Knowledge Discovery Based on the Identification of Relationships Among Medical Concepts by Clustering Candidate Descriptors

Shizuka Yamazaki[a], Mariko Iwasawa[b], Shin-ichi Nakayama[b], Natsuo Onodera[b], Yusuke Tanigawara[a]

[a] *Department of Pharmacy, School of Medicine, Keio University, Japan*

[b] *Graduate School of Library, Information and Media Studies, University of Tsukuba, Japan*

Introduction

- The discovery of hidden connections within the medical literature could give new and plausible knowledge.

Objective

- This study proposes and examines a new methodology for hypothesis generation and knowledge discovery using cluster analysis.

Methods

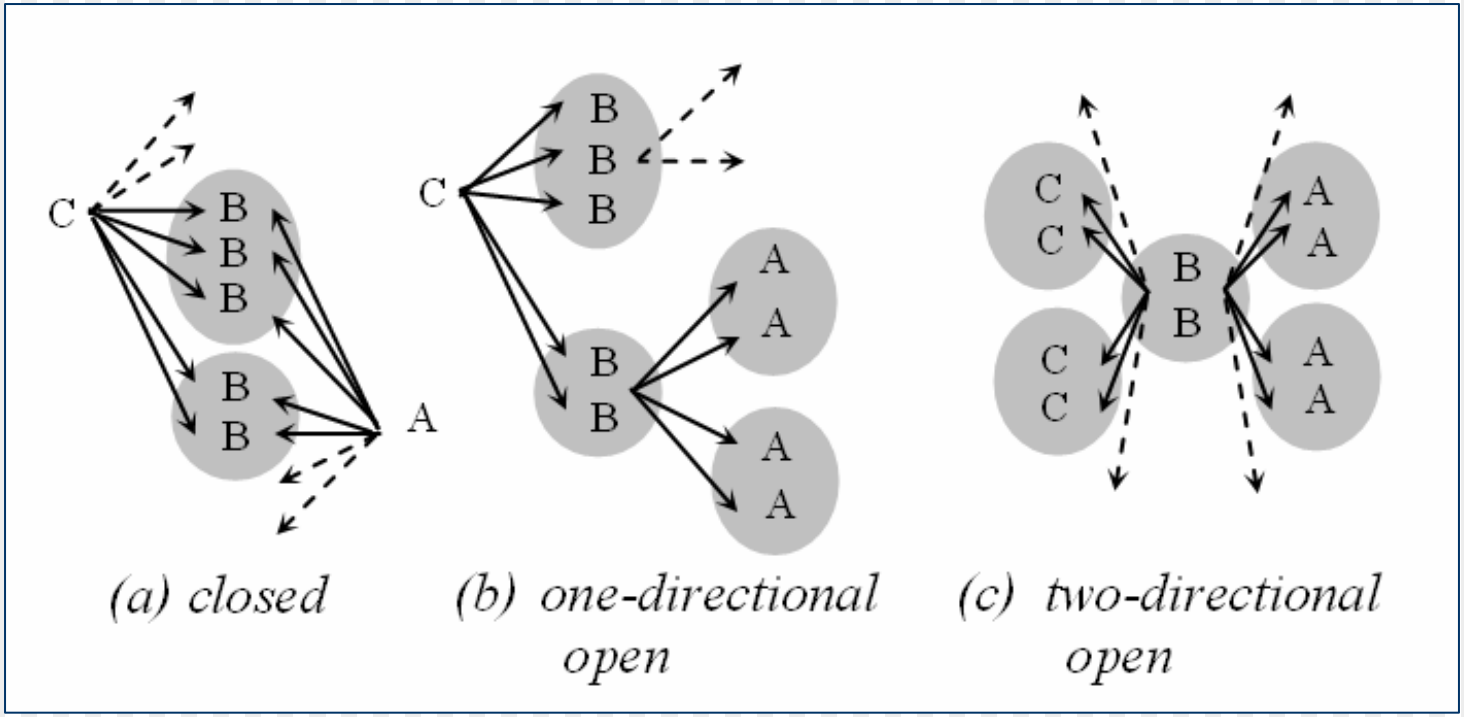
Background

- Don R. Swanson (1986), in his the ABC model, showed that unknown relationships between a chemical substance (A) and a disease (C) could be found by identifying a concept (B) that connects A and C in the literature .
- Closed and one-directional open discovery processes were reported by Marc Weeber et al. (2001).
- Most prior works used ranking based on term frequency. Such methodology may bring on only a part of the concepts.

We propose grouping candidate MeSH terms by means of hierarchical clustering for obtain knowledge overview.

Methods

Discovery process



We constructed the term-document matrix for clustering candidate MeSH terms.

Methods

(a) Closed discovery process

The B terms were MeSH terms that co-occurred in the document sets A and C.

i. Creating document sets A and C (B-terms collection)
ii. B-terms grouping

(b) One-directional open discovery process

The B terms were MeSH terms in the set C. These B terms were grouped and the B terms in each group were used to extract set A from MEDLINE.

i. Creating document set C (B-terms collection)
ii. B-terms grouping
iii. Creating document set A (A-terms collection)
iv. A-terms grouping

(c) Two-directional open discovery process

The A and C terms were MeSH terms in the set B

i. Creating document set B (A-terms, C-terms collection)
ii. A-terms, C-terms grouping

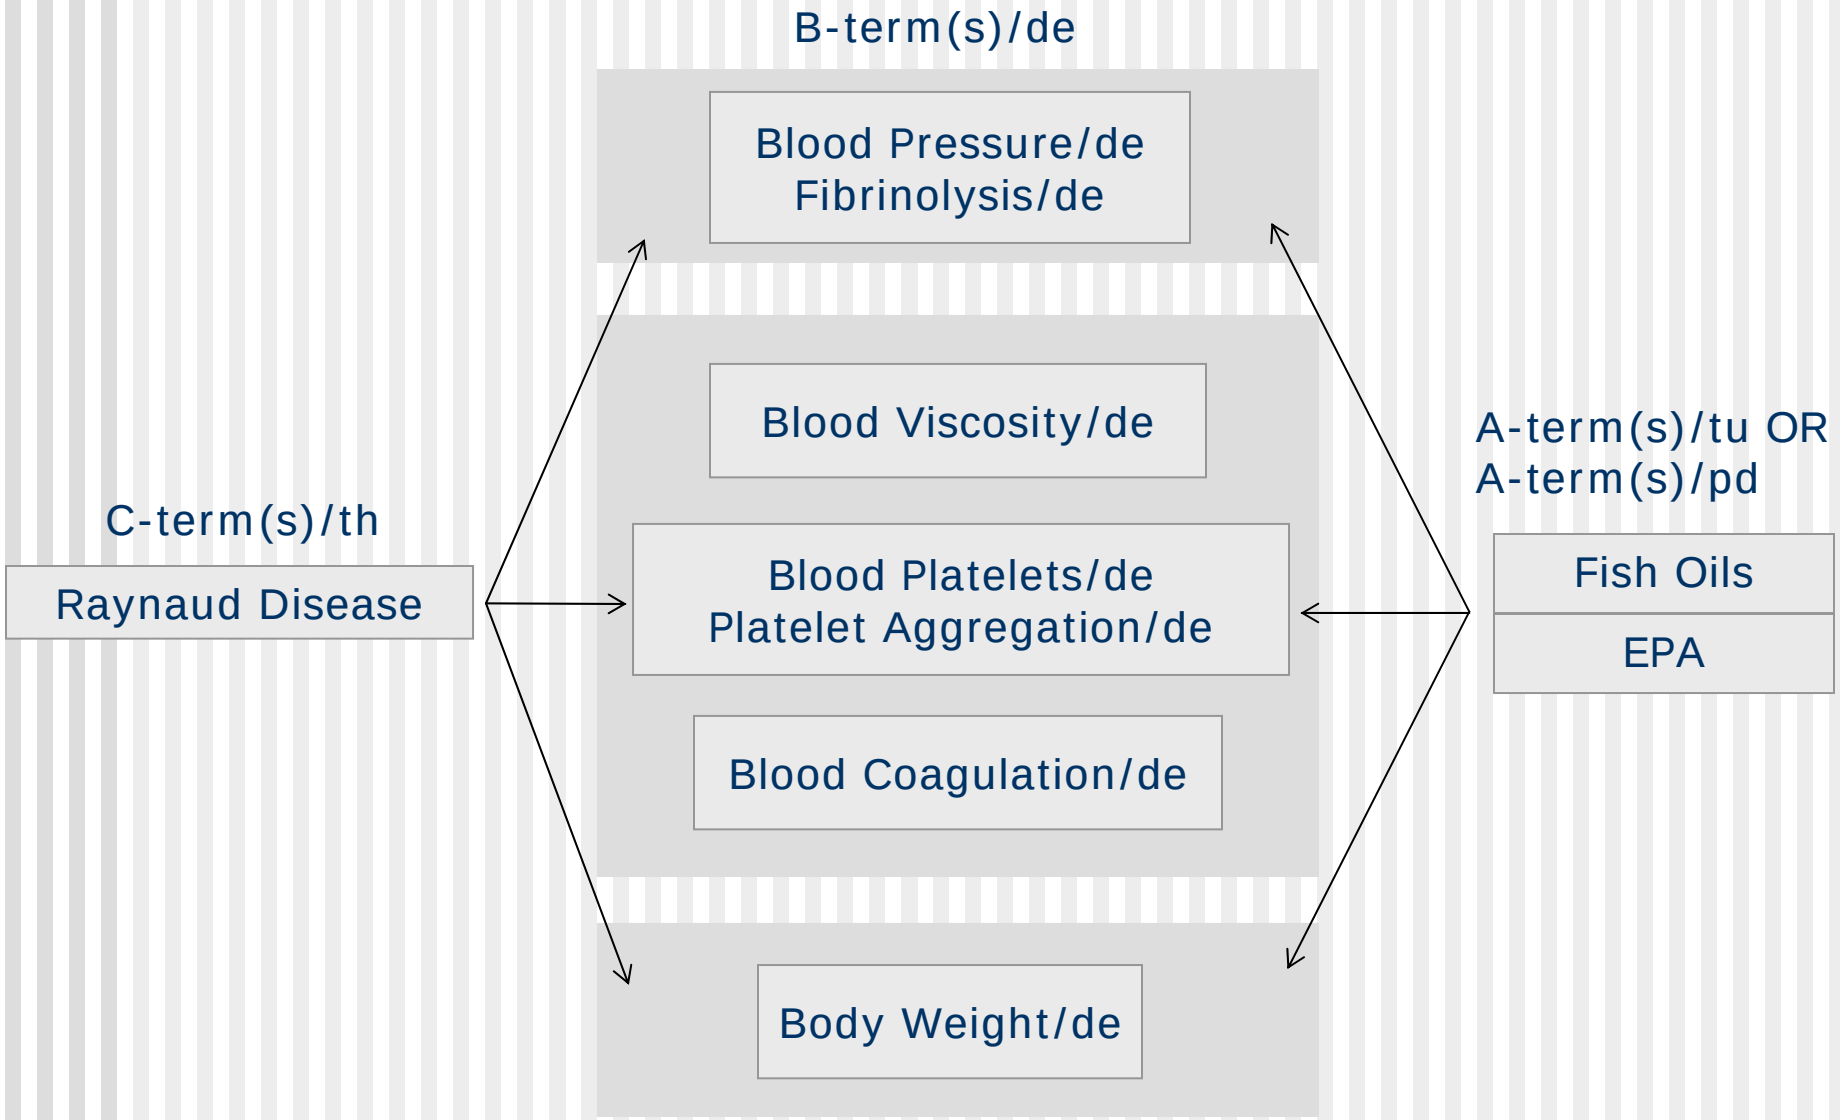
Methods

- We searched for particular terms with the relevant subheading:

C-term(s)/th [therapy]
- B-term(s)/de [drug effect]
  - A-term(s)/tu [therapeutic use] OR A-term(s)/pd [pharmacology].

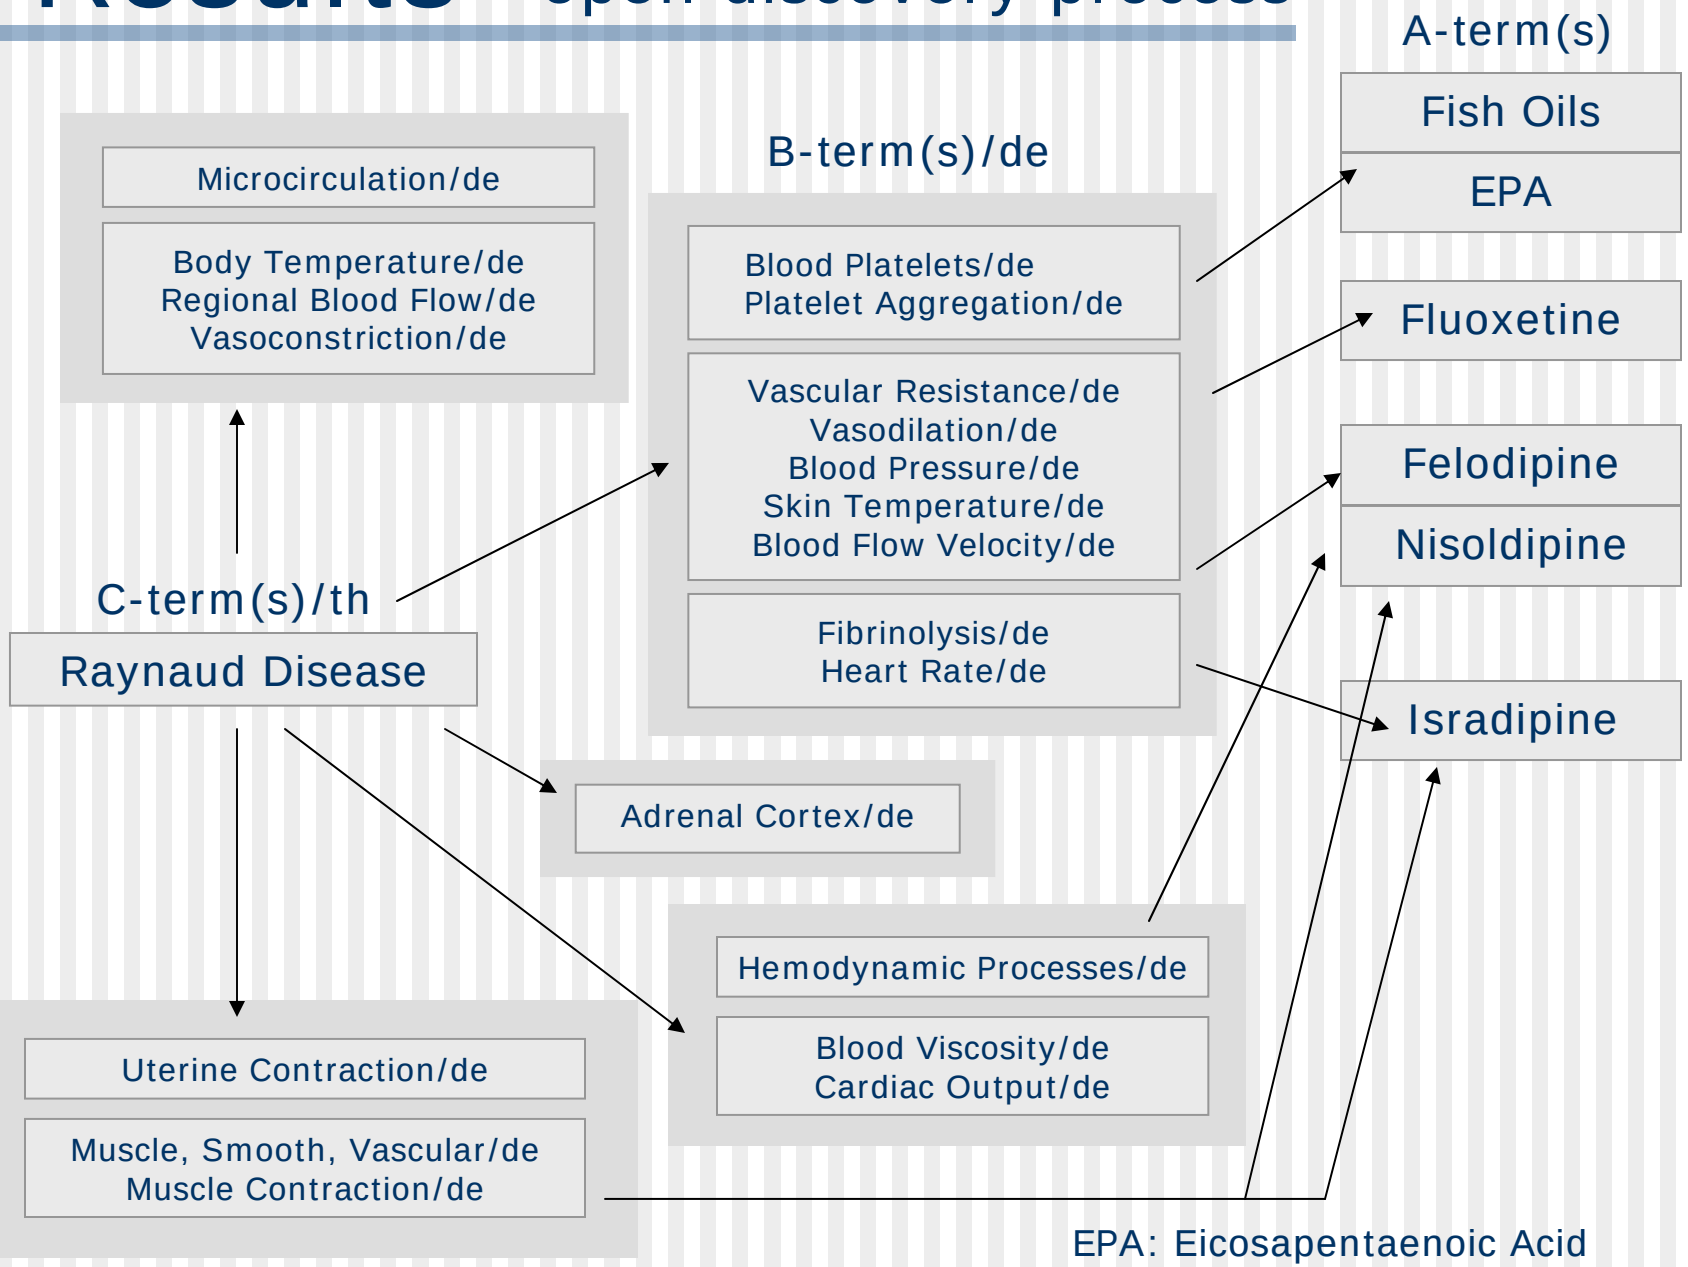
- In each process, the stop list of MeSH terms used was similar to that applied in Swanson's method (2006).
- Our discovery processes were applied in an attempt to identify relationships between fish oil and Raynaud's disease from MEDLINE documents as an experimental test of Swanson's hypothesis.
  Database: PubMed http://www.ncbi.nlm.nih.gov/PubMed/
  ("1983/01/01"[PDAT] : "1985/12/31"[PDAT])

Results Closed discovery process



Results

One-directional open discovery process



EPA: Eicosapentaenoic Acid

Results

One-directional open discovery process

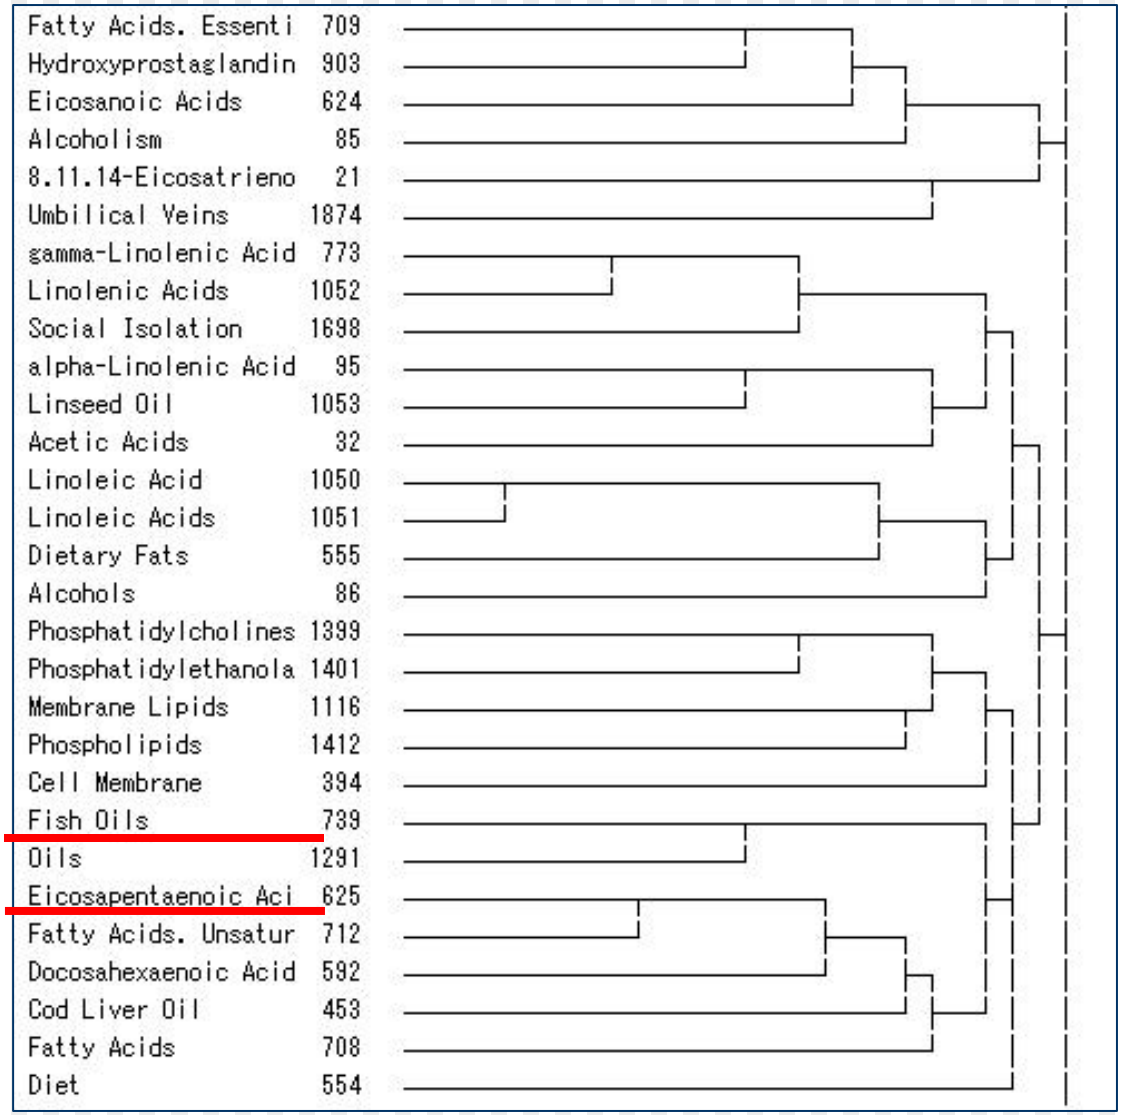
B-term(s)/de

- Blood Platelets/de
  Platelet Aggregation/de
- Vascular Resistance/de
  Vasodilation/de
  Blood Pressure/de
  Skin Temperature/de
  Blood Flow Velocity/de
- Fibrinolysis/de
  Heart Rate/de

↓

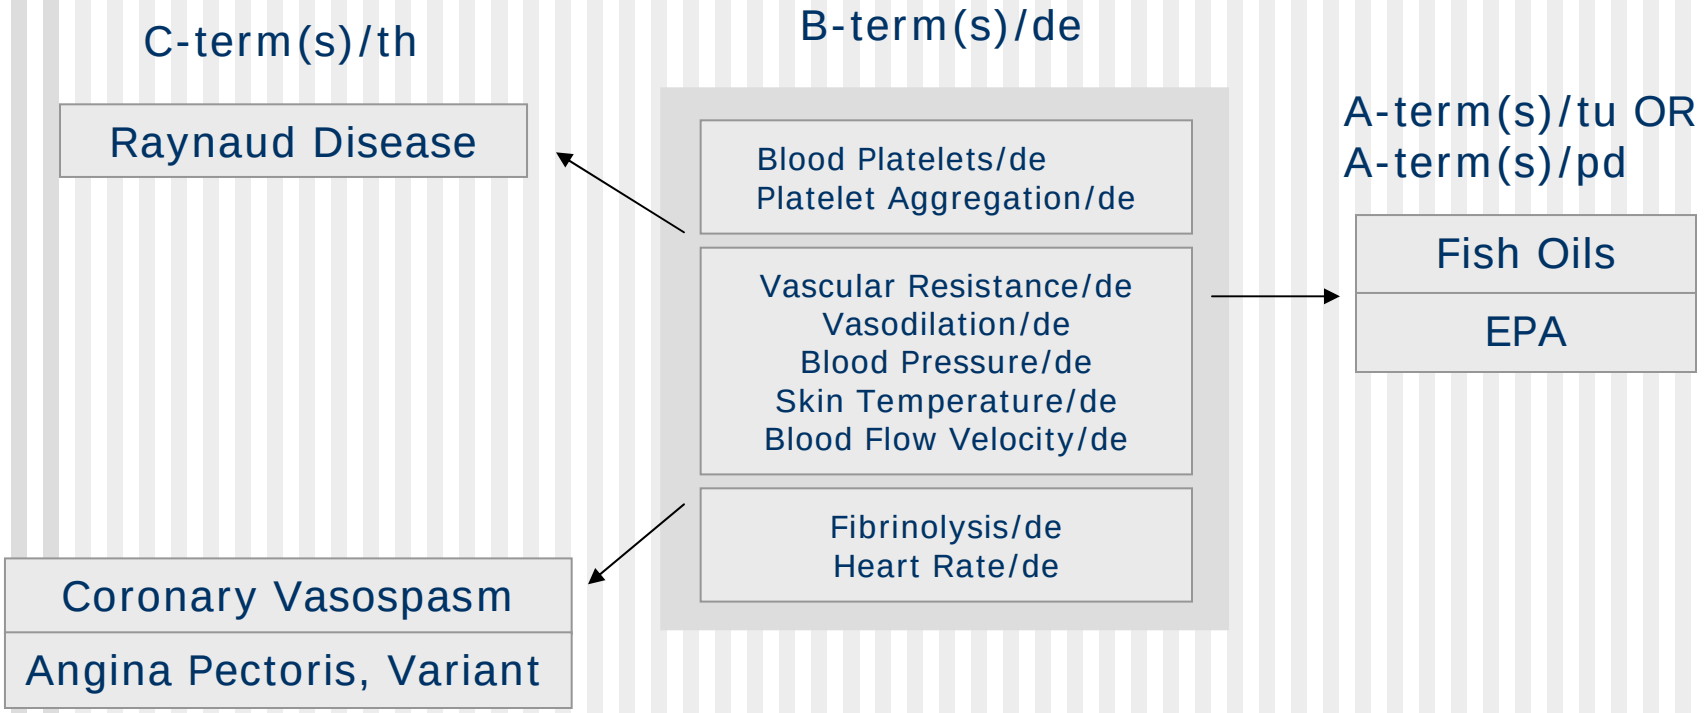
A-term(s)

- Fish Oils
- EPA



Results

Two-directional open discovery process



Discussion and conclusion

- By grouping candidate descriptors using cluster analysis, we succeeded in detecting invisible connections between medical concepts.
- It is important to obtain knowledge on relationships between various phenomena observed in clinical practice. All relationships are not always direct connections, however.
  Our new methodology was effective in identifying hidden connections between medical concepts.
- The resulting knowledge overview could be helpful in clinical practice.

Developing the Knowledge Base for Health Informatics: from the Otley Think-tank to the IMIA Strategic Plan

Peter J. Murray[a], Graham Wright[a], Nancy M. Lorenzi[b]

[a] *Centre for Health Informatics Research and Development (CHIRAD), United Kingdom*
[b] *Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, Tennesse, USA*

Abstract

The original aims of the Otley (UK) 'Education Steps' think-tank meeting were to explore the evidence base for and theoretical constructs underpinning health informatics. From these, the aim was to identify and explore the educational issues and implications, including the need for, and so content of, different levels of education in health informatics. This work has become part of a larger research project that is being jointly funded by the International Medical Informatics Association (IMIA) and the British Computer Society Health Informatics Forum (BCSHIF). This paper explores the methods used, and the initial results, from the first two phases of the project. The research process used in the 2005 Otley think tank workshop (Phase 1) are explored in detail, and illustrative examples of the outcomes are provided. The methods being used in Phase 2 are discussed, together with plans for validation of the outputs by the wider international community. The outputs of the project will now help to define the knowledge core at the centre of IMIA's Strategic Plan.

Keywords:

medical informatics, information science, knowledge, review literature

Introduction

Researchers based in CHIRAD, the Centre for Health Informatics Research and Development (an Academic Institutional Member of IMIA, the International Medical Informatics Association, and the first Institutional Member of the European Federation for Medical Informatics, EFMI), have been attempting to build a mapping of the discipline of health informatics. The *Education Steps* think-tank meeting (March 2005 in Otley, UK) was the first stage of this project, which was initiated and originally funded by the Health Informatics Forum of the British Computer Society (BCSHIF) and conducted by CHIRAD. The original primary aim was to explore the theoretical constructs underpinning health informatics, and from this, identify and investigate the educational issues. The further aims were to consider the evidence base of health informatics, and examine the existence of, or need for, and so content of, different levels of education in health informatics. Following considerable reflection by the CHIRAD research term and BCSHIF on the initial outputs of the Otley meeting, [1,2] and taking into account the development of the IMIA Strategic Plan, [3] it became apparent that this work could form part of a larger project that could benefit many sectors of the international health informatics community.

A second phase of research, now jointly funded by BCSHIF and IMIA, is contributing to the development of an international mapping of the discipline of health informatics, using a triangulation of expert opinion, document analysis and literature review. It is intended that this will contribute to the development of the knowledge core of IMIA's Strategic Plan.

This paper addresses the context of the phases of the project; the educational framework selected for the first phase; the approaches used for conducting the Otley workshop; and a summary of the discussions and opinions of the participants. Finally, it presents the approaches being used in the current work (phase 2) that builds on the outputs of the Otley meeting, together with some initial results and emerging issues for the future development of the project.

