Differences
  - Political

- ***Technologies for Id Security***
  - Tokens
  - Biometrics
    - Fingerprint recognition
    - Face image
    - Iris Recognition
    - Hand Geometry
    - Signature dynamic
    - Voice recognition
    - Vascular biometrics
    - DNA analysis

Standards Developing Organisations concerned with eHealth security



Consortium and Competences

- **GSF - National Research Center for Environment and Health**, Germany
  Coordinator; links to academical, industrial and political bodies
- **Bull Hungary**, Hungary
  Industrial Partner; development of health related security technologies (health cards, Near Field Communication (NFC)), links to Insurance Bodies, involved in the development of the Hungarian eHealth platform
- **CNR-IBB - National Research Council of Italy**, Italy
  Convenor of ISO/IEC JTC1/SC37 WG7 (Biometrics); Expert in ethical and societal issues concerning identity management and the use of the new technologies in healthcare

Consortium and Competences

- **ITS Norway**, Norway
  Standardisation expert; involved in id management and biometrics; e-government and the definition of the Norwegian e-passports
- **IMA -Institute of Microelectronic Applications**, Czech Republic
  Small Medium Enterprise deals with intelligent security solutions, involved in many security related projects, new developments with RFID, advisor for the National Czech e-solutions
- **eHCC – eHealth Competence Center**, University of Regensburg, Germany
  Expert for Security in eHealth ; involved in many standardisation bodies and activities

By the end of 2008 BioHealth aims to have

- A training programme on eHealth standardisation
- Guidelines on eHealth standards
- Increased the knowledge and use of eHealth standards
- Set up a lasting network on eHealth standardisation

Use of Medical Informatics to Improve Patient Safety, Quality of Care and Training: Innovative Software for Resident Hand Off Communication and Training.

Vinod Chacko, Mahesh Krishnamurthy, David G. Kemp

Department of Medicine, Easton Hospital, Academic Affiliate Drexel University School of Medicine, Philadelphia, Pennsylvania, USA

Abstract:

Missed hand-offs and breakdowns in verbal and written communications are key sources of medical injury and thus major concerns in the delivery of safe patient care. The Joint Commission on Accreditation of Healthcare Organizations [JCAHO] has recognized these pitfalls and added this as a new requirement in the National Patient Safety Goals. We designed an electronic application called eHand-offs to standardize and supervise communications among medical residents about patient information during admissions, transfers, and discharges. eHand-offs also functions as a surveillance tool for administrators to track patient hand-offs, ensuring added patient safety and enhancing resident supervision and training. With this background, a national survey of program directors of internal medicine residencies was conducted to get a national consensus about hand-off communication. It was concluded from the survey that standardization and tracking of hand-off data using an electronic, secure, and standardized software application, will help improve continuity of care, reduce medical errors and improve resident supervision and training. A secure software application with face-to-face communication is preferred as the hand-off method of choice by our respondents.

Keywords:

handoffs, healthcare communication, patient safety, electronic sign out

Methods

The objective of this study was to assess the current opinions held and strategies used within residency programs with respect to the hand-off communication during shift changes. The contemporary strategies for hand-offs and program directors' opinions on the future of these hand-offs were two important issues investigated. An online survey link was posted utilizing the Association of Program Directors of Internal Medicine [APDIM] list serve. This survey consisted of ten questions, some of which are single answer type others with multiple answers. Responses were analyzed and are presented in the form of graphs.

Results

A total of 107 respondents completed the survey. Of these, 26% were unaware of the standardization of hand-offs as a JCAHO patient safety goal. The most commonly used methods at present are paper-based (44%) and face-to-face sign-out (44%). More than 95% of respondents agreed that hand-offs should be standardized and that standardization will prevent medical errors. 92% of respondents believe that sign-out communication is important in liability issues and 69% agree that standardization of sign-outs will help in reducing liability lawsuits. However, when the question of whether hand-off data should be made a part of the permanent medical record, 71% said it should not. 77.5% respondents were agreeable to using a secure server along with a Face to Face sign-out. Excel/Word sign-out along with a telephone sign-out was unpopular at 17.6%, but Excel/Word in conjunction with Face-to-Face sign-out was satisfactory to 55.9%. Face-to-Face sign-out by itself was given a 47.1 % approval rating. Lack of resources, resident non-compliance, and administrative issues were the top three problems selected as reasons why implementing a secure computerized hand-off system might fail.

Conclusion

It may be extrapolated that standardization of hand-off communication and tracking of hand-off data using an electronic, secure, and standardized software application like eHand-offs, will help improve continuity of care, reduce medical errors and improve resident supervision and training. A secure software application with face-to-face communication is preferred as the hand-off method of choice by our respondents. Facilitating resident cooperation via educating them to develop the culture of patient safety, persistent will power from administrators and appropriate resources are all needed to implement this choice.

Analyzing Content of Patient-Physician messages with Self-Organizing Maps

Karita H. Ilvonen[a], Steven M. LeVine[b], Joseph F. Terdiman[c]

[a] *Stanford Medical Informatics,Stanford University California, USA.*
[b] *Division of Research, Kaiser Permanente, USA.*
[c] *Division of Research, Kaiser Permanente,, USA.*

Abstract and objective

This paper is a part of an extensive research effort, in which our overall objective is to understand the impacts of patient-physician messaging service on provider efficiency and use of resources. In this poster presentation we evaluate the usefulness of Self Organizing Maps (SOM) technology for analysis of unstructured patient-originated electronic messages. A one-by-one hand analysis of a subset of the messages was performed in order to evaluate the accuracy of the topographic method. This study looks at two specific research questions: 1) What broad categories of requests are submitted by the patients 2) how can the requests be understood in the context of health care information provisioning by primary care physicians to patients with a specific chronic disease. Topographic mapping of message types confirmed the patterns seen through manual analysis. Sub-mapping of messages by symptom themes allowed more granular understanding of the clinical decision processes involved. SOM technology has potential for analyses of large data sets of unstructured messages for research purposes.

Keywords:

patient-physician messaging, chronic care management, self-organizing map, efficiency

Methods

A study cohort of 281 diabetic patients receiving primary care at the Kaiser Permanente Medical Center in Oakland, California was defined. The cohort consisted of self-selected patients using the CyberKaiser electronic messaging system during a study period of one year (March 2003-February 2006). We combined Electronic Health Record Data, messaging free text data and demographic data for our analysis. Diabetics were defined on the basis of ICD-9 codes. We used Foundation™ software to analyze the unstructured text of the patient messages and categorized the messages manually into 12 different categories (e.g. appointment request, medical advice, lab result interpretation etc.) based on the initial requests made in them. We also recorded the number of request made in individual messages. The software used draws Self Organizing Maps (SOMs) from the unstructured data and helps us to circumscribe major categories and to identify the most frequently used terms ('themes') in the messages.

CyberKaiser system

CyberKaiser is a secure web-based electronic mail system designed to support the transmission of clinical information between members and physicians of the Kaiser Permanente health care system, based in Oakland, California. Patients and providers were recruited on a voluntary basis, at no extra charge to the patient. There are no intermediary agents pre-selecting or filtering the messages, which are sent directly to and from the physicians. The service level agreement for physician replies is two business days. Proxy accounts for family members of patients are allowed where a dependent adult-adult or adult-child relationship can be attested.

Self Organizing Maps

Self Organizing Map (SOM) was used for the broader context analysis. However, in-depth analysis of the complexity of the messages required categorizing them by hand. We examined the initial message of each thread send by the patient within the study period for review. Request types were categorized and statistical analysis performed on the results.

Results

The visualization of CyberKaiser messages send by diabetic patients grouped messages by common themes. The visualization recognized five large groups of messages talking about appointments, pain and symptoms, prescriptions, 'thank yous' and administrative issues. The topographic mapping software was also used for identifying 30 most commonly used words in the messages.

The one-by-one hand analysis found that most messages have a single request on action on them and provide a lot of background information.

Conclusions

Self-organizing maps allow parsing of large amounts of text information contained in patient-provider email. Context analysis findings and categorization of the requests are expected to advance the future development of these ser-

vices and answer to some concerns on the messaging as an appropriate medium for healthcare communication.

Analyzing Content of Patient-Physician messages with Self-Organizing Maps

Lic (Tech.) Karita H. Ilvonen – Helsinki University of Technology
MD Steven LeVine – Division of Research, Kaiser Permanente
MD, PhD. Joe Terdiman - Division of Research, Kaiser Permanente

Objective

- Part of an extensive research effort, in which our overall objective is to understand the impacts of patient-physician messaging service on provider efficiency and use of resources.
- We evaluate the usefulness of Self Organizing Maps (SOM) technology for analysis of unstructured patient-originated electronic messages.
- A one-by-one hand analysis of a subset of the messages was performed in order to evaluate the accuracy of the topographic method.
- Two specific research questions: 1) What broad categories of requests are submitted by the patients 2) how can the requests be understood in the context of health care information provisioning by primary care physicians to patients with a specific chronic disease.
- Topographic mapping of message types confirmed the patterns seen through manual analysis. Sub-mapping of messages by symptom themes allowed more granular understanding of the clinical decision processes involved.

Methods

- A study cohort of 281 diabetic patients receiving primary care at the Kaiser Permanente Medical Center in Oakland, California was defined.
- The cohort consisted of self-selected patients using the CyberKaiser electronic messaging system during a study period of one year (March 2003-February 2006).
- We combined Electronic Health Record Data, messaging free text data and demographic data for our analysis.
- Diabetics were defined on the basis of ICD-9 codes.

Methods 2

- We used Foundation™ software to analyze the unstructured text of the patient messages and categorized the messages manually into 12 different categories (e.g. appointment request, medical advice, lab result interpretation etc.) based on the initial requests made in them.
- We also recorded the number of request made in individual messages.
- The software used draws Self Organizing Maps (SOMs) from the unstructured data and helps us to circumscribe major categories and to identify the most frequently used terms ('themes') in the messages.

Self Organizing Map

- Self Organizing Map (SOM) was used for the broader context analysis. However, in-depth analysis of the complexity of the messages required categorizing them by hand.
- We examined the initial message of each thread send by the patient within the study period for review.
- Request types were categorized and statistical analysis performed on the results.
- Figure 1 presents and example graphic of a SOM used for the context analysis. This graphic organizes all messages sent by diabetic patients in the cohort to a map outlining five different areas. For example an area where the most common themes are refill, prescriptions and pharmacy includes mostly messages where patients request to refill their prescriptions.