Background to and context of the Otley meeting

In the UK health informatics community there has been a growing concern about the pre-dominant modules/competencies approach, with work-based, skills-oriented delivery of health informatics education. While it was recognised that this work had a valuable role to play, it seemed, to some people, to be resulting in a 'lowest common denominator' approach that did not provide an atmosphere for the higher level scientific and theoretical development of the discipline of health informatics. Indeed, it could be argued that the approach potentially threatened an atmosphere in which one could nurture the exploration of the higher level scientific discussions.

The CHIRAD research team and BCS HIF recognised that there existed, from developments over the previous 5-10 years, and primarily funded through the former NHS Information Authority (NHSIA), much good work relating to skills and competency frameworks for health informatics. As this area had been well rehearsed, it was not the inten-

tion of the project to revisit this work (but to take cognisance of it) . It was also not the aim of the project to seek to define health informatics or explore the most appropriate name for the field (i.e., health, medical or biomedical informatics). Rather, the intention was, through essentially a mapping exercise that drew on the experience and views of health informatics experts, to examine the core components of the discipline by collating the scientific elements of the subjects and thematic areas within the domain.

It could be argued that much of the work envisaged within the project had already been undertaken, within the UK and internationally. In the UK, the NHS Information Authority had developed check lists of competencies for a wide range of staff, focused largely on IT skills but including issues such as security, confidentiality, data quality etc. which were considered vital or useful for different staff groups. These approaches formed a large part of the UK Department of Health's human resource strategy, and provided the basis for Professional Qualifications in IM&T. The adoption of the European Computer Driving Licence as the minimum standard in IT skills for NHS staff has perpetuated the competency driven approach.

The participants in the Otley workshop saw several important possible uses of the outcomes of the think-tank, including:

1. trying to answer the question of whether health informatics exists as an identifiable academic subject domain;
2. assisting in the maturing of the identity of the health informatics profession;
3. bringing together education and training elements of health informatics; and
4. contributing to the academic rigour of the United Kingdom Council for Health Informatics Professions (UKCHIP - www.ukchip.org) framework.

Why use Bloom's taxonomy?

The cognitive domain of Bloom's taxonomy [5] was used as a theoretical framework within which to situate discussions. As CHIRAD's research team has a strong academic background, and many years' experience in delivering education, designing curricula, and research and publication, they felt that the project needed an appropriate academic context. Bloom's taxonomy is well known from health, medical and nursing curricula, and provides a hierarchical framework for categorising levels of abstraction for objectives within educational settings, and maps well against other academic levels, e.g. progression from undergraduate to postgraduate levels.

Bloom identified three domains of educational activity: the cognitive, relating to knowledge and mental skills, the affective, relating to attitude, feelings and emotions, and the psychomotor, relating to manual or physical skills. Bloom's cognitive domain recognises six levels of educational objectives, from the lowest, knowledge, through comprehension, application, analysis, synthesis, to evaluation, the highest level. The intention was that participants in the workshop would collate the conceptual basis of health informatics to elucidate the elements that could be categorised as knowledge, comprehension, application, analysis, synthesis and evaluation.

In preparation for the workshop, we asked participants to familiarise themselves with documents such as the IMIA Scientific Content Map [4] and any other similar documents to which they had access. We asked, in particular, that participants should bring with them either the module descriptions from any health informatics programme that they were involved with, which should include the aims and objectives or learning outcomes, and indicative content; or a list of the models, theories and laws, constructs and concepts that framed their understanding of the discipline of health informatics.

The Otley workshop: the ducks and ponds metaphor

The Otley meeting was an intensive 24-hour residential think-tank, with workshop format and comprising small group and plenary discussions. It brought together 25 international health informatics experts, from varioushealth informatics groups, including BCS Health Informatics Forum, BCS Health Informatics Specialist Groups, ASSIST (The Association of ICT Professionals in Health and Social Care) and IMIA. Most of the participants were from the UK, whilst others came from other European countries, Australia, South Africa and the USA.

The workshop aimed to capture all the elements of the discipline of health informatics, and also the broad themes or subject areas into which these elements might be grouped. The metaphor of 'ducks' (for the individual elements) and 'ponds' (for the broad themes of the framework) was felt to be an appropriate way of helping participants to visualise the tasks they would be undertaking. The six levels of the cognitive domain of Bloom's taxonomy were used to form the basis of the grouping of the 'ducks' within the 'ponds', and it was felt that they might contribute to understanding the development of the curriculum at different academic levels.

Participants in the Otley meeting were asked to identify 'ducks' (health informatics elements), but at the same time, to think 'what does a duck look like?' This meant that in describing them, there was a need to include an active verb from one of Bloom's cognitive levels, plus a generic principle. It was also felt that we would need to identify as many 'ducks' as possible, that is, capture the fullest size of

the 'flock of ducks' (total numbers). The CHIRAD team acted as facilitators in encouraging the discussion groups to pursue this challenging exercise, as there existed the risk of discussion focusing on a few examples if different participants had differing views on the nature or importance of particular 'ducks'; however, we also felt that the breadth of experience of participants would help in capturing a large number of different 'ducks'. The broad themes (ponds) were also identified. Within small groups, participants identified the main subject areas (ponds) from their own lists, curricula or knowledge and experience. Participants identified elements (ducks) of subject areas within small groups. Participants finally assigned each duck to a subject area and, if possible, to a level from Bloom's cognitive domain.

The first set of 'ducks' and 'ponds'

With 'ducks' and 'ponds' representing respectively the finer elements of the discipline and the broad themes within which those elements could be clustered, a first set of outputs comprise 221 'ducks' in total, grouped into 13 'ponds'.

Table 1 – Sample from Otley workshop

Theme ('pond')	Element ('duck')
Health Informatics standards	Assess quality of draft message design process standard
	Assess utility of a clinical interface
	Clinical coding systems
	Describes Technical Infrastructures
	Design of specific clinical message
	Explains the needs for technical standards
Health and social care – care processes	Apply telehealth solutions to the elderly population
	Describe systems currently used by clinicians to gather clinical information
	Evaluates how Health Informatics affects outcomes
	Knows the method of primary to secondary to tertiary care referral and the flows of information

An example of the current level of detail of one 'pond' and set of 'ducks' is given in Table 1. The ponds varied in size, with the smallest containing 6 ducks and the largest 37, although it was already recognised by participants that the largest pond would likely be divided following further discussions.

The 13 ponds are currently named as follows (although the names may change as a result of ongoing discussions):

- Health and social care - care processes;
- Health (care) records;
- Health informatics standards;
- Computer Science for Health Informatics (ICT for Health);
- Health and Social care Industry;
- Knowledge Domains & Knowledge Discovery;
- Legal & Ethical;
- People in organisations;
- Politics and policy;
- Terminology, classification and grouping;
- Toolkit (systems);
- Uses of clinical information; and
- Uses of informatics to support clinical healthcare governance.

The full set of outcomes can be found through the CHIRAD website on the Education Steps project website at:

http://www.differance-engine.net/educationsteps/documents/otley2005outputs.htm

Validating and disseminating the Otley outputs

The first lists resulted from a time-limited discussion among a relatively small group, albeit of nationally and internationally recognised experts. All participants recognised the provisional nature of the lists and the need for further reflection and refinement, which was envisaged as being conducted through international discussions in the later phases of the project, to generate a widely accepted list of ducks and ponds. The Otley participants were invited to comment on the list, and to propose amendments, through a mixture of individual commentary and online group discussions. There was a general feeling that the set of 'ducks' and 'ponds' that had been developed and agreed was not complete, and that others would emerge. There was a general consensus on the first listing, but it had been evident in the discussions that some people felt that what had been identified as 'ponds' might, as a result of further discussion and reflection, be seen to be simply 'ducks'.

In attempts to validate the outputs of the Otley workshop, in March 2006, a further 24 hour workshop was held in Belfast, which focused specifically on refining the technical and computing themes developed at Otley. This resulted in some success, as it included several of the Otley participants, and provided the time for immersion in the discussions. The outputs from Otley have been used to help formulate an undergraduate biomedical informatics degree programme. [6]

Reflections on the process and outputs

The question naturally arising from any project with seemingly limited outputs is 'would we do the same again, and in the same way?' Bringing together a group of 25 health informatics experts, from a range of practical and theoretical backgrounds, with a wide range of special interests, and collectively with in excess of 500 years experience in health informatics, and asking them to explore, and possibly challenge, the fundamental basis of their discipline, was always going to be a potentially risky undertaking. It is a tribute to the professionalism and enthusiasm for their areas of expertise that the participants at the Otley meeting engaged in the process so enthusiastically and that they felt that the beginnings of something useful resulted from the time and effort. The overall structure of the workshop was felt to work well,with the greatest complaint being the lack of time devoted to each stage of the process, and in particular to some of the discussions and sessions when there was an attempt to reach consensus where several disparate views clearly existed. The level of knowledge displayed by participants, the passionate defences of their views, and the enthusiasm displayed at all stages of the workshop clearly showed that we had the right types and mix of people involved. That we have had no-one significantly disclaiming the outputs indicates that some form of valuable output has been achieved.

Participants in the Otley meeting found that, although the metaphor had limits and could be stretched in many ways, it was a useful way of starting to think about what are the essential broad themes ('ponds') within health informatics as a discipline, and what are the essential finer-grained components ('ducks'). As the project evolves, the metaphor may become less useful. As might be expected from experts with strongly-held views and coming from a wide range of practical and theoretical backgrounds and interests, the discussions were wide-ranging. It was quickly acknowledged that the scope of the task was huge and that we could only make a small start. The attempt to focus on the cognitive domain of the discipline, and to break free of the constraints of thinking only about psychomotor skills and competencies, caused problems for some participants. Yet it is remarkable that, even within a short period of intense discussion, we managed to make some progress towards agreement on some of the broad themes.

Contributing to IMIA's Strategic Plan

Work on the development of IMIA's Strategic Plan, 'Towards IMIA2015' [3] was formally launched by incoming President Nancy Lorenzi at Medinfo2004, with the aim of having a final version ready for IMIA's endorsement at Medinfo2007. The core vision and conceptual framework for the IMIA Strategic Plan place knowledge at the core of IMIA's activities, and has lead to a realisation of the need to update the 2001 IMIA Scientific Content Map. Building on, in part, the Otley outputs, a second phase of work is being jointly funded by IMIA and BCSHIF to develop the knowledge core for IMIA, and the wider international health informatics community.

Phase 2 methods and pilot results

In Phase 1, the Otley workshop, a group of health informatics experts was asked to identify the elements of the discipline of health informatics. For Phase 2, the published and peer-reviewed literature is taken to be a valid proxy for such expertise. A literature analysis examining the emerging themes and high level descriptors is being undertaken, using document and discourse analysis software and methods. This is based in an analysis of available electronic literature, and will additionally use established and novel indexing and analysis techniques. The method is acknowledged to be similar to that used by Lorenzi to develop the original IMIA Scientific Map, but makes use of materials and methods not available at that time.

The research team is seeking to collect all the electronically available health informatics literature, i.e. in CD-ROM format and available via the Internet. This includes conference proceedings (e.g. Medinfo, AMIA, MIE), as well as journal articles and textbooks. To date, we have a corpus approaching 7,000 articles, items and chapters, most of which are in PDF format and comprise a total of 2GB of files. We are still seeking additional material, although expect that a saturation point will be reached in respect of identifying themes from only a small portion of this corpus.

Several searching and indexing methods have been used to determine the size of the available corpus of literature, and as a pilot test for the analysis methods being employed. An online search in August 2006 using Google Scholar, for example, returned 92,800 citations using the term 'medical informatics', 80,600 using 'health informatics' and 42,500 using 'clinical informatics. Using the Reference Manager 11 software to undertake online searches of PubMed returned 6,249 papers when using the term 'medical informatics', 3,611 using 'health informatics and 1,785 using 'clinical informatics'.

The corpus of articles collected so far is stored on a network hard drive and we have used several indexing tools to index the articles and then search them using a subset of the Otley outputs as a pilot analysis. Google Desktop, Copernic and ASK, as commonly available tools have been used. Table 2 illustrates some of the similarities and differences encountered in using the same search terms in different engines and algorithms. This work is ongoing, and is expected to be completed in early 2007, although several issues are already emerging. There will be a need for the research team to replicate and validate some of the indexing and searching, as different search algorithms are yielding differing results. The contextual nature (i.e., using

Bloom's taxonomy) of the Otley outputs may not match well to the more restricted searching allowed by some of the algorithms. Use of keywords in many publications depends on author selection as opposed to a consistent approach, and is causing some issues in indexing, and different 'in vogue' terms in different places and times seem to be skewing some of the results of the literature searches. All of these issues are important factors that we will be a an analysing as the current research phase unfolds.

The whole project seeks to use a triangulation of research methods (literature review, document analysis, and expert opinion) to obtain different perspectives on the issue of mapping the discipline if health informatics, and with the expectation that the different views will provide some congruence. Once the literature analysis has been completed, the results will be made available for discussion and refinement to the international health informatics community. A consensus conference will be held, to explore the commonalities and differences between the Otley outputs with the document analysis. An international advisory board of health informatics experts, especially including those who have undertaken work in health informatics education and aspects of defining the discipline, is advising on the methods being used and facilitating access to the source materials.

Conclusions

From an initially small scale project, a first set of elements was developed to contribute to a mapping of the cognitive elements of the discipline of health informatics. This work is now contributing to a larger international project, jointly funded and co-ordinated by IMIA and BCSHIF, that will contribute to the knowledge core of IMIA's Strategic Plan. As the results of the current phase of the research emerge, the CHIRAD, BCSHIF and IMIA research team will be inviting members of the international health informatics community to contribute to their refinement and validation, and so be involved in developing a commonly shared – but dynamically evolving – map of the discipline of health informatics.

Acknowledgments

The first phase of the project was funded by the British Computer Society Health Informatics Forum (BCSHIF). Phase 2 is jointly funded by BCSHIF and the International Medical Informatics Association (IMIA).

Using GLIF and GLEE to Facilitate Knowledge Management in Development of Clinical Decision Support Systems

Dongwen Wang[a], Mor Peleg[b]

[a]*Biomedical Informatics Program, University of Rochester, USA*
[b]*Department of Management Information Systems, University of Haifa, Israel*

Abstract

Effective knowledge management is a critical challenge to development of clinical decision support systems (CDSSs). We have been using the GuideLine Interchange Format (GLIF) and the Guideline Execution Engine (GLEE) to facilitate knowledge modeling, adaptation, and validation for CDSSs that address a variety of healthcare problems. Based on a review of case studies, we synthesized three major functions of GLIF and GLEE during this process: (1) improving communication between CDSS developers and domain experts, (2) facilitating fast prototyping of CDSSs, and (3) providing multi-stage system validation. We argue that development of CDSSs should start from analyses of user needs and identification of knowledge sources, followed by an evolving process with multiple rounds of conceptualization, encoding, simulation, and evaluation. Our review has shown that GLIF and GLEE can be used effectively to facilitate this process.

Keywords:

clinical decision support systems, knowledge management, practice guidelines, GLIF, GLEE

Introduction

Development of clinical decision support systems (CDSSs) needs effective translation of domain knowledge and their adaptation to specific application environments. We have been using the GuideLine Interchange Format (GLIF) and the Guideline Execution Engine (GLEE) as tools to facilitate knowledge management for a variety of healthcare problems. In this paper, we review our experience of using GLIF and GLEE for knowledge modeling, adaptation, and validation, focusing on analyses of their specific functions and examinations of the overall process.

Methods

Our analyses included two aspects: (1) the specific functions provided by GLIF and GLEE in development of CDSSs, and (2) the overall process to use GLIF and GLEE for CDSS development. The examinations were based on data of specific case studies drawn from finished or ongoing projects. These data were then integrated and synthesized along the two dimensions of function and process. A variety of healthcare problems have been addressed by these case studies, including childhood immunization, cough management, influenza vaccination, hyperkalemia screening, diabetic foot care, post-CABG recovery, depression screening, and tobacco cessation.

Results

Functions of GLIF and GLEE in development of CDSSs

Improving communication between CDSS developers and domain experts

Improving communication between CDSS developers and domain experts is one of the most challenging issues in development of CDSSs. Effective communication between CDSS developers and domain experts is especially important when decisions need to be made to extract and to translate specific pieces of domain knowledge from their original sources, to organize knowledge in well-defined structures, and to identify the potential points in healthcare processes where interventions can be delivered in appropriate formats. The GLIF model provides a conceptual-level representation of healthcare processes using a flowchart-like graphical presentation. This level of representation and visualization has been used intensively in development process to exchange ideas between CDSS developers and domain experts. Paper-based flowcharts have also been used widely for conceptualization purposes, but typically with various problems from computational prospective. In contrast, the flowchart-like algorithm in GLIF is supported by the underlying computational model. Thus, once the conceptual-level algorithm is developed, it can be directly used for computational purposes. An important aspect in development of an algorithm is its testing through the stand-alone user interface of GLEE, which can simulate the execution of specific patient cases through particular paths of the algorithm. These features of GLIF and GLEE can significantly improve the effectiveness and efficiency of communication when presenting the encoded knowledge base to domain experts and seeking their feedback.

Fast prototyping for knowledge modeling and adaptation

Development of CDSSs is an evolving process that typically requires multiple rounds of knowledge encoding, modification, and validation. During this process, fast prototyping of a knowledge base can significantly improve the efficiency of development. With the three-level representation of GLIF (the conceptual flowchart, the computation model, and the interface for integration and implementation) and the simulation function of GLEE, their combination as a tool set provides a unique and powerful testing environment for CDSS development such that the knowledge base of a CDSS can be prototyped without the need to be fully integrated with the final applications. The ability to create such prototypes and test them quickly was essential to the iterative and interactive process of CDSS development.

Facilitating multi-stage system validation

System validation is a critical step in CDSS development. Since development of CDSSs requires significant investment of resources, identifying system errors in early stages of development is important. The combination of GLIF and GLEE provides a unique chance to discover potential problems earlier and thus to prevent/reduce expensive errors in later stages. Specifically, the conceptual level flowchart-like algorithm of GLIF has been used widely to facilitate communication between CDSS developers and domain experts, which can significantly improve mutual understanding on organization of medical knowledge and their adaptation to local practices and settings at an early stage of development. In addition, the simulation function of GLEE that can be used to examine the execution path of an individual patient case provides an added value for validation, as this approach can be easily understood by clinicians. Finally, the batch execution mode of GLEE can be used to process large-scale simulation data that can be further analyzed with powerful statistical methods for formal evaluation.

Overall process of using GLIF and GLEE to facilitate knowledge management in development of CDSSs

Based on the findings documented or reported in case studies, we summarize an overall process to use GLIF and GLEE for development of CDSSs. This process consists of 12 steps: (1) identifying clinical needs of a system; (2) identifying knowledge sources; (3) initializing communications (first round) or reviewing results (later rounds) with domain experts to conceptualize or to modify system functions; (4) defining specific clinical tasks, decisions, and care processes along with the patient data required to perform the tasks and to make the decisions; (5) working with domain experts to identify potential points of interventions in care processes; (6) encoding an algorithm to conceptualize the clinical tasks, decisions, and processes; (7) encoding the specifications at computational levels; (8) performing simulations on individual patient cases; (9) performing simulations in a larger scale for formal analyses; (10) designing appropriate interventions at specific points of care processes and integrating system components; (11) deploying system and evaluating its actual use; and (12) maintaining system. It is important to note that development of CDSSs is an evolving process. It typically requires multiple rounds of conceptualization, encoding, simulation, and evaluation for successful development of a system.

Discussions

We identified three major functions and a twelve-step process of using GLIF and GLEE to facilitate knowledge management for CDSS development. Compared with other research, our unique contribution is to focus on facilitating communication between CDSS developers and domain experts. Based on many years' experience in development of CDSSs, we observed that it is unnecessary or infeasible to translate each and every piece of information from the original paper sources into a CDSS. The medical knowledge behind the useful features of a CDSS is typically a combination of small pieces of information from multiple origins. Thus, we have been moving toward an approach to starting from analyses of clinical needs and identifying the knowledge sources that can support these needs. The subsequent steps of conceptualization, encoding, simulation, and evaluation all serve for this original goal. We believe it is more promising to develop CDSSs with such clearly-defined, user-required, and focused objectives. This approach is also consistent with the theory of user-centered system design that has been widely reported in human-computer interaction research.

There are a few limitations of our studies. First, most of our experience up to now is only to use GLIF and GLEE for knowledge modeling. The actual integration of knowledge base with real world applications will introduce many further challenges. Steps 11 and 12 of the overall process summarized in the result section thus need to be further examined, refined, and reported. Second, we only focus on CDSSs that deliver patient-specific recommendations, while delivering of generic (vs. patient-specific) information in the right context can also generate significant positive impacts. In this scenario, a document model or a hybrid model can play an important role, which is what GLIF and GLEE lack of. Finally, GLIF is not a comprehensive process model. For example, it does not support quantitative temporal modeling, and it is not based on formal logic. Thus, it might not be the best choice to use GLIF for applications with such requirements.

Conclusion

GLIF and GLEE can be used as a set of tools in CDSS development to improve communication between CDSS developers and domain experts, to facilitate fast prototyping of CDSSs, and to provide multi-stage system validation. These functions are embedded within an evolving process with multiple rounds of conceptualization, encoding, simulation, and evaluation. Future studies are required to investigate the use of GLIF and GLEE in deployment of CDSSs.

Abstract

In order to update a semi-structured medical observation entry form, we studied previously completed forms, revealing physicians' actual needs in clinical settings, and guidelines, reflecting the evolution of medical knowledge. Statistical analysis of completed forms pointed to items almost never used by clinicians and some of them were removed from the form. Terminological analysis of free text answers in previously completed forms and of guidelines revealed concepts relevant for clinical practice. Accordingly, some new items were added in the structured part of the form.

Keywords:

computerised medical records systems,
medical history taking, user-computer interface,
natural language processing

Introduction

Computerised and structured data entry forms can improve the reliability, availability and reuse of clinical data for patient care (including decision support), medical audit, activity coding and clinical research [1,2]. Once an entry form has been modelled, maintenance issues arise with the evolution of medical knowledge and practice.

Natural language processing (NLP) of free-text records has already been used to design or improve clinical data entry forms [3,4]. We present an extended approach, relying on statistical analysis of previously completed forms and terminological analysis of free text answers and clinical guidelines. This procedure has been applied to a computerized clinical record form used since 1975 for hypertension management [5,6].

Material and methods

We analysed 5109 completed entry forms from a single hypertension unit (year 2005), including 176 optional questions, with either structured (Boolean, checklist, numeric) or free-text answers. When a question or a predefined answer was used less than 50 times, its deletion was considered. This threshold, approximately 1% of the analysed forms, was arbitrary chosen as a compromise between signal (identification of items seldom used that should be deleted because they are indeed useless) and noise (identification of items seldom used that should not be deleted because they are nonetheless useful).

In order to find recurrent clinical concepts in free text answers, we used the NLP tools SYNTEX and UPÉRY to perform their terminological analysis [7]. When a concept appeared more than 50 times in the corpus, we discussed the inclusion of a corresponding item in the form. For example, the concept of sleep apnoea syndrome appeared about 80 times in the corpus. It was subsequently added as a predefined answer to the pre-existing checklist question "Respiratory disorders?" in the form. We also separately analysed eight hypertension guidelines. Each new clinical concept found in guidelines was considered for inclusion in the form, regardless of its occurrence rate.

A staff of four senior clinicians took the final decisions to remove old items or add new ones. Besides the statistical and terminological results, they took other factors into account, like the value of the data for medical decision making or clinical research. The physicians explicitly favoured objective questions with reproducible answers. However, in order to restrain the drive toward excessive structuring, they also considered the burden of data entry during the patient visit and the drawbacks of an inflexible, excessively structured, clinical record [8].

Results

Among the 176 questions, 19 were completed less than 50 times and 16 of them were deleted. Among the 203 predefined answers to the 39 checklist questions, 78 were ticked less than 50 times and 47 of them were deleted. Physicians judged the remaining items too important to be deleted.

Terminological analysis of free text answers (respectively guidelines) yielded 103 (respectively 95) concepts not found in the structured part of the entry form. Thirty-two of these concepts were common to both sources. Accord-

ingly, items were added in the form: eight numeric and four free-text questions; six checklist questions and 28 associated answers; and four new answers for pre-existing checklist questions.

The conclusion of the visit was previously recorded in a single free-text question. Some of the new questions contributed to structure a more standardised and informative closing. Four checklist questions on hypertension aetiology, pattern, severity and complications now allow stating the characteristics of the patient's disease. They are followed by a question on the specific blood pressure goals and two checklist questions about the prescribed lifestyle changes and treatment modifications. Additional closing thoughts and decisions can still be recorded in the free-text question.

Discussion

The presented approach allowed us to update a long-standing medical record form. Statistical analysis guarantees that no frequently used item is removed during the process. Terminological analysis of free-text answers and guidelines, critically appraised by senior clinicians, guarantees the pertinence of the new items for patient care, audit and/or clinical research.

Terminological analysis of free-text answers is always possible but will indicate recurrent concepts only if clinical cases exhibit some homogeneity. The approach relies on guidelines to reflect the state of current medical knowledge, but could also use less formal review articles. However, guidelines and review articles only pertain to well circumscribed clinical domains. In all these regards, the context of hypertension management was ideal, since it is limited, highly repetitive and well standardised. To which extent and with which results our approach can be generalized to other clinical settings remains to be investigated, especially for broad specialities like internal or emergency medicine.

Another shortcoming of our approach is that we only involved senior clinicians with an extensive experience of the data entry form. Inputs from naive users would have been helpful to identify ambiguous or vague items and eventually improve their content or phrasing.

Conclusion

Our approach allowed us to revise content and organisation of a medical record form, relying on the analysis of its previous use (reflecting clinicians' actual needs in practice) and on the analysis of recent clinical guidelines (reflecting the evolution of medical knowledge). It should be possible to reproduce this approach in other clinical domains, if they are specialised enough to be covered by guidelines and for free text answers of entry forms to show some recurrent patterns.

[c]AP-HP, DSI/STIM, Paris, F-75014 France.

Structured data entry Benefits

Improves data reliability, availability and reusability for:

- Patient care
- Audit
- Activity coding
- Clinical research
- Teaching

Structured data entry
Costs

- Needs a sound clinical information model
- Requires dedicated hardware and software
- Changes users' habits:
  - Data entry by physicians (typing skills)
  - Templates may be too close-ended
  - ➔ Disrupts the patient – physician relationship
- Must be maintained

Structured data entry Maintenance

- Correction of initial modelling errors
- Adaptation to contextual changes:
  - Patients recruitment
  - Clinical circumstances
  - Medical knowledge and practice

Purpose

To update a computerized record form used in a hypertension clinic, considering:

1- the physicians needs in actual practice, as ascertained by their use of the record

2- the evolution of medical knowledge, as synthesized in guidelines

Material

1- A computerized clinical record form used for hypertension management since 1975

- 5.109 forms completed in year 2005
- 176 optional questions, either date, numeric, Boolean, checklist or free-text
- Free-text answers from year 2005 make a 350.000 words corpus

2- Eight guidelines for hypertension management, making a 56.000 words corpus

Methods

1- Statistical analysis of the answer rate of each question and of the use of each predefined answers in checklists during year 2005

- ➔ Seldom used questions / answers are candidates for deletion

2- Terminological analysis of the two text corpora (free-text answers and guidelines)

- ➔ Recurrent or new clinical concepts are candidates for inclusion as structured items

Statistical results

- 19/176 questions were completed less than 50 times in 2005 and 16 were deleted
- 78/203 predefined answers for 39 checklist questions were ticked less than 50 times in 2005 and 47 were deleted
- Questions and predefined answers of significant value for patient care or clinical research were not deleted, even if seldom used

Terminological results

- 166 clinical concepts not already found as structured items in the form were identified:
  - 103 occurred more than 50 times in free text answers
  - 95 were extracted from guidelines
  - 32 were common to both sources

- These concepts lead to 50 new items the form:
  - 8 numeric and 4 free text questions
  - 6 checklist questions with 28 associated answers
  - 4 new answers for pre-existing checklist questions

Strengths of the approach

- It relies on empirical data providing clues for changes, which are critically appraised for validation by senior clinicians
- Analysis of previously filled forms reflects the clinicians' actual needs in practice
- Analysis of guidelines reflects the evolution of medical knowledge

Limits of the approach

- It suits well hypertension management, which is highly repetitive and standardized. To which extent and with which results it can be adapted to other settings must be investigated.

- It does not address the issue of vague or ambiguous question labels, which are also amenable to improvements. In this regard, inputs from naïve users should be helpful.

Open Platform for A Longitudinal Study in Dental Implant

Hyun Namgoong, Senator Jeong, Hong-Gee Kim, Dong Hwan Lee, Young-Won Nam, Myeon Ki Kim

School of Dentistry, Seoul National University, Korea

Abstract

With aesthetical and functional aspects, dental implant is regarded as mostly effective treatment to restore missing teeth. Accordingly, a longitudinal study on the implant is important for both patients and dentists. However, because of the limitation in collecting cases and records, the studies concentrate on only one or few considerable variables. As an effort to solve these problems, we suggest an open platform model to facilitate longitudinal studies in dental implant. It unburdens researchers to collect, share, assess and utilize the related research and reported cases.

Keywords:

dental implants, dental research, information networks, methodology

Introduction

Despite of a short history, dental implant is considered as mostly effective treatment to restore missing teeth. With aesthetical and functional aspects, it is becoming more popular [1][2]. Accordingly, a longitudinal study on the implant is important to help a dentist choose a suitable operational option prior to therapy or manage patient's subsequent events such as a side effect and a failure. However, pinpointing factors of a success and a failure of dental implant is not simply determined because they are either very salient or monotonous. It is also a toilsome study that involves periodic observations of similar cases over long periods of time. Given the requirement for evaluating pre-examinations, treatments and re-call checks, the efforts become much weighted.

As an effort to solve these problems in a dental implant study, we propose an open platform for a longitudinal study to mitigate researchers' burden to collect, share, assess, and utilize the related research and reported cases. Our initiative, inspired by current paradigm to Web 2.0 [3], is in the pursuit of achieving a collaborative intelligence among dental implant researchers and practitioners. We also expect that the concept of an open platform provides solutions to the prolonged problem of the longitudinal study through massive data acquisition, broad ranging collection of cases, and identifying the repetition of the same cases.

Design of the open platform

The proposed open platform is primarily designed to effectively support a longitudinal study of a researcher. We are also objective to solve the problems which even appear at upper level studies. Before, describing the design of the platform, let us list general steps of the conventional studies.

(1) *Identification of a problem and modeling of a hypothesis from one's intuition or survey*: For example, a dentist observed a particular situation from his patients. The dentist constructed a hypothesis about causal relationship describing the situation.

(2) *Background research for a given problem*: To examine any previous work and refutation, the doctor searched MEDLINE and other online medical literature databases.

(3) *Collection of data*: The doctor decided to test the hypothesis by collecting the related data. He can gather the data, e.g., cases and surgical records, from direct hand contacts or some paper works published in conferences and journals.

(4) *Assessment of data quality*: To decrease a risk of bias, a series of data are classified through his own assessment.

(5) *Extracting data according to required form*: He makes an electronic data extraction form to format and to list extracted data into the forms.

(6) *Data synthesis*: From formatted data, he can identify whole connection between considerable valuables.

(7) *Result Interpretation*: Standardization and formalization are performed on the causal relationship identified from the study.

These series of steps require hard works and are sometimes even painful. It is mainly because of the difficulties of data collection, data extraction, and assessment of data quality. By employing the notion of the current web 2.0 and a collaborative intelligence, the platform will mitigate researchers' burden for these steps.

Functionalities of the platform

With postulated desiderata of the open platform for supporting efficient and effective longitudinal studies, the open platform offers functionalities described here.

- *Store & Categorization*: As a basic function, the platform stores and categorizes received data such as surgical reports, summarized records and performed research.
- *Search*: A researcher can easily find out a particular report, record and study through the platform. By a search with single and multiple factors, the platform should enable controversies to be easily caught.
- *Relatives*: A researcher can speculate the specific research and records related to a given problem. Based on the corresponding complications, research are summarized and shown.
- *Import/Export*: A researcher can import/export needed data. To be used in various applications, the data are formatted with an interoperable electronic document like XML and RDF (Resource Description Framework).
- *Collaborative assessment*: A researcher can appraise the study and record whether it is archived by an explicit evaluation method or methodology. The assessment is archived collaboratively to avoid unreliable data.
- *Extraction*: For his/her own research, a researcher can extract and sample specified data from the platform. It is able through an optional selection provided in a user interface.
- *Statistical view*: Statistical difference of selected data and variation of particular field are observed. It provides an overlook on the interested relation.

These functionalities unburden a large part of the steps for the study. For instance, a research can get an inspiration or a problem from the platform by seeking controversial arguments. He also can look for related research topics and results from it, then he can obtain data for the study from it, and so on.

Conceptual view of the system

The figure 2 shows a conceptual view of the system. In the platform, the main users can be divided into two groups; individual clinicians and research groups. Through the platform, individual clinicians can import their case reports for the qualification of their skill or reporting methods. The simple search of a case and an expectation using the case are other benefits individual clinicians can take. The other part of involver is serious research groups. To possess the every benefit of the platform, they may use total functionalities of the platform including a 'Relative', 'Collaborative assessment' and 'Extraction'.

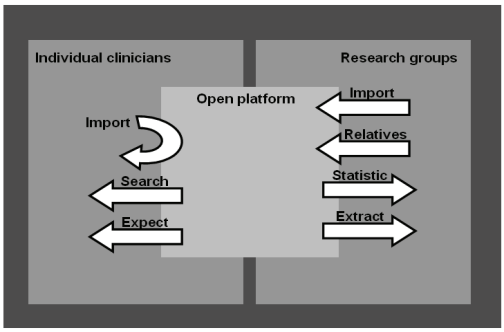

Figure 2 – Conceptual view of the open platform

Conclusion and discussion

We proposed an open platform for a longitudinal study in dental implant. By encourging involvment of positive participants, we expect the platform relieves the burdens to collect, share, assess, and utilize the research and cases for the study. We also have some concerns on keeping it as a sound platform. The first one is from a worry about unreliable and inaccurate data. Even the system employs collaborative assessments for evaluation; it is still remaining problems because of the user with mischief and unseriousness. Another problem is a free-riding of users. If every user wants to get something but to give anything, it will make a trouble in maintenance of the platform. These problems remain as significant challenges to develop a sound system.

List of Contents

Introduction

- Proposing Open platform for A Longitudinal Study in Dental Implant
  - To mitigate researchers' burden to collect, share, assess, and utilize the related research and reported cases
  - Inspired by current paradigm to Web 2.0 and collaborative intelligence
  - Providing solutions to the prolonged problem of the longitudinal study through massive **data acquisition**, broad ranging collection of cases, and **identifying the repetition** of the same cases.

- Dental implant
  - Effective treatment to restore missing teeth
  - With aesthetical and functional aspects
- Longitudinal study
  - Help a dentist choose a suitable operational option prior to therapy or manage patient's subsequent events

Related Works

- Medical knowledge sharing and positive web sites
  - GenBank: www.ncbi.nlm.nih.gov/Genbank
    - Sharing DNA and amino acid sequence and protein structure data by depositing them publicly available web databases
  - Telemakus
    - A tool to facilitate analyzing, displaying, and summarizing research reports across a domain: it provides three component
  - Delicious (http://del.icio.us)
    - Social book-marking service enabling its users to keep and share their tags and to discover new sites on the Web
- Longitudinal upper level studies
  - Problems
    - Data acquisition is rarely possible to come up with a decisive conclusion,
    - Data from papers are sometimes considerably convergent toward a particular conclusion.
    - A kind of positive effect tends to be published more often than those that do not; it is called 'Publication bias'

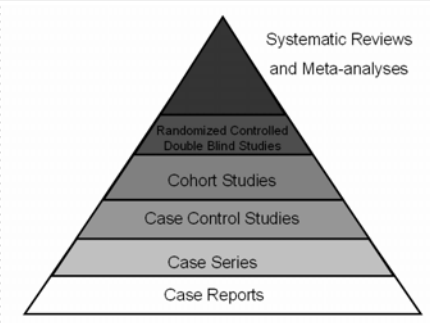

Figure 1 – Upper part of the Evidence Pyramid

Conventional steps for Longitudinal study

- **(1) *Identification of a problem and modeling of a hypothesis from one's intuition or survey*:** For example, a dentist observed a soft tissue inflammation of his patient who did not quit smoking even right after an implant treatment. The dentist constructed a hypothesis that there is a causal relationship between smoking and soft tissue inflammation.
- **(2) *Background research for a given problem*:** To examine any previous work and refutation, the doctor searched MEDLINE and other online medical literature databases. Then, he became aware of the problem that is not completely solved yet.
- **(3) *Collection of data*:** The doctor decided to test the hypothesis by collecting the related data concerning smoking, smoking amount, a condition of soft tisuue after surgery, and etc. He can gather the data, e.g., cases and surgical records, from direct hand contacts or some paper works published in conferences and journals.
- **(4) *Assessment of data quality*:** To decrease a risk of bias, a series of data are classified through his own assessment. The classification is to establish whether the data meet the inclusion criteria or not. The other criterion is whether the data measured through a right examination.
- **(5) *Extracting data according to required form*:** He makes an electronic data extraction form. Required data, for example, demographic data, implant sites, number and type, and RSTV, are extracted independently of what data extraction forms are used.
- **(6) *Data synthesis*:** From formatted data, he can identify whole connection between smoking and soft tissue inflammations.
- **(7) *Result Interpretation*:** Standardization and formalization are performed on the causal relationship identified from the study.

Design of the Open Platform - Desiderata

- The platform must be based on a collaborative intelligence widely opened to everybody. It should incite the collaborative works of researchers and research organization through the web. It also should also provide several beneficial functionalities to encourage independent researchers and get diverse cases from them.
- The platform must have efficient functions for the research. It should support most steps of a study for longitudinal analysis.
- The platform must be cost effective. Even there are diverse shapes in research information or actual data, the platform should process the data transparently to the user.
- The platform must be a richly connected network of data to enable a variety of studies. It enables researchers to identify, relate and compare research and data from multiple perspectives.
- The platform must help a researcher easily find controversial arguments according to the supported evidence. For instance, some researchers argue that mercury has lethal to patient's health while others have the other end of extreme insisting there is no evidence. Researchers can easily catch this controversial through the platform.
- The platform must be easy to use. It includes various digital record forms and interfaces for longitudinal study. Through the form and interface, it must be simple to enter, search, and access to data stored in it.

Design of the Open Platform - Functionalities

- ***Store & Categorization***: As a basic function, the platform stores and categorizes received data such as surgical reports, summarized records and performed research. A researcher can also continuously update the corresponding data.
- ***Search***: A researcher can easily find out a particular report, record and study through the platform. By a search with single and multiple factors, the platform should enable controversies to be easily caught.
- ***Relatives***: A researcher can speculate the specific research and records related to a given problem. Based on the corresponding complications, research are summarized and shown.
- ***Import/Export***: A researcher can import/export needed data. To be used in various applications, the data are formatted with an interoperable electronic document like XML and RDF (Resource Description Framework).
- ***Collaborative assessment***: A researcher can appraise the study and record whether it is archived by an explicit evaluation method or methodology. The assessment is archived collaboratively to avoid unreliable data. For example, by the collaborative assessment, a study exploiting a perio-test for bone quality measurement can be regarded as a more reliable research than a simple 4-degree leveling.
- ***Extraction***: For his/her own research, a researcher can extract and sample specified data from the platform. It is able through an optional selection provided in a user interface.
- ***Statistical view***: Statistical difference of selected data and variation of particular field are observed. It provides an overlook on the interested relation.

A Longitudinal Study with Proposed platform

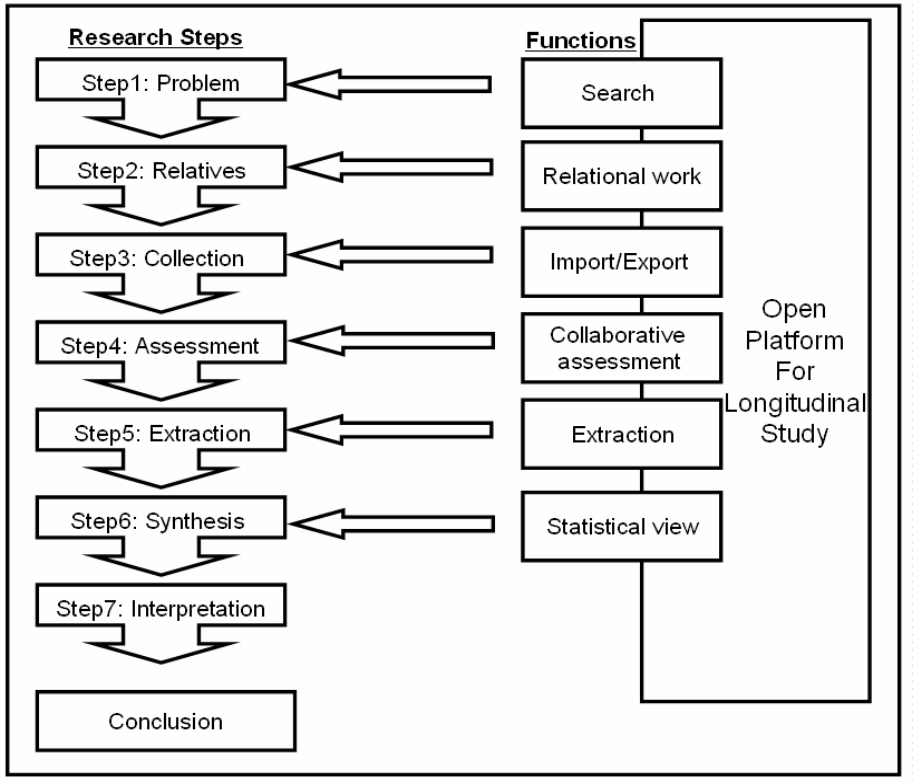

Figure 2 –Revised Scenario

Design of the Open Platform - Sorts of Data

- *Table 1 – Data Record Format for a Research*

Research	Record data	
Title	Year of Publish	
	Authors or Performers	
	Publisher	
	Related Complications	
	Linkage to Data	
	Summary of Data	Criteria for inclusion
		Reported Outcomes
		Methods of Evaluation
		Time interval

- *Table 2 – Classification of Data for Dental Implant study*

Pre-Operative Examination	Treatment & Operative Record	Post-Operative Evaluation & Maintenance
Demographic Variables	Choice of treatment	Maintenance and Follow-Up Protocol
Health Status Variables	Anatomic Variables related to operative sites	Evaluation of Patient's comfort and satisfaction
Social/ Psychological/Financial Variables	Implant-specific Variables	Periodontal Evaluation of soft tissue health around implants
Dental variables related to Oral exam	Abutment-specific Variables	Radiographic Evaluation of implant fixture
Prognosis for remaining dentition	Prostheses Variables	Complication Assessment of implant prosthesis
Operator Variables		

Conceptual view of the system

- Individual clinicians
  - Import their case reports for the qualification of their skill or reporting methods
  - Search of a case and an expectation using the case
- Research groups
  - Possess the every benefit of the platform
  - Use total functionalities of the platform including a ‘Relative’, ‘Collaborative assessment’ and ‘Extraction’.

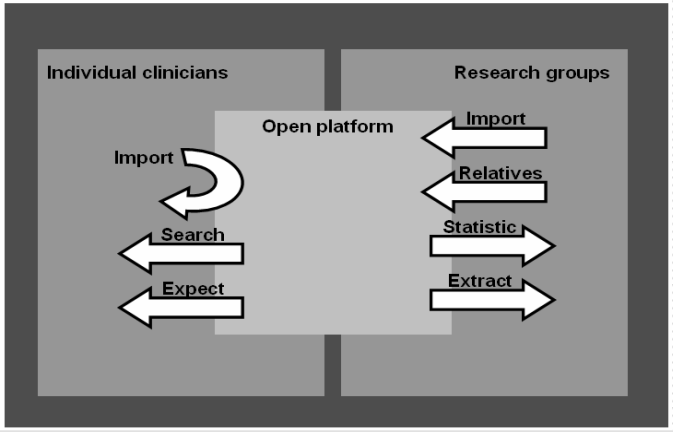

Figure 3 – Conceptual view of the open platform

Conclusion and Discussion

- We expect the platform relieves the burdens to collect, share, assess, and utilize the research and cases for the study.

- Empowering the upper level longitudinal studies at three kind of view.
  - Massive acquisition of data will lead and support decisive conclusions.
  - The broad ranging collection of records and data can be easily used for a refutation to a conclusion unevenly supported by positive pieces of results.
  - Identifying the repetition of same cases will prevent publication bias.

- Expected problems
  - Unreliable and inaccurate data
    - Problems because of the user with mischief and un-seriousness.
  - Free-riding of users.
    - Tangible benefits or compensations should be offered

Structure and Functional Overview of a Web Based Knowledge Management Tool in Healthcare Organizations

Charalampos Balis, John Mantas

Laboratory of Health Informatics, Faculty of Nursing, National and Kapodistrian University of Athens, Greece

Abstract

In this poster we present the development and the evaluation of a Web-based knowledge management tool for healthcare organizations. We make clear the necessity for the existence of a knowledge management system and we analyze all the functions of the tool we have developed. The evaluation of the system is achieved through the examination of a sample of users according their satisfaction from the tool. Finally, we report the evaluation results, the conclusions and the future work which we have to do for the improvement of our system.

Keywords:

Healthcare Informatics, Knowledge Management, Healthcare Organizations

Introduction

The healthcare organizations face a lot of challenges, because of the changes that take place in the structures and the more general frame of health systems. Increased costs, economic restrictions, bigger emphasis in the medical responsibility and transparency, changes in the education, enormous developments in the biomedical research, new collaborations in the area of health, are the main factors that influence the effectiveness of healthcare organizations. At the same time, with the above factors, a new difficulty in the work of clinicians is added in our days, which tends to become a permanent characteristic of a healthcare environment. The healthcare professionals are called continuously to absorb information on new drugs, new illnesses, new clinical processes and biomedical techniques, governmental directives, warnings on negative effects of medicines and new scientific discoveries in the medicine. It is almost impossible for a doctor to absorb completely and to apply rightly the new knowledge, which is included in big volume of texts that he receives daily. He is allocated to dedicate concrete effort and small period of time for this procedure. Also, each doctor has specific capabilities of memorizing and retracting information. Similarly, a nurse should be able to think and to act using his own judgment, through the big volume of information that he gets from various sources. There are the doctor's commands, the patient's demands, the patient family's needs, new nursing activities and simultaneous demands from various departments of the healthcare organization [2]. So, the area of healthcare requires precise, complete and comprehensive data for efficient clinical practice, effective clinical management, control, education and research.

These data should be provided in a healthcare organization with the help of a Knowledge Management system, which will be managed and organized by specialized healthcare professionals. In this paper we present and evaluate a Knowledge Management Tool which provides the capability for integrated and effective Knowledge Management in a Healthcare Organization.

Materials and methods

System analysis and development

In order for a doctor or a nurse to be capable to face all these above challenges, able to be fully informed, to cover his cognitive voids and to apply the new knowledge with the most effective way at the appropriate time, it requires that he has the capability for access in qualitative information and knowledge. This is feasible through a Knowledge Management environment, which gives the capability in each healthcare professional who is seeking knowledge inside or outside the limits of his organization, acquiring and storing this knowledge, organizing and categorizing it in corresponding categories of data. Furthermore, through this environment, the healthcare professionals can recover easily the knowledge of the organization whenever they want, can communicate with professionals who are related with it, and finally, be able to share the knowledge with other users of the system [1].We present a Web based system which integrates the above operations.

The application is built on Windows Advanced Server 2000 with the object-oriented programming framework ASP.net, which is one of the elements of .NET Platform and is used for building powerful Web Applications. It is based on Web Standards and practices, fully supports existing Internet technologies and provides an easy and dynamic Web User Interface. As development Database was chosen SQL Server 2000, which is a common and reliable well known database but the application itself could be build on any other relational database [3].

The capabilities of this system, succinctly, are determined in the followings:

- It has been built on a relational database which has the appropriate infrastructure to storage data of various departments and operations of a healthcare organization.
- The knowledge can be in various formats. Each element of knowledge that exists in the application is called 'object'.
- The knowledge can be stored in a central server via the interface of the application. Each object can be available to the public for time interval that its owner wishes.
- There is a User Profile, which contains personal data, studies, scientific interests etc. After each action from a user, his profile is updated automatically according to his fields of knowledge.
- The objects of knowledge have been organized and classified according the thematic unit and the scientific field that they concern, aiming at the easy search and retrieval of knowledge by the user.
- There is search capability for knowledge within all the knowledge base and users of the system. The search results are categorized in objects, individuals, localities of knowledge and other relative categories. For this aim, meta-data are used, which are collected by the application every time a user interacts with it.
- The tool we present emphasizes equally on the technical aspect of knowledge (storage and organization of knowledge) and on its distribution between the users (personal contact of users).
- The application can be connected with the database of any other applications of the healthcare organization for retrieving information

Tool evaluation and results

Our purpose was to evaluate the effectiveness and usefulness of the application. The application was installed in the Faculty of Nursing (National and Kapodistrian University of Athens) in order for its operation to be tested. The system was tested and evaluated by a representative sample of users, undergraduate and postgraduate students. For the evaluation procedure, we used specific scenarios and questionnaires according to user's satisfaction and the effectiveness of the tool. The questionnaires and scenarios are based on standard questionnaires such as QUIS (Questionnaire for User Satisfaction), SUMI (Software Usability Measurement Inventory), WAMMI (Website Analysis and Measurement Inventory), CSUQ (Computer System Usability Questionnaire), ASQ (After Scenario Questionnaire) and other well known questionnaires and they have been improved and adapted to the special characteristics of a Knowledge Management system. Some of the basic criteria we used for the evaluation are the following [2]: *Speed*, *Flexibility in use, Flexibility in data source,. Ease to use, Interactivity, Accuracy, Efficiency, Control, Search engine facility, Traceability and activity links*. The evaluation results has been collected and analyzed and they will be presented in the MedInfo2007 Conference.

Conclusions and future perspectives

Through the presentation of the tool we have developed and its evaluation, we intend to define with concrete way the practical usefulness of such systems in the daily practice of healthcare professionals. Our main future work is to complete the evaluation of the application in a real clinical environment such as a hospital. Also, the next step in the research on the field of Knowledge Management in healthcare has to do with the complete incorporation and integration of a KM tool with the potentials of the technology of intranets, electronic medical records, document management, visualization tools, collaborative tools and data mining tools in order to provide more personalized Knowledge Management and capabilities for creating new Knowledge [4]. A research on the development of Knowledge Management systems leads to the awareness for the creation of conditions, which can help healthcare professionals to face most efficiently the problems that are related with the knowledge and the information in the field of healthcare.

Structure and functional overview of a Knowledge Management Environment In Healthcare Organizations

Charalampos Balis, John Mantas

Health Informatics Laboratory, Fuculty of Nursing,

National and Kapodistrian University of Athens, Greece

Introduction

The healthcare organizations face a lot of challenges:

- Increased costs
- Economic restrictions
- Bigger emphasis on medical responsibility and transparency
- Changes in education
- Enormous developments in biomedical research
- Initiatives that focus in the distribution of knowledge

All the above factors influence the effectiveness of healthcare organizations and lead to the increased need for changes

The current situation

Healthcare professionals are called continuously to absorb information on:

- new drugs
- new illnesses
- new clinical processes and biomedical techniques
- EU and state directives or guidelines
- warnings on negative effects of medicines
- new scientific discoveries in medicine
- big volume of information from various sources
- patient's demands for quality treatment and better healthcare services

They are obliged to dedicate concrete effort and small period of time for the above procedure. Also, each doctor has specific capabilities of memorizing and retracting information.

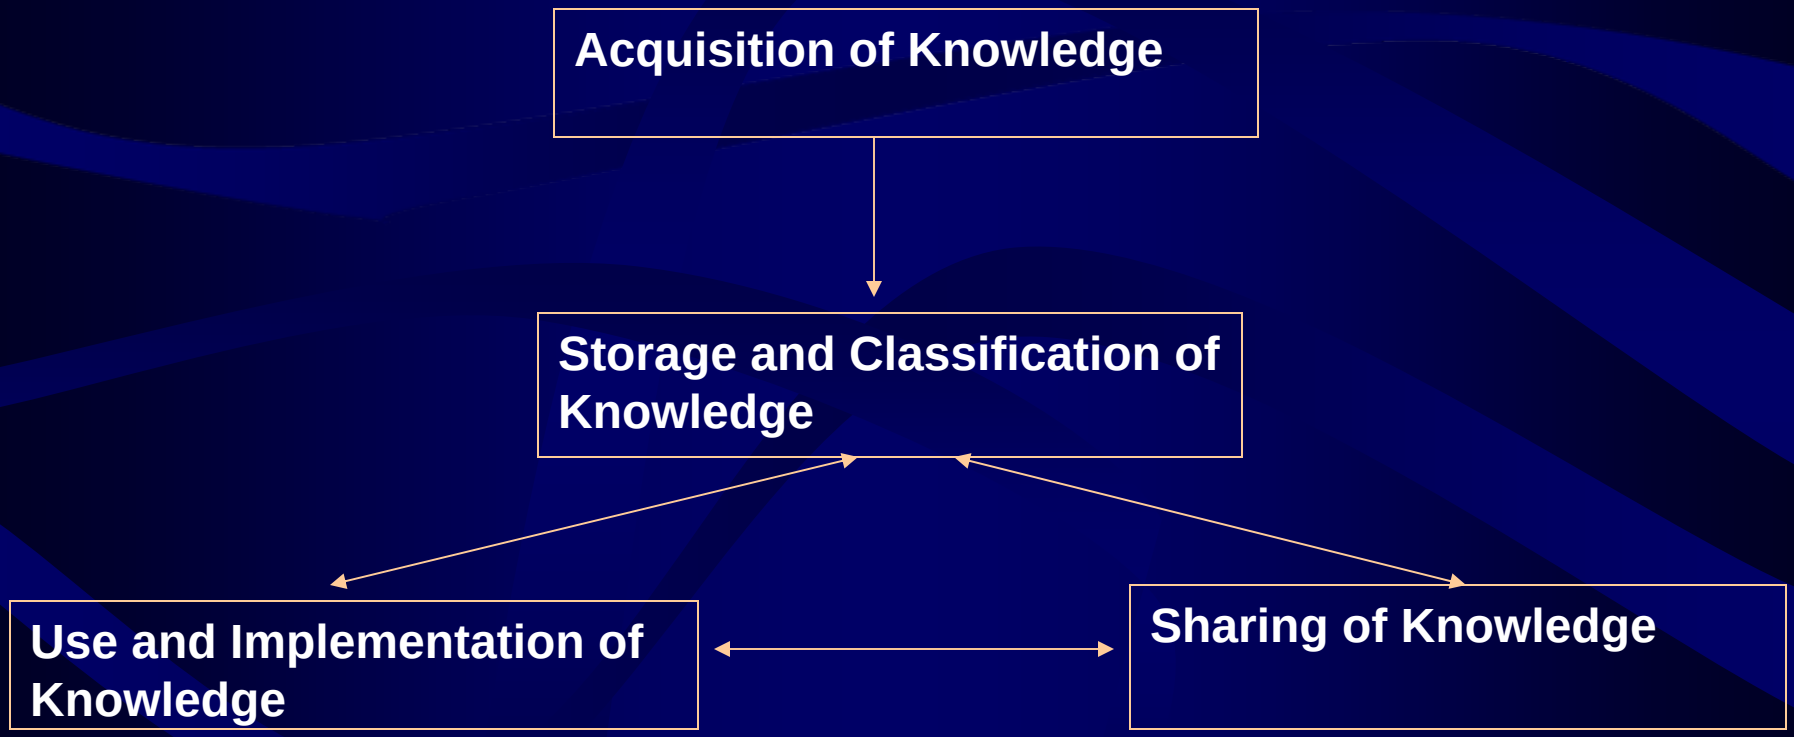
Related Technologies

- Methods and tools for supporting the dissemination of new discoveries and treatments via the Internet
- Document and workflow management applications
- Collaboration systems and communication tools
- Development and use of modern medical terminology and classification

These technologies, however, are not Knowledge Management applications, because each one of them emphasizes in a particular operation.