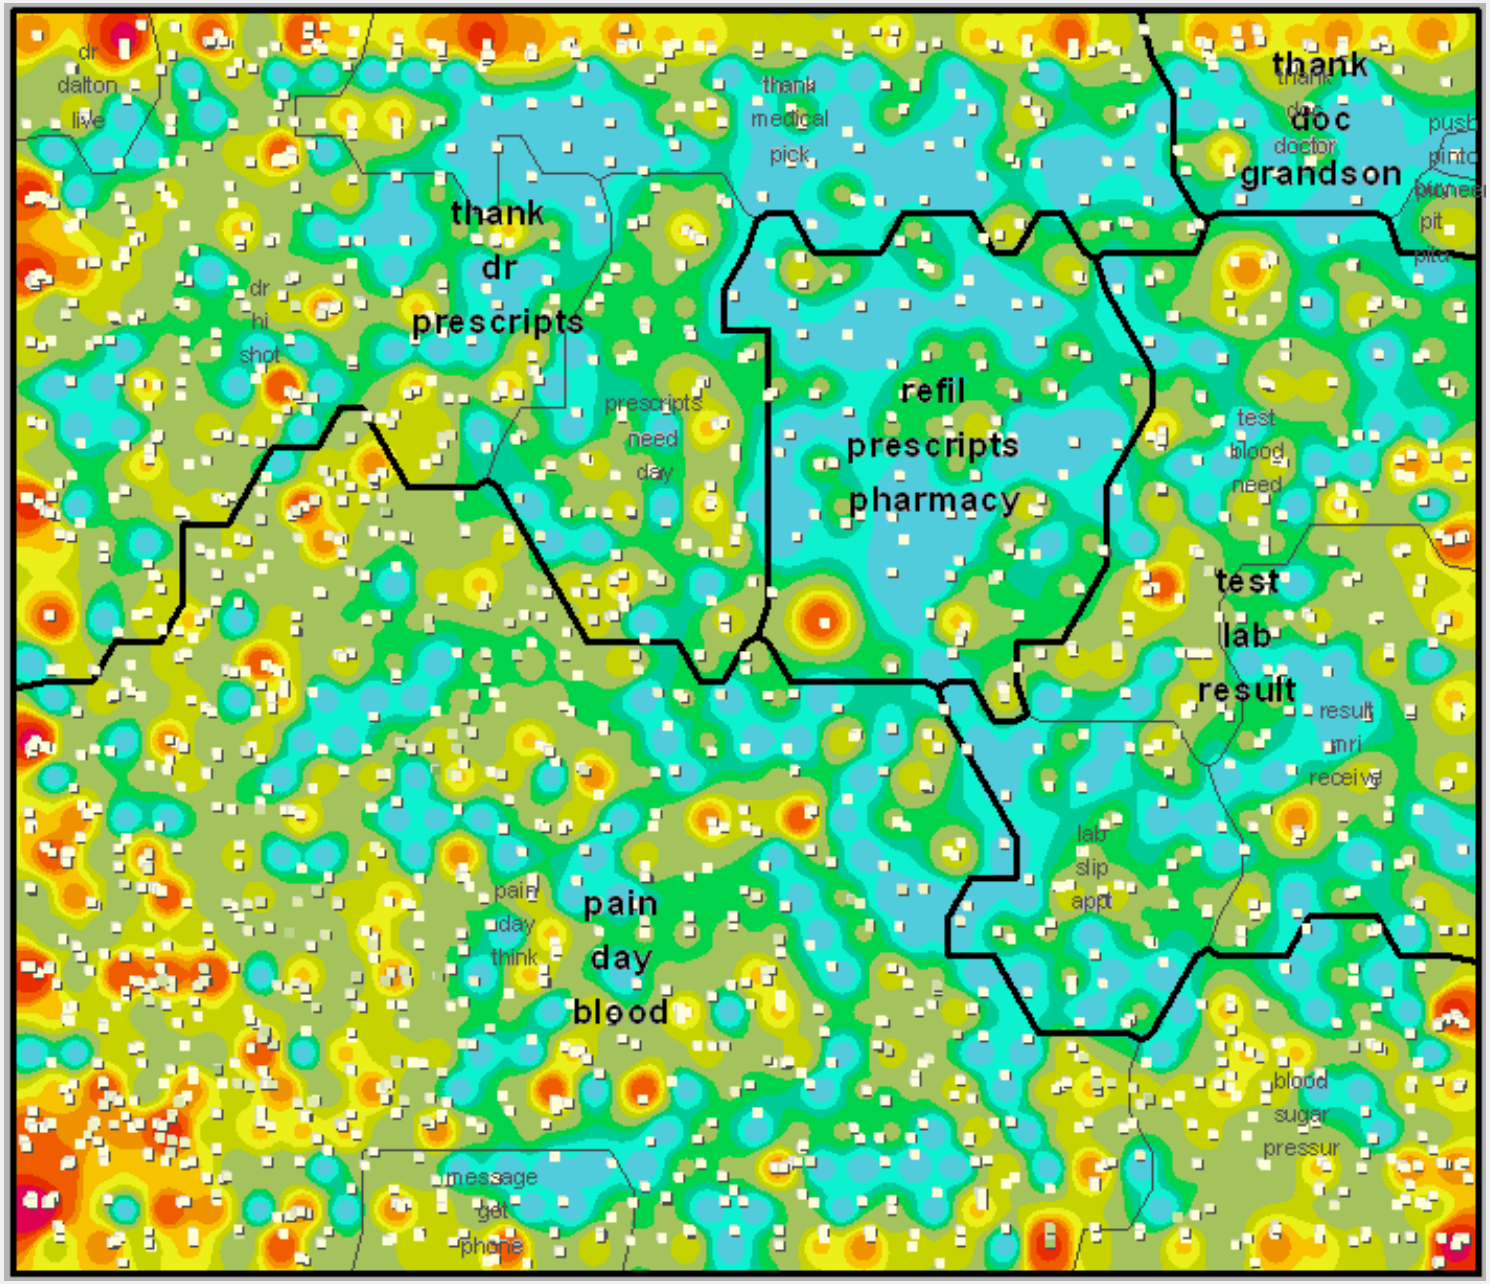

Figure 1: Self Organizing Map (SOM) of all messages sent by diabetic patients in cohort

Using a glossary

- The categorization presented in figure 1 is on a very abstract level because words that are likely to appear in a message with any topic like ‘thank’ and ‘dr’ are still included.
- A diabetes glossary was used to vertically classify the themes identified in unstructured data when using the Foundation Software.
- Vertical classification of unstructured data refers to the process of capturing unstructured data and organizing it so that it can be meaningfully accessed and analyzed according to specific topic(s) as identified in the glossary.
- Glossaries are lists of related words, their meanings and synonyms. We used a glossary of clinical and other diabetes related words in running the following SOM (figure 2).

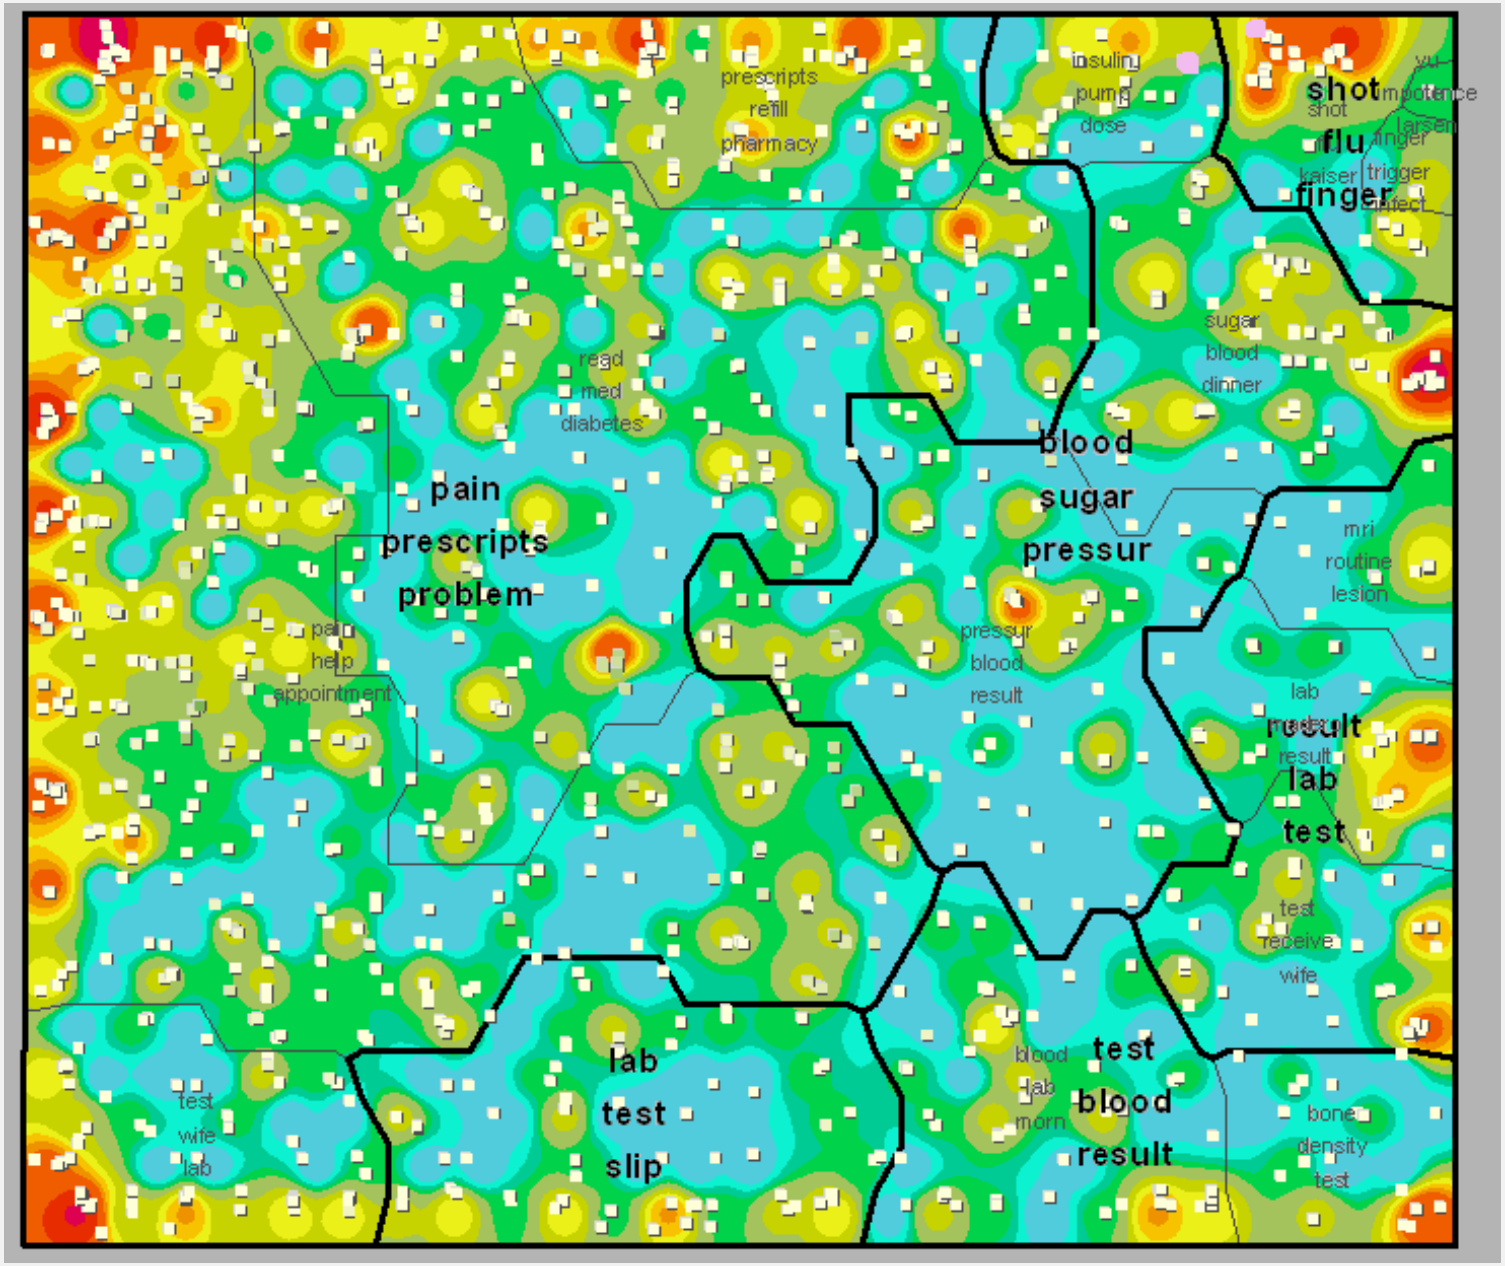

Figure 2: Diabetes messages using a glossary

Results

- The visualization of CyberKaiser messages send by diabetic patients grouped messages by common themes.
- The visualization recognized five large groups of messages talking about appointments, pain and symptoms, prescriptions, ‘thank yous’ and administrative issues.
- The topographic mapping software was also used for identifying 30 most commonly used words in the messages.
- The one-by-one hand analysis found that most messages have a single request on action on them and provide a lot of background information.

Conclusions

- Self-organizing maps allow parsing of large amounts of text information contained in patient-provider email.
- Context analysis findings and categorization of the requests are expected to advance the future development of these services and answer to some concerns on the messaging as an appropriate medium for healthcare communication..

Using the Latest Web Technologies to Improve Communication and Implement a Cultural Change in Junior Doctors in a Large UK Health Trust

Louise Beckham, Jonathan Shaw, Su Underwood, Jonathan Bloor

Bristol Royal Infirmary, United Bristol Healthcare Trust, Bristol, UK

Abstract

The Internet is universally accepted as a means of communication and is an under used resource within the NHS. We developed a Junior Doctors Website and content management system and in doing so have seen a cultural change in how information is communicated in United Bristol Healthcare Trust

Keywords:

junior doctor, internet, communication

Introduction

United Bristol Healthcare Trust is a large NHS Teaching Hospital Trust. It employs 360 Junior Doctors across 4 different sites. They are employed on a semi-permanent basis and rotate between specialties, hospital sites and other Trusts. A Junior Doctors Committee was formed to represent these Junior Doctors and found significant difficulty in communicating with them. In particular the Trust was unable to disseminate medico-legal information, clinical guidance and Trust news. In turn, Junior Doctors felt unable and unaware of how to feedback problems to the Trust and wanted better access to clinical and career guidance, time management information and social news. The principal reason for the breakdown of communication was a reliance on a Trust e-mail system. Access was only available on-site, limited and slow and relied on Junior Doctors registering and using an account. There was no list of personal e-mail addresses.

With changing work patterns as a result of the European Working Time Directive and less face to face contact within the hospital the need for excellent communication is greater than ever. The internet is universally accepted as a means of communication. Our aim was to develop a Junior Doctors website accessible from work and home. As part of its development it needed to contain useful content to entice continuing and regular use. It required the ability for users with privileges to be able to directly and easily create areas on the site and upload information as and when necessary creating a live system.

Methods and results

We formed a Junior Doctors web development team. 4 members divided responsibilities into content management, technical development, marketing and overall coordination. We initially designed a static HTML site, residing in our Trust intranet. Using Server Side technologies we were able to develop a content management system as well as other interactive aspects including notice boards, timetables and rotas. We used our secure logon system to create a database of Users e-mails to further aid communication.

There were a number of hurdles to overcome to reach this point. We had to engage the IT department and Trust Board to show the value of our proposals and then obtain their backing to progress with the development and deployment of the site. To ensure awareness of the site across the Trust we also ran an advertising campaign. We have developed an internet site managed by Junior Doctors for the Junior Doctors and the Trust. The site is now being used by doctors of all levels as a means of communication and as a clinical resource and will indirectly improve patient care.

Discussion and conclusions

By forming a Junior Doctors' based web team and using our skills and knowledge of web technologies we are resolving our communication problems. In doing so we are changing the culture of how information is disseminated and received in out Trust. This site requires on going commitment to provide up to date content as well as technical development. The communication problems we encountered are unlikely to be confined to our Trust and other NHS Trusts may benefit from hearing about the process we have been through. We would also like to hear about other groups experiences and learn from them. Our ultimate goal is to create a system that can be used as a Junior Doctors management tool that could be used in all Trusts across the NHS.