Our proposal

Basic processes of the Knowledge Management tool that we propose

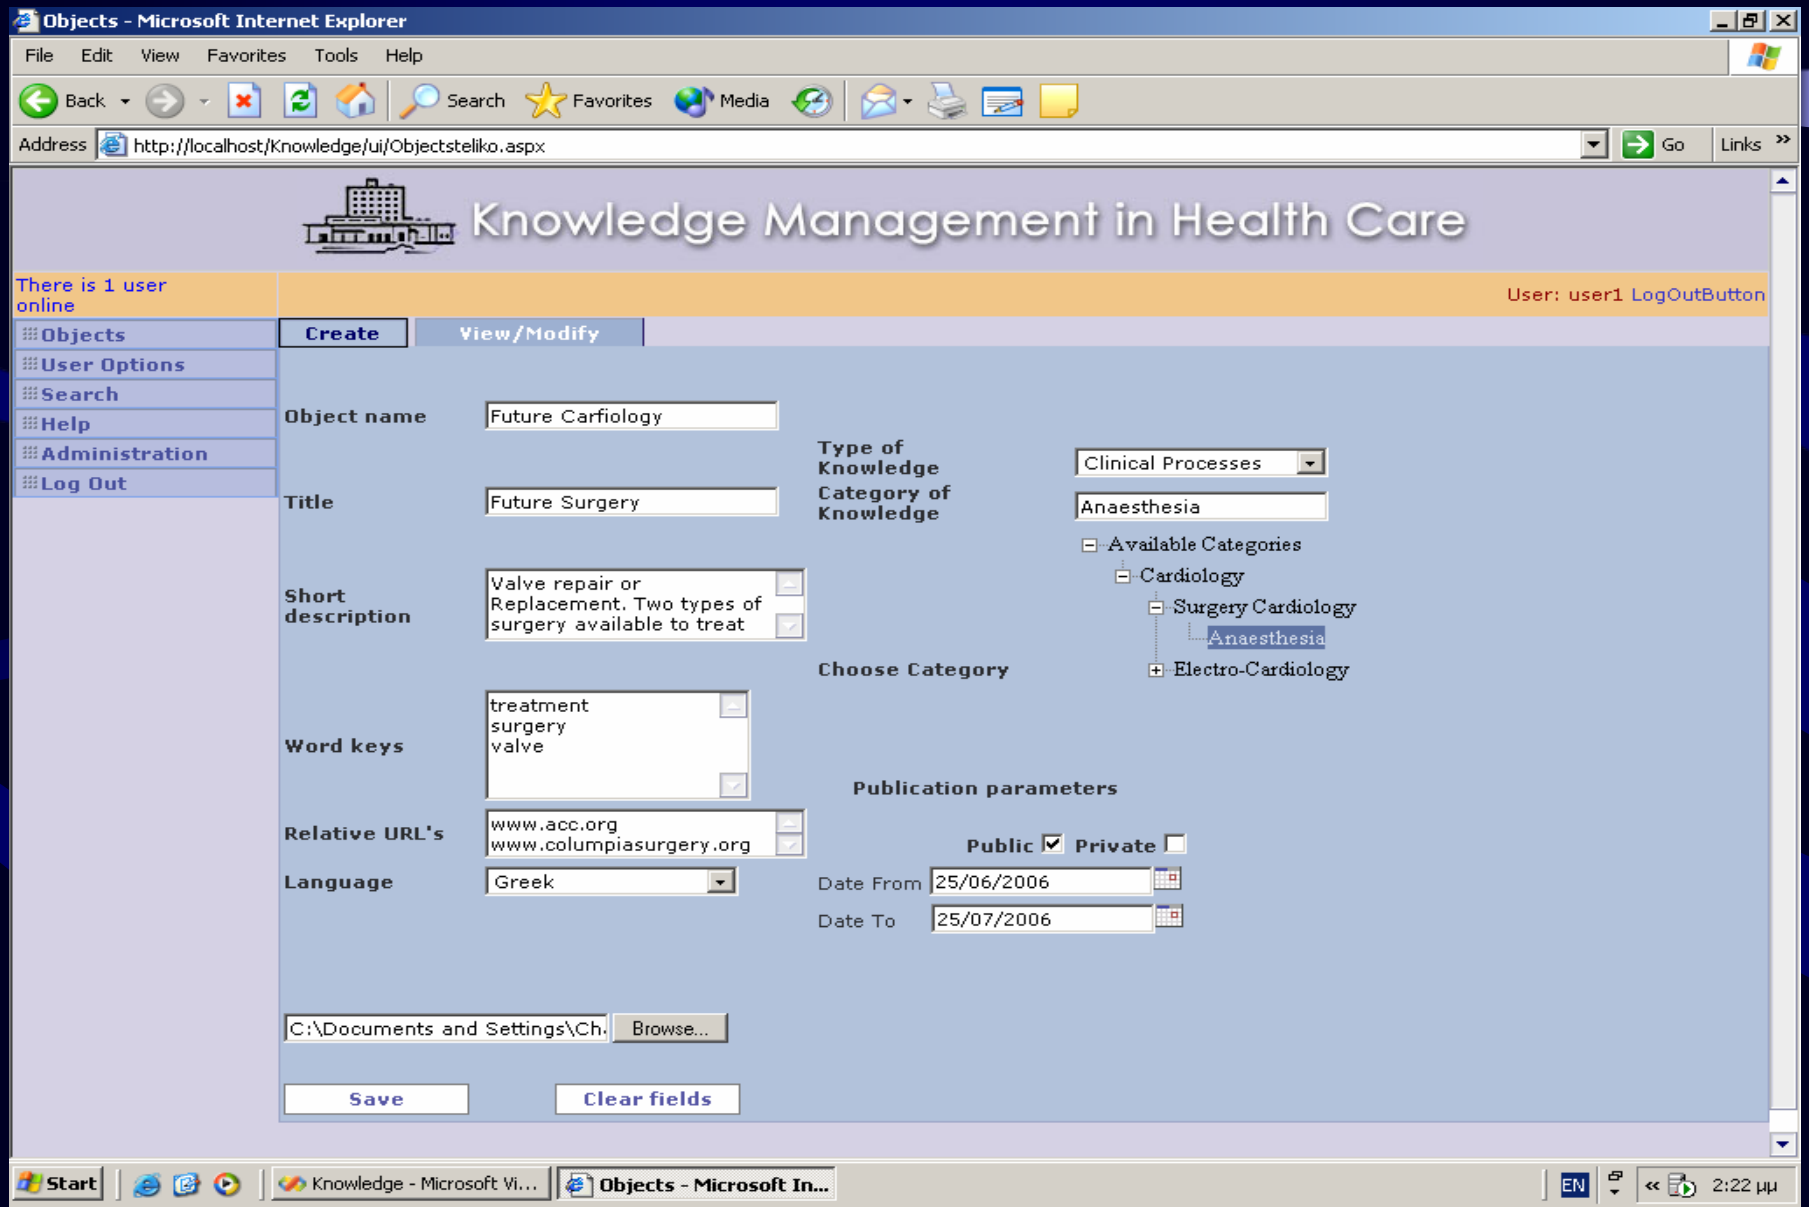


Functions of the application

1. Knowledge (Objects) can be stored in various format: documents, spreadsheets, pictures, video, sound, text etc.
2. The Objects are stored in a central Database server via the interface of the application
3. Knowledge is organized and classified in Types and Categories of Knowledge according to the thematic unit and the scientific field that it concerns
4. User Profile: contains personal data, studies, scientific interests etc. Each user can create and update his own profile. After each action from a user, his profile is updated automatically according to his fields of knowledge
5. Search objects and people through various ways
6. Search results are categorized in objects, individuals, localities of knowledge and other relative categories within the category of search.

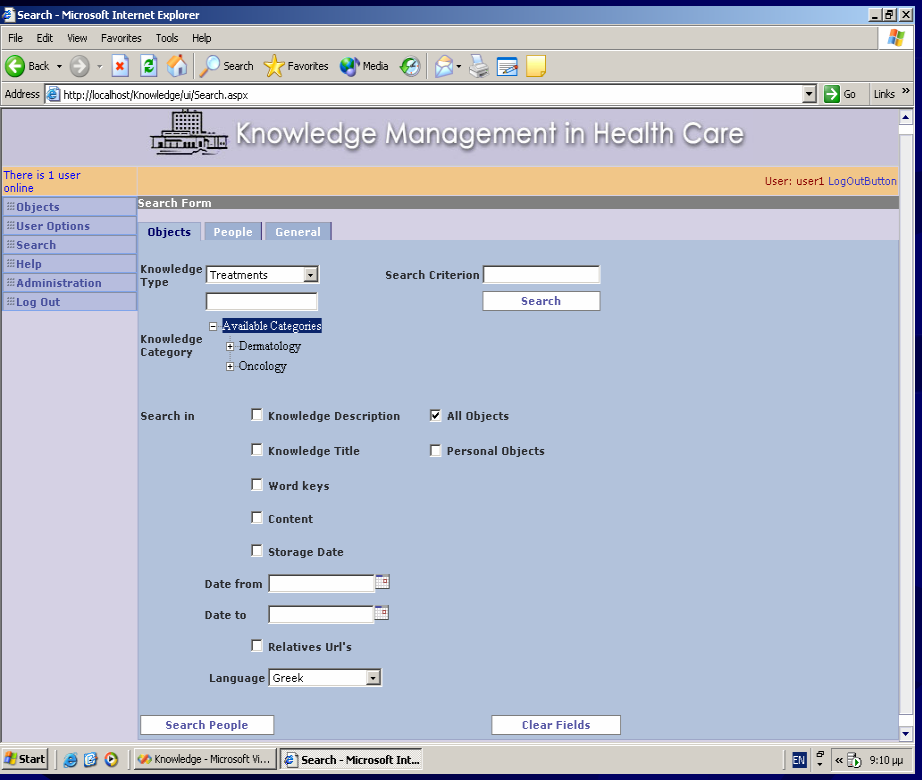
Development of the tool

Storing and classifying objects

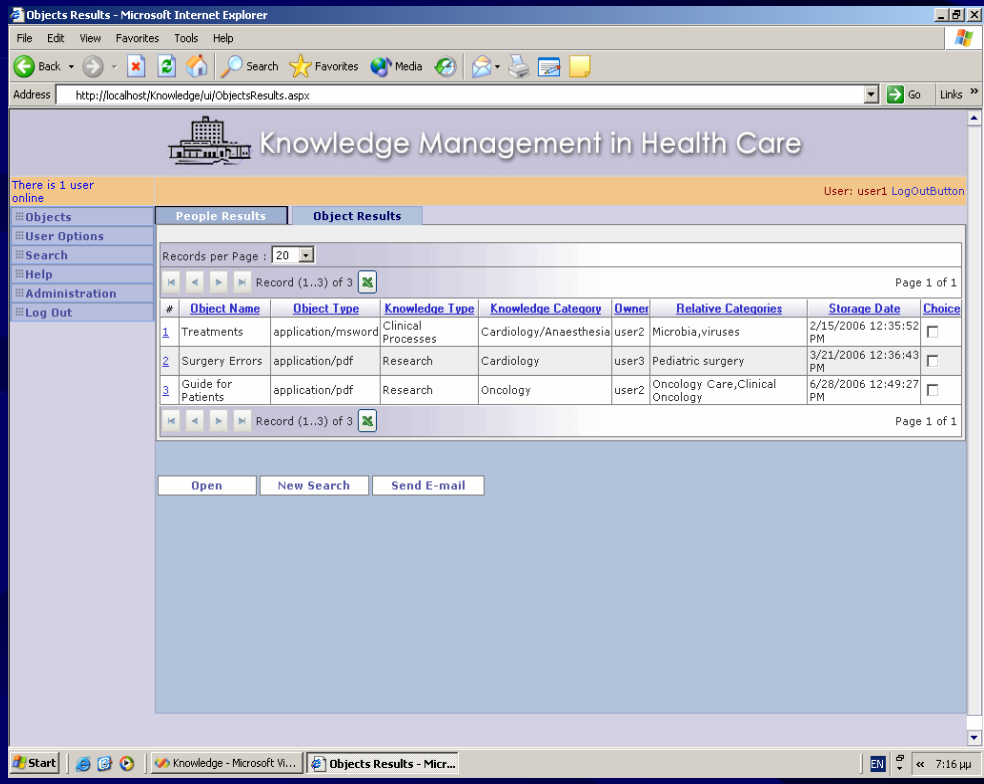


Development of the tool

Search Screen



Search Results for objects



Evaluation

- The application was installed in the Faculty of Nursing (National and Kapodistrian University of Athens). The system was tested and evaluated by a representative sample of users, undergraduate and postgraduate students.
- Questionnaires and scenarios :

  QUIS (Questionnaire for User Satisfaction), SUMI (Software Usability Measurement Inventory), WAMMI (Website Analysis and Measurement Inventory), CSUQ (Computer System Usability Questionnaire), ASQ (After Scenario Questionnaire) and other well known questionnaires.

Evaluation Criteria

- *Speed*
- *Flexibility in use*
- *Flexibility in data sources*
- *Ease to use*
- *Accuracy*
- *Interactivity*
- *Efficiency*
- *Control*
- *Search engine facility*
- *Traceability*

Conclusions and Future Perspectives

The main conclusion is:

- The existence of a Knowledge Management system in every modern healthcare organization is imperative

Future work :

- To install the application in a real clinical environment

- Focus on the complete incorporation and Integration with:
  - OLAP tools
  - document management
  - visualization tools
  - collaborative tools
  - data mining tools

in order to provide more personalized Knowledge Management and capabilities for creating new Knowledge

Use of the Vector Space Model for Expansion of Medical Queries

Wallnöfer R[1], Rammer Th[1], Schabetsberger Th[2], Pfeiffer KP[1], Göbel G[1]

[1]*Department for Medical Statistics, Informatics and Health Economics,Medical University of Innsbruck, Austria*
[2]*University for Health Sciences, Medical Informatics and Technology, Innsbruck - Austria*

Abstract and objective

We present an application of the Vector Space Model in connection with Medical Thesauri. The general idea is to use the Vector Space Model for a weighted expansion of medical queries. The application is based on the standardized ontology format OWL and – as first step – the concerning MeSH thesaurus. This includes an more generic approach than others. The application is implemented as prototyp web-service.

Keywords:

internet, information retrieval, Vector space model , MeSH

Introduction

Information Retrieval (IR) has become an important practice for millions of people in nearly every area. Especially in the area of Health Information Retrieval there is a lack of tools which support customers (patients, citizens) to find relevant and satisfying information. Most systems are based on full-text search. One example is Apache Lucene [1]. If you formulate a query you often get a lot of non relevant results because the system doesn't use any semantic relations. Another approach is used by Zeng et al [9]. With this tool the user is supported by a Query Assistant which assists the user to formulate his\her query.

This work focuses on the application of the vector space model on medical domain knowledge. Additionally to full-text search techniques the semantic relations between terms from a given domain should be considered. A simple and very common form of Information Retrieval is the Boolean model [2, 3]. This model is binary in other words documents are considered depending upon the presence or absence of the query term. Further, the queries are build by combining terms with Boolean operators (AND, OR, NOT). This model does not use weighting of terms. In this paper individual weighting of terms shall be reached with a variant of the vector space model [4, 5, 15]. The semantic relation between each search term shall become extracted with the Main Headings from the medical thesaurus "Medical Subject Headings" (MeSH) [6] which was published by the National Library of Medicine. With input from the desired search term an acyclic graph (represented by an n x n adjacent matrix) including all related terms (from the thesaurus) is generated. Furthermore the distance to each received term is calculated from the matrix by using the Floyd-Warshall Algorithm [7]. Finally, the calculation of the similarity between the search term and the existing documents is done regarding the vector space model.

Methods

The following components are used and form the base for this work:

- Medical Subject Headings (MeSH) thesaurus [6]
- Using vector space model for medical domain knowledge [8]
- Web Services, Apache Web Services [10,11]
- RDF/OWL [12,13]
- Converting Thesauri to RDF/OWL [14]

Based on [8] we develop a tool which makes a weighted query-expansion based on MeSH terms available via a web service.

Results

The results are implemented as web-service based on the vector space model using state of the art technologies. As the software will be realized as a web service it will be available on a server and can be used by a client from each arbitrary location through the Standard Internet Protocol (HTTP). The medical thesaurus MeSH is used as domain knowledge, as already stated above. MeSH is mainly used to index and to search for articles in large databases (e.g.: MEDLINE/PubMED). However this thesaurus is only available in a proprietary XML format. To be compatible with the semantic web standard format RDF(S) the MeSH thesaurus shall be used in RDF/OWL format. A description for converting thesauri to RDF/OWL is available at [14].

If a user is searching for information in a distinct subject area, conventional full-text based search engines often deliver a lot of non relevant responses. With this work it will be much easier for a user to find similar documents, related to his request, in a defined document pool. The user submits a suited search term (MeSH term) to the system and gets as a result the documents which will be most similar to the given search term. The calculation of the similar documents is done with the additional received Main

Headings from the MeSH thesaurus on the bases of the vector space model in combination with the Floyd-Warshall Algorithm.

Conclusion

By using domain knowledge in a standardized format in the future it is possible to use other medical knowledge domains like ICD-10 or SNOMED for searching similar documents. But it is important that these domains are also available in the same standardized format. In any case Information Retrieval will be much easier with this web service and vector space model based tool. Especially in the health Information Retrieval area customers will profit from this approach that take as a first step the MeSH thesaurus as a knowledge domain.

Description of Implementation of Clinical Decision Support Alert in Response to a Case Report of a Preventable Adverse Drug Event

Andrew C. Seger [a,c], Tejal K. Gandhi [a,c], Saverio M. Maviglia [b], Tonya M. Hongsermier [b], Eileen Yoshida [b], Teal K. Petaja [b], John F. Nolan [b], David W. Bates [a,c]

[a] *Division of General Medicine Brigham & Women's Hospital, Boston MA, USA*
[b] *Clinical Informatics Research & Development, Partners HealthCare Systems. Inc, Wellesely, MA, USA*
[c] *Clinical & Quality Analysis, Partners HealthCare Systems Inc, Wellesley, MA USA*

Abstract and objective

While Clinical Decision Support Systems (CDSS) can be developed as a large group of rules- based advice occasionally, cases of preventable adverse drug events come to the attention from various pathways, both through clinical and policy activities. At Partners HealthCare Systems, there is a centralized knowledge management structure that allows for clinicians to present information to a Medical Knowledge Committee (MKC) in a structured way so that any information can be properly vetted. A case of a fatality due to the administration of 2 medications concurrently and the understanding that key decision support components were not available to the prescribing clinicians, drove us to implement this advice in both our acute care and ambulatory clinical systems.

Keywords:

decision support systems, clinical, medical informatics, medication errors, drug interactions

Introduction

Clinical Decision Support Systems (CDSS) can assist clinicians in the proper use of medications[1]. While the large majority on clinical situations can be addressed with CDSS there are potentially some situations that occur in clinical care that require addition of clinical knowledge to CDSS. We describe a case that came to a team member in his work as a reviewer for a newsletter and while attending a pharmacy board meeting. Utilizing this information, a team approach to vetting this case information into our current CDSS architecture to ensure that all clinicians who write medication orders will receive this intervention alert.

Methods

We became aware of a case of a patient who received azathioprine prescribed in ambulatory setting, was admitted to a hospital and ordered for 6-mercaptopurine (the metabolic product of azathioprine) and discharged on both medications. The patient developed myelosupression, sepsis and died. Utilizing this knowledge, the case was presented to the Medical Knowledge Committee. The MKC oversees the knowledge base for the drug-drug interaction alerting across all platforms at Partners Healthcare Systems, an integrated delivery network. An interruptive alert, but not one that is a hard stop was developed and rolled out to all applications utilizing drug-drug interaction alerting.

Results

The utilization of a case of a preventable adverse drug event to develop a single piece of clinical knowledge can be a way to increase the quality and safety of care provided in both the acute and ambulatory care settings. Clinical and informatics professionals can utilize case reports to supplement clinical knowledge at their local sites. A team approach is essential to ensure that the alert is implemented in a structured way.

Information Systems

Partners HeatlhCare System

MedInfo 2007 August 20-24, 2007

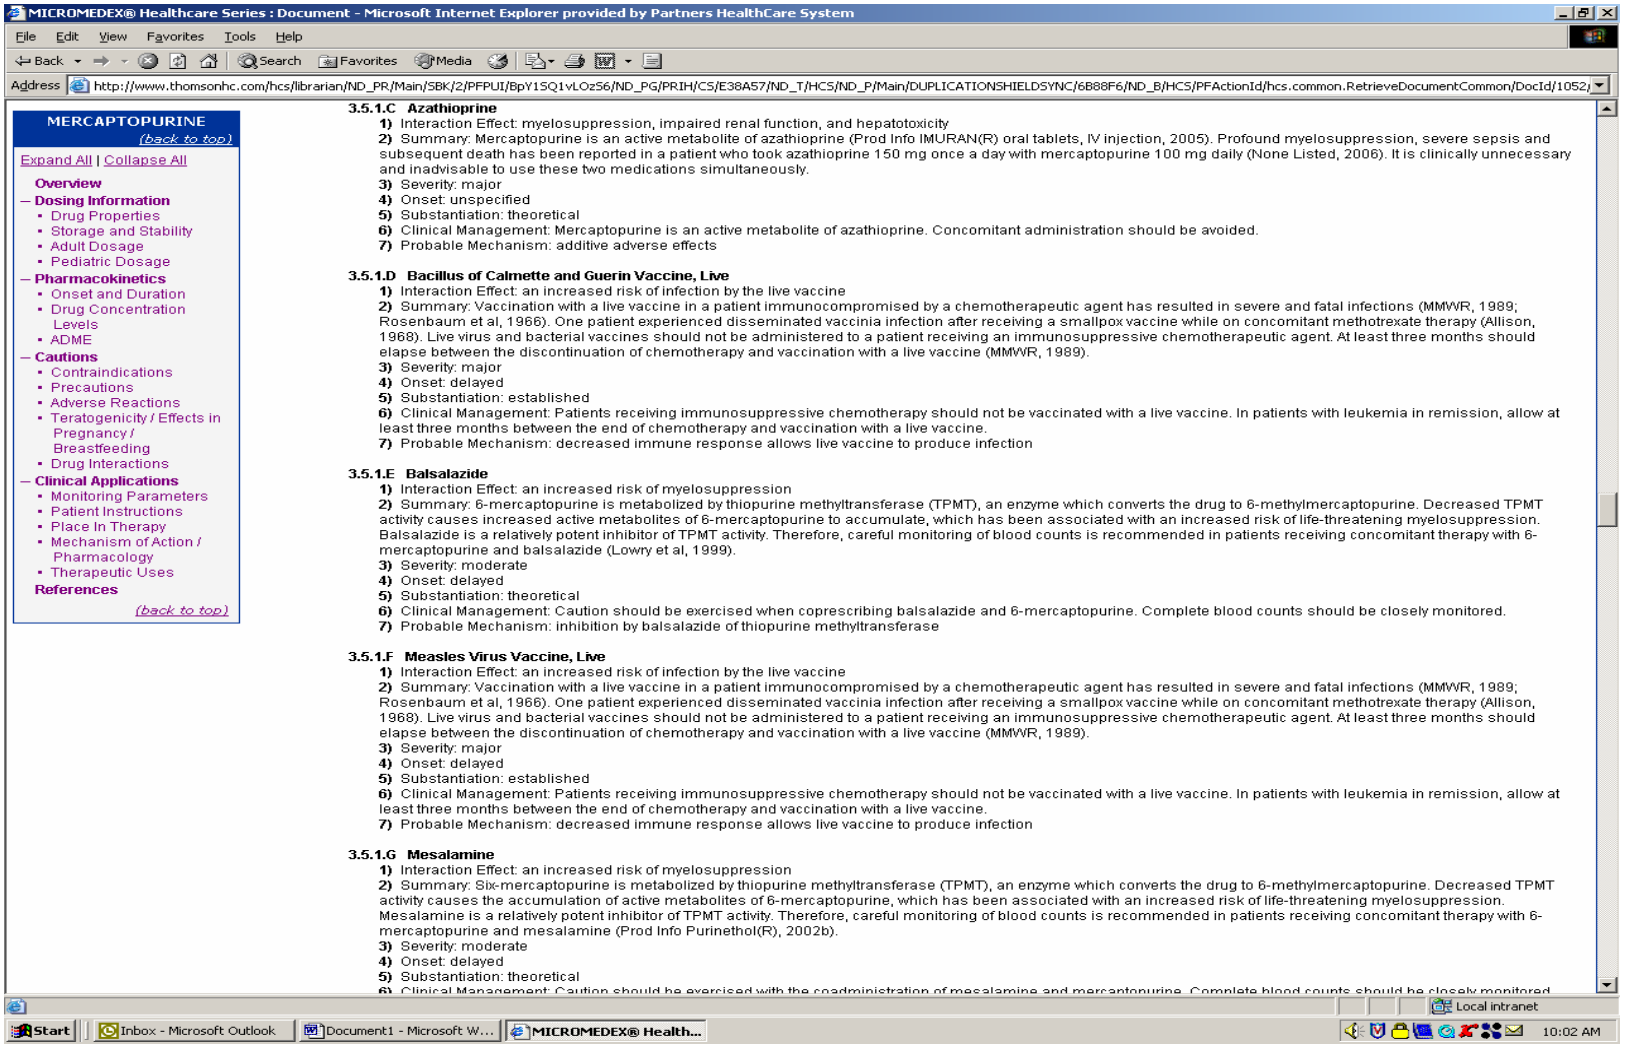
Objective

- Clinical Decision Support Systems
- Case Report of Medication Error
- Editor of Newsletter
- Attended Board of Pharmacy meeting
- Case of death due to sepsis
- Patient prescribed known interacting drugs
- Utilize this information to create an alert

Introduction

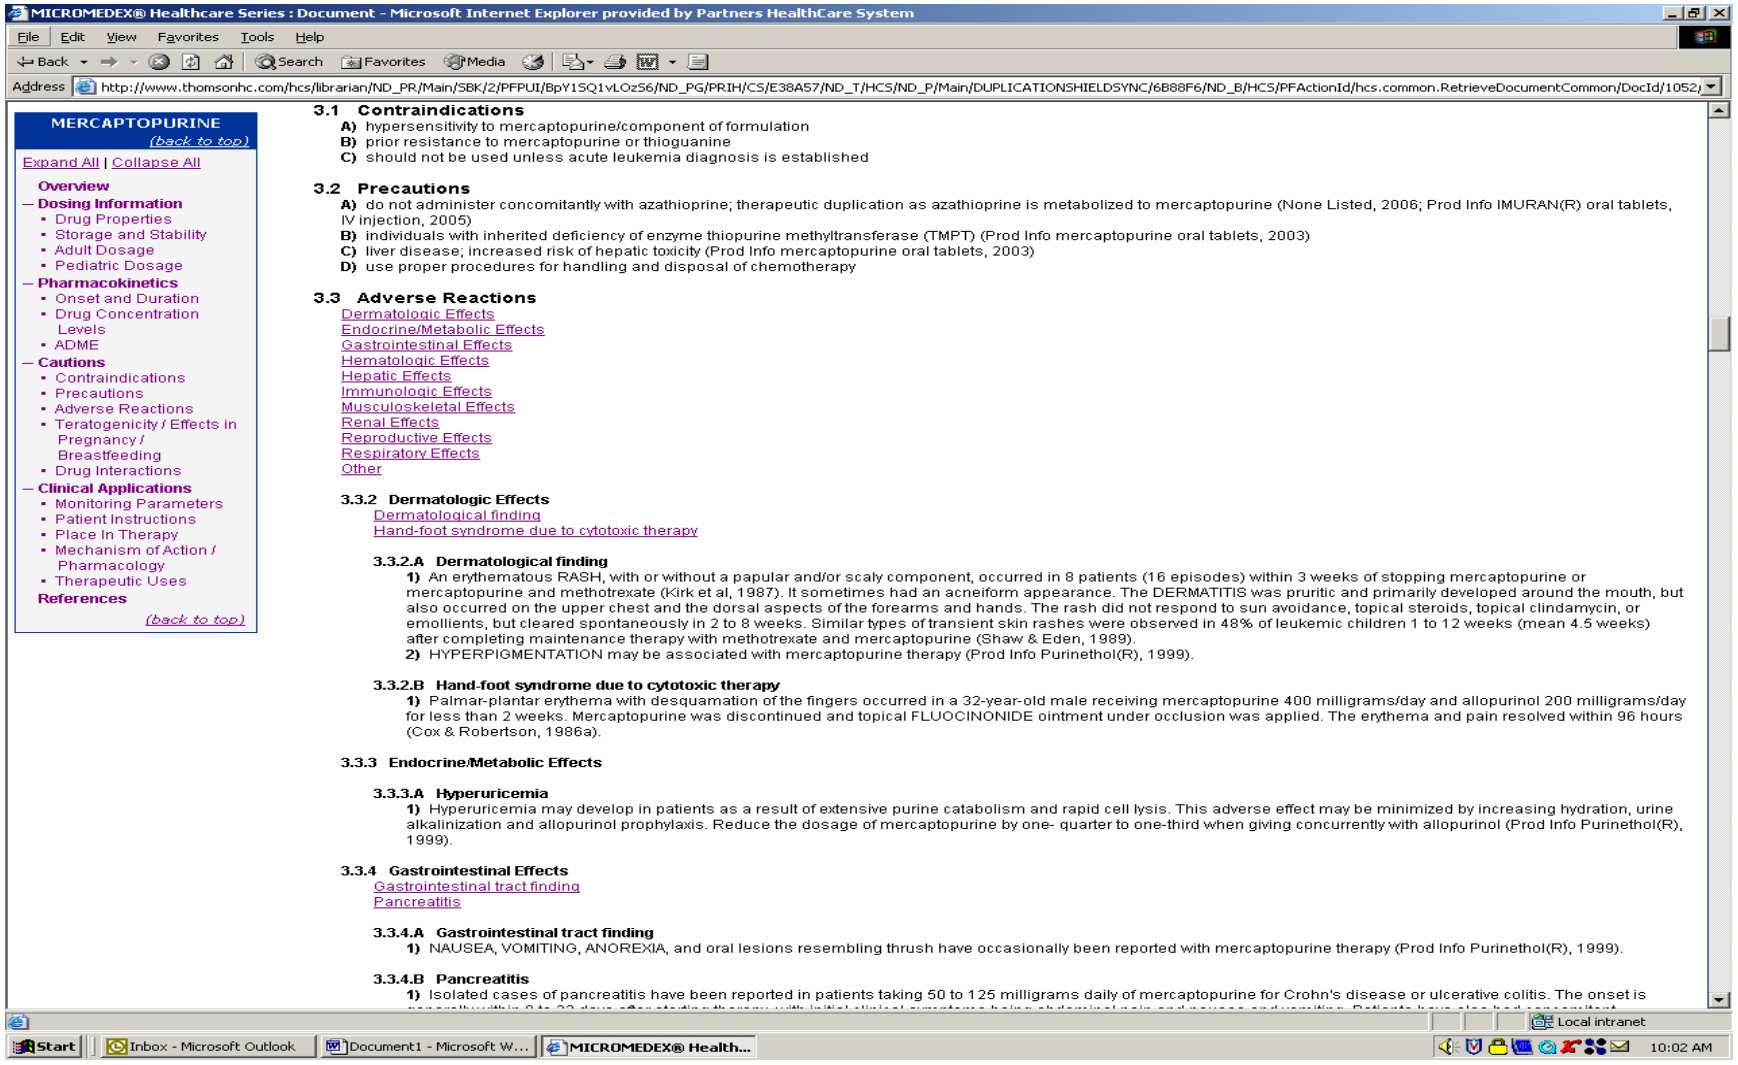
- Clinical Decision Support Systems (CDSS)
- Azathioprine/6-mercaptorpurine (the metabolic product of azathioprine)
- Listed in Micromedex® as both a DDI and therapeutic duplication
- How do we integrate this piece of knowledge into CDSS
- Medical Knowledge Committee (MKC)