The Improvement of Timeliness and Data Quality of Notifiable Disease Reporting by Implementation of an Electronic Reporting System

Anna YH Tong, N T Cheung, Watson CH Tsui, Chris HY Choi, Joycelyne KH Cheung, Vicky H Fung, WN Wong, Antonio CH Sek

Health Informatics Section, Hospital Authority of Hong Kong

Abstract and objective

Physicians' reporting of suspicious or confirmed communicable diseases to government department of infectious disease management is very important for prompt outbreak identification and control to protect the community. The inefficient paper and fax reporting traditionally used cannot cope with imminent infectious risk An electronic reporting system has been developed to facilitate frontline case reporting and infection management works. A proper design and implementation of the reporting system integrated with clinical workflow gains clinicians' acceptance and in turns improves the timelines and data quality of the case reporting. The electronic reporting data available in the system is then be used by different users of the infection management by providing real time operational management reports to facilitate infection management works. Study has been started to use the electronic reporting data to further improve case notifications by cross-checking with laboratory data and cluster outbreak identification across the territory.

Keywords:

electronic notification, infectious diseases, reporting, infection, surveillance

Methods

Hospital Authority of Hong Kong (HA) manages 43 public hospitals with 47 specialty outpatient clinics and 74 general outpatient clinics (GOPCs). Centre of Health Protection (CHP) of Department of Health is the government body for the infection management of the community. Clinicians are required by law to report suspicious and confirmed cases of 32 Notifiable diseases to Central Notification Office (CENO) of CHP, together with hospital Infection Control Teams (ICTs) and Head Office Infection Control Team (CCID). The inefficient paper and fax reporting traditionally used cannot cope with imminent infectious risk and an electronic reporting system named Notifiable Disease and Outbreak Reporting System (NDORS) has been developed to facilitate frontline case reporting and infection management works.

A NDORS Project Working Group with frontline hospital infection control teams and head office infection management staff, clinicians, health informaticians and IT staff was established in April 2005 for detailed study the user requirements, the clinical workflow of case reporting and the follow-up actions of different levels of hospital infection control teams, and development and implementation of an the electronic reporting system. The problems of paper and fax reporting were identified to be dealt with the electronic reporting system (*appendix*). A 4-month pilot study of NDORS implementation was carried out in 3 public hospitals and 3 GOPCs in March 2006. After pilot evaluation, NDORS was fully implemented to HA hospitals and clinics in July 2006. Study has been started to use the electronic reporting data to further improve case notifications by cross-checking with laboratory data and cluster outbreak identification across the territory.

Results

For the 3-month full roll-out period of NDORS, in parallel with paper and fax reporting, there were 2330 cases (i.e. 95%) reported via NDORS to relevant parties. Since the pilot run of NDORS, there was 1059 clinicians used NDORS to report the Notifiable diseases. The average time interval taken between a doctor submitting a case and receiving the CENO system reply was 35s (2s to 4min18s). About 15 cases (1 %) of the NDORS reported cases were sent to CENO system via auto fax, due to server or network problems and non-compliance with validation rules set for electronic data transfer between the two systems. Positive feedbacks were received from different levels of users including convenience, timeliness and data quality (both for the completeness of data and the decrease of duplication of case reports) of case reporting with NDORS. The efficiency of infection disease management works was improved with the electronic reporting data and real time management reports.

Conclusion

Prompt identification and control of infectious disease outbreaks would minimize the impact of the communicable diseases outbreak to the community. Proper design and implementation of electronic reporting system improves the acceptance of the users and in turns, the timeliness and data quality of infectious disease notification. The effi-

ciency of infection management works is improved. The reporting data would be used to further facilitate the case notification and surveillance of cluster outbreak in the community.

Appendix

Comparison of Paper & Fax Reporting and Notifiable Disease and Outbreak Reporting System (NDORS)

Paper & Fax Reporting	NDORS	Benefits
Filling paper form	▪ Clinicians report case via all the CMS workstation during their clinical care of the patients ▪ Interfacing with patient master index demographic data ▪ Electronic forms with structured data fields with different checking rules	▪ Improve timeliness of case reporting by providing a more convenient way of reporting which is integrated with clinical workflow ▪ Decrease time used for reporting ▪ Improve data quality
Fax to Hospital ICTs, CCID of HAHO & CENO of CHP	▪ Submission of case reports to Hospital ICTs, CCID of HAHO & CENO of CHP simultaneously by clicking the "submit" button ▪ Updated information can be accessed +/- sent to 3 different parties via auto fax	▪ Decrease works used for reporting ▪ Prevent discrepancy of data among the 3 different parties
Loss of paper forms	▪ All case reporting records are stored in and viewed by clinical staff via NDORS	▪ Better history tracking for notifiable disease reporting records ▪ Decrease duplication of case reporting (by providing case report history view and checking rules of case report duplication) ▪ Records can be edited & updated via NDORS and updated information can be accessed +/- sent to 3 different parties via NDORS ▪ Online management reports for infection control management, surveillance and research
Reporting with reference to different sources of criteria for reporting (paper records, CHP website)	▪ Information provided on the updated list of notifiable diseases to be reported, the updated criteria of reporting &the updated contact details of different parties	▪ Improve data quality ▪ Decrease works for reporting ▪ Improve communication among different users

*The **improvement** of **timeliness** and **data quality** of **Notifiable disease reporting** by implementation of an **electronic reporting system***

Anna YH Tong, N T Cheung, Watson CH Tsui,
Chris HY Choi, Joycelyne KH Cheung, Vicky H Fung, WN Wong,
Antonio CH Sek

Health Informatics Section
Hospital Authority of Hong Kong

Goals

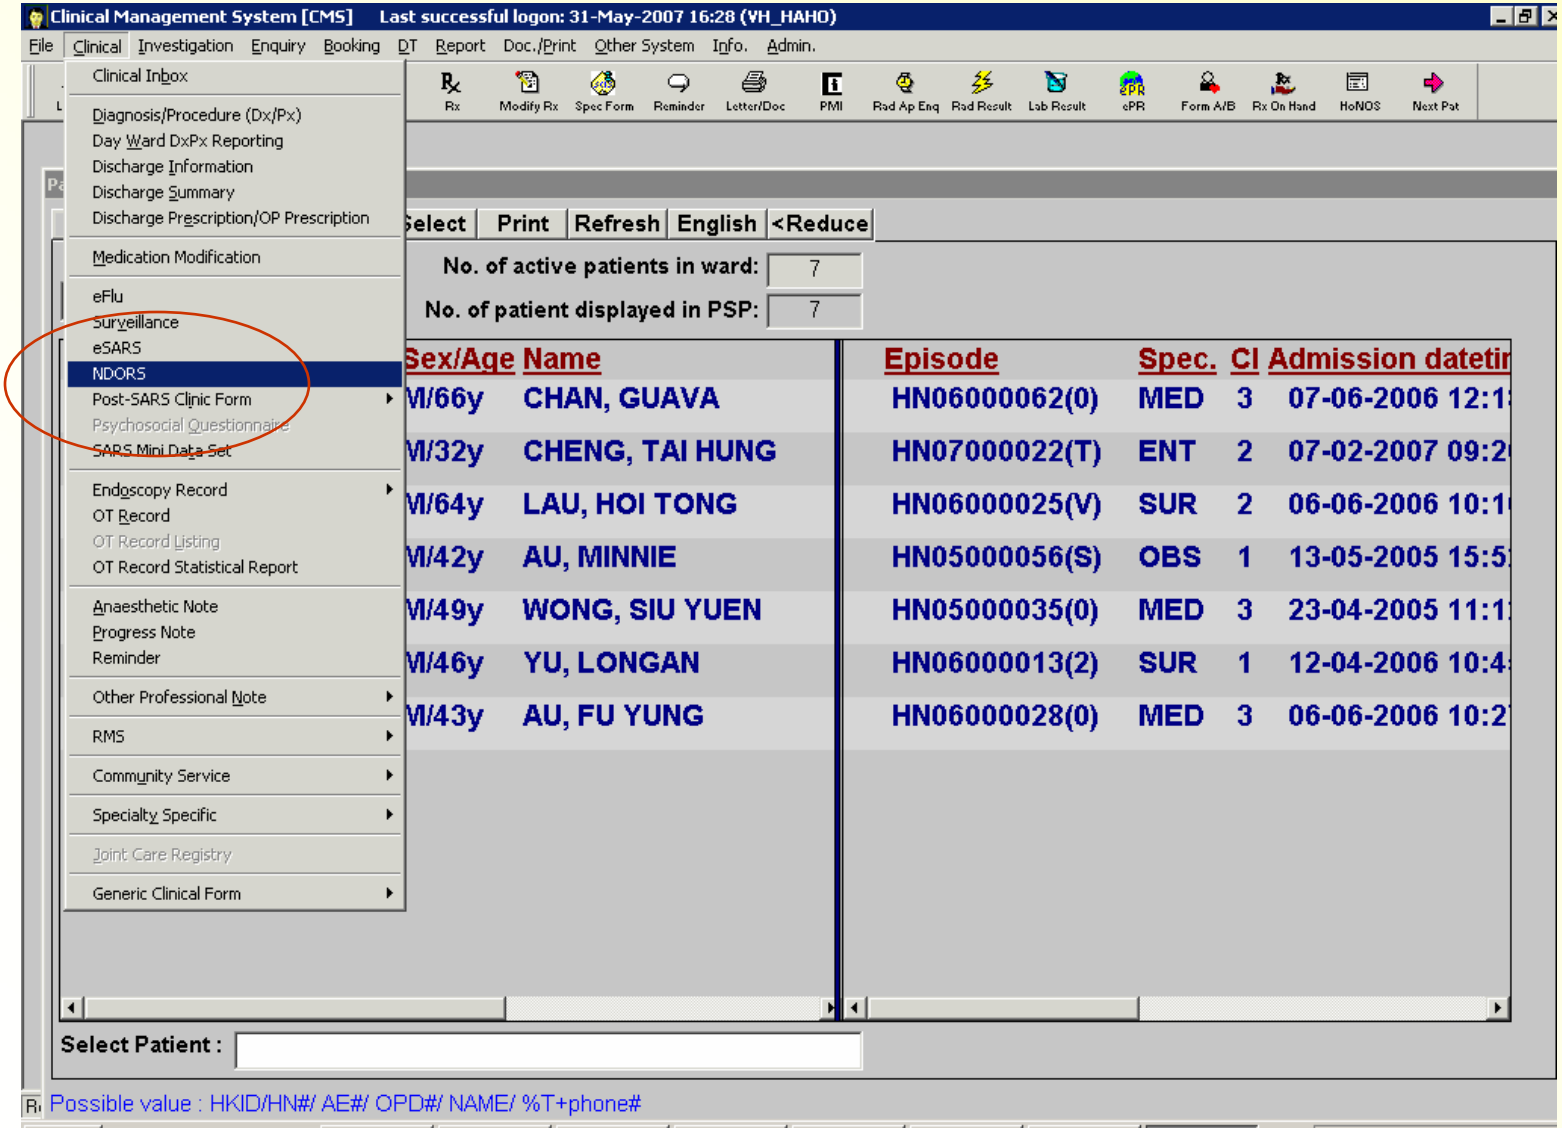
- More **convenient** way of reporting
- **Timely** reporting to relevant parties
- **Accurate** and structured / standardized data
- Real time access & sharing of the most updated data by different group of users
- **Prompt** Outbreak identification and control across Clusters

⇨ Better than paper & fax reporting, both in timeliness and data quality

Functions

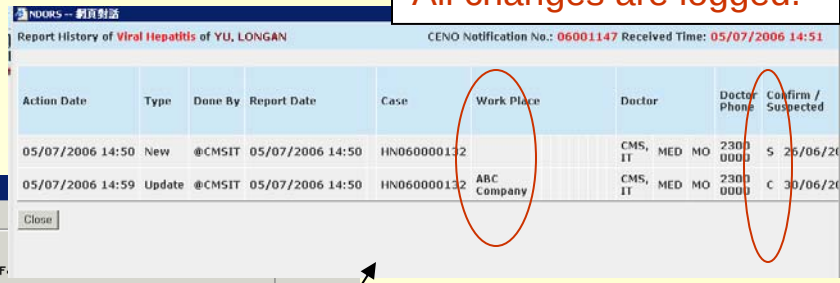
- **To report Notifiable Diseases thru' CMS**
- **Electronic data to be sent to CENO of CHP and to be accessed by ICT/CCID of HA in a timely manner**
- **Data can be updated by different parties and updated information can be shared with different users online**
- **Have report functions**
- **To alert different parties on a timely manner**