6-Mercaptopurine/Azathioprine DDI



BRIGHAM AND WOMEN'S HOSPITAL

Therapeutic Duplication

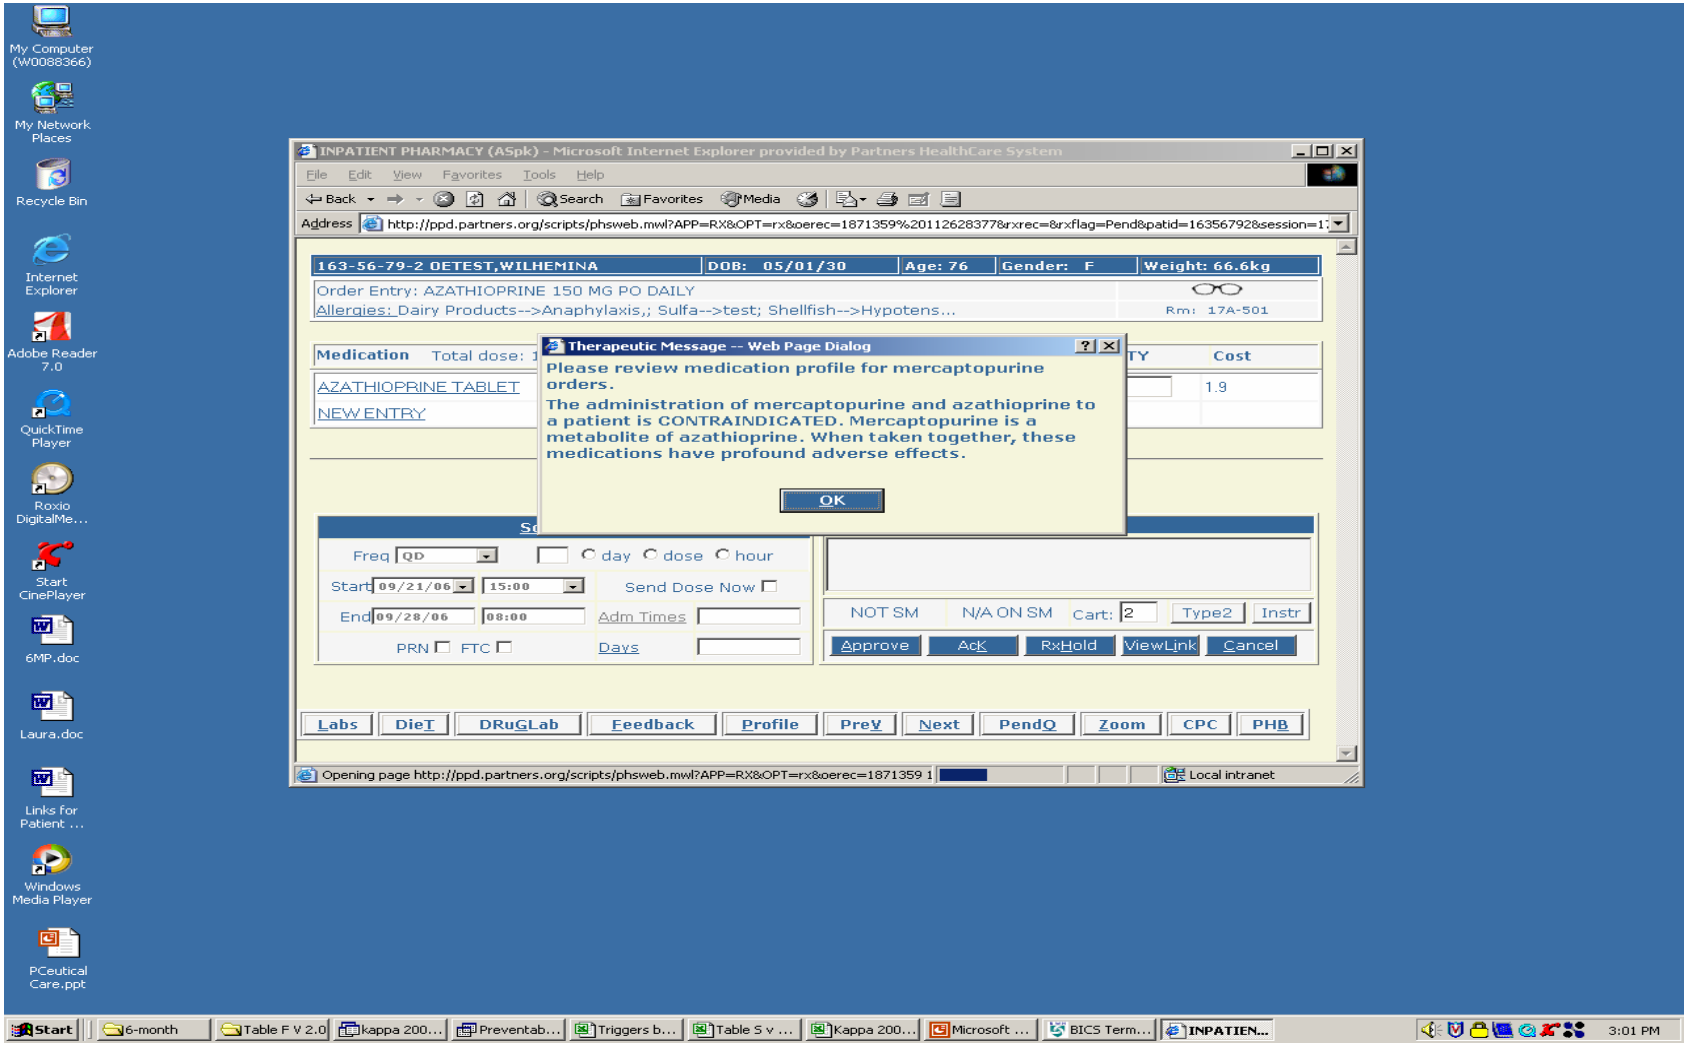


BRIGHAM AND WOMEN'S HOSPITAL

Methods

- Present information to MKC
- MKC's Medical Director is concerned that others will try to utilize exception to propose therapeutic duplications as inclusion in DDI knowledge base
- Utilization of TD will allow only outpatient clinicians to see alert
- Inpatient pharmacists are the ONLY one alerted in CPOE

Pharmacy OE/Pre-Implementation



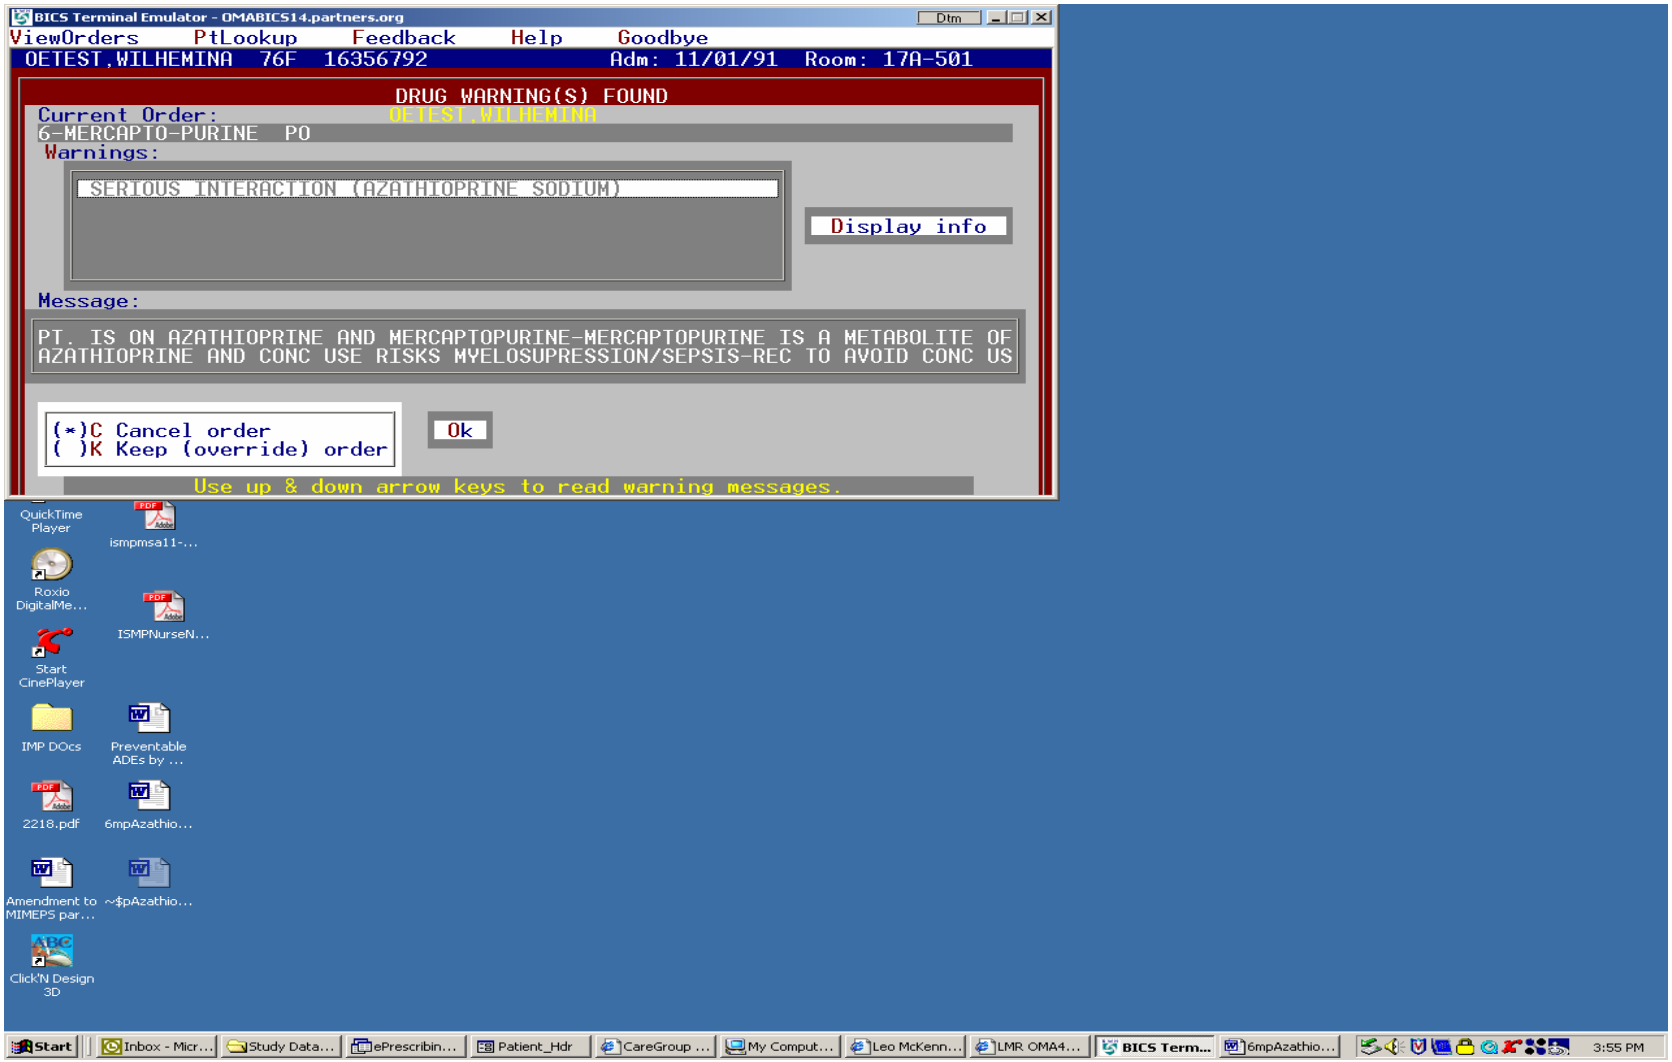
BRIGHAM AND WOMEN'S HOSPITAL

Results

- After discussion with Medical Director of MKC, present information to full MKC
- The concerns of Medical Director of MKC also presented at meeting
- These are taken into account in conjunction with presented material
- Decision is made to include in DDIs as benefits outweigh risk

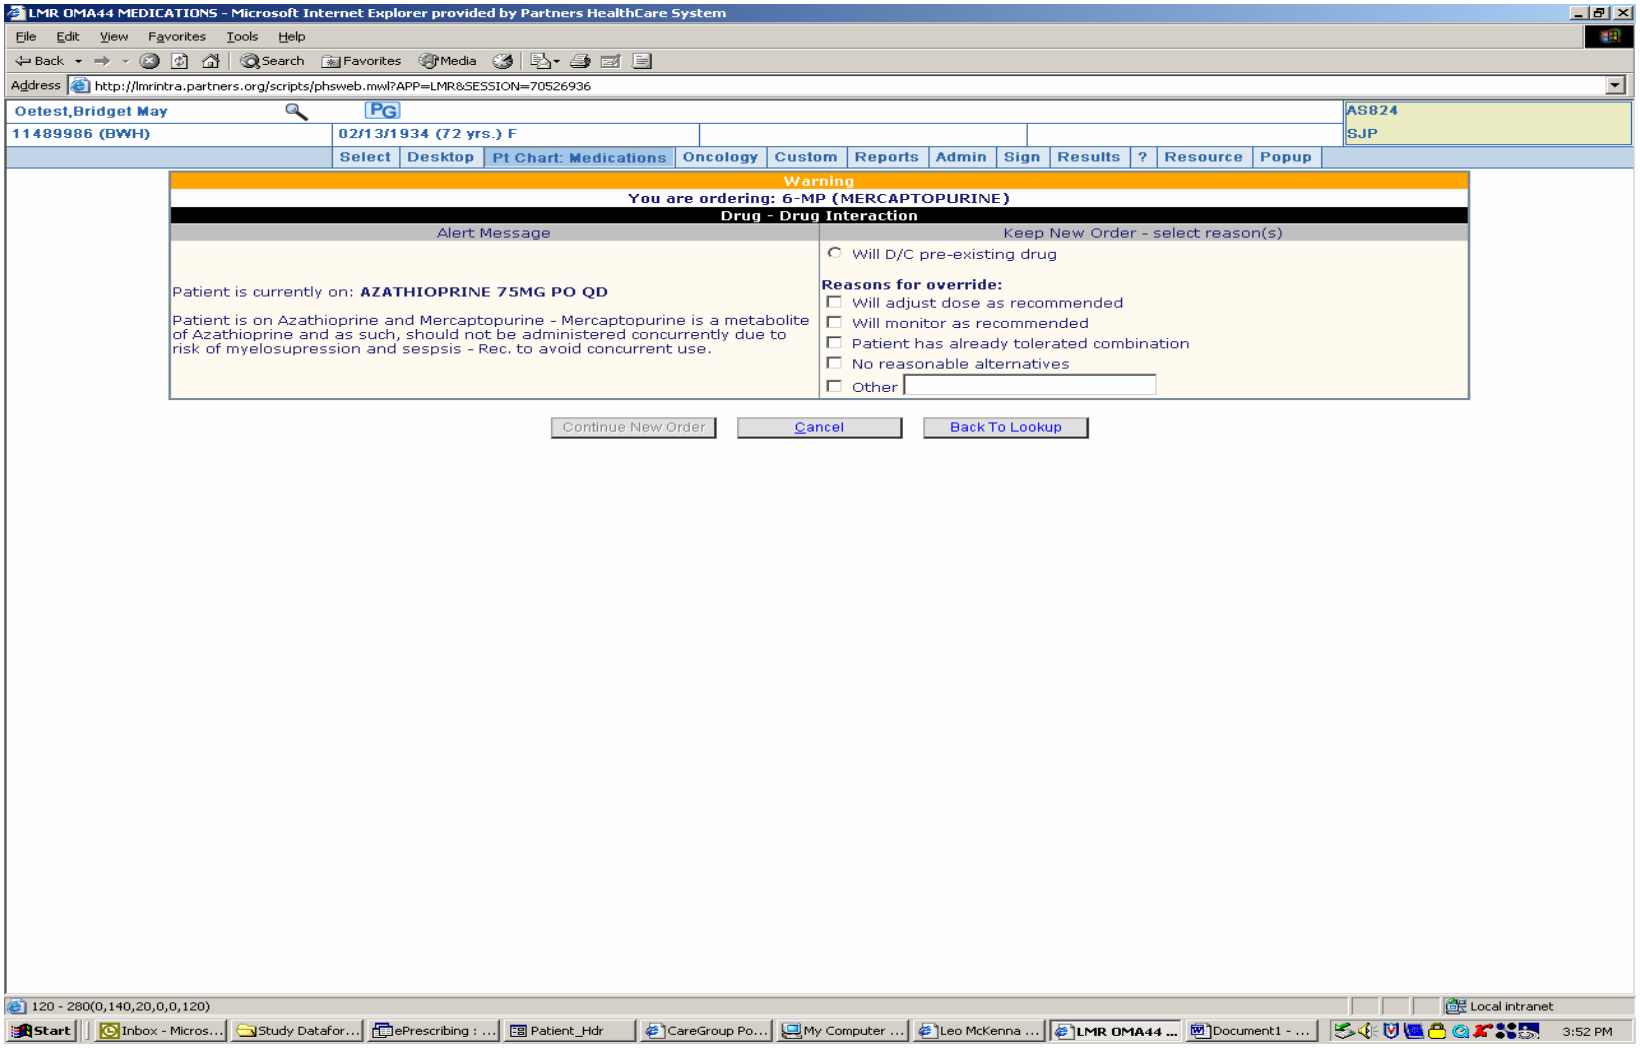
BRIGHAM AND WOMEN'S HOSPITAL

Screen Shot CPOE Inpatient/Post Implementation



BRIGHAM AND WOMEN'S HOSPITAL

Screen Shot Outpatient/Post Implementation



BRIGHAM AND WOMEN'S HOSPITAL

Conclusion

- Utilization of medication error data can enhance CDSS
- Information must be presented in a logical, concise form
- Utilization of team concept ensures all issues are vetted and contributes to a more robust knowledge structure

An Ethnographic Focus for the Study of Information Needs in the Emergency Center of the Hospital Italiano de Buenos Aires

HOSPITAL ITALIANO de Buenos Aires

Department of Medical Informatics

Acronyms

- **IN**: Information Need
- **PIN**: Possible Information Need
- **EC**: Emergency Center
- **HIBA**: Italian Hospital of Buenos Aires
- **EHR**: Electronic Health Record

Rationale

Why to study Information Needs?

- The HIBA is designing an EHR integrated with decision support tools for the EC
- It is a challenge to create decisions tools useful to and used by physicians
  - Developers must have accurate models of end users
    - What information the physycians use while they are caring for patients?
    - How much information do they need?
    - What kinds of information do they need?

It is necessary to identify the IN of the physicians

Problems for studying INs

Published studies of physicians' information needs have reported widely disparate results, with quantitative estimates of information need that vary by several orders of magnitude (Gorman)

Why?

➔ The method for eliciting requirements

➔ The definition of INs

Problems for studying INs

- **The method for eliciting requirements**
  - →Oral/written user reports
    - Nobody know/realizes his own practices
    - To report IN is a signal of professional incompetence
      - ➔ **Incomplete and incorrect identified INs**
      - ➔ **Out of the context of the daily work**

- **The definition of IN**
  - →Neither explicit nor univocal definition of IN
    - By type of information (Patient data; Population statistics; Medical knowledge; Logistic information; Social influences)
    - By the intention of search (Unrecognized needs; Recognized needs; Pursued needs)
      - ➔ **Identification depends on the point of view of the researcher**

The ethnographic approach

- **Based in direct observation of the scenarios**
- **Applied by Forsythe to elicit requirements in medical settings**

  →It allows...

  - **to identify any kind of physician's doubts**
  - **to understand the interrelationship between the requirement and the work flows**

Background

Forsythe's definition of IN

"Conscious expressions (verbal or non-verbal) of a desire for more information by one or more people"

⟶Any type of message that implies a desire for information is registered, independently of the nature of the information wanted

⟶The researcher registers the expressions he considered an IN

- ➔ **It is more feasible to identify verbal messages**
- ➔ **It depends on the researcher**

Objectives of the study

- To identify Information Needs of physycians in the EC of the HIBA...
  - Embodied in the daily work of the emergency setting
  - Independently of the type of information
  - Based on the perspectives of the stakeholders

Methodology

Definition of the object of study

Given the complexity of those involved in the information system for the EC, to decide whether an expression constitutes an IN or not will depend on the perspectives of the person faced with this question

Possible Information Need: the registry of a verbal or gestural single message considered by the researcher a lack of information

Information Need: PIN validated by the stakeholders as an information necessity within the EC

Methodology

Design of the study: Qualitative research

1) Eliciting PINs:

→Participant observation

- Carried out by observers of different professional formations (doctors, nurses and sociologists) that accompany the emergentologists and the residents during their daily work

2) Defining INs:

→Focus groups

- The PIN list will be discussed in focal groups with the interested parties and those responsible for the design of the EHR for the EC

Methodology
Methods

1) Participant observation

- 1 hour observation in the EC, in different moments of the day and the week, during at least 1 month and until saturation of the analysis. The registry (including messages and context) will be recorded manually after the observation and discussed within the research team for identification of the PINs

2) Focus groups

- Homogeneous groups of 5 to 6 of residents, emergentologysts, developers, medical IT specialists, hospital administrators. The previously identified PINs will be exposed for the group discusion. Textual registries will be analyzed and the Information Needs defined by each stakeholder will be identified

Abstract

The development of informatics resources which meet the Information Needs (IN) of those who use them is an important challenge for the developers, and demands a profound knowledge of those needs. At the same time IN vary according to setting and the kind of work to be carried out. Classically, users' IN are clarified by asking the users direct questions but this type of evaluation brings with it an under-reporting of IN. The ethnographic investigation method allows an analysis of the IN of users in their workplace, and offers an understanding of those needs in the context in which they arise. Our purpose is to identify the IN of the physicians who work in the Emergency Center of a University Hospital, using the ethnographic method. The preliminary results of the investigation show that both the work dynamic of the Emergency Center and the context of emergency make it difficult to recognize physicians' IN , but following the methodology proposed by Diane Forsythe, we think it possible to achieve informatics developments which answer the real needs of the users.

Keywords:

information management, anthropology, cultural, needs assessment; emergency medical services

Introduction

In their daily practice, professionals systematically search for and use information of varying kinds. Clinical Decision Support Systems integrated with an electronic health record (EHR), have been proposed as one of the ways in which professionals can access the information they need in the different contexts of their professional life. However, it is difficult to develop systems which respond to the need for information in the process of decision making and in accordance with the requirements of their professional practice [1] To identify those requirements, common sense tells us that it should be sufficient to ask the users what they need, and in fact the majority of developments in information systems use this method [1-3]. However, the information that people give in response to direct questions leads to an under-registering of information needs [4]. Self-reporting tends to be incomplete and at times even incorrect [5].

The problematic of studying information needs (IN) is even more complex, in part because there is no explicit definition of the term "information needs" and a wide range of phenomena has been investigated under the rubric of Information Needs [6]. The majority of publications that we have found until now make reference to academic information [5].

Ethnography is a method of anthropological investigation which allows us to understand the context of the nature of knowledge; that is to say how it is personally experienced and used by each one of those who work in different cultural and organizational contexts [7]. Seen from this perspective the concept of IN is not restricted only to academic doubts, but rather to an absence of information that could interfere with the workflow. Studies based on ethnographic methods have revealed a greater diversity and quantity of information needs than those based solely on self-reporting [1, 8].

The Italian Hospital of Buenos Aires (HIBA) is a tertiary care, teaching and research hospital. Since 1998 a full-scale Health Information System has gradually been implemented. At this stage we are beginning the design of an electronic medical record for the Emergency Center (EC) and defining users' IN.

In the literature that we have found up until now, the information needs which are described are, in the majority of cases, related to the ambulatory area. We have found no literature making reference to what happens in the context of an EC. And no work of this nature has been carried out in Latin America.

The present study proposes to identify the Information Needs of doctors in the context of their daily work in the EC of the HIBA, using ethnographic methodology, decide which of these messages can be considered IN for the final users and to classify the IN according to the possibility of developing decision making support systems based on them.

The definition of the object of study

Forsythe propose to study "conscious expressions (verbal or non-verbal) of a desire for more information by one or more people and distinguish them from information deficits, which may or may not be conscious: only expressed

and therefore conscious information needs were recorded". In the Preliminary Results, we present the modifications that we propose in order to study the concept of IN.

Materials and methods

Qualitative investigation based on ethnographic methodology by means of participating observation. The observation and registration will be carried out by observers of different professional formations (doctors, nurses, sociologists) who will accompany the attending doctors in the EC, and will register the expressions of IN without prejudging the nature of or the occasion for the doubts. They will also register the context in which each IN is produced. This will allow these expressions to be validated by those who express the IN, whose observations and reflections will be incorporated in the register as part of the same process of analysis. Another investigator will provide an initial list of Possible Information Needs (PIN) for use in the joint discussions of the observers.

The PIN list will be discussed in focal groups with the interested parties and those responsible for the design of the EHR for the EC, to decide which of these possible needs are recognized by the doctors as true information needs and analyze which of these needs could be met by an informatics system. After this stage, we will have the views of the different parties involved on the role which the system should play, enriched by the contextual experience of practice in the EC.

Preliminary results

Following the definition proposed by Forsythe, IN is a wish or intention, which may or may not be made effective, in order to seek some type of datum. Methodologically this approach implies identifying questions and doubts, and interpreting them as IN. Therefore, any type of message that implies a desire for information is registered, independent of the nature of the information wanted, be it strictly clinical, academic, and administrative or of any other kind which may arise. Once the observer has identified and registered these expressions, he should interpret which of them could imply a potential search for information.

The EC presents characteristics different from those for which Forsythe's definition of IN proved both adequate and productive (morning rounds of residents who discussed a case with a hierarchical superior around the bed of a patient). The ambit of the EC is highly dynamic, and guided by the principle of economy of words and gestures. Accordingly, verbal interactions are few and brief and the observer must base his registers on gestures, proximity and space, all signs which, from a semiotic point of view, are little codified and whose meaning is indecipherable if they do not have a verbal anchorage which gives them meaning.

On the other hand, the professionals of the EC, unlike the residents who wait for the morning round to express their doubts, are little disposed to recognize that they have any significant doubts. We believe that the No-doubt condition would be, in our context, in some way related to the professional workplace of these doctors.

Both suppositions were corroborated by the preliminary observations which we carried out (n=20; words= 18.411; hours 11; persons observed=18; observers= 4), this led us to the conclusion that participant observation would allow us to identify, from verbal and gestural interactions, textual fragments which we could consider "Possible Information Needs". However, the ratification of these textual fragments as IN, given the complexity of those involved in the development and use of an information system for the EC, it should not be interpretative; for the answer – deciding whether an expression constitutes an IN or not – will depend on the perspective and the interests of the person faced with this question.

Methodologically, this implies the need for different view at the issue to decide which of these messages can be considered as IN, from the perspectives of the different people involved in the definition of what are and what are not IN. Finally, we propose that the PIN be validated by those parties involved in order to be considered true IN.

Introduction

In their daily practice, professionals systematically search for and use information of varying kinds. Clinical Decision Support Systems integrated with an electronic health record (EHR), have been proposed as one of the ways in which professionals can access the information they need in the different contexts of their professional life. However, it is difficult to develop systems which respond to the need for information in the process of decision making and in accordance with the requirements of their professional practice [1] To identify those requirements, common sense tells us that it should be sufficient to ask the users what they need, and in fact the majority of developments in information systems use this method [1-3]. However, the information that people give in response to direct questions leads to an under-registering of information needs [4]. Self-reporting tends to be incomplete and at times even incorrect [5].

The problematic of studying information needs (IN) is even more complex, in part because there is no explicit definition of the term "information needs" and a wide range of phenomena has been investigated under the rubric of Information Needs [6]. The majority of publications that we have found until now make reference to academic information [5].

Ethnography is a method of anthropological investigation which allows us to understand the context of the nature of knowledge; that is to say how it is personally experienced and used by each one of those who work in different cultural and organizational contexts [7]. Seen from this perspective the concept of IN is not restricted only to academic doubts, but rather to an absence of information that could interfere with the workflow. Studies based on ethnographic methods have revealed a greater diversity and quantity of information needs than those based solely on self-reporting [1, 8].

The Italian Hospital of Buenos Aires (HIBA) is a tertiary care, teaching and research hospital. Since 1998 a full-scale Health Information System has gradually been implemented. At this stage we are beginning the design of an electronic medical record for the Emergency Center (EC) and defining users' IN.

In the literature that we have found up until now, the information needs which are described are, in the majority of cases, related to the ambulatory area. We have found no literature making reference to what happens in the context of an EC. And no work of this nature has been carried out in Latin America.

The present study proposes to identify the Information Needs of doctors in the context of their daily work in the EC of the HIBA, using ethnographic methodology, decide which of these messages can be considered IN for the final users and to classify the IN according to the possibility of developing decision making support systems based on them.

The definition of the object of study

Forsythe propose to study "conscious expressions (verbal or non-verbal) of a desire for more information by one or more people and distinguish them from information deficits, which may or may not be conscious: only expressed

and therefore conscious information needs were recorded". In the Preliminary Results, we present the modifications that we propose in order to study the concept of IN.

Materials and methods

Qualitative investigation based on ethnographic methodology by means of participating observation. The observation and registration will be carried out by observers of different professional formations (doctors, nurses, sociologists) who will accompany the attending doctors in the EC, and will register the expressions of IN without prejudging the nature of or the occasion for the doubts. They will also register the context in which each IN is produced. This will allow these expressions to be validated by those who express the IN, whose observations and reflections will be incorporated in the register as part of the same process of analysis. Another investigator will provide an initial list of Possible Information Needs (PIN) for use in the joint discussions of the observers.

The PIN list will be discussed in focal groups with the interested parties and those responsible for the design of the EHR for the EC, to decide which of these possible needs are recognized by the doctors as true information needs and analyze which of these needs could be met by an informatics system. After this stage, we will have the views of the different parties involved on the role which the system should play, enriched by the contextual experience of practice in the EC.

Preliminary results

Following the definition proposed by Forsythe, IN is a wish or intention, which may or may not be made effective, in order to seek some type of datum. Methodologically this approach implies identifying questions and doubts, and interpreting them as IN. Therefore, any type of message that implies a desire for information is registered, independent of the nature of the information wanted, be it strictly clinical, academic, and administrative or of any other kind which may arise. Once the observer has identified and registered these expressions, he should interpret which of them could imply a potential search for information.

The EC presents characteristics different from those for which Forsythe's definition of IN proved both adequate and productive (morning rounds of residents who discussed a case with a hierarchical superior around the bed of a patient). The ambit of the EC is highly dynamic, and guided by the principle of economy of words and gestures. Accordingly, verbal interactions are few and brief and the observer must base his registers on gestures, proximity and space, all signs which, from a semiotic point of view, are little codified and whose meaning is indecipherable if they do not have a verbal anchorage which gives them meaning.

On the other hand, the professionals of the EC, unlike the residents who wait for the morning round to express their doubts, are little disposed to recognize that they have any significant doubts. We believe that the No-doubt condition would be, in our context, in some way related to the professional workplace of these doctors.

Both suppositions were corroborated by the preliminary observations which we carried out (n=20; words= 18.411; hours 11; persons observed=18; observers= 4), this led us to the conclusion that participant observation would allow us to identify, from verbal and gestural interactions, textual fragments which we could consider "Possible Information Needs". However, the ratification of these textual fragments as IN, given the complexity of those involved in the development and use of an information system for the EC, it should not be interpretative; for the answer – deciding whether an expression constitutes an IN or not – will depend on the perspective and the interests of the person faced with this question.

Methodologically, this implies the need for different view at the issue to decide which of these messages can be considered as IN, from the perspectives of the different people involved in the definition of what are and what are not IN. Finally, we propose that the PIN be validated by those parties involved in order to be considered true IN.

Cross-Scale Mapping of Gene Expression to Neuroimaging Datasets via Semantic Decomposition

Spiro P. Pantazatos[a1], Jianrong Li[b1], Paul Pavlidis[a2], John D. Van Horn[d], Yves A. Lussier[b3]

[a] *Department of Biomedical Informatics, Columbia University, New York, NY, USA*
[b] *Center for Biomedical Informatics, Department of Medicine, University of Chicago, Chicago, IL, USA*
[d] *Department of Psychological and Brain Sciences, Dartmouth College, Hanover, NH, USA*

Abstract

A labor-intensive step towards heterogeneous neuroscience data interoperability is the development of compatible metadata models that formally describe entities, attributes and the relationships between them in the underlying data. An alternative and complementary approach is proposed that uses Natural Language Processing (NLP) and a knowledge-based phenotype organizer system (PhenOS) to link terms to underlying data from each database, and then maps these terms using SNOMED CT®, a comprehensive Description-Logic (DL) ontology that describes anatomies across biological scales and morphologies related to disease. (See http://phenos.bsd.uchicago.edu/public/supplement-1-medinfo2007.doc for supplemental information.) A prototype was developed using sample datasets from the fMRI Data Center, Gene Expression Omnibus (GEO) at NCBI and Neuronames that allowed for complex and loosely-defined queries such as "List all disorders with a finding site of brain region X, and then find the closest references to these disorders (identical or subtypes) in all participating databases." The utility of this system in increasing interoperability between databases in domains as diverse as neuroimaging and gene expression, albeit on a semantic level, is discussed.

Keywords:

computational ontologies, phenotypes,
database interoperability, Mediated Schema, SNOMED

Introduction

Increasingly, there is an understanding that well-managed, comprehensive databases and their interoperability will be necessary for important further advancement in neuroscience (1). In contrast to the reliance on and advancements of informatics in other biosciences, such as molecular biology and genomics, or which data is primarily text-based, the tremendous complexity of neuroscience data is a major impediment in consistent informatics integration and implementation (2). One promising approach has been to use Ontologies employing Description Logic (DL), such as those that have been introduced into biomedical domains, as a flexible and powerful way to capture and classify biological concepts and potentially be used for making inferences from biological data (3-5). A major challenge to the use of DL ontologies in mediating between diverse databases is the differences in concepts and terms used to describe the underlying data in each database (6). This has been addressed by the development of automated methods for the lexical mapping of terminologies and medical vocabularies onto a major medical DL ontology used to link disparate information systems, typically the UMLS (7-9), but also SNOMED as was recently done for ontology-based query of tissue microarray data (10). The current effort differs from the abovementioned approaches because we are mapping very distinct datasets (that may not share many concepts) to SNOMED, which allows for the use of both hierarchical relationships and semantic decomposition between the anatomies and morphologies related to a disease to find relevant relationships across scales of biology. In effect, the proposed approach is also more effectively utilizing a 'reference model' of disease, such as that contained in SNOMED.

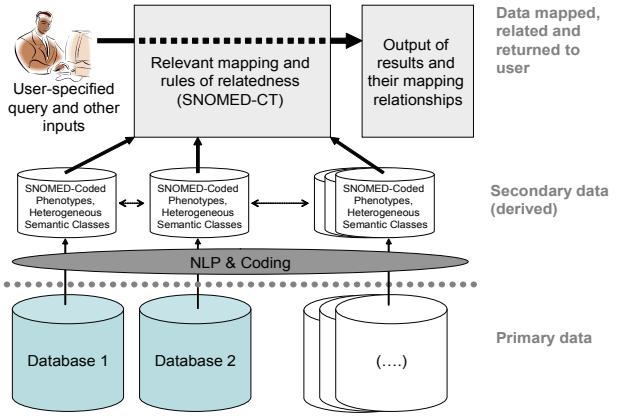

Figure 1 - Overall scheme for heterogeneous database integration. Natural Language Processing & Coding (PhenOS) was first used to assign terms (and their corresponding SNOMED codes) to underlying data (Primary data) for each of the participating databases. These were organized into tables (Secondary data) whose fields were then related and mapped using ancestor-descendant and translation tables generated from SNOMED-CT (Data mapping)

Materials and methods

(Details in *Supplement*, obtained at the URL supplied in the abstract.) The current method (outlined in **Figure 1**) employed four general steps: 1) conceptualization of the general query model **(Figure 2)**, that defines the traversable paths (hierarchical relationships and semantic switches) used in mapping relationships between terms contained in each database 2) mapping of database terms to SNOMED via NLP and coding 3) mapping rules of relatedness (according to the general query model) and 4) query construction and implementation. Mapping of database terms to SNOMED was conducted using PhenOS, a knowledge-based phenotype organizer system (14), which was also used in assigning phenotypic context to Gene Ontology Annotations (15). **Figure 3** depicts a query model path that was traversed in answering an example query, and **Figure 4** depicts the semantic mapping for one result of the example query.

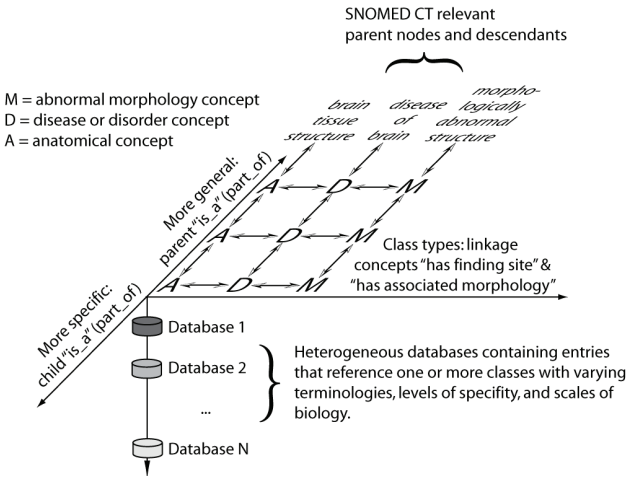

Figure 2 - General Query Model. The SNOMED ontology extends along the 'y-axis'; parent nodes are 'most positive'. The relatable semantic classes extend along the 'x-axis'; Anatomies (A) can be related to Diseases (D), which can be related to Abnormal Morphologies (M). Participating databases extend down along the 'z-axis'. The model is extendible; the 'y-axis' is extended as more specific terms are added to SNOMED with upcoming revisions, and more relatable semantic classes could be added along the 'x-axis'

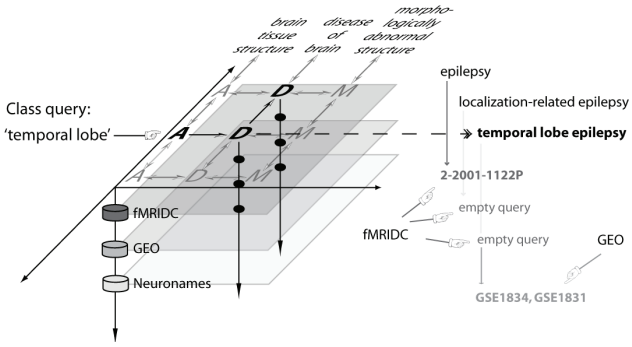

Figure 3 - Graphical depiction of the class-based query: "List all diseases with Finding Site 'temporal lobe' and then find references to these diseases (identical or subsuming) in all participating databases." In this example, 'temporal lobe epilepsy' is directly referenced in GEO, but must be expanded to subsuming ancestor term 'epilepsy' to find the closet match in fMRIDC

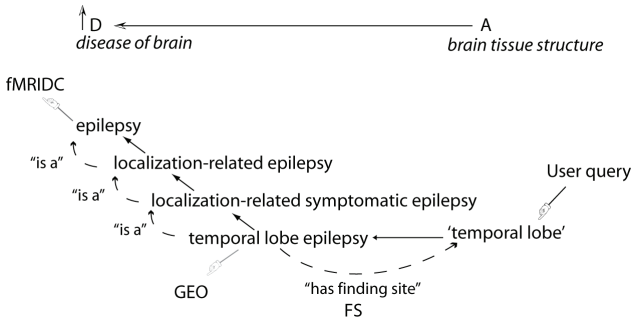

Figure 4 – 'Close-up' depiction of semantic navigation path through the SNOMED ontology in answering the class-based query "List all diseases with Finding Site 'temporal lobe' and then find references to these disease (identical or subsuming) in all participating databases." Solid arrows are query navigation path, and dashed arrows are SNOMED directed relationships ("has finding site" and "is a"). "temporal lobe epilepsy" is found to be referenced in GEO, whereas only the more general term "epilepsy" was found in fMRIDC

Results

5,497 unique pair-wise mappings were generated for seven types of relationships between each of the datasets: 1) **Identity -** terms are identical or similar between one dataset and another 2) **Subsuming** – terms in the one dataset subsume terms in the second 3) **Subsumed** – terms in one dataset are subsumed by terms in the second 4) **A,MD** - terms in one dataset are either an Anatomical Structure or Abnormal Morphology and terms in the second dataset are Diseases that subsume diseases that have as finding site or associated morphology the term in the first dataset 5) **A,MD** - terms in one dataset are either an Anatomical Structure or Abnormal Morphology and terms in the second dataset are Diseases that are subsumed by diseases that have as finding site or associated morphology the term in the first dataset 6) **DA,M** - terms in one dataset are Diseases and terms in the second dataset are either an Anatomical Structure or Abnormal Morphology that subsume finding sites or associated morphologies of terms in the first dataset 7) **DA,M** - terms in one dataset are Diseases and terms in the second dataset are either an Anatomical Structure or Abnormal Morphology that are subsumed by finding sites or associated morphologies of terms in the first dataset. Table 1 (see *Supplement*) shows the number of mappings for each relationship between each pair of datasets.

Discussion

(Details in *Supplement*.) The current work presents a novel method for query implementation that makes use of the modeling in SNOMED to decompose semantic information allowing for mapping between anatomies or morphologies related to disease. This allows for the mapping of heterogeneous data with different biological scales, such as arrays and imaging, because the decomposition of a diagnosis or disease to its cell type, anatomical and/or morphological component allows for the spanning of more biological scales than the diagnosis would alone.

Abstract

A labor-intensive step towards heterogeneous neuroscience data interoperability is the development of compatible metadata models that formally describe entities, attributes and the relationships between them in the underlying data. An alternative and complementary approach is proposed that uses Natural Language Processing (NLP) and a knowledge-based phenotype organizer system (PhenOS) to link terms to underlying data from each database, and then maps these terms using SNOMED CT®, a comprehensive Description-Logic (DL) ontology that describes anatomies across biological scales and morphologies related to disease. (See http://phenos.bsd.uchicago.edu/public/supplement-1-medinfo2007.doc for supplemental information.) A prototype was developed using sample datasets from the fMRI Data Center, Gene Expression Omnibus (GEO) at NCBI and Neuronames that allowed for complex and loosely-defined queries such as "List all disorders with a finding site of brain region X, and then find the closest references to these disorders (identical or subtypes) in all participating databases." The utility of this system in increasing interoperability between databases in domains as diverse as neuroimaging and gene expression, albeit on a semantic level, is discussed.

computational ontologies, phenotypes,
database interoperability, Mediated Schema, SNOMED

Introduction

Increasingly, there is an understanding that well-managed, comprehensive databases and their interoperability will be necessary for important further advancement in neuroscience (1). In contrast to the reliance on and advancements of informatics in other biosciences, such as molecular biology and genomics, or which data is primarily text-based, the tremendous complexity of neuroscience data is a major impediment in consistent informatics integration and implementation (2). One promising approach has been to use Ontologies employing Description Logic (DL), such as those that have been introduced into biomedical domains, as a flexible and powerful way to capture and classify biological concepts and potentially be used for making inferences from biological data (3-5). A major challenge to the use of DL ontologies in mediating between diverse databases is the differences in concepts and terms used to describe the underlying data in each database (6). This has been addressed by the development of automated methods for the lexical mapping of terminologies and medical vocabularies onto a major medical DL ontology used to link disparate information systems, typically the UMLS (7-9), but also SNOMED as was recently done for ontology-based query of tissue microarray data (10). The current effort differs from the abovementioned approaches because we are mapping very distinct datasets (that may not share many concepts) to SNOMED, which allows for the use of both hierarchical relationships and semantic decomposition between the anatomies and morphologies related to a disease to find relevant relationships across scales of biology. In effect, the proposed approach is also more effectively utilizing a 'reference model' of disease, such as that contained in SNOMED.

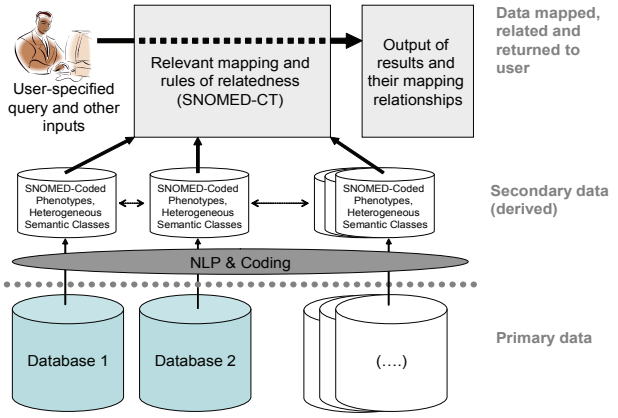

Figure 1 - Overall scheme for heterogeneous database integration. Natural Language Processing & Coding (PhenOS) was first used to assign terms (and their corresponding SNOMED codes) to underlying data (Primary data) for each of the participating databases. These were organized into tables (Secondary data) whose fields were then related and mapped using ancestor-descendant and translation tables generated from SNOMED-CT (Data mapping)

Materials and methods

(Details in *Supplement*, obtained at the URL supplied in the abstract.) The current method (outlined in **Figure 1**) employed four general steps: 1) conceptualization of the general query model **(Figure 2)**, that defines the traversable paths (hierarchical relationships and semantic switches) used in mapping relationships between terms contained in each database 2) mapping of database terms to SNOMED via NLP and coding 3) mapping rules of relatedness (according to the general query model) and 4) query construction and implementation. Mapping of database terms to SNOMED was conducted using PhenOS, a knowledge-based phenotype organizer system (14), which was also used in assigning phenotypic context to Gene Ontology Annotations (15). **Figure 3** depicts a query model path that was traversed in answering an example query, and **Figure 4** depicts the semantic mapping for one result of the example query.

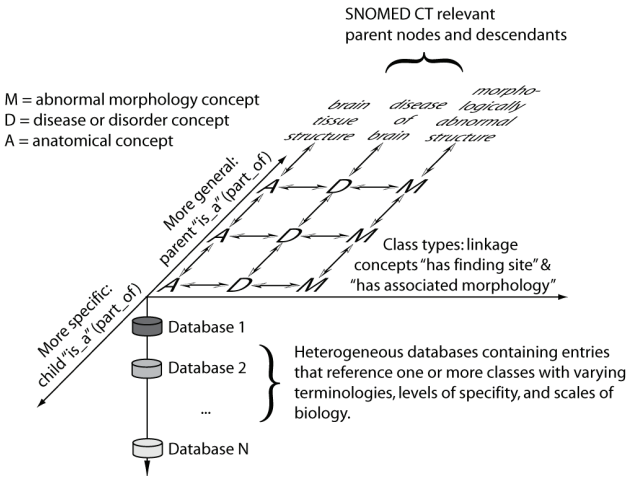

Figure 2 - General Query Model. The SNOMED ontology extends along the 'y-axis'; parent nodes are 'most positive'. The relatable semantic classes extend along the 'x-axis'; Anatomies (A) can be related to Diseases (D), which can be related to Abnormal Morphologies (M). Participating databases extend down along the 'z-axis'. The model is extendible; the 'y-axis' is extended as more specific terms are added to SNOMED with upcoming revisions, and more relatable semantic classes could be added along the 'x-axis'

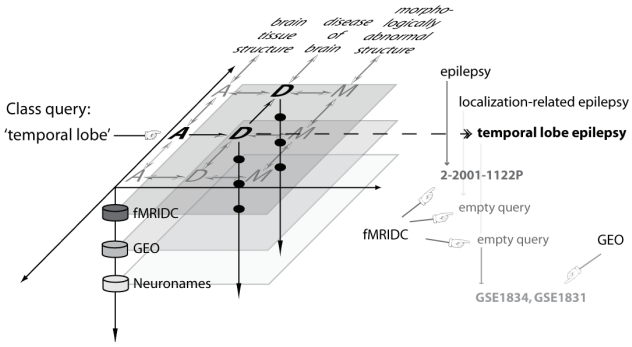

Figure 3 - Graphical depiction of the class-based query: "List all diseases with Finding Site 'temporal lobe' and then find references to these diseases (identical or subsuming) in all participating databases." In this example, 'temporal lobe epilepsy' is directly referenced in GEO, but must be expanded to subsuming ancestor term 'epilepsy' to find the closet match in fMRIDC

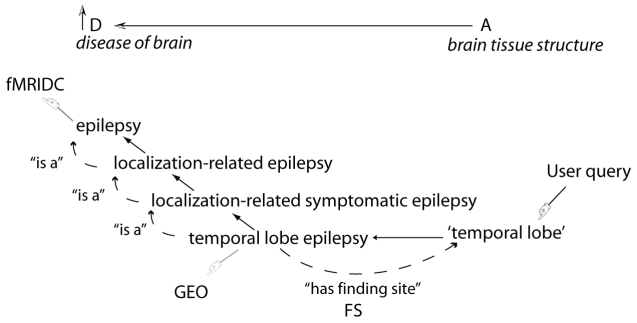

Figure 4 – 'Close-up' depiction of semantic navigation path through the SNOMED ontology in answering the class-based query "List all diseases with Finding Site 'temporal lobe' and then find references to these disease (identical or subsuming) in all participating databases." Solid arrows are query navigation path, and dashed arrows are SNOMED directed relationships ("has finding site" and "is a"). "temporal lobe epilepsy" is found to be referenced in GEO, whereas only the more general term "epilepsy" was found in fMRIDC

Results

5,497 unique pair-wise mappings were generated for seven types of relationships between each of the datasets: 1) **Identity -** terms are identical or similar between one dataset and another 2) **Subsuming** – terms in the one dataset subsume terms in the second 3) **Subsumed** – terms in one dataset are subsumed by terms in the second 4) **A,MD** - terms in one dataset are either an Anatomical Structure or Abnormal Morphology and terms in the second dataset are Diseases that subsume diseases that have as finding site or associated morphology the term in the first dataset 5) **A,MD** - terms in one dataset are either an Anatomical Structure or Abnormal Morphology and terms in the second dataset are Diseases that are subsumed by diseases that have as finding site or associated morphology the term in the first dataset 6) **DA,M** - terms in one dataset are Diseases and terms in the second dataset are either an Anatomical Structure or Abnormal Morphology that subsume finding sites or associated morphologies of terms in the first dataset 7) **DA,M** - terms in one dataset are Diseases and terms in the second dataset are either an Anatomical Structure or Abnormal Morphology that are subsumed by finding sites or associated morphologies of terms in the first dataset. Table 1 (see *Supplement*) shows the number of mappings for each relationship between each pair of datasets.

Discussion

(Details in *Supplement*.) The current work presents a novel method for query implementation that makes use of the modeling in SNOMED to decompose semantic information allowing for mapping between anatomies or morphologies related to disease. This allows for the mapping of heterogeneous data with different biological scales, such as arrays and imaging, because the decomposition of a diagnosis or disease to its cell type, anatomical and/or morphological component allows for the spanning of more biological scales than the diagnosis would alone.

A Semantic Web Based Framework for Modeling Clinical Practice Guidelines to Develop Clinical Decision Support Systems

Sajjad Hussain, Syed SR. Abidi

NICHE Research Group, Faculty of Computer Science, Dalhousie University, Halifax, Canada

Abstract

In this paper we present a Semantic Web based framework for the computerization and execution of Clinical Practice Guidelines via a Clinical Decision Support System (CDSS). Our framework involves multiple ontologies to represent different CPG, domain and patient knowledge. We have developed a tool to specify the CPG's decision logic as decision-rules that are executed via a proof-engine to derive patient specific recommendations. We provide a justification tree of the reasoning process to explain to the user the CPG-mediated recommendations suggested by the CDSS.

Keywords:

Clinical Practice Guidelines, knowledge management, Decision Support System, Semantic Web, ontologies

Introduction

Clinical Practice Guidelines (CPG) are systematically developed disease-specific recommendations to assist clinical decision-making in accordance with the best evidence [1]. However, the uptake of CPG is rather minimal in actual healthcare settings due to a range of behavioral, operational and technical issues. Indeed, CPG can be more effectively used if they are computerized and incorporated within Clinical Decision Support Systems (CDSS) that are available at the point-of-care[2].

In our work, we take a knowledge management approach to computerize CPG and develop a CPG-based CDSS. We apply the Semantic Web framework [3] to (i) Computerize a CPG by semantically representing disease-specific knowledge inherent within a CPG, whilst specifying the relationships and interactions between the key CPG elements to realize a functional and executable CPG plan; (ii) Transform the decision logic inherent within a CPG into executable logic-based decision rules; (iii) Execute the computerized CPG based on patient information, in order to provide CPG-mediated, patient-specific recommendations; and (iv) Justify the CDSS's recommendations by providing CPG-based explanations. The Semantic Web purports the semantic modeling and markup of knowledge, its properties and its relations using well-defined semantics such as formal definitions of terms, ontological definitions of domain concepts and resources. The semantically modeled knowledge can then be operationalized via proof engines employing logic-based reasoning methods to infer 'trusted' solutions.

In this paper we present a Semantic Web based framework for developing CDSS. The key elements of our framework are (a) modeling the CPG knowledge and (b) executing the CPG knowledge. To model the entire working environment and knowledge essential to derive a CPG-based recommendation, we developed three unique ontologies as follows: (i) A CPG Ontology that models the computerized structure of the CPG. We model the CPG using the Guideline Element Model (GEM) [4] structure, and therefore our CPG ontology is based on the GEM DTD; (ii) A Domain Ontology, in OWL, that models the CPG's medical knowledge; and (iii) A Patient Ontology that models the patient in terms of various health information. We used Protégé [5] to develop all the ontologies.

Our CDSS is divided into two main modules, namely CPG Encoding Module and CPG Rule Authoring and Execution Module. The CPG Encoding Module is used to encode the text-based CPG into the CPG ontology and to annotate the decision variables and logic structures inherent within the CPG. Both the CPG Ontology and the Domain Ontology are used for CPG encoding. The CPG Rule Authoring and Execution Module is used to define the decision logic rules in a CPG and to execute them based on patient data. A novel feature of our CPG Execution Module is that it provides an automated justification trace of inferred recommendations. Figure 1 shows the architecture of our Semantic Web based CDSS.

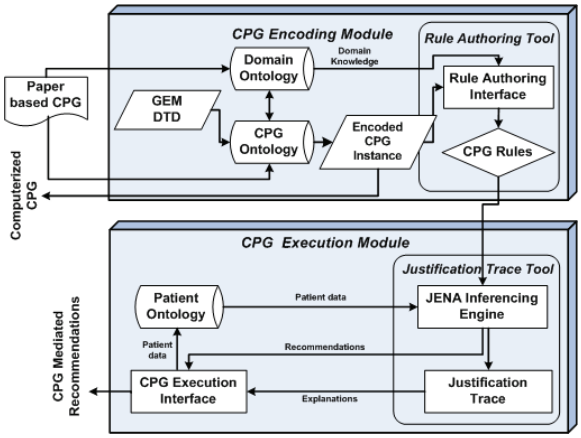

Figure 1- System Design of our CDSS

CPG Encoding Module

The CPG encoding module comprises two components: (a) a CPG representation formalism to convert the paper-based CPG into an electronic format; (b) a CPG ontology to model the structure of the CPG; and (c) a patient ontology to describe the characteristics of a patient. The *CPG Ontology* is based on the GEM DTD [4]. The *Patient Ontology* mirrors an Electronic Patient Record (EPR) and models a patient in terms of various health information and patient clinical situations.

CPG Rule Authoring and Execution Module

The CPG Rule Authoring and Execution module is designed to capture the CPG's clinical decision making logic in terms of logical rules—the logical rules were executed by a reasoning engine to derive CPG-based recommendations given a patient health record. To achieve the above functionality, we built three sub-modules namely, Rule Authoring Sub-Module, Execution Sub-Module and Justification Trace Sub-Module.

Rule Authoring Sub-Module uses the GEM encoded CPG to allow the user to identify the logical constructs within the CPG and define them as CPG (decision logic) rules using our CPG Rule Syntax. Upon completion of the rule authoring process, we apply a rule transformation algorithm to transform the CPG rules into the JENA syntax so that they can be executed the Execution Sub-Module that leverages the JENA inference engine [6].

Execution Sub-Module invokes the JENA inference engine to execute a CPG in order to infer recommendations based on patient profiles. We model instances from the Domain Ontology, CPG Ontology and Patient Ontology as RDF graphs, which serve as the knowledge base for JENA. JENA inference engine uses both the knowledge base and the CPG rule-set in a backward reasoning mode to infer CPG-mediated recommendations based on the given knowledge.

Justification Trace Sub-Module generates a justification trace of the rule execution to assist medical practitioners in understanding the logic behind the inferred recommendations. The justification derivation includes the linear representation of premises (facts) under which the JENA rules are satisfied and the conclusions based on those rules. The justification trace initiates with a derived patient recommendation (derived facts) from the JENA model (knowledge base) and generates facts which served as premises for deriving the patient recommendation, recursively.

The working of our CPG Authoring and Execution Module involves the following sequence of actions: (a) Input a text-based CPG and loads its pre-defined Domain Ontology and the Patient Ontology; (b) Encode the CPG in terms of the CPG Ontology and the Domain Ontology; (c) Specify the CPG (decision) rules. The CPG rules are transformed to JENA rule syntax and passed to the JENA reasoning system; (d) Execute the CPG based on a given patient instance to infer CPG-mediated recommendations; and (e) Justify the inferred recommendations through a justification tree.

Concluding remarks

The Semantic Web provides an interesting framework both for modeling and executing a CPG. Our Semantic Web based approach for CDSS development features the integration of multiple ontologies—we integrated two ontologies, each representing the form and function of a CPG—i.e. the *Domain Ontology* describing the CPG function and the *CPG Ontology* representing the CPG structure. We presented an intuitive CPG rule syntax that medical practitioners can use to write clinical decision rules from the CPG. We internally transformed the CPG rules into a complex rule syntax so that they can be executed via a inferencing engine to infer CPG based recommendations for a specific patient. Using our CDSS development approach we have developed two CDSS—i.e. (a) Breast Cancer Follow-up and (b) Imaging radiation protection—each based on a specific CPG.

The use of CPG in a CDSS not only provides an evidence based knowledge-base, but it relives CDSS developers from the perennial knowledge engineering problem. By design, CPG entail a decision logic that is structured in an algorithmic format that can be used to generate explicit symbolic clinical decision-support rules to suggest CPG-guided clinical recommendations. The knowledge management paradigm of the Semantic Web extends a logic-based framework to semantically model medical knowledge to provide a variety of knowledge-mediated services. Our CDSS approach is quite generic and can be extended to other medical problems.

A Semantic Web Based Framework for Modeling Clinical Practice Guidelines to Develop Clinical Decision Support Systems

Sajjad Hussain, Syed SR. Abidi

NICHE Research Group, Faculty of Computer Science, Dalhousie University, Halifax, Canada

Abstract

In this paper we present a Semantic Web based framework for the computerization and execution of Clinical Practice Guidelines via a Clinical Decision Support System (CDSS). Our framework involves multiple ontologies to represent different CPG, domain and patient knowledge. We have developed a tool to specify the CPG's decision logic as decision-rules that are executed via a proof-engine to derive patient specific recommendations. We provide a justification tree of the reasoning process to explain to the user the CPG-mediated recommendations suggested by the CDSS.

Keywords:

Clinical Practice Guidelines, knowledge management, Decision Support System, Semantic Web, ontologies

Introduction

Clinical Practice Guidelines (CPG) are systematically developed disease-specific recommendations to assist clinical decision-making in accordance with the best evidence [1]. However, the uptake of CPG is rather minimal in actual healthcare settings due to a range of behavioral, operational and technical issues. Indeed, CPG can be more effectively used if they are computerized and incorporated within Clinical Decision Support Systems (CDSS) that are available at the point-of-care[2].

In our work, we take a knowledge management approach to computerize CPG and develop a CPG-based CDSS. We apply the Semantic Web framework [3] to (i) Computerize a CPG by semantically representing disease-specific knowledge inherent within a CPG, whilst specifying the relationships and interactions between the key CPG elements to realize a functional and executable CPG plan; (ii) Transform the decision logic inherent within a CPG into executable logic-based decision rules; (iii) Execute the computerized CPG based on patient information, in order to provide CPG-mediated, patient-specific recommendations; and (iv) Justify the CDSS's recommendations by providing CPG-based explanations. The Semantic Web purports the semantic modeling and markup of knowledge, its properties and its relations using well-defined semantics such as formal definitions of terms, ontological definitions of domain concepts and resources. The semantically modeled knowledge can then be operationalized via proof engines employing logic-based reasoning methods to infer 'trusted' solutions.

In this paper we present a Semantic Web based framework for developing CDSS. The key elements of our framework are (a) modeling the CPG knowledge and (b) executing the CPG knowledge. To model the entire working environment and knowledge essential to derive a CPG-based recommendation, we developed three unique ontologies as follows: (i) A CPG Ontology that models the computerized structure of the CPG. We model the CPG using the Guideline Element Model (GEM) [4] structure, and therefore our CPG ontology is based on the GEM DTD; (ii) A Domain Ontology, in OWL, that models the CPG's medical knowledge; and (iii) A Patient Ontology that models the patient in terms of various health information. We used Protégé [5] to develop all the ontologies.

Our CDSS is divided into two main modules, namely CPG Encoding Module and CPG Rule Authoring and Execution Module. The CPG Encoding Module is used to encode the text-based CPG into the CPG ontology and to annotate the decision variables and logic structures inherent within the CPG. Both the CPG Ontology and the Domain Ontology are used for CPG encoding. The CPG Rule Authoring and Execution Module is used to define the decision logic rules in a CPG and to execute them based on patient data. A novel feature of our CPG Execution Module is that it provides an automated justification trace of inferred recommendations. Figure 1 shows the architecture of our Semantic Web based CDSS.