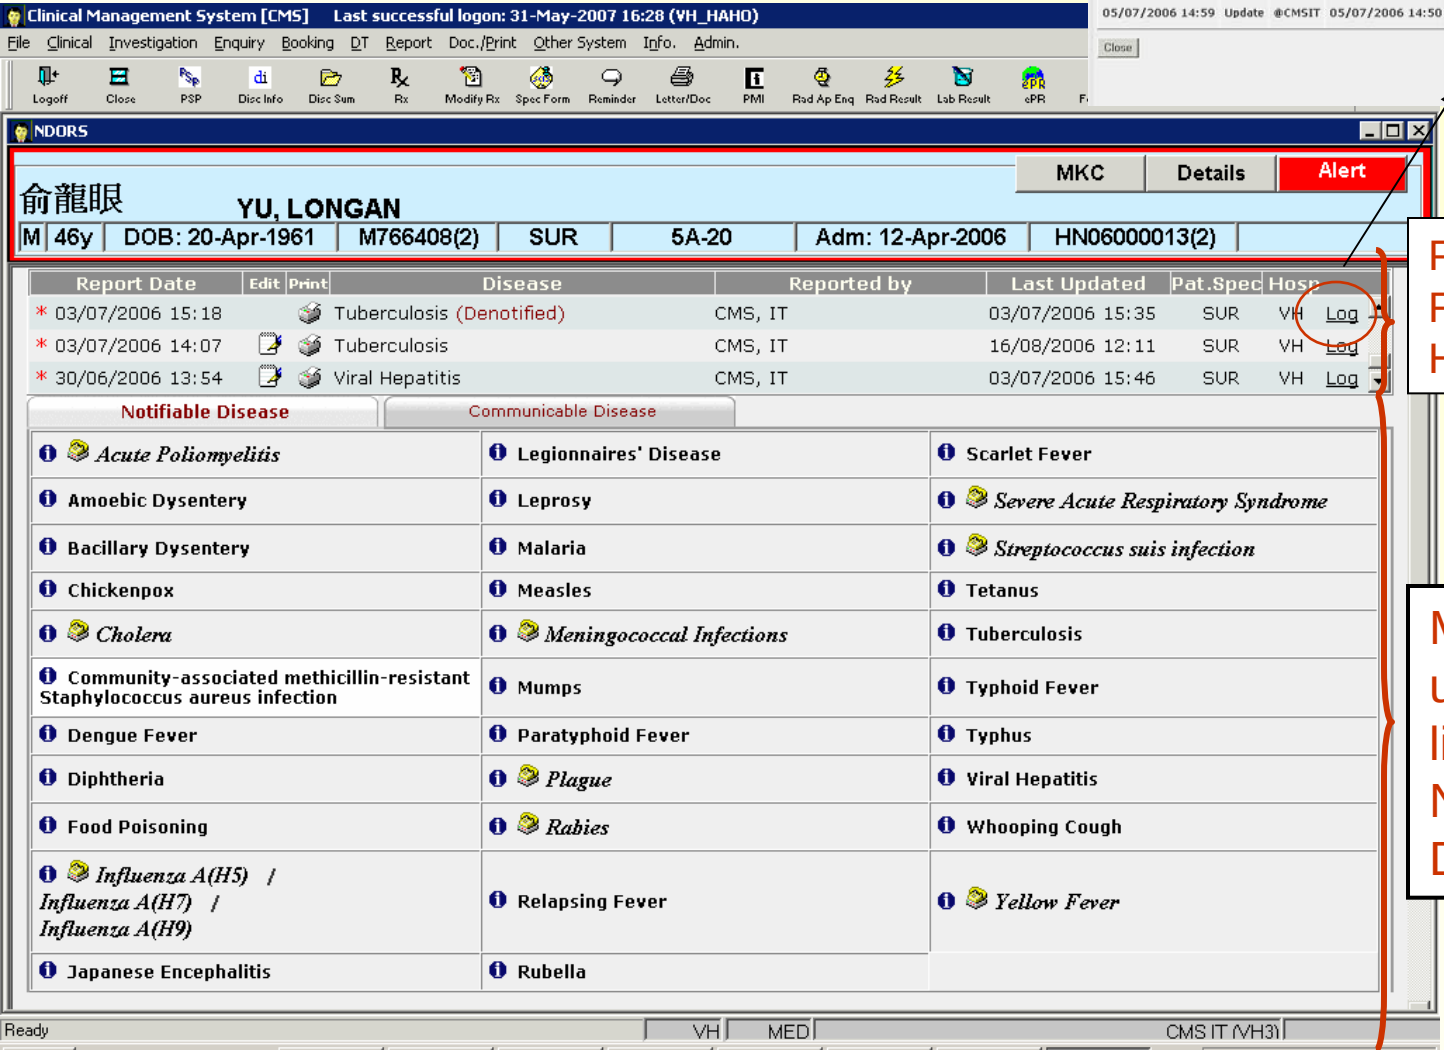
Notifiable Disease & Outbreak Reporting System



Provision of most updated info about Notifiable Diseases & case reporting history of the patient

All changes are logged.

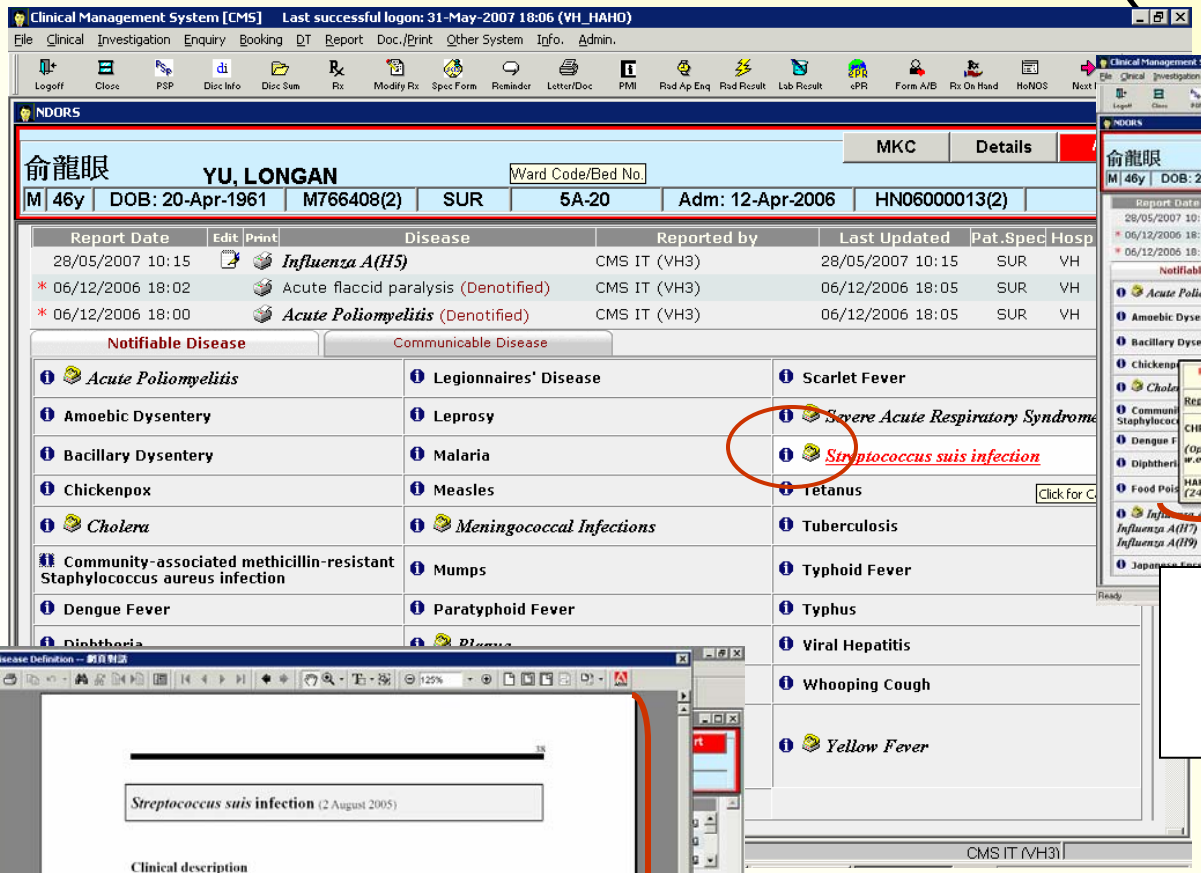


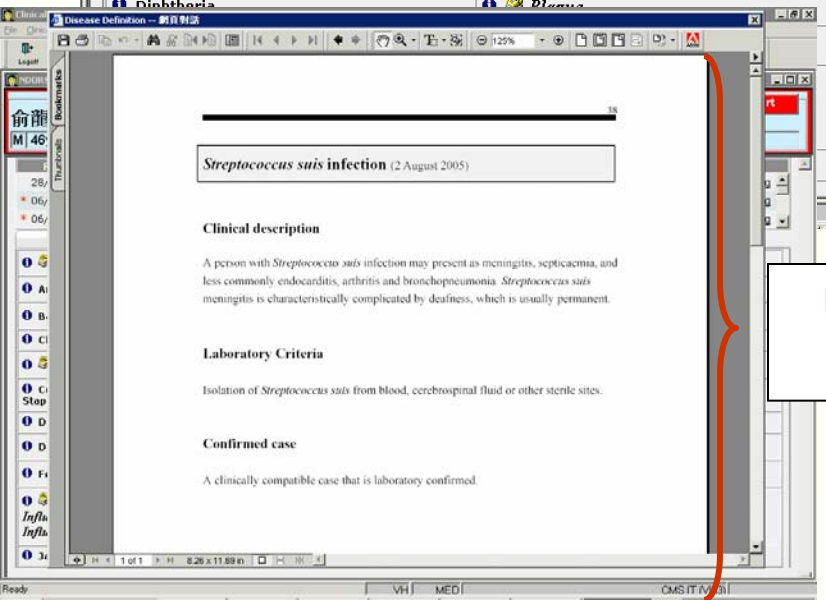


Patient's Reporting History

Most updated list of Notifiable Diseases

Provision of most updated info about Notifiable Diseases (cont')



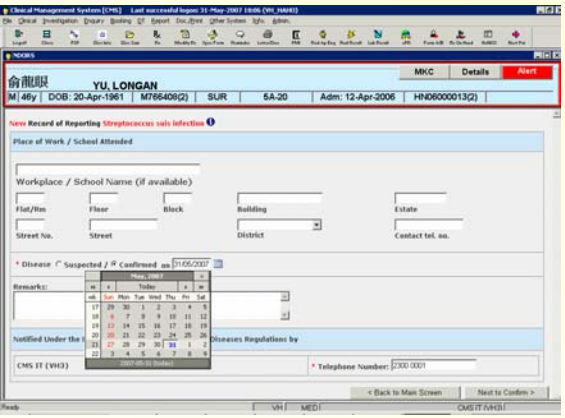


Updated criteria for reporting

Relevant information

e.g. Communication mechanisms with Infection Control Team

Just a "Click" → case reporting information is accessed by Infection Control Teams within HA & other government department in a timely way



Structured scope and data format

Using the Latest Web Technologies to Improve Communication and Implement a Cultural Change in Junior Doctors in a Large UK Health Trust

Louise Beckham, Jonathan Shaw, Su Underwood, Jonathan Bloor

Bristol Royal Infirmary, United Bristol Healthcare Trust, Bristol, UK

Abstract

The Internet is universally accepted as a means of communication and is an under used resource within the NHS. We developed a Junior Doctors Website and content management system and in doing so have seen a cultural change in how information is communicated in United Bristol Healthcare Trust

Keywords:
junior doctor, internet, communication

Introduction

United Bristol Healthcare Trust is a large NHS Teaching Hospital Trust. It employs 360 Junior Doctors across 4 different sites. They are employed on a semi-permanent basis and rotate between specialties, hospital sites and other Trusts. A Junior Doctors Committee was formed to represent these Junior Doctors and found significant difficulty in communicating with them. In particular the Trust was unable to disseminate medico-legal information, clinical guidance and Trust news. In turn, Junior Doctors felt unable and unaware of how to feedback problems to the Trust and wanted better access to clinical and career guidance, time management information and social news. The principal reason for the breakdown of communication was a reliance on a Trust e-mail system. Access was only available on-site, limited and slow and relied on Junior Doctors registering and using an account. There was no list of personal e-mail addresses.

With changing work patterns as a result of the European Working Time Directive and less face to face contact within the hospital the need for excellent communication is greater than ever. The internet is universally accepted as a means of communication. Our aim was to develop a Junior Doctors website accessible from work and home. As part of its development it needed to contain useful content to entice continuing and regular use. It required the ability for users with privileges to be able to directly and easily create areas on the site and upload information as and when necessary creating a live system.

Methods and results

We formed a Junior Doctors web development team. 4 members divided responsibilities into content management, technical development, marketing and overall coordination. We initially designed a static HTML site, residing in our Trust intranet. Using Server Side technologies we were able to develop a content management system as well as other interactive aspects including notice boards, timetables and rotas. We used our secure logon system to create a database of Users e-mails to further aid communication.

There were a number of hurdles to overcome to reach this point. We had to engage the IT department and Trust Board to show the value of our proposals and then obtain their backing to progress with the development and deployment of the site. To ensure awareness of the site across the Trust we also ran an advertising campaign. We have developed an internet site managed by Junior Doctors for the Junior Doctors and the Trust. The site is now being used by doctors of all levels as a means of communication and as a clinical resource and will indirectly improve patient care.

Discussion and conclusions

By forming a Junior Doctors' based web team and using our skills and knowledge of web technologies we are resolving our communication problems. In doing so we are changing the culture of how information is disseminated and received in out Trust. This site requires on going commitment to provide up to date content as well as technical development. The communication problems we encountered are unlikely to be confined to our Trust and other NHS Trusts may benefit from hearing about the process we have been through. We would also like to hear about other groups experiences and learn from them. Our ultimate goal is to create a system that can be used as a Junior Doctors management tool that could be used in all Trusts across the NHS.