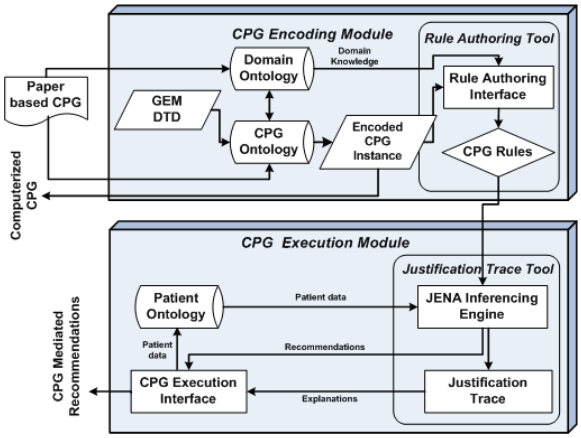

Figure 1- System Design of our CDSS

CPG Encoding Module

The CPG encoding module comprises two components: (a) a CPG representation formalism to convert the paper-based CPG into an electronic format; (b) a CPG ontology to model the structure of the CPG; and (c) a patient ontology to describe the characteristics of a patient. The *CPG Ontology* is based on the GEM DTD [4]. The *Patient Ontology* mirrors an Electronic Patient Record (EPR) and models a patient in terms of various health information and patient clinical situations.

CPG Rule Authoring and Execution Module

The CPG Rule Authoring and Execution module is designed to capture the CPG's clinical decision making logic in terms of logical rules—the logical rules were executed by a reasoning engine to derive CPG-based recommendations given a patient health record. To achieve the above functionality, we built three sub-modules namely, Rule Authoring Sub-Module, Execution Sub-Module and Justification Trace Sub-Module.

Rule Authoring Sub-Module uses the GEM encoded CPG to allow the user to identify the logical constructs within the CPG and define them as CPG (decision logic) rules using our CPG Rule Syntax. Upon completion of the rule authoring process, we apply a rule transformation algorithm to transform the CPG rules into the JENA syntax so that they can be executed the Execution Sub-Module that leverages the JENA inference engine [6].

Execution Sub-Module invokes the JENA inference engine to execute a CPG in order to infer recommendations based on patient profiles. We model instances from the Domain Ontology, CPG Ontology and Patient Ontology as RDF graphs, which serve as the knowledge base for JENA. JENA inference engine uses both the knowledge base and the CPG rule-set in a backward reasoning mode to infer CPG-mediated recommendations based on the given knowledge.

Justification Trace Sub-Module generates a justification trace of the rule execution to assist medical practitioners in understanding the logic behind the inferred recommendations. The justification derivation includes the linear representation of premises (facts) under which the JENA rules are satisfied and the conclusions based on those rules. The justification trace initiates with a derived patient recommendation (derived facts) from the JENA model (knowledge base) and generates facts which served as premises for deriving the patient recommendation, recursively.

The working of our CPG Authoring and Execution Module involves the following sequence of actions: (a) Input a text-based CPG and loads its pre-defined Domain Ontology and the Patient Ontology; (b) Encode the CPG in terms of the CPG Ontology and the Domain Ontology; (c) Specify the CPG (decision) rules. The CPG rules are transformed to JENA rule syntax and passed to the JENA reasoning system; (d) Execute the CPG based on a given patient instance to infer CPG-mediated recommendations; and (e) Justify the inferred recommendations through a justification tree.

Concluding remarks

The Semantic Web provides an interesting framework both for modeling and executing a CPG. Our Semantic Web based approach for CDSS development features the integration of multiple ontologies—we integrated two ontologies, each representing the form and function of a CPG—i.e. the *Domain Ontology* describing the CPG function and the *CPG Ontology* representing the CPG structure. We presented an intuitive CPG rule syntax that medical practitioners can use to write clinical decision rules from the CPG. We internally transformed the CPG rules into a complex rule syntax so that they can be executed via a inferencing engine to infer CPG based recommendations for a specific patient. Using our CDSS development approach we have developed two CDSS—i.e. (a) Breast Cancer Follow-up and (b) Imaging radiation protection—each based on a specific CPG.

The use of CPG in a CDSS not only provides an evidence based knowledge-base, but it relives CDSS developers from the perennial knowledge engineering problem. By design, CPG entail a decision logic that is structured in an algorithmic format that can be used to generate explicit symbolic clinical decision-support rules to suggest CPG-guided clinical recommendations. The knowledge management paradigm of the Semantic Web extends a logic-based framework to semantically model medical knowledge to provide a variety of knowledge-mediated services. Our CDSS approach is quite generic and can be extended to other medical problems.

Using GLIF and GLEE to Facilitate Knowledge Management in Development of Clinical Decision Support Systems

Dongwen Wang[a], Mor Peleg[b]

[a]*Biomedical Informatics Program, University of Rochester, USA*
[b]*Department of Management Information Systems, University of Haifa, Israel*

Abstract

Effective knowledge management is a critical challenge to development of clinical decision support systems (CDSSs). We have been using the GuideLine Interchange Format (GLIF) and the Guideline Execution Engine (GLEE) to facilitate knowledge modeling, adaptation, and validation for CDSSs that address a variety of healthcare problems. Based on a review of case studies, we synthesized three major functions of GLIF and GLEE during this process: (1) improving communication between CDSS developers and domain experts, (2) facilitating fast prototyping of CDSSs, and (3) providing multi-stage system validation. We argue that development of CDSSs should start from analyses of user needs and identification of knowledge sources, followed by an evolving process with multiple rounds of conceptualization, encoding, simulation, and evaluation. Our review has shown that GLIF and GLEE can be used effectively to facilitate this process.

Keywords:

clinical decision support systems,
knowledge management, practice guidelines,
GLIF, GLEE

Introduction

Development of clinical decision support systems (CDSSs) needs effective translation of domain knowledge and their adaptation to specific application environments. We have been using the GuideLine Interchange Format (GLIF) and the Guideline Execution Engine (GLEE) as tools to facilitate knowledge management for a variety of healthcare problems. In this paper, we review our experience of using GLIF and GLEE for knowledge modeling, adaptation, and validation, focusing on analyses of their specific functions and examinations of the overall process.

Methods

Our analyses included two aspects: (1) the specific functions provided by GLIF and GLEE in development of CDSSs, and (2) the overall process to use GLIF and GLEE for CDSS development. The examinations were based on data of specific case studies drawn from finished or ongoing projects. These data were then integrated and synthesized along the two dimensions of function and process. A variety of healthcare problems have been addressed by these case studies, including childhood immunization, cough management, influenza vaccination, hyperkalemia screening, diabetic foot care, post-CABG recovery, depression screening, and tobacco cessation.

Results

Functions of GLIF and GLEE in development of CDSSs

Improving communication between CDSS developers and domain experts

Improving communication between CDSS developers and domain experts is one of the most challenging issues in development of CDSSs. Effective communication between CDSS developers and domain experts is especially important when decisions need to be made to extract and to translate specific pieces of domain knowledge from their original sources, to organize knowledge in well-defined structures, and to identify the potential points in healthcare processes where interventions can be delivered in appropriate formats. The GLIF model provides a conceptual-level representation of healthcare processes using a flowchart-like graphical presentation. This level of representation and visualization has been used intensively in development process to exchange ideas between CDSS developers and domain experts. Paper-based flowcharts have also been used widely for conceptualization purposes, but typically with various problems from computational prospective. In contrast, the flowchart-like algorithm in GLIF is supported by the underlying computational model. Thus, once the conceptual-level algorithm is developed, it can be directly used for computational purposes. An important aspect in development of an algorithm is its testing through the stand-alone user interface of GLEE, which can simulate the execution of specific patient cases through particular paths of the algorithm. These features of GLIF and GLEE can significantly improve the effectiveness and efficiency of communication when presenting the encoded knowledge base to domain experts and seeking their feedback.

Fast prototyping for knowledge modeling and adaptation

Development of CDSSs is an evolving process that typically requires multiple rounds of knowledge encoding, modification, and validation. During this process, fast prototyping of a knowledge base can significantly improve the efficiency of development. With the three-level representation of GLIF (the conceptual flowchart, the computation model, and the interface for integration and implementation) and the simulation function of GLEE, their combination as a tool set provides a unique and powerful testing environment for CDSS development such that the knowledge base of a CDSS can be prototyped without the need to be fully integrated with the final applications. The ability to create such prototypes and test them quickly was essential to the iterative and interactive process of CDSS development.

Facilitating multi-stage system validation

System validation is a critical step in CDSS development. Since development of CDSSs requires significant investment of resources, identifying system errors in early stages of development is important. The combination of GLIF and GLEE provides a unique chance to discover potential problems earlier and thus to prevent/reduce expensive errors in later stages. Specifically, the conceptual level flowchart-like algorithm of GLIF has been used widely to facilitate communication between CDSS developers and domain experts, which can significantly improve mutual understanding on organization of medical knowledge and their adaptation to local practices and settings at an early stage of development. In addition, the simulation function of GLEE that can be used to examine the execution path of an individual patient case provides an added value for validation, as this approach can be easily understood by clinicians. Finally, the batch execution mode of GLEE can be used to process large-scale simulation data that can be further analyzed with powerful statistical methods for formal evaluation.

Overall process of ssing GLIF and GLEE to facilitate knowledge management in development of CDSSs

Based on the findings documented or reported in case studies, we summarize an overall process to use GLIF and GLEE for development of CDSSs. This process consists of 12 steps: (1) identifying clinical needs of a system; (2) identifying knowledge sources; (3) initializing communications (first round) or reviewing results (later rounds) with domain experts to conceptualize or to modify system functions; (4) defining specific clinical tasks, decisions, and care processes along with the patient data required to perform the tasks and to make the decisions; (5) working with domain experts to identify potential points of interventions in care processes; (6) encoding an algorithm to conceptualize the clinical tasks, decisions, and processes; (7) encoding the specifications at computational levels; (8) performing simulations on individual patient cases; (9) performing simulations in a larger scale for formal analyses; (10) designing appropriate interventions at specific points of care processes and integrating system components; (11) deploying system and evaluating its actual use; and (12) maintaining system. It is important to note that development of CDSSs is an evolving process. It typically requires multiple rounds of conceptualization, encoding, simulation, and evaluation for successful development of a system.

Discussions

We identified three major functions and a twelve-step process of using GLIF and GLEE to facilitate knowledge management for CDSS development. Compared with other research, our unique contribution is to focus on facilitating communication between CDSS developers and domain experts. Based on many years' experience in development of CDSSs, we observed that it is unnecessary or infeasible to translate each and every piece of information from the original paper sources into a CDSS. The medical knowledge behind the useful features of a CDSS is typically a combination of small pieces of information from multiple origins. Thus, we have been moving toward an approach to starting from analyses of clinical needs and identifying the knowledge sources that can support these needs. The subsequent steps of conceptualization, encoding, simulation, and evaluation all serve for this original goal. We believe it is more promising to develop CDSSs with such clearly-defined, user-required, and focused objectives. This approach is also consistent with the theory of user-centered system design that has been widely reported in human-computer interaction research.

There are a few limitations of our studies. First, most of our experience up to now is only to use GLIF and GLEE for knowledge modeling. The actual integration of knowledge base with real world applications will introduce many further challenges. Steps 11 and 12 of the overall process summarized in the result section thus need to be further examined, refined, and reported. Second, we only focus on CDSSs that deliver patient-specific recommendations, while delivering of generic (vs. patient-specific) information in the right context can also generate significant positive impacts. In this scenario, a document model or a hybrid model can play an important role, which is what GLIF and GLEE lack of. Finally, GLIF is not a comprehensive process model. For example, it does not support quantitative temporal modeling, and it is not based on formal logic. Thus, it might not be the best choice to use GLIF for applications with such requirements.

Conclusion

GLIF and GLEE can be used as a set of tools in CDSS development to improve communication between CDSS developers and domain experts, to facilitate fast prototyping of CDSSs, and to provide multi-stage system validation. These functions are embedded within an evolving process with multiple rounds of conceptualization, encoding, simulation, and evaluation. Future studies are required to investigate the use of GLIF and GLEE in deployment of CDSSs.

Tooth Positional Ontology Represented in OWL

Seon Gyu Park, Hong-Gee Kim, Myeng-Ki Kim

Department of Dental Management & Informatics, College of Dentistry, Seoul National University, South Korea

Abstract

In the practice of dentistry, few biomedical ontologies exist that support dentists' decisions or meet their clinical needs. Unlike other medical domains, a dental concept requires specific identification in terms of position. In order to assist with dentists' clinical tasks, we created a tooth ontology in Web Ontology Language (OWL) with embedded spatial relations. In this paper, we share our experiences in building and maintaining this tooth ontology.

Keywords:

tooth ontology, OWL, biomedical ontology

Introduction

Representing knowledge in a medical domain is advantageous for supporting decisions based on clinical judgment and reusing patient information for clinical research or quality assessment. An ontology provides a way to compile medical knowledge in a reusable, sharable, machine-understandable way. In medicine, research on biomedical ontologies is a response to the need of handling large volumes of patient data in a more comprehensible and effective way [1].

Although the current ontologies are designed to minimize ambiguities and redundancy, none of these ontologies have been used in dentistry. The main reason for generally accepted mereological relations, such as **part-of** and its inverse **has-part**, are complex in *classes* between material and nonmaterial entities, parthood over time, parthood and spatial location, and parthood between occurrents [2]. Ontologies built in a given domain must be foundational and robust with regard to interpretation, to prevent human-dependent semantic bias.

We do not argue that **part-of** and **has-part** are the most important roles in a biomedical ontology, but we must address the necessity of identifying more specific spatial relations. A more detailed expression may be needed to define the positional relationships among the anatomical structures in the oral and maxillofacial region, compared to other body structures.

Materials and methods

Each adult human has 32 teeth distributed evenly, with eight teeth in each quadrant: the central incisor, lateral incisor, canine, first premolar, second premolar, first molar, second molar, and wisdom tooth. Incisors and canines are front teeth that are essential to one's appearance. Premolars and molars are located in the back of the oral cavity and play an important role in chewing and digesting food. In other words, we can divide teeth into two categories: anterior (front) teeth and posterior (back) teeth.

There are four central incisors, which are classified by position as left, right, upper, and lower. When we refer to a tooth as a *Central_Incisor*, we do not know which is being indicated. To identify whether a specific tooth is positioned on the left or right, three different dental notation systems are commonly used: the universal numbering system, the Palmer Notation Method, and the two-digit World Dental Federation (FDI) notation. In this paper, we adopt the two-digit FDI notation, which is also known as the ISO-3950 notation. We insert this notation in the *ToothNumber* class.

There are three different relations connecting a physical entity to the positional quality. These properties take their ranges with their positional quale from the *Positional_Value_Partition,* which has six leaf subclasses: *Anterior, Posterior, Right, Left, Upper*, and *Lower.* The value of **hasAP_Position** is either *Anterior* or *Posterior*, the value of **hasRL_Position** is either *Right* or *Left*, and the value of **hasUL_Position** is either *Upper* or *Lower.*

In order to use the *Anterior* class as the only representation of "Anterior" value, we made **hasAP_Position** as a functional property with the restricted domain such as *Anterior* and *Posterior*. A functional property is a property that every individual to which the property applies has at most one image along the relation [3].

The class *ToothNumber* has 32 subclasses, which have the three properties listed above: **hasAP_Position, hasRL_Position,** and **hasUL_Position**.

To build and share our ontology more consistently and unambiguously, we adopted formal relationships in biomedical ontologies [4]. Since we can select symmetry as a characteristic of **co-adjacent_to** in OWL, we use it as a

vehicle to connect neighbors. For example, *W11,* one of the subclasses of *ToothNumber,* is a neighbor to *W12* and *W21*.

We defined *AnteriorTooth* that has only the **hasAP_Position** property linking to the class *Anterior* using a closure axiom [5]. Similarly, we made the classes *PosteriorTooth, LeftTooth, RightTooth, UpperTooth,* and *LowerTooth*, for the purpose of identifying position.

We can infer a class as part of another class based on this definition, which is strength of description logic. The following shows the results after classification.

Results

Given the definition of our tooth position ontology written in OWL, we expect that any tooth located anteriorly to be in the appropriate subclass of the *AnteriorTooth* class. **has_Position** relations tie the positional concept to all relevant classes. There is no inconsistency. From this result, we easily recognize which the *ToothNumber* class is in a subsumptive relation to the class *AnteriorTooth.*

Discussion

In light of the above results, we can observe the arbitrary classification of the classes *ToothName* and *ToothNumber* into the expected positional classes depending on the user's intention (*e.g., AnteriorTooth, LowerTooth*). This positional concept of teeth helps to build a dental decision support system that lets the computer know where a tooth is positioned [6].

In addition, one can modularize the other tooth-related concepts such as dental materials and dental treatments using our pre-defined positional ontology, so that the maintainability, reusability, and interoperability are easy to obtain. They are crucial features in ontology development written with OWL.

Smith et al. [4] showed that consensus was recently reached concerning the foundational relationships in biomedical ontologies. However, the real application of temporal relations has a weakness in weaving binary ontological plots with OWL. Interestingly, the temporal concept requires more than two arity, which is impossible in OWL. Although there are several approaches to enable OWL with n-arity relations, we cannot find a formal methodology to incorporate temporal concept to our ontology within OWL. Because of that, we just employ spatial relations of the several proposed relations of *Smith et al.* [4] into our tooth positional ontology written with OWL. Above practice, the application of temporal relations leaves some issues unanswered, even though temporal perspective can be a fundamental role in dentistry in order to define a missing tooth and a milk tooth sufficiently.

Conclusion

This paper shows how spatial relations are specified using a special property (**has_Position**). Well designed properties help the ontology engineer to grasp clear definitions and usage. Here, the powerful interdependent concept classification in OWL-DL allows us to build our modularized ontology.

Identifying the position of a tooth is crucial in a dental ontology since ontology users must identify a specific tooth in order to make a correct decision. For example, a tooth colored restoration should be used for a decayed anterior tooth. The main limitation of our approach is due to simplification, for which well-designed relations in OWL-DL are still necessary.

Affiliation of a Resource Type to a MeSH Term in a Quality-Controlled Health Gateway

Stéfan J. Darmoni[a], Benoit Thirion[a], Filip Ionut-Florea[a], Alexandrina Rogazan[a], Catherine Letord[a], Gaétan Kerdelhué[a], Jean Nicolas Dacher[a]

[a] *CISMeF, Rouen.University Hospital & GCSIS, LITIS EA 4051, Institute of Biomedical Research, University of Rouen, France*

Introduction

Among several quality-controlled health gateways, CISMeF ([French] acronym for Catalog and Index of French Language Health Resources on the Internet) was designed to catalog and index the most important and quality-controlled sources of institutional health information in French in order to allow end-users to search them quickly and precisely (N=14,714). CISMeF is manually indexed by a team of four indexers, which are medical librarians and systematically checked by the chief information scientist (the "super-indexer"). Its URLs are http://www.chu-rouen.fr/cismef or http://www.cismef.org.

CISMeF uses two standard tools for organizing information: the MeSH thesaurus and several metadata element sets, in particular the Dublin Core metadata format (URL:http://www.dublincore.org). The use of specific metainformation is crucial in order to improve the recall and precision of internet searches As proposed by Hoelzer et coll., CISMeF uses XML and RDF to meet these requirements.

The heterogeneity of Internet health resources led the CISMeF team to enhance the MeSH thesaurus with the introduction of two new concepts, respectively resource types (RT) and metaterms (MT). CISMeF resource types (RT) are an extension of the publication types of MEDLINE. As defined by the Dublin Core Metadata Initiative (URL: http://www.dublincore.org/documents/dcmi-terms/), a RT is used to categorize the nature or genre of the content of the resource. MeSH (term/subheading) pairs describe the topic of the resource. RT is one of the fifteen Dublin Core repeatable and optional elements.

However, the MeSH thesaurus was originally intended to index scientific articles for the MEDLINE database. In order to customize it to the broader field of health Internet resources, we have been developing several enhancements to the MeSH since 2000, including the generalization of Major/Minor weights to RT and MT.

The goal of this article is to describe and to evaluate another new enhancement of the CISMeF terminology: affiliation of a RT to a MeSH term or to a MeSH (term/subheading) pair. The main idea is to obtain a new affiliation concept [MeSH (term/subheading)\CISMeF RT] constituting a triplet, in order to be more precise during the manual indexing process and therefore during the information retrieval process. Affiliation of a RT is similar conceptually to the affiliation of SH, taking into account the respective definitions of a RT and a SH (see above).

Materials and methods

Background

Compared to the publication types of MEDLINE, the CISMeF RTs are more diverse, with specific RTs dedicated to electronic health resources, such as *association, patient information, community networks*, or *clinical guidelines*. For example, in the case of a clinical guideline about carbon monoxide intoxication, 'carbon monoxide poisoning' is the MeSH term and 'clinical guidelines' is the resource type. CISMeF RTs are organized similarly to MeSH terms and subheadings, in a hierarchical structure with subsumption relationships (allowing the explode property) and a maximum of five-level depth. The MEDLINE publication types were mainly a flat list till 2005 (see URL: http://www.nlm.nih.gov/mesh/pubtypes2005.html). Since 2006, MEDLINE publication types has also a hierarchical structure. The overall number of resources types in December 2006 is 257.

Nonetheless, this list is largely inspired by the MeSH thesaurus as 187 RTs (76%) are deliberately ambiguous because they are also MeSH terms (e.g. magnetic resonance imaging). The objective of this ambiguity is to maximize the recall then the search answers (which means the Doc'CISMeF search ORes the answers for the MeSH term and the answers for the RT) when the request contains this kind of ambiguous term. Furthermore, to be as close to a standard as possible, 28 RTs (11%) are also MEDLINE publication types (e.g. technical

Affiliation

In April 2004, the creation of medical image types led us to propose a refinement of the CISMeF terminology and thus a refinement of manual indexing procedures: for a number of specific RTs, mainly images types but not exclusively (e.g. *multiple choice quiz* also applies here),

we proposed to affiliate a RT to a MeSH term or to a MeSH (term/subheading) pair. Thus we can obtain a [MeSH (term/subheading)\CISMeF RT] triplet, where the backslash character '\' represents the RT affiliation (the slash character / represents in MEDLINE the affiliation of subheading to a term). This approach can be viewed as an extension of the affiliation of a subheading to a MeSH term. Since April 2004, all the CISMeF resources indexed with an image RT (N=1288 out of 14,714; 8.8%) have been reviewed by the five CISMeF medical librarians to check the need of any affiliation of a RT.

Evaluation

To evaluate the precision of the affiliation of RTs, we have selected the 15 diseases from the C and F MeSH trees which are the most frequently used for the indexing in the CISMeF catalogue. For the RT, we have chosen the top level hierarchy "image" because it is the most used RT for affiliation. For each MeSH term, two requests were performed: one request with floating RT (MeSH term AND image) and one request with affiliated RT (MeSH term\image). We compared the precision of the affiliation of RTs with the affiliation of subheadings in the same catalogue. We have used the most frequently employed subheading in the CISMeF catalogue: therapy (N=4,267, 29.0% of the catalogue).

Results

The number of resources with at least one affiliation of a RT is 412 (2.8%) in the overall CISMeF catalogue. This figure is significantly lower than the number of resources with at least one affiliation of a SH (N= 8,110; 55.1%; p<0.0001; Mac Nemar's test). A significant difference was also present in the evaluated sample (see Table 1) between the number of resources with at least one affiliation of a RT vs. the number of resources with at least one affiliation of a SH (39/2,019 (1.9%) vs. 1,001/2,019 (49.6%); p<0.0001; Mac Nemar's test). The number of resources with at least one affiliation of a RT (and of a SH) in the last 500 resources included in CISMeF is higher when compared to the overall catalogue. (173/500; 34.6% for RT vs. 415/500; 83.0% for SH). Nonetheless, in the sample of the last 500 resources included in CISMeF, there is still a significant difference between the number of resources with at least one affiliation of a RT vs. the number of resources with at least one affiliation of a SH (p <0.0001; Mac Nemar's test).

Furthermore, the average use of RTs per resource is also significantly lower than the average use of SHs in the overall CISMeF catalogue (1.95 vs. 4.47, p <0.0001; paired Student's T test). This result is correlated by the significant difference between the number of resources with the floating RT image (Request: MeSH term AND image) vs. the number of resources with the floating subheading therapy (Request: MeSH term AND therapy) in the evaluated sample: 344 (17.0%; 344/2,019) vs. 1,368 (67.8%; 1,368/2,019) (p <0.0001; Mac Nemar's test). In the evaluated sample, to measure the precision of the affiliation of RTs, we compared the number of resources affiliated with at least one RT of the RT tree "image" vs. the number of resources with a floating RT image (Request: MeSH term AND RT image). The ratio is 39/344 (11.3%). Therefore, in our sample, a request with an affiliated RT is nine times more precise than the equivalent request with a floating RT.

Then, to measure the precision of the affiliation of SHs, we compared the number of resources affiliated with the SH "therapy" vs. the number of resources with the floating SH "therapy" (Request: MeSH term AND SH therapy). The ratio was 1,001/1,368 (73.2%). In our sample this means that a request with an affiliated SH is only 1.3 times more precise than the equivalent request with the floating SH. The possibility to affiliate RTs has been implemented in the Doc'CISMeF search engine in every search mode (Simple, Advanced, Boolean, and Step by Step). Nonetheless, by default, this improvement will not modify the information retrieval process in the Doc'CISMeF search engine (URL: http://doccismef.chu-rouen.fr), in the Simple Search mode. As described in , this information retrieval process is based by default on implicit query processing and the algorithm is based on maximizing the recall. Implicit query processing means that the end-user does not interact with the system to improve the quality of the information retrieval. In that case, the search engine tries to maximize the mapping of the end-user's request to the CISMeF terminology. This CISMeF mapping algorithm has similarities with PubMed's Automatic Term Mapping.

For example, an ambiguous query such as "Diagnosis of choledocholithiasis with ultrasonography", will be transformed into the following Boolean query in order to provide the user with the wider range of documents likely to meet their needs, using MeSH terms, floating SHs and floating RTs: "diagnosis AND choledocholithiasis AND ultrasonography". Nonetheless, a trained user may use the affiliation of RTs (combined or not with the affiliation of SH) to obtain a more precise retrieval process. In the last example, the user may enter the triplet "(choledocholithiasis/diagnosis)\ultrasonography" to be as precise as possible if s/he is searching for an image of ultrasonography to diagnose choledocholithiasis.

To lead CISMeF users to use this refinement among others enhancements of the CISMeF terminology, two training sessions are organized on a monthly basis by the CISMeF team, targeting mainly medical students, as well as librarians and health professionals. How to use the affiliation of

RT will part of the training session as it is already the case for affiliation of a subheading.

Conclusion

Affiliation of a RT to a MeSH (term/subheading) to create a triplet allows a better precision of the information retrieval in a quality controlled health gateway

Applying AI Model-Checking Techniques to Clinical Guidelines

Laura Giordan[a], Alessio Bottrighi[a], Stefania Montani[a], Paolo Terenziani[a]

[a]*DI, Univ. del Piemonte Orientale "Amedeo Avogadro", Spalto Marengo 33, 15100 Alessandria, Italy,*
E-mail: {terenz, alessio.bottrighi, laura, stefania}@mfn.unipmn.it

Abstract

We describe the advantages of extending computer-based approaches to clinical guidelines with the facilities provided by model-checkers developed by the AI community.

Introduction and background

Clinical guidelines represent the current understanding of the best clinical practice, and constitute an important area of research in Artificial Intelligence (AI) in medicine. Several computer-based approaches have been introduced to automatically manage clinical guidelines. GLARE (Guideline Acquisition, Representation and Execution) is a prototypical system which has been built from 1997 under the leadership of physicians of Az. Osp. S. Giovanni Battista, Turin, Italy [1]. It is a domain-independent system to acquire, represent and execute clinical guidelines, which has been tested on several guidelines, including asthma, cardiac diseases, ischemic stroke.

Recently, in AI, the *model-checking* techniques have gained an important role. They are widely used, e.g., for agent verification. In this work, we extend GLARE to explore the advantages of applying such techniques to clinical guidelines.

Methods

In order to enhance GLARE with model-checking facilities, we provided a loosely-coupled integration of GLARE with the model-checker SPIN [2]. Roughly speaking, we have devised a tool to map clinical guidelines acquired by the GLARE system into the Promela language, which is the language used by SPIN. Promela allows a high level model of a distributed system to be defined in an extended pseudo-C code, including synchronization primitives and message exchange primitives. Once we have the translation of GLARE's guidelines in Promela code, we can use SPIN as a general-purpose engine to prove any property that can be expressed in the temporal logic LTL. In fact, SPIN automatically translates each process defined in the Promela code into a finite automaton representing the global state space of the system, and the global behaviour of the system is obtained by computing an asynchronous interleaving product of automata. The property which has to be verified on the system is passed to the verifier through an interface, which maps it into a temporal formula, as required by SPIN. SPIN automatically converts the negation of the temporal formula into an automaton and computes its synchronous product with the system global state space. If the language of the resulting automaton is empty then the property is true on all the possible execution of the system (otherwise the verifier provides a counterexample for the property).

Results

The methodology above provides a way of providing GLARE with the possibility of automatically checking several types of properties concerning guidelines. Specifically, we have identified four different classes of properties:

i) **Properties concerning a guideline "per se"**. One can check if the guideline contains a path of actions satisfying a given set of conditions (e.g., a path including actions X, Y and Z, or a path nor requiring a given laboratory test, or a path requiring only a given set of resources, and so on);

ii) **Properties of a guideline in a given context.** Specific contexts may impose limitations on executable actions, related, e.g., to the lack of resources (e.g., laboratory instruments). The consequences of such limitations may be automatically checked using the model checker. For instance, the model checker can prove whether there is or not a therapy for a patient affected by a given disease, in the case a specific set of resources is available (not available).

iii) **Properties of a guideline when applied to a specific patient.** Provided that the model checker has in input all the data in the patient record, the feasibility of a given action or path of actions on the patient can be proved.

iv) **Integrated proofs.** Since SPIN is flexible and task-independent, any combination of the above types of proofs is feasible. E.g., one may ask whether, given a patient with a specific disease and set of symptoms, and given a specific set of resources, there is a path in the guideline which applies to the patient and satisfies a given set of properties.