Using the Latest Web Technologies to Improve Communication and Implement a Cultural Change in Junior Doctors in a Large UK Health Trust

Jon Shaw, Louise Beckham, Su Underwood, Jonathan Bloor

United Bristol Healthcare Trust, Bristol, UK

Contents

- Introduction
- Problems identified
- Solutions devised
- The site developed
- E-mail system developed
- Content management system developed
- Conclusions and future developments
- Contacts and acknowledgements

Introduction

- A communication problem was identified between the Trust and Junior Doctors
- The European Working Time Directive has changed working patterns
- Communication becomes even more important
- Technology is available to aid communication
- This technology is underutilised in the NHS
- We used the latest web technologies to improve communication

Communication Problems

- 360 Junior Doctors
- Transient population
- 4 Hospital sites
- Rotation between different Trusts
- Rotation between different specialties
- Junior Doctors Committee unable to contact all Junior Doctors
- Severe time pressure at work
- No available list of Junior Doctors
- No list of used e-mail addresses
- Important information not disseminated
- Changing work patterns due to European Working Time Directive

IT Problems

- Reliance on Trust e-mail system
- Trust e-mail only accessible from work
- Slow computer access
- Limited computer access
- No access to information from home

Solutions

- Internet site
- New e-mail system
- Database of users and e-mail addresses
- Content management system
- Continuing development of above

Junior Doctors Site

A Web-based Clinical Information System Supporting Pattern Identification Examination of a Stroke in Oriental Medicine

Bo Young Kim, Ho Yeon Ko, Byung Kap Kang, Mi Mi Ko, Jin Seok Moon, Sun Mi Choi

Dept. of Medical research, Korea Institute of Oriental Medicine, Korea

Abstract

We developed a web-based clinical information system that can examine symptoms for Stroke in oriental medicine. This research enforced clinical research to examine closely Stroke's symptoms in oriental medicine. In this clinical research, We made out case report form(CRF) by many oriental medicine specialists to normalize typical symptoms that examine the Stroke. It needs confirmation whether clinical data by this CRF can examine. So, we confirmed if specialist's diagnosis views only CRF consist with specialist's diagnosis in real clinical environment. At this phase, we need system that should be convert the CRF row data to oriental medical language and then specialists can diagnoses by it. In addition to, we have developed a web-based system because it works anywhere, anytime through several specialists.

Keywords

Stroke, Clinical Laboratory Information Systems, Oriental Medicine, Signs and Symptoms, World Wide Web

Introduction

Unfortunately, an oriental medicine has not yet standardized most of disease and symptoms. That's why pattern identification for examination of various symptoms in oriental medicine is so important. So, we decided to do symptoms examination about cerebrovascular disease that happens most frequently. In this research, it is most important that establish the gold standard of Stroke diagnosis. Therefore, we developed a web-based clinical information system of pattern identification to establish gold standard about Stroke.

Methods

In this research, we developed the CRF entry system on web and then keep it in the web database. Specialist (it means Oriental Medical Doctor) sees clinical information that is stored on web and then diagnose. Because it can not diagnose from CRF row data, the data has converted to Oriental Medicine standard terminology.

A web database has the metadata table that being combined each CRF question and answer information do mapping to a symptoms. A metadata table is comprised of mapping information of CRF item and symptoms terminology in Oriental Medicine by several specialists. When specialist logged in, the web page shows doing to do mapping per CRF clinical item that is stored recently. A mapping result of per item is same that see a patient. That is, a CRF data that is gathered in this research is data of such as medical record contents that a doctor sees a patient. Specialist sees this web page and input diagnosis result. And then several specialists decide diagnosis accuracy with this diagnosis result and clinical data of CRF.

Results

This system shows hereafter that such mapping mechanism is possible for conversion to medical records from CRF clinical data. Also, it can know that is possible to link composition with standard terminology. Forward research, we will progress a research about medical document applied HL7 CDA conversion and Clinical Document Repository (CDR).

Data Protection in Shared Health Records: Requirements and Challenges

Yara Mohammad , Lampros K. Stergioulas and Maryati Mohd. Yusof

School of information Systems, Computing & Mathematics, Brunel University, UK

Abstract:

This short paper presents the evolution of electronic health records and focuses on their main characteristics and requirements. Furthermore, it also examines the conflicting goals of health information availability and data protection for shared health record systems.

Keywords:

shared health records, data protection, privacy and confidentiality

Introduction

One of the very first uses of computers in health care was for administrative and financial purposes [1]. Healthcare professionals have tried to find systems that would provide easy and intuitive access to the information which they need during consultations with their patients [2]. The advent of computers and computer networks offered us the capability to access medical information from anywhere and anytime[3,4].

The implementation of shared health records demands a satisfactory level of security. This is invariably achieved through applying and enforcing strict, and often quite complicated, rules and procedures in the access process, which perplex and confuse users. The current challenge is to implement a shared health record system, which is easy and secure to use, and satisfies all stakeholders, such as patients, health professionals, healthcare providers, and other groups in terms of legal or financial requirements.

Electronic health records characteristics and requirements

The new communication technologies offer clinicians creative ways to interact with their patients and to provide higher quality of care [2]. The Internet evolves and supports broadband communications, it becomes the technology of choice for linking medical experts with other clinicians and patients at a distance [5,6] Indeed today, distribution of biomedical information through the internet is increasingly commonplace and accepted [7].

Successful implementation of shared health records will have to meet the users' needs for acceptable levels security and privacy, and also to address some important legal issues.

The basic requirements of shared health records are:

- Comprehensiveness
- Confidentiality
- Accessibility
- Liability
- Authentication
- Flexibility
- Permission
- Accessibility in emergency cases
- Maintaining Integrity of the health record

There are some legal issues regarding health records such as:

- Jurisdiction
- Legally valid agreements
- Legal implications of shared practice of medicine
- Patient's right to review and release their records

Current and future challenges of data protection in shared health records

Some patients and doctors have expressed concerns about the use of the new technology in shared health care record services. Most of these concerns are related to data protection and confidentiality issues. Also some doctors are afraid that shared care record service will damage confidentiality.

Some issues should be considered while moving from a paper-based record system to a computer-based one, such as the needed time of transmission, resources, management and administration tolls and staff, and basic technology infrastructure. These factors often relate to technical challenges. Another risk is system failures. In case of system failure, stored information may be unavailable at the time of need. In this case, paper records could serve as backup until the computer system becomes available again [2, 8]. This matter of availability might be one of the major problems of security.

People will always try to destroy security systems, no matter how sophisticated they are.

Some people will find ways to get secure information by exploiting human weakness to bring pressure to bear on someone with legitimate access to health information. [8].

The concept of security is intrinsically correlated with other aspects of EHR, including legal, technical, social, political and financial. The nature of these relationships between security and other issues depends on the specific user of the electronic patient records.

Conclusion

In every generation of health records, their implementation has faced serious challenges. The most recent phase of EHR, based on internet technology, presents us with a number of critical challenges related to security and privacy.

The concept of information security, as a whole, comprises the three aspects of confidentiality, integrity and availability. The advanced technologies needed for implementing secure systems almost always make the use of the system more complex for the users. This complexity can reduce the benefits of using new technology and limit its advantages. The grand challenge for the future will be to provide a secure and at the same time user friendly electronic health record system.

Abstract

The Electronic Child Record for Youth Health Care (ECR YHC) is seen as the solution for the problems that are experienced with information exchange. An integral ECR YHC will support youth health care and early risk detection. The Dutch government strives for the introduction of this national ECR YHC on 1 January 2008. Eight organizations had planned a route to involve users in the system development. Method: Eight institutions described technical and functional requirements that serve as a basis for the ECR YHC. For this, the Delphi method was used. Results: An expert panel of 52 experts has given its opinion on the Basis Data Set YHC, functional requirements for an ECR YHC, the data that are exchanged in electronic messages, the flow chart YHC based on the national guideline for YHC, and usability requirements. This showed a high level of consensus on the functional requirements. Conclusion: the method followed yields a high support among the care professionals and the results of this project will be used for the national tender of an ECR YHC.

Keywords:

Electronic Child Record, youth health care, Delphi technique, requirements gathering, system specifications

Introduction

Information exchange is important for a qualitative well functioning youth health care. Optimization of the information exchange is inevitable in two areas. First, the availability and exchange of data between perinatology, the administrations of immunizations, the council administration and the institutions that deliver the care to the youth of zero to nineteen years old. Second, the information exchange at population level for the purpose of epidemiological research like national monitoring. Hereby ICT will play an important role.

In the present situation the information exchange does not run optimal. Problems are [1]:

- Obtaining recent data of the youth costs a lot of effort. Thus, there is no insight in the correlation between the data whereby preventive actions are hard to perform.
- Monitoring of YHC is not possible to the full extend because it is hard to access data or because data are lacking.
- It is hard to indicate what added value the sector delivers to the health of children and the prevention of the risks for health.
- The aims of the national guideline YHC for 0-19 year old children are impossible to reach without information and communication technology (ICT) support. Because uniformity in information and in health care can not be realized, the quality of care is not guaranteed.

The implementation of an ECR for the YHC should optimize the information exchange whereby existing problems will be solved [1]. The Electronic Child Record implies the following for the youth health care institutions involved [2]:

- Optimal care will be given to the youth of 0-19 years.
- Care professionals can have current and relevant data of the child at their disposal at all times.
- Data of the council administration, administration of immunization and birth can be obtained automatically by electronic messages.
- Records can easily, safely and completely be transferred to other institutions by the use of standards for data and messages. For this the Health Level 7 version 3 (HL7 v3) [3] standard will be used.
- More insight in the work processes will be obtained whereby the processes can be organized in a better way.
- Research for the organization itself but also for the system for following the child and for policymaking can take place easier.

For this it is necessary to connect to the' National Health Index (landelijk schakelpunt in Dutch)', an indexing system that makes it possible to electronically query and exchange patient information in a safe way [4] This is part of the national health information infrastructure developed by NICTIZ, the Dutch National IT Institute for Healthcare [4].

For realization of the objectives a project has been started with eight institutions for YHC. The research question for

this phase of the project was: What are the requirements of the care providers for the ECR YHC? The Basis Data Set YHC of NICTIZ [5] and the electronic HL7 v3 messages [3] need to be part of the research.

Materials and methods

Design

To determine the requirements of the care providers a consensus method, the Delphi method, was used. Delphi method is used to systematically reach consensus for certain issues in different rounds by means of the judgment of experts. Normally a Delphi study consists of two to four rounds that follow each other in a period of some weeks. One of the benefits of the Delphi technique is that there is no social pressure on the participants. This makes it easier to give deviant opinions [6]. After each round the answers of the panel are analyzed, summarized and reported.

Different forms of the Delphi method can be distinguished. In this study we used mainly the policy version, because this so called Kantian approach is characterized by problem solution via synthesis of different parts to a rounded product [7, 8]. This is a constructivist form that can contribute excellently to a suitable approach of the development and use of an ECR YHC. Van Houten [9] indicates that this Delphi version is usable for incompletely structured problems that know several solutions and only can be dealt with from several disciplines or points of view [8].

In other sources the nominal group technique [10] for reaching consensus will be addressed as well. The specific thing of this method is that in the final round the anonymity is cancelled by organizing a meeting. For the ECR YHC project two rounds have been carried out: one anonymous written round an one panel meeting. The anonymity in this second round was kept by using voting devices with numbers, so the individual responses could not be retrieved.

Expert panel

The expert panel for this study existed of 66 experts in the field of YHC. The participating organizations themselves were responsible for an equal representation of the experts. All relevant health professions were represented in the expert panel.

Questionnaire

A questionnaire was developed because there was no questionnaire available to make an inventory of the requirements of the care providers. For this questionnaire existing documents from YHC and literature on electronic records were used. The questionnaire starts with a couple of characteristics of the respondent including the discipline and institution to which the respondent belongs.

First the Basis Data Set YHC developed by NICTIZ, in collaboration with the Organization of Care Operators (Z-org), GGD Nederland (the Dutch Council Care Service) and the Vereniging Nederlandse Gemeenten (the Association of Dutch Councils) is used. The Basis Data Set YHC is a collection relevant data that is minimally needed for the exchange of data between organizations in youth health care. It is a standard with respect to content with concepts and data relevant to youth health care. With the Basis Data Set YHC it is also possible to perform research in YHC. The set as a whole is included in the questionnaire.

Second, a cluster of unique personal details is presented. NICTIZ has made arrangements on these often occurring data groups, called HL7 v3 Common Message Element Types [3], for the connection to the national infrastructure arrangements. For patient details the CMET patient can be used. Similar arrangements have been made for health professionals in the CMET Provider. All messages from and to the ECR YHC use the same data. The CMET Patient NL has been admitted to the questionnaire as an addition to the Basis Data Set YHC. This consists of common patient data like name, date of birth, gender address and insurance, adapted to the Dutch situation.

Third, to get insight in the workflow of the preventive care for youth of 0-19 and to improve these, a flow chart has been developed (Figure 1). The chart gives an overview of the workflow that are part of the Basis Tasks Package YHC [11]. By means of a time line phases of life that a child goes through from 0-19 years are shown. On this time line the processes and moments of contact are put down. This makes the flow chart an important description of the functionality of the ECR to support the workflow.

The fourth part of the questionnaire are the functional specifications developed by GG&GD Amsterdam and GGD Rotterdam. In these functional requirements it has to be indicated exactly what the ECR YHC should be able to, to make sure that care providers can make complete and reliable reports. These specifications are complemented with requirements for usability of the ECR YHC.

Next to that, the questionnaire has been complemented with results of analysis of documents that are used in the participating institutions.

Cut off point for consensus

The aim of the Delphi method is reaching consensus on the requirements of the care providers for the ECR YHC [6,7,8,9]. For answering the questions a three point Likert Scale has been used. This had the following answering possibilities:

- 0 for not agree
- 1 for unclear or doubt

- 2 for agree

The cut off points for consensus were the following [12]:

1. A percentage agreement equal to or higher than 75%: When 75% or more of the panel members agree with the specification this accepted. Specifications for which there is disagreement have been presented again to the panel in the consensus meeting, together with the comments and the arguments that have been given by the panel members. As a result of these comments some new statements have been formulated.
2. From the remarks that have been given for a specification by the panel members should emerge that the subject was unambiguously understood. When this is not the case, the item is not due for consensus and is presented again, if necessary with explanation.

For questions that do not result in consensus, statements are formulated with the help of the remarks and suggested changes

of the expert panel. In the consensus meeting these statements are presented to the expert panel. By means of electronic voting devices the panel voted using the same answering possibilities and cut off points as described above.

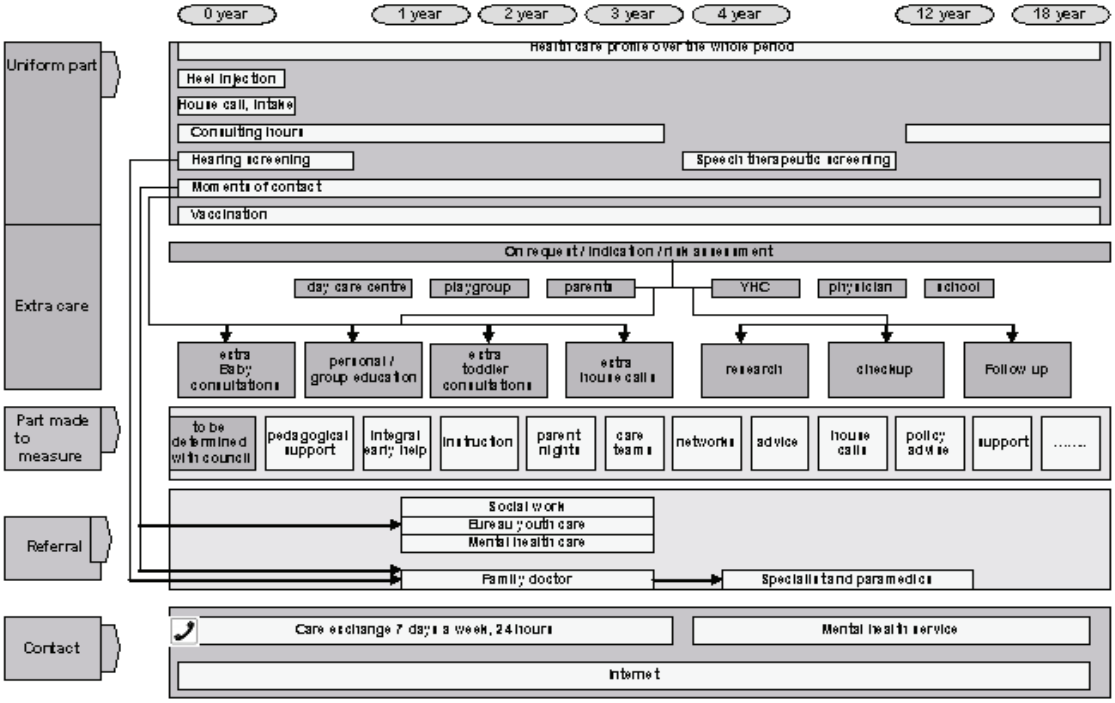

Figure 1 - The workflow chart for the Youth Health Care

Analysis

For analysis of the scores on the questionnaire SPSS software has been used. For answering the question, descriptive statistics has been used. The programme for the electronic voting generates these statistic measures itself.

Results

In total 66 questionnaires have been sent, 52 have been completed and returned (response of 79%). The professions of the respondents are shown in Table 1. The project started with five organizations. After the questionnaire was sent out, another three joined the project. Because of the later participation the representation of these organisations is relatively low compared to the other five. Next to that, for one of the organizations three members of the expert panel filled in the questionnaire together because of time pressure for returning the questionnaire. This has been indicated as three respondents.

At the consensus meeting 52 experts were present (response 79%). On some concepts not everybody voted.

Abstinence of voting on a concept has mainly been done because the subject was one in which one was not involved or not informed.

With the help of the Basis Data Set YHC [4] a Data Set ECR YHC has been developed. The Basis Data Set YHC consists of 53 concepts. For every concept attributes (observation or variable) and value sets (answering possibilities) are formulated.

The 53 concepts of the Basis Data Set YHC have been added to the questionnaire.

The expert panel members were asked for their opinion with reference to the completeness of the data and they were asked if they had additions. The additions needed to be specified as completely as possible. This meant specification in attributes, preferably with value sets.

In the written question round consensus has been reached for 25 concepts (47,2%). For the concepts for which no consensus was reached, 57 statements were formulated. These statements were presented in the consensus meeting. On 47 statements voting took place, for 29 of these, consensus has been reached (62%). On 10 statements no voting took place because new information was available, whereby statements were no longer relevant. The statements for which no consensus was reached have been discussed in focus groups consisting of representatives of the expert panel. The focus groups have decided which concept should be added to the Basis Data Set YHC, in what form and in what way addition should take place.

Example congenital heart defect

In the questionnaire the following statement has been presented to the expert panel: “The specifications ‘congenital heart defect’ are complete.” Sixty percent of the expert panel agreed with this statement. This meant no consensus was reached on this statement. In connection with the written remarks of the expert panel, the following statement has been presented at the consensus meeting: “Heart defect is added in accordance with the national standard Tracing of inherent heart defects.” There was no voting on this statement because one agreed unanimously.

In the focus group it was decided to add the following attributes and value sets to the Basis Data Set YHC (see Table 2).

Table 1 - Panel

Discipline	Amount	%
Health centre physician	9	17,3
Health centre assistant	3	5,8
Physician	4	7,7
Nurse of staff	1	1,9
District nurse	13	25,0
Physician of youth health care	6	11,5
Nurse of youth health care	3	5,8
Assistant youth health care	2	3,8
Remedial educator	1	1,9
Speech therapist	1	1,9
Epidemiologist	2	3,8
Manager	5	9,6
Secretariat	1	1,9
Assistant physician of youth	1	1,9
Total	52	100

Patient data

Of the four statements that have been presented to the expert panel consensus has been reached for three of them (75%). For the concept ‘occupation’ no consensus was reached.

Flow chart YHC

Figure 1 shows the flow chart. The statement about the flow chart was as follows: ”In the flow chart all important processes that are relevant for the ECR YHC have been taken in.” For this statement there was a 82,2% consensus. This meant that the flow chart developed by two of the organisations (ICARE and GGD Drenthe) has been accepted by the other six organisations. That is why the flow chart will serve as a starting point for the design of the ECR YHC and is inserted in the specification.

Functional specifications

On the functional specifications ECR YHC of the GG&GD Amsterdam and Rotterdam 13 statements have been formulated. For two of the functionalities no consensus had been reached. Next, nine statements have been formulated for the consensus meeting. In this meeting consensus was reached for seven statements (78%).

Example

In the questionnaire the following statement has been presented to the expert panel: “The specifications in relation to the data registration are complete.” In round one 60,4% of the expert panel agreed on this statement. As a result the following statements were presented at the consensus meeting:

1. Add: For research it is possible to search in all records on the basis of entries. For this statement 100% agreed.
2. Add the working area of the employee, for example for which school district one works. For this 56.8% agreed. The statements and the results have been discussed in a focus group. The group decided that it should be possible to mention the school in the ECR YHC.
3. In one glance it should be visible what risk factors there are for a child. For this statement there was 100% consensus. This requirement was added.
4. The system gives a timely alert when certain time limits are about to be exceeded. For this 97,8% agreed. This requirement was added to the specifications.
5. It should be possible to register in the system how many times parents/care takers call to consulting hours by telephone and with what questions. For this 90,5% agreed. This requirement was added to the specifications.

Table 2 - Additions for the concept of 'Congenital heart defect

Attribute	Value set
Examined	0=Not examined 1= Examined, no special circumstances 2= Examined, special circumstances
Intervention	0=None 1=Education/advice 2=Extra moment of contact 3=Referral
Follow up	Free text
Overall impression researcher	1=Fatigued 2=Passive 3=Undernourished impression, thin 4= Dysmorphism
Overall impression parents	Free text
Effort tolerance	First year during feeding of effort (for example crying): 1=Easily fatigued 2=Perspire 3=Rapid breathing 4=Hungry, but can not empty bottle 5=Stops drinking from the mother's breast 6=Blue or grey skin colour Toddler age: 7= Rapid fatigue with effort like walking (stairs), cycling 8= interruption of play by crouch School going and Adolescent age: 9= Fainting (in particular with effort) 10=Easily fatigued 11=Heart palpitation 12=Pain in the chest

Usability requirements

On the requirements for usability 29 statements have been formulated. For 25 statements (86,2%) consensus was reached. In the consensus meeting three new statements were presented to the expert panel. For these 100% agreement was reached.

Example

In the questionnaire the following statement had been presented to the expert panel: "I can work in more than one record at a time." Next, in the consensus meeting the following statement has been presented: "More records of children of one family can be edited at the same time." For this 96% agreed and it was added to the specifications.

Discussion and conclusion

Aim of this project was to determine the requirements for an Electronic Child Record for Youth Health Care. This aim has been reached to a high extend. For most concepts there was agreement. For some concepts consensus could not be reached and were elaborated on in focus groups of experts. The response in round one (the questionnaire) was 79 %. The attendance at the consensus meeting was high as well, again 79%. All members of the project team participated enthusiastically in determining the Data Set ECR YHC and further specifications for the system.

Despite everyone's effort a short comment on the study should be given. First on the Delphi method. In this study two rounds were used: one written question round and one consensus meeting. Next, in the focus groups it has cost time and effort to get to complete specifications for the data set ECR YHC and the system. It might be that this effort would not have been necessary when extra rounds had been scheduled. We did not choose to have extra rounds because of planning of the project and the amount of investment in time and manpower that these extra rounds would have cost.

The second comment relates to the completeness of the Data Set YHC. Performing the study was under time pressure because of project planning. Because of that the results of the written question round have not all been checked with the Basis Data Set of NICTIZ. In the consensus meeting a discussion started on a couple of statements because these were about concepts that were already in the Basis Data Set YHC. Next to that, for a statement on the immunization administration new information was presented during the consensus meeting what made the statement irrelevant. Because of the effort of the experts in both the consensus meeting and in the focus groups, a Basis Data Set ECR YHC and a list of specifications were created that gained a lot of professional support.

The controversial subjects that still exist have been discussed in the focus groups. A part of these subjects relate to the planning of contact moments and registration of data for both internal and external use. At that moment it was decided to start a working group that had to tackle the issues concerning requirements for the ECR related to planning and registration. Currently, a national tender is ongoing for the procurement of the ECR YHC, and this work is part of the specifications.

Acknowledgments

We want to thank the eight youth health care institutions, ICARE, GGD Drenthe, GGD regio Noord Veluwe, GGD Gelre-IJssel, Vérian, Yunio, Zuwe and Vitras, for their devoted participation in this study.

Determining Requirements for an Electronic Child Record in Youth Health Care

Het project EKD JGZ

Anneke Goossen-Baremans, Lisanne van Beek, Lejo Bouma, Judith van der Kooij, William Goossen

On behalf of the Evean group, Icare, Meppel, the Netherlands.

Introduction

The following issues exist in the present information management in youth health care (YHC) in the Netherlands:

- Obtaining recent data about children's health costs a lot of effort
- Monitoring is not possible because it is hard to access data or because data are lacking
- It is hard to determine what added value the YHC delivers to the health of children and the prevention of the risks for their health
- The national guideline YHC for 0-19 year old children requires support with information and communication technology (ICT): an electronic child record

The project

- A project to develop a electronic health record for children has been started by eight YHC institutions.

- The research question for this phase of the project was: ‘What are the requirements of the care providers for the ECR YHC?’

- To determine the requirements of the care providers the Delphi consensus method was applied, using two rounds of questionnaires: round one a traditional questionnaire sent via email and round 2 a consensus meeting with an electronic voting system.

Delphi method applied

- Expert panel: 66 experts in the field of YHC
- Questionnaire 1 was based on the national dataset for YHC, documents from YHC, literature on electronic records, Health Level 7 version 3 patient data specifications, the workflow chart for preventive care for youth, and existing functional specifications
- Questionnaire 2 contained items with no consensus in round 1 and new input / clarifications on the same topics
- Cut off point for consensus: a percentage agreement equal to or higher than 75% and the remarks given by the panel members indicate that the subject was unambiguously understood
- Analysis: first round descriptive statistics, second round electronic voting program with descriptive statistics

Results

- Response of 79% in both rounds (n=52)
- National dataset for YHC: 25 of 53 concepts obtained consensus in round 1 (47,2%). In round 2, the consensus meeting, 57 statements were presented. Voting took place on only 47 statements: 29 of 47 obtain consensus (62%).
- The statements for which no consensus was reached have been discussed in focus groups, resulting in additional concepts
- Flow chart YHC: 82,2% consensus
- Functional specifications: 11 of 13 statements obtain consensus (85%)
- Usability requirements: first round: 25 of 29 statements obtain consensus (86,2%), second round: 100% consensus

Results: (example) data items for YHC, required additions to national set:

Data on growth and development, for example the national Van Wiechenschema

Audio logic screening

Screening of visual impairments

Target height calculation

Calculation of Body Mass index

Calculation of growth charts

Care plan

Mood

Behavior

Concentration

Hygiene

Allergies

Life events

Child abuse

Heart rhythm, tone, murmur

Speech assessment

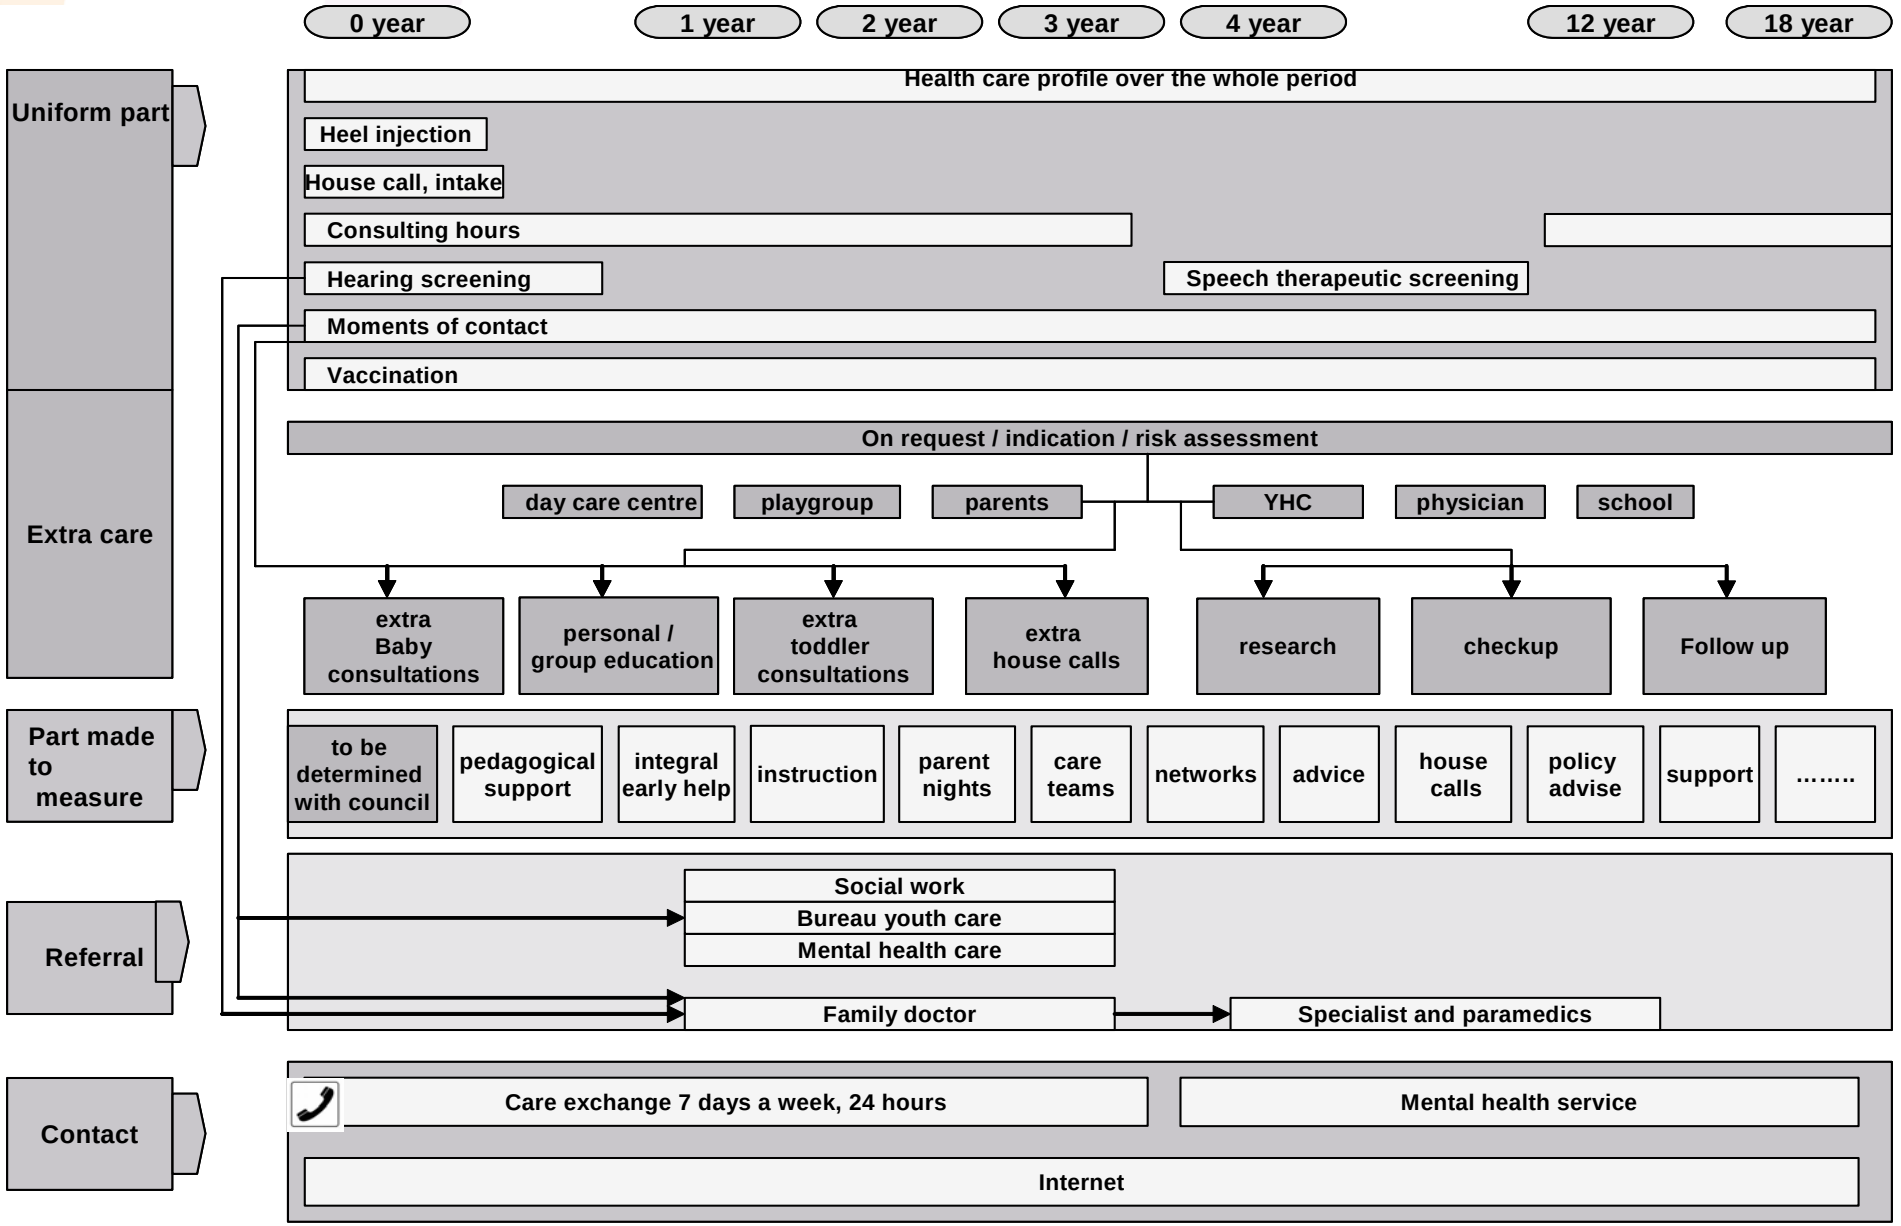
Use of alcohol / drugs / smoking

Example added concept:

‘Congenital heart defect’

Attribute	Value set
Examined	0=Not examined 1= Examined, no special circumstances 2= Examined, special circumstances
Intervention	0=None 1=Education/advice 2=Extra moment of contact 3=Referral
Follow up	Free text
Overall impression researcher	1=Fatigued 2=Passive 3=Undernourished impression, thin 4= Dysmorphism
Overall impression parents	Free text
Effort tolerance	**First year** during feeding of effort (for example crying): 1=Easily fatigued 2=Perspire 3=Rapid breathing 4=Hungry, but can not empty bottle 5=Stops drinking from the mother’s breast 6=Blue or grey skin colour **Toddler age:** 7= Rapid fatigue with effort like walking (stairs), cycling 8= interruption of play by crouch **School going and Adolescent age:** 9= Fainting (*in particular with effort*) 10=Easily fatigued 11=Heart palpitation 12=Pain in the chest

Result: example workflow



Example functional requirements

- For research it is possible to search in all records on the basis of entries
- Add the working area of the employee, for example for which school district one works
- It should be possible to mention the child's school in the record system for YHC
- In one glance it should be visible what risk factors apply to a child
- The system gives a timely alert when certain time limits are about to be exceeded
- It should be possible to register in the system how many times parents/care takers call to consulting hours by telephone and with what questions

Discussion & Conclusion

- The method followed yields a high support among the care professionals for concepts that need to be included in the electronic child record (ECR) in YHC
- Due to time pressure, double statements were presented in round 2, which could have been prevented
- Focus groups needed a lot of time, which might have been prevented by adding a third round
- The results of this project will be used for the national tender of an ECR for YHC

Does Healthcare Staff Change Working Procedures in Relation to Inter-Disciplinary Documentation in the Electronic Patient Record?

Lisbeth Nicolajsen[a], Ghita Ølsgaard[b]

[a] *Department of Gynaecology and Obstetrics Y, Aarhus University Hospital, Skejby, Denmark*
[b] *Centre of Quality Improvement, Region Mid-Jutland, Denmark*

Abstract

A comparativ and qualitative investigation with observation studies, interviews with staff observed and focus group interviews.

The study design included two groups: Group 1 (mono-professional documentation) consisted of two departments that had not introduced the electronic patient record (EPR). Group 2 consisted of two departments that had introduced the EPR.

The study showed that working procedures and division of work with documentation had not changed when comparing departments with EPR with departments without EPR. The division of work in departments with EPR clearly showed that decisions on the department's working procedures had not been taken. Decisions on who does what when a new electronic tool is introduced have not been taken. The mono-professional documentation thus continues as a new documentation method for inter-disciplinary documentation has not been considered.

Keywords:

working procedure, inter-disciplinary documentation, inter-disciplinary collaboration, electronic patient record

Introduction

Denmark is about to introduce an EPR for systematic and structured documentation enabling retrieval and reuse of data. The EPR is supposed to be inter-disciplinary and not just a common record.

It is expected that the EPR will result in organisational changes, changed work procedures and ways of dividing the work [1], in documentation of treatment and care and thus health professional services [2]. These changes will be a part of the construction of the EPR taking its starting point in a B-EPR (Basic structure of the EPR) made by the Danish National Board of Health [3].

When the EPR is introduced it is expected that there will be a change from mono-professional to inter-disciplinary documentation. This will be a major change for healthcare staff.

The approach to documentation in healthcare staff is different and influenced by ways of organising knowledge, insight, skills and education. Consensus thus has to be reached con-

cerning documentation methods and education in the new documentation methods. Fink [4] writes: ”The organisation based on profession and science constitutes a risk that the profession does not stick to the case and that the case is considered secondary or is neglected in the professional work"

Methods

A comparative and qualitative investigation [5] with

- Observation studies
- Interviews with observed staff
- Focus group interviews.

The study design included two groups. Group 1 consisted of two departments that had introduced the EPR (paper documentation form). Group 2 consisted of two departments that had introduced the EPR (electronically based documentation form). The study was carried out in June 2005.

Observation studies were conducted at four surgical departments with similar specialities. The departments in question collaborate concerning surgical specialities.

Routines of documentation and communication concerning patients were observed at all four departments for two days at each department using the same observation guide. Working procedures were recorded by the two observers (the authors of this paper) in a table (Figure 1).

Communi-cation Nurse	*Documenta-tion Nursing record*	*Documenta-tion Medical record*	*Communi-cation Doctor*

Figure 1 - Observation guide

Analysis of the completed tables from the observation studies are compared in the following way:

- Mono-professional documentation
- Everything noted by each healthcare professional on personal notes
- Inter-disciplinary communication

Figure 2 shows a schematic view of specific times when collection of professional documentation/communication data on a patient was made.

Time	***Documentation***	***Parts in the documenta-tion***
Morning	*Written documentation of the patient from the day before.*	*Nursing record Medical record*
Morning	*Oral report written down*	*Nurse-nurse dialogue*
Before meeting the patient	*Written down what the nurse has communicated to the doctor*	*Nurse-doctor dialogue*
Before meeting the patient	*Written down the communi-cation between doctor and nurse*	*Doctor-nurse + other healthcare staff dialogue*
Meeting with the patient	*Written down communica-tion between patient, doctor and nurse*	*Patient-doc-tor-nurse dia-logue*
After meeting with the patient	*Included written documen-tation in medical and nurs-ing records and record of other healthcare staff*	*Medical record Nursing record Other health-care staff records*
	Included written supporting notes	*Nurse's own notes*

Figure 2 - Specific times in the observation study

Observation studies were followed by individual interviews with the observed healthcare staff using a structured interview guide. The interviews were used to validate the observations. The interviews were opinion condensed and subsequently opinion categorised.

As follow-up on observation studies and interviews with individual staff focus group interviews were conducted at each of the two departments with EPR.

The focus group interviews were opinion condensed and subsequently opinion categorised.

Participants

The following participated in the study:

- 12 doctors with seniority between 4 and 30 years
- 11 nurses with seniority between 5 and 33 years.

Results

Results on working procedures concerning documentation and communication concerning the patient were divided into:

- Collection of information
- Communication before meeting with the patient
- Meeting with the patient
- Communication after meeting with the patient
- Documentation

Collection of information

Before healthcare staff met with the patient information was collected.

At the two departments without EPR the nurse on night duty either gave a thorough status on patients or no report.

The nurses themselves also read the paper records.

At the departments with EPR the nurse on night duty at one of the departments made a deviation report on one observation day but no deviation report was given on the second observation day. Furthermore, the daytime nurse read the EPR. At the other department with EPR the nurses read about patients in the EPR without having received report from the nurse on night duty.

The doctors started with a morning conference where they received report on patients from the attending doctor. Patient records were not used at morning conferences. The working procedure applied to all departments involved in the study.

In focus group interviews doctors at one of the departments with EPR reported that they searched information about patients as a supplement to the morning conference.

Healthcare staff collected more information before meeting with the patient and the other staff involved in the care of the patient. Here the available information was medical and nursing records or the EPR.

The nurses collected the continuing documentation material during the day on a note. All eight used notes. The note was the nurse's own or a common note for the department including all patients where comments are written on each individual patient.

The observation studies revealed that all healthcare staff read the documentation of their own staff group before meeting with the patient. The doctors did not read the documentation on patients they knew. One doctor from a department without EPR read the documentation during the meeting with the patient.

The distribution of reading other staff groups' documentation showed that five in eight nurses always read documentation of other staff groups; three in eight nurses sometimes read documentation from other staff groups. None of the eight doctors read documentation of other staff groups.

In focus group interviews doctors said they read documentation by other staff groups.

In the interviews in connection with the observation studies it was asked directly if documentation from other staff groups was read. Two in nine possible in departments without EPR answered "no" and one in ten possible in departments with EPR answered "no". In departments without EPR seven in nine possible answered "yes" and in departments with EPR nine in ten possible answered "yes". This is not in accordance with the results of the observation studies.

In departments without EPR all nine read documentation from other staff groups compared with eight in ten at departments with EPR. In departments without EPR eight in ten consulted other staff groups compared with ten in ten in departments with EPR.

The admission description in the medical record and the nursing record were read by the nurses. Relevant parts of the medical record were read by a third of the informants at department without EPR compared with half at departments with EPR.

Doctor's notes from rounds were read by one in nine at departments without EPR. Notes from rounds were not used in the daily documentation.

The medicine list was checked by doctors and nurses by five in nine at departments without EPR and by three in ten at departments with EPR. At the two departments without EPR the medicine list was electronic. This was also the case for one department with EPR. At departments without EPR, blood samples were checked by both doctors and nurses in three out of nine compared with two in ten at departments with EPR.

At departments with and without EPR all nurses read the daily notes by nurses.

The healthcare staff 's patient information comes from oral reports in three out of four in departments without EPR and no persons reported in departments with EPR.

However, doctor-nurse communication was highlighted by both doctors and nurses at departments with and without EPR.

Communication before meeting with the patient

In six of the eight observation studies there was communication/dialogue between the doctor and the nurse to prepare before meeting with the patient. The two cases where there was no communication took place at a department with EPR. This is in accordance with doctors knowing the patient in advance.

Observations showed that in departments without EPR communication took place before meeting with the patient. The same observation was made at departments with EPR.

In focus group interviews one department stated that they were now better prepared for rounds because they had consulted the record before meeting with the patient. They also stated to have a better overview of the patient's situation.

At the same time it was pointed out that it can be difficult to get an overview of complicated cases where patients have been admitted for a longer period.

Meeting with the patient

In the department without EPR the doctor brought the medical record with him to the meeting with the patient.
Doctor-nurse communication during the meeting with the patient took place in six out of eight cases. In one case where there was no communication there was no direct meeting with the patient. The doctor was briefed by phone by the nurse and the doctor made prescriptions by phone. This was unusual and caused by an emergency surgery. In the other case dialogue was sparse due to external circumstances.

Communication after meeting with the patient

At departments without EPR there was only doctor-nurse communication after the meeting with the patient in two out of four possible situations.

At departments with EPR there was no doctor-nurse communication after meeting with the patient.

Documentation

After the meeting with the patient documentation was made in the medical record.

At departments without EPR healthcare staff groups each had their own record. The doctor dictated notes to the medical record and the nurse wrote in her own mono-professional record.

In departments with EPR the nurses all made their own documentation in the EPR; two doctors dictated to the EPR and two doctors made their own documentation in the EPR.

At the two departments with EPR the design of the patient records was different. There was non-structured and structured documentation. Before the department with non-structured documentation began using the EPR they analysed present and future workplace procedures.

The other department worked with structured documentation and standard plans. In the standard plans there were some charts which could be used by all healthcare staff. At this department with EPR they had not worked consciously with workplace procedures only indirectly by working with functionalities in the use of the EPR in different situations.

When asking the question how to pass on information concerning the patient, all dictated or wrote in the record as described above. Based on the answers it appeared that healthcare staff communicated internally about the patient.

At departments both with and without EPR nurses passed on problems/deviations orally to other nurses.

At departments both with and without EPR the junior doctors dicussed with another doctor whereas more experienced doctors did not.

Documentation of the meeting with the patient was made by the doctor immediately after the meeting at departments both with and without EPR.

The nurses made their documentation at the end of the day except for one who made her documentation immediately after the meeting as she had the available time that day.

Another general pattern was that doctors and nurses did not document the same number of times during a day. The nurses documented three times a day and the doctors once a day unless there were complications in the patients.

Conclusion

We conclude:

- That work porcedures and division of work concerning documentation had not changed significantly in departments with EPR compared with departments without EPR.
- That the daily communication between staff groups had not disappeared using the EPR as attention was given to communicate nuances in the treatment and care of patients orally.

Specifically concerning the documentation and communication flow we can conclude:

Collection of information for doctors and nurses had not changed significantly in departments with EPR. The doctors' morning conferences were still run without using the patients' records. The use of notes was also the same in departments with EPR. Doctors' notes from rounds were still only read by a few in staff groups including the doctors themselves; on the other hand, nurses' daily notes were still read by all nurses in the departments with EPR. The admission notes from the doctor and the nursing record were read by all nurses. Relevant parts of the medical record were read by more people in departments with EPR compared with departments without EPR. Communication took place between healthcare staff groups before meeting with the patient by reading the EPR. This was also the case in departments without EPR.

The meeting with the patient had changed as the patient's record was not brought to the meeting in departments with EPR. The healthcare staff had read the EPR, which is always accessible and updated, before the meeting and felt more updated on the patient's situation.

Communication after the meeting with the patient had changed as departments with EPR did not have any communication after the meeting with the patient.

Mono-professional work procedures in departments without EPR concerning documentation and communication including dialogues about the patient still existed in departments with EPR except in one EPR department where it was still possible to dictate to the medical secretary. At the EPR departments it was possible to see notes from all health professionals concerning the patient. However, we can conclude that this possibility was used to a limited extent. New procedures on documentation and communication had not been described or communicated to end users at the EPR departments. We can concluded that the work procedures used were similar to procedures in the same specialised departments without EPR. The timing of documentation of treatment and care was similar to departments without EPR and doctors still made their documentation immediately after treatment while the nurses collected notes and made their documentation at the end of their shift.

Discussion

When the health professional content must be ensured in the EPR organisational changes are necessary. We chose Leavitt's organisation model [1] to focus on the different variables of an organisational change. The variables in the model have been adapted to the areas we wanted to shed light on. In one department with EPR it was stressed again and again that the healthcare staff was better up-dated on the patient than before the EPR. EPR has thus changed/ increased the professional level from an inter-disciplinary perspective. At the same time their behaviour has changed. Doctors and nurses communicate and read the EPR together before they meet with the patient. This communication is very important for healthcare staff in order not to lose knowledge providing poor conditions for the inter-disciplinary work on a long term basis.

The work procedure has also partly changed documentation. At especially one department it has resulted in double-documentation to be minimised. This is due to the structure of EPR and the use of standard plans. At this department they have used the possibilities in the EPR to support healthcare professional processes through standard plans based on the guidelines in the department and reference programs [6][7].

Artefacts, notes - both common and personal - survive in departments with EPR. The overview provided by the artefacts has not been achieved by the two different EPRs as we have observed. According to Leavitt [1] new procedures have not been used in connection with different artefacts and the use has thus not changed.

Healthcare staff has not focused on these artefacts or learned how to work without using the artefacts. New procedures using the artefacts through the EPR could assist in providing an overview of the patient's documentation where problems are highlighted using the common data.

EPR has changed some procedures but still staff do as they normally do. EPR has to be used for some time before procedures are changed. Procedures will change, but gradually [8].

If procedures are not analysed and adapted, EPR can be perceived as a disturbing element and healthcare staff will experience that they do not control their own daily work [9].

Our observations showed that EPR had not influenced previous work procedures. The notes from rounds at EPR department were still not read. Despite this doctors continued to write notes from rounds every day, which means they continued the same procedures without considering if documentation could be made someplace else. This could be because it is not an activity for the doctors to document in the EPR but the purpose is to produce a detailed copy of what has happened. According to Berg M [10] documenting in the EPR is an activity which is directly relevant for the work itself, a process of finding "the right diagnosis".

The possibility of reading the patients' records electronically during the doctors' morning conference had not been used. If the procedure in connection with the doctors' morning conferences had been analysed at departments with EPR the result could have been to change morning conferences from conferences without using records to conferences using records. Doctors would thus not have to remember the patients' treatments etc. but could view the entire amount of documentation at the conference and make decisions accordingly.

Today healthcare staff knows the work division concerning documentation but it is not described in detail or discussed in the departments.

The future with common data in connection with e.g. meeting with the patients means that the inter-disciplinary effort must be focused to ensure necessary data are collected to use in different databases according to the Danish Quality Model [11], and that the meeting with the patient is the responsibility of the entire inter-disciplinary group.

Collection and use of high quality data also mean that documentation must be real-time. Today documentation is not real-time for the nurses. They still make their documentation at the end of a shift at departments with and without EPR.

The doctors at the one department with EPR still dictate to the medical secretary which is not real-time either. Moreover, there are differences in the documentation frequency; doctors document once a day and the nurses three times a day.

The lack of real-time registration will have consequences for patient safety due to mistakes in documentation if documentation is not up-dated.

The strengthening of the professional profile and the collabo-

ration on common data will increase the professional level according to Leavitt [1] affecting the three other variables. The variable documentation will change as a new method of documentation is needed to collect and use multi-disciplinary patient data instead of mono-professional.

Acknowledgments

Inspiration and professional coaching during the study have been provided by Povl Erik Rostgård Andersen, senior lecturer, PhD, The Aarhus School of Business and Jørgen Schøler Kristensen, consultant, DrMsc, Aarhus University Hospital, Aarhus Sygehus.

We would like to thank for the interest and commitment from the surgical departments where we collected data. Department managements and the clinical departments have been very positive.

Thank you to the Research Initiative at Aarhus University Hospital for supporting this study financially and thereby help to provide new knowledge related to the multi-disciplinary electronic patient record in the Danish healthcare system.

Abstract

Standardized documentation of clinical data is essential to achieve semantic interoperability in today's heterogeneous clinical IT structures. In order to enhance data quality and user acceptance it is necessary to develop suitable user interfaces for Clinical Documentation Systems (CDS). Also, choosing the optimal storage format particularly depends on the specific purposes of the desired system. A system implementation based on the HL7 Clinical Document Architecture (CDA) is presented. There are promising results and a good user acceptance. Our approach provides a generic platform to build domain-specific user interfaces for structured data entry in a flexible and easily extensible way for multi-centric research networks.

Keywords:

remote data entry, electronic data capture, clinical documentation system, XML, HL7 CDA

Introduction

Clinical Documentation Systems (CDS) and standardized documentation can reduce the costs for data entry while the user interfaces can provide a high ease of use and support high data quality through data validation [1-2]. For storing medical data, XML standards like HL7 CDA [3] or CDISC ODM [4] can be applied. Both standards are developed by two independent organizations (HL7, CDISC) with two different objectives (primary care, medical research). In the following sections an approach is presented to integrate a Remote Data Entry (RDE) module into an existing telemedicine platform [5] using HL7 CDA. The module supports a user interface for clinical documentation (structured data and genealogies) in the German multi-centric research network for Epidermolysis Bullosa (EB), a rare hereditary skin disease. The EB network consists of 7 research centers throughout Germany involved in basic research as well as patient care.

Materials and methods

In close collaboration with the multi-centric research network the requirements for the RDE module and the structured data entry (SDE) forms were gathered. Flexibility (adjustable for different medical domains), extensibility (easy addition of further forms), maintainability (easy modifications of forms) and interoperability (interface to EPRs or EHRs) were identified as relevant requirements. A pool of data items for the SDE forms was determined and the items were grouped by topic and occurrence. The SDE forms should allow single-acquisition at patient recruitment as well as multiple-acquisition during the course of the study. Extensible table lists where data entry tables can be dynamically extended at runtime should also be possible.

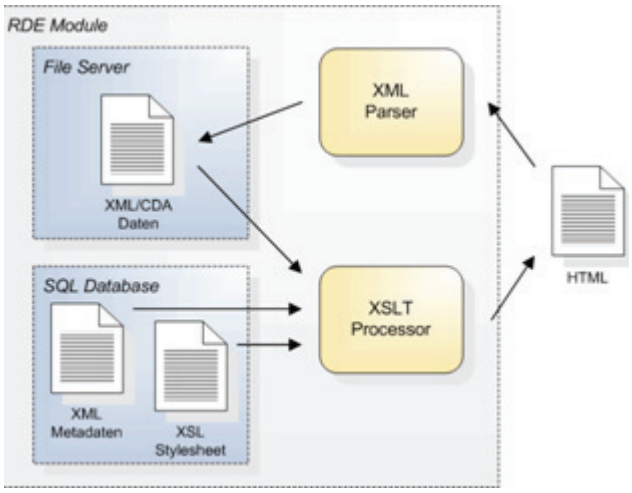

Figure 1 - Workflow for viewing and manipulating SDE forms