Development of a Specialist Medical Vocabulary for Radiation Oncology

A. Andrew Miller[a], Ping Yu[b]

[a]*Department of Radiation Oncology, Illawarra Cancer Care Centre, The Wollongong Hospital, Wollongong, Australia*
[b]*Health Informatics Research Centre, School of Information Systems and Technology, University of Wollongong, Australia*

Abstract

Controlled specialist medical vocabularies (SMV) include some terms used in Radiation Oncology (RO), although no objective specification of the specialist medical terms used in RO has been published.

We are developing a Specialist Medical Vocabulary for Radiation Oncology (SMV-RO) using an objective and systematic method of discovery of data elements. The importance of any data element to radiation oncologists is judged according to the criterion that it was included in a report deemed worthy of publication in the RO literature.

From a defined period, 97 articles were retrieved. Analysis of 80 articles found 622 individual data elements and 2392 instances of use. Infrequent data elements comprised the majority of individual data elements (54%), and frequently used data elements were a minority (27 individual data elements with 10 or more instances of use). However these 10 data elements comprised 49.5% of the total data elements found.

Keywords:

vocabulary, controlled, radiation oncology, clinical,
specialist medical vocabulary,
oncology information system

Introduction

Radiation oncologists are medical specialists who treat cancer patients with high energy x-rays and work with software designed to minimize human error in the delivery of radiation to patients which also includes an electronic medical record module (the OIS-EMR).

Specialist Medical Vocabularies (SMV) list standardized terms devoid of relationships [1], but are the first step in defining ontologies. Any SMV should undergo frequent review to addressing inadequacies [2] as clinically unused SMVs appear to decay over periods of only 4-5 years [3].

Clinical data in a SMV format informs clinical decision making [4] and clinical outcomes, but must be stored in matching data structures in the OIS-EMR. This will enable successful data retrieval with its standardized meaning intact, which is a requirement for successful implementation of a national electronic health record (EHR) which derives its information for patient interaction.

The oncology data is a small proportion of a patient's EHR. A SMV for Radiation Oncology (SMV-RO) has not been developed, although there is some overlap with general terminologies (MeSH thesaurus, SNOMED), and specific collections (NCI's Common Data Elements dictionary for oncology trials [5]).

Research aims

We aim to document the SMV used in the domain of RO.

Research methodology

The SMV-RO should be determined by systematic extraction of terms from a corpus of text which is carefully sampled to be maximally representative.

The corpus that informs the practice and knowledge of RO is the published literature. The importance and relevance of the data sets used in the literature is determined by its acceptance for publication after peer review.

Content analysis can analyze and classify written communications in conjunction with domain specific knowledge. A methodology of "*text deconstruction*" was developed and applied by a radiation oncologist (AAM) to find and list the data elements used in a report's description of data collection, measurement and analysis. Aggregation of these data elements formed the SMV-RO. The initial manual analysis establishes a gold standard within a well defined corpus of the literature, against which to later compare automated tools.

A focused PubMed search was undertaken for articles describing the use of radiotherapy in the month of February 2006 (search "Major MeSH Heading [Radiotherapy] AND 2006/02[pdat]"). Other specialist RO journals, general oncology journals and general medical journals were also surveyed.

Results

The data collection and analysis for the first 97 articles are presented, which revealed 622 data elements used in the analysis or description of study groups. Seventeen articles did not include patient data and were excluded.

A total of 2392 instances of data element were catalogued (mean of 3.8 instances/data element). The data elements were unevenly distributed as is seen in Table 1.

Table 1 - Distribution of data elements

Frequency of occurrence	Individual data elements (count)	Total number of occurrences (sum)	% of data elements (count)	% of occurrences (sum)
5n1	523	886	84.1	37.0
10n6	44	331	7.1	13.8
15n11	25	308	4.0	12.9
20n16	9	163	1.4	6.8
25n21	3	69	0.5	2.9
30n26	6	168	1.0	7.0
35n31	3	100	0.5	4.2
40n36	5	187	0.8	7.8
45n41	2	83	0.3	3.5
50n46	2	97	0.3	4.1
55n51	0	0	0.0	0.0
60n56	0	0	0.0	0.0
Total	622	2392	100	100

The commonest data elements used include: Diagnosis (n=65), Date of Birth (n=50), Histology (n=47), Surgery Decision (n=42), Radiotherapy Decision (n=41), and Date of Death (n=38). Data elements seen once were commonest (345 occurrences), but while one to five occurrences produced 37% of the total elements found, the remaining 15.9% of data elements produced 64% of the total elements found.

Inferred data elements were common. The most frequent inferred data element is the date of event which has preeminence in the analysis of outcome in oncology reports.

Data elements were categorized into physical and temporal separations within the oncology treatment and management process as shown in Table 2.

Table 2 - Distribution of data elements within the Corpus

	Individual data elements	Total frequency of	Entries per data element (mean)
PATIENT	305	1044	3.4
Disease	240	764	3.2
Diagnosis	35	429	12.3
THERAPY	258	1232	4.8
Surgery	15	151	10.1
Radiotherapy	111	453	4.1
Drugs	20	106	5.3
Chemotherapy	71	335	4.7
Other Therapy	1	2	2
OUTCOMES	60	181	3.0
Recurrence	14	99	7.1
Response	8	37	4.6
Patient Milieu	**341**	**576**	**1.7**

Many data elements defined the tumour's characteristics (e.g., oncogenes expressed). The 'Patient Milieu' group comprises patient assessments of anatomy (imaging), physiology (blood tests), psychology (Quality of Life items), and clinical status (signs & symptoms) undertaken initially, while on treatment and after treatment, and constituted 54.8% of the total, and were used infrequently (mean 1.69 entries/data element).

Discussion

Assessments form a very large part of this SMV, although the usage frequency is low. The correlation of biological factors with clinical outcome may improve cancer therapy and indicates that authors should itemize their data sets (data elements and choices) to permit similar data collection. Other departments should be able to include new assessments into the OIS-EMR to permit medical staff to assess and record data in identical formats for later analysis. The Common Data Elements approach of the NCI is a relevant example and easily reviewed for potential terms [5].

The lack of relationships between terms within this specialist medical vocabulary were apparent. The data elements discovered always related to an event related to a patient, a patient's diagnosis, or the patient's treatment for their diagnosis. When the vocabulary is used to define an ontology and OIS-EMR, the storage of these terms should allow for reconstruction of the relationships present at collection. For example, an assessment of an entity such as depression could be measured as a psychological factor as well as part of a Quality of Life Assessment, an eligibility factor for an intervention, or a biological factor modifying the response to therapy, a prognostic factor predicting outcome, or an outcome of therapy.

To cover the complete range of assessment terms is impossible by the method we have used. The dynamic nature of oncological knowledge argues for the establishment of a modern data set with periodic updates [8], ideally through the submission of data sets by the authors of the published reports as part of the submission for publication.

Conclusion

While the vocabulary is a starting point that has successfully demonstrated that specified terms used in Radiation Oncology can be derived from the Radiation Oncology literature, further work remains to reflect the complexity of this vocabulary by the inclusion of concepts and relationships, in particular any ontology must explicitly quantify the time of measurement [6]. Future work should map this vocabulary into other systematic nomenclatures (SNOMED, DICOM, and ultimately the UMLS), as well

as seek software methods to automate discovery of new terms.

The nature of many terms already discovered argues that the OIS-EMR should possess an assessment tool that can assign assessments to the correct setting, that are scalable to include many data elements that are used infrequently and are able to be drawn from established nomenclatures.

Specialist Medical Vocabulary For Radiation Oncology

Conclusions

- This specialist medical vocabulary (SMV) defined manually from the literature can act as a gold standard for later automated efforts
- The SMV of clinical notes should be compared
- The SMV should be mapped to 'standard' nomenclatures and ontologies (e.g., SNOMED-CT)
- OIS-EMRs should be constructed to hold this SMV, and respect their relationships, and allow units to reproduce the same data collection as reported in the literature
  - Reports submitted for publication might be more useful if they listed the data elements used

Introduction_1

- In Korea, the Government leads an Electronic Medical Record (EMR) system development for the 152 public health centers, and this is planned to be expanded to a national Electronic Health Record (EHR) system.

- As a part of this project, a study on the development of clinical decision support system (CDSS) is currently being undertaken.

Introduction_2

- This study is one step in the construction of a guideline-based CDSS that will be used for hypertension management in public care settings
- A development of domain ontology is an essential part in representing knowledge in a computerized method, but it is also important for the reuse of knowledge in the interesting domain area.
- For the sharing of medical knowledge nationwide, a knowledge management method such as ontology is the main issue from the point of view of CDSS.

Materials and Methods_1

- This ontology is primarily based on the concepts extracted from 12 published hypertension guidelines, including JNC 7.

- The hypertension management ontology provides formal definitions, relationships and usage of various concepts relevant to patients with hypertension.

Materials and Methods_2

- Concepts were defined at the modeling stage, and defined concepts were classified according to semantic category.
- Relations and attributes of concepts were defined, and the Protégé 3.1.1 environment was used.
- Because the development of ontology is an iterative process, the modification and reconstruction will be continuous during the process of guideline encoding.

Abstract

For the development of a guideline-based hypertension management system, ontology was adapted as a method for enabling me to represent and to reuse the domain guideline knowledge consistently. Based on 12 of the published guidelines, including the 7th report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of high blood pressure (JNC 7), concepts extracted from the guidelines on the hypertension management and relations between concepts were identified. This ontology includes 11 high-level classes and covers over 300 low-level concepts, and it also defines instances of each concept. This work will help to create a tool for acquiring more specific hypertension knowledge and will contribute to representing, managing and sharing knowledge logic. It will also be used in the further development of hypertension guidelines.

Keywords:

ontology, hypertension management,
computerizing clinical guideline,
knowledge representation

Introduction

In Korea, the Government leads an Electronic Medical Record (EMR) system development for the 152 public health centers, and this is planned to be expanded to a national Electronic Health Record (EHR) system. As a part of this project, a study on the development of clinical decision support system (CDSS) is currently being undertaken. This study is one step in the construction of a guideline-based CDSS that will be used for hypertension management in public care settings. A development of domain ontology is an essential part in representing knowledge in a computerized method, but it is also important for the reuse of knowledge in the interesting domain area.

For the sharing of medical knowledge nationwide, a knowledge management method such as ontology is the main issue from the point of view of CDSS. Ontology has often been used to formalize a shared understanding of a domain, and it enables software applications and humans to share and reuse knowledge consistently.

Materials and methods

This ontology is primarily based on the concepts extracted from 12 published hypertension guidelines, including JNC 7. The hypertension management ontology provides formal definitions, relationships and usage of various concepts relevant to patients with hypertension. Concepts were defined at the modeling stage, and defined concepts were classified according to semantic category. Relations and attributes of concepts were defined, and the Protégé 3.1.1 environment was used. Because the development of ontology is an iterative process, the modification and reconstruction will be continuous during the process of guideline encoding.

Results

In our ontology prototype, about 300 concepts relevant to hypertension management were defined. A medication prescription, laboratory test, physical examination and other related conditions were included in the related concepts. Based on all of this, high-level classes which contained medication, clinical finding, laboratory test, patient education, problem, patient case, event, rule, therapeutic adjustment, temporal predicate and eligibility criteria were defined as the main axis. Each class included subordinate concepts of is-a relation. After that, attributes of concepts were defined.

Conclusion

Through this approach, the creation of a tool for the purpose of acquiring particular domain knowledge is expected to be easier. Furthermore, it is believed that the ontology of hypertension management for a guideline-based clinical decision support system will contribute to the sharing and deploying of knowledge and to the dissemination of standardized clinical guidelines through the reuse of this knowledge

Poseacle: An Ontological Infrastructure for Managing Clinical Archetypes in Semantic Web Environments

Jesualdo Tomás Fernández-Breis[a], Marcos Menárguez-Tortosa[a], Pedro José Vivancos-Vicente[a], Rafael Valencia-García[a], David Moner[b], José Alberto Maldonado[b]

Abstract

There are currently different standards for representing and exchanging EHR information among different systems. In advanced EHR approaches, clinical information is represented by means of archetypes. Most of these approaches use ADL to specify archetypes. In this paper, an alternative representation in OWL is presented. The OWL representation has some advantages such as its formal condition, its suitability for sharing and reuse, and the possibility of reasoning over OWL content. This new representation allow for managing clinical information in Semantic Web settings.

Keywords:

Medical Informatics, Information Management, Electronic Healthcare Records, Semantic Web

Introduction

The lifelong clinical information of any person supported by electronic means configures his Electronic Health Record (EHR). As pointed out in [3], EHR systems must support life-long EHR, be technology and data format independent, facilitate sharing of EHRs via interoperability at data and knowledge levels, integrate with any/ multiple terminologies, support for clinical data structures and prioritize the patient / clinician interaction. Nowadays, there are different advanced standards and architectures [3] for representing and communicating electronic healthcare records, such as HL7 [8], OpenEHR [6] and the CEN ENV13606 [7]. Each standard defines its own information models and manages the information in a particular way. This implies that clinical information systems of different clinical organizations might differ in how electronic healthcare records are managed. Current advanced EHR standards make use of the dual model architecture approach [1]. This architecture is based on the meta-modelling of healthcare records, based on two basic principles. First, two conceptual levels are distinguished: (1) reference model, and (2) archetypes. This work is focused on the latter level. Archetypes are typically represented by using the Archetype Definition Language (ADL), which is a formal language for expressing archetypes, which are constraint-based models of domain content. However, ADL document are syntactic rather that semantic. In this paper, an alternative semantic representation, based on the Ontology Web Language (OWL) [5], which is the W3C recommendation for exchanging semantic content on the web, is proposed.

Methods

Tim Berners-Lee [2] defined the Semantic Web as an extension of the current Web, in which information is given well-defined meaning, better enabling computers and people to work in cooperation. Amongst the different available Semantic Web technologies, ontologies are considered a basic technology to promote semantic interoperability between independent and heterogeneous systems. An ontology represents a common, shareable and reusable view of a particular application domain, and they give meaning to information structures that are exchanged by information systems. In practical settings, ontologies have become widely used due to the advantages they have: reusability and shareability (see for instance [4]). The "de facto" standard language for representing ontologies is the Ontology Web Language(OWL), which can formally describe the semantics of classes and properties used in Web contents. In order to represent archetypes in OWL, a semantic interpretation of the archetype level has to be performed.

Apart from their different nature, the parsing and processing of information is also different in ADL and OWL. When parsing an ADL document, the result is an Archetype Object. This object contains the lists of codes, names of terms, constraints and so on. All the elements of these lists are strings so that the relations between the different elements must be explicitly searched for. In this sense, mistakes are more likely to be committed when defining an ADL document. Moreover, the processing of OWL content does both the parsing of the OWL and the capture of consistent clinical information, whereas ADL parsing does only obtain the information without guaranteeing the consistency of the clinical information. In fact, it does not perform any analysis related to clinical information contained in the archetype.

Results

The first step was to analyze the representation of clinical archetypes, so a semantic interpretation might be performed. Figure 1 shows the result of the semantic interpretation of clinical archetypes to produce an ontological representation suitable for being modeled in OWL. The top part of Figure 1 shows the ontological representation of the definition of an archetype and their links with issues such as translations, terms, audit information or terminologies. This part is common for any EHR architecture. The lower part of the figure contains some architecture specific items, such as the clinical data structures and data types. This OWL modeling brings all the information concerning a particular term together (code, name, binding, translations, constraints) so that a particular information item can be accessed and analyzed in its context.

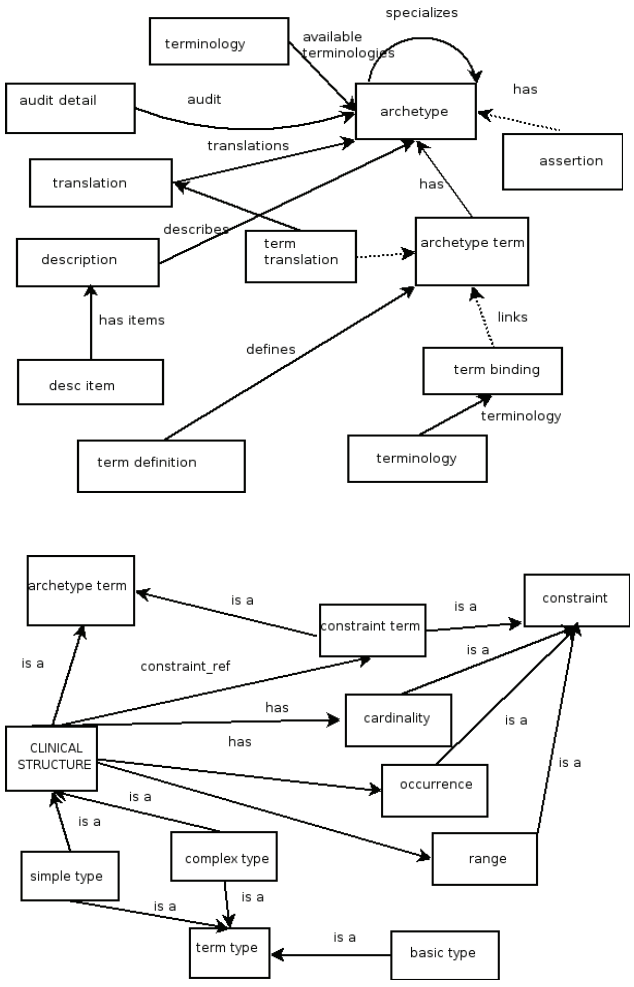

Figure 1 - Ontological representation of the semantic interpretation of clinical archetypes

Through this research work, the POSEACLE set of ontologies has been developed, providing a semantic web-oriented representation of clinical archetypes. Amongst the available EHR standards, our work has been focused on CEN ENV13606 and OpenEHR. By following the archetype approach shown in Figure 1, a set of OWL ontologies for the standards have been developed. These ontologies are available at http://klt.inf.um.es/~poseacle.

Different clinical archetypes for both CEN and OpenEHR have been manually built for clinical concepts such as measurements for Cholesterol, Creatinine, Coagulation or Blood Pressure. These archetypes can be found at the referred web portal. To simplify the use of the ontologies, an OWL archetype template is also available; then, the user only needs to instantiate the ontology to define the archetype.

Discussion and conclusions

In this work, a Semantic Web-oriented ontological modeling of clinical archetypes has been presented. This approach is based on semantic technologies rather than syntactic ones such as ADL, so that more efficient knowledge management mechanisms can be developed. As a result of this work, different ontologies have been obtained to represent archetype models for CEN and OpenEHR. Hence, the ontologies developed can also be used by Semantic Web applications in the health domain. These ontologies can be used as a starting point for defining a framework for the consecution of semantic interoperability across clinical information systems.

Acknowledgments

This work has been possible thanks to the Spanish Ministry for Science and Education through the project TSI2004-06475-C02.

LinkEHR: A Tool for Standarization and Integration of Legacy Clinical Data

Diego Boscá, David Moner, José Alberto Maldonado, Carlos Angulo, Montserrat Robles

Biomedical Informatics Group, BET, Technical University of Valencia

Abstract

It is just a matter of time that standard based information systems for medicine become completely necessary. However, the system migration can turn to a huge loss of information if the pre-standard subsystems are not integrated on the electronic health records (EHR) system. LinkEHR aims to help integrating those pre-standard subsystems into the main EHR system providing at the same time a terminology binding and semantic improvement of the information. Using archetypes known as "integration archetypes" let us to map data sources to standard based EHR information systems.

Keywords:

standardization, systems tntegration,
Electronic Health Record

Introduction

During years, the lack of a standard on Electronic Health Records (EHR) has become one of the main issues on communication and interoperability of medical systems. Nowadays, obtaining a complete patient medical record still turns into a great effort on manual integration of the distributed systems among the organization. To solve this, organizations like European Committee for Standardization (CEN), OpenEHR or HL7 are providing new standards for EHR. CEN and OpenEHR are based on a dual model methodology that makes use of archetypes to manage the separation between information and knowledge [1].

However, although new standard based systems will have a standardized reference model making systems interoperable, it is not acceptable to lose current patient medical records. There is a need for a tool that helps to integrate those non-standard EHR in some way into the new information system. LinkEHR is a multi reference model tool that gives solution to this problem allowing the creation of standard-based archetypes offering mapping capabilities on data sources.

LinkEHR Features

- Multi reference model: LinkEHR is able to handle different reference models in order to guide the archetype's definition process. The importation of a new reference models is done by analyzing the XML Schema Definition (XSD) of the imported reference model. LinkEHR currently fully supports CEN and OpenEHR standards. In fact, LinkEHR is the first archetype editor for CEN EN13606.
- Data source mapping: One of LinkEHR's main features is the capability to define mappings between archetypes and data sources. The only requirement data source must fit is to be representable as XML (such as relational data bases or XML documents). The mapping syntax allows the definition of some useful transformation functions between data sources and archetypes. Mappings are stored with the textual representation of the archetype (ADL [2]) as an extension of it. These are the so called "integration archetypes".
- Semantic validation: The creation of archetypes in LinkEHR is fully guided by the reference model and parent archetype (if it exists). LinkEHR assures that the new archetypes satisfies both the constraints stated in the reference model entity being archetype and the archetype being specialized.(subsumption operation compliance [3]).

Conclusion

Standards-based EHR are undoubtedly the future on information systems development. LinkEHR will allow health institutions to integrate existing medical records into the new systems providing a fully semantic view of stored data.

Abstract

Objective: *For the development of computer-assisted chemotherapy planning system, we present a chemotherapy planning model emphasizing on decision-making process and associated heuristic knowledge.* ***Methods:*** *We analyzed the information structure of chemotherapy regimens based on the requirements that we set. i) Creating a chemotherapy planning model emphasizing on physician's decision-making process. ii) Building up expressions to reason about particular knowledge associated with each decision-making process.* ***Results:*** *We developed a model consisting of three kinds of sub-models: an entity model of chemotherapy regimen, a process model of chemotherapy work-flow, and a model of expression language to represent decision criteria. For experiment and evaluation of the model, we implemented a prototype system.* ***Conclusions:*** *We developed a model for chemotherapy planning, which emphasize on physician's decision-making. Through the implementation of the prototype system, our model seems promising because it seems to reflect the knowledge of chemotherapy correctly.*

Keywords:

knowledge representation, decision support system, chemotherapy

Methods

We analyzed the information structure of chemotherapy regimens [1] and divided it according to the role. Also, we clarified typical scenes of decision-making in chemotherapy work-flow through discussing with physicians. To document our results of requirement analysis, we applied the Unified Modeling Language [2]. For experiment and evaluation, we developed a prototype system of computer-assisted chemotherapy planning and alerting system based on the proposed model.

Results

Classification of chemotherapy knowledge

We classified the knowledge of chemotherapy into three categories. 1) Entities of chemotherapy. 2) Process of chemotherapy work-flow. 3) Heuristic knowledge for a physician to intervene in a chemotherapy schedule. Then, we developed sub models for each category: an entity model of chemotherapy, a process model of chemotherapy work-flow, and a model of expression language to represent decision criteria.

Entity model of chemotherapy

Figure 1 shows an entity model of chemotherapy. *Therapy cycle* class consists of *Chemotherapy drug* class that has a standard dosage, a dosage rate, a maximum dosage, and an administration specification as attributes. An administration schedule is conducted by the *Date allocation* class and the administration specification.

Recommendations, which consist of combination of a specific patient status and a therapy action, are important for decision-making of a physician. *Pretreatment evaluation* is carried out at the time of beginning of chemotherapy, therapy cycle, and daily administration. When a patient status doesn't meet each criterion, discontinuance of chemotherapy or therapy cycle is recommended. *Dosage modification* represents a recommendation of modification of a drug dosage according to a patient status.

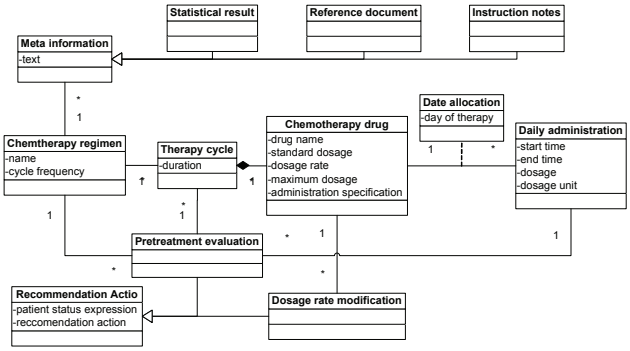

Figure 1 - The entity model of chemotherapy regimen

Process model of chemotherapy work-flow

Whole chemotherapy work-flow consists of repetition of a therapy cycle, and a therapy cycle consists of repetition of a daily administration. There are four kinds of decision-making process in those repetitions, *Pretreatment evaluation of chemotherapy, Pretreatment evaluation of therapy*

cycle, Pretreatment evaluation of daily administration, and *Dosage modification of chemotherapy drug.* Figure 2 shows a perspective of a work-flow of chemotherapy.

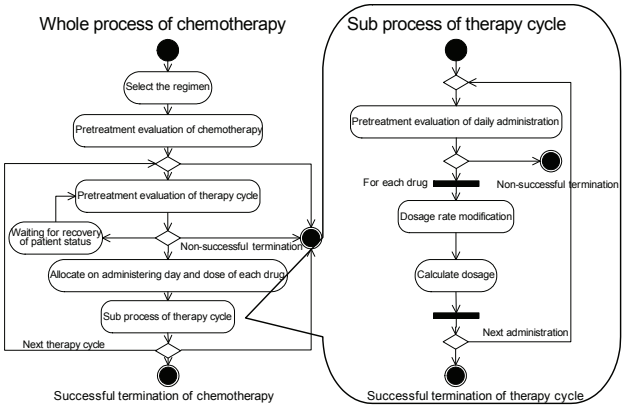

Figure 2- Perspective of a work-flow of chemotherapy

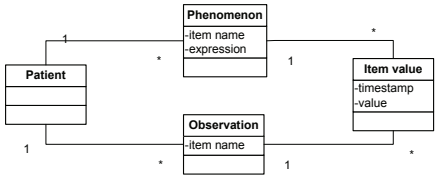
Model of expression language to represent decision criteria

To construct decision criteria by building up expressions to reason about a particular status of a patient, we defined a data model of a patient and a model of rule expression language including decision criteria (Figure 3). Here, decisions about patient status often depend on the past data as well as on the current data. Therefore, the effective time of the data has to be specified as *Time Context* in our model.



(1) Observation("creatinine") .greaterThan(2.0, "mg")

(2) Phenomenon : NCI-CTC Leukocytes grade:
IF Observation ("leukocyte").greaterThan(4000, "ul")
THEN Phenomenon("Leukocytes grade").setItemValue(0)
IF Observation ("leukocyte").lessOrEqual (4000, "ul")
AND Observation ("leukocyte").greaterThan(3000, "ul")
THEN Phenomenon("Leukocytes grade").setItemValue(1)
...
(3) Dose Modification of Doxorubicin: Time context: 14days
IF Phenomenon("Leukocytes grade").greaterThan(3)
THEN Decrease Doxorubicin to 50% dose

Figure 3 - Data model of patient and examples of heuristic rule expression. (1) "Serum creatinine is greater than 2.0mg" (2) Definition of Phenomenon "NCI-CTC Leukocytes grade" decision criteria. (3) Decision criteria of dosage modification of doxorubicin

Implementation of a prototype system

For the experiment of the proposed models, we developed a prototype system for chemotherapy planning and alerting. The entity model and the rule expression language were combined into structured chemotherapy regimen and became knowledge base of the prototype system. An overview of the system architecture is shown in Figure 4. There are two functions in the system. 1) Providing decision support for a physician to create an administration schedule. In each decision-making process such as pretreatment evaluation and dosage modification, system evaluates a decision criterion according to a patient status. 2) Providing real-time notification for the physician. When the dosage should be modified according to additional patient data, the system sends a recommendation message to the physician.

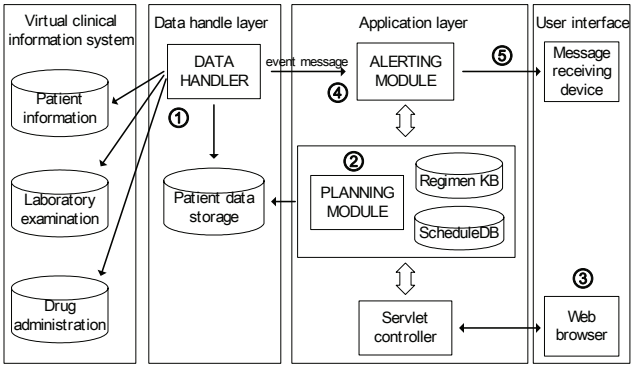


Figure 4 - 1) Different kinds of patient data are collected and unified into data storage. 2) PLANNING MODULE provides an administration schedule while evaluating recommendation criteria. 3) A physician can operate planning module to create an administration schedule. 4) ALERTING MODULE is evoked by DATA HANDLER and evaluates a drug dosage, cooperating with planning module. 5) When the drug dosage should be modified, alerting module sends a recommendation massage to the physician

Conclusion

We presented a model for chemotherapy planning consisting of three kinds of sub-models: the entity model of chemotherapy regimen, the process model of chemotherapy work-flow, and the model of expression language to represent decision criteria. Using this model, we implemented a prototype system for supporting chemotherapy planning and alerting. Our model seems promising because it seems to reflect the knowledge of chemotherapy correctly.

Objective

- **Developing a computer-assisted cancer chemotherapy planning and alerting system.**
  - To prevent iatrogenic injury.
  - To improve patient safety and quality of care.

For that purpose…

- **Presenting a model of chemotherapy planning.**
  - Emphasizing physician's decision-making process.
  - Representing associated heuristic knowledge.

Methods

- **Analyzing**
  - Analyze an information structure of chemotherapy regimens [1] and categorize it.
  - Clarify typical scenes of decision-making through discussing with physicians.
- **Representing**
  - Document out our models using Unified Modeling Language [2].
- **Developing**
  - Develop a prototype system based on the proposed models.

Results

- **Classified and expressed the knowledge of chemotherapy into three categories.**

  a. Entities of chemotherapy.

     Entity model of chemotherapy.

  b. Process of chemotherapy work-flow.

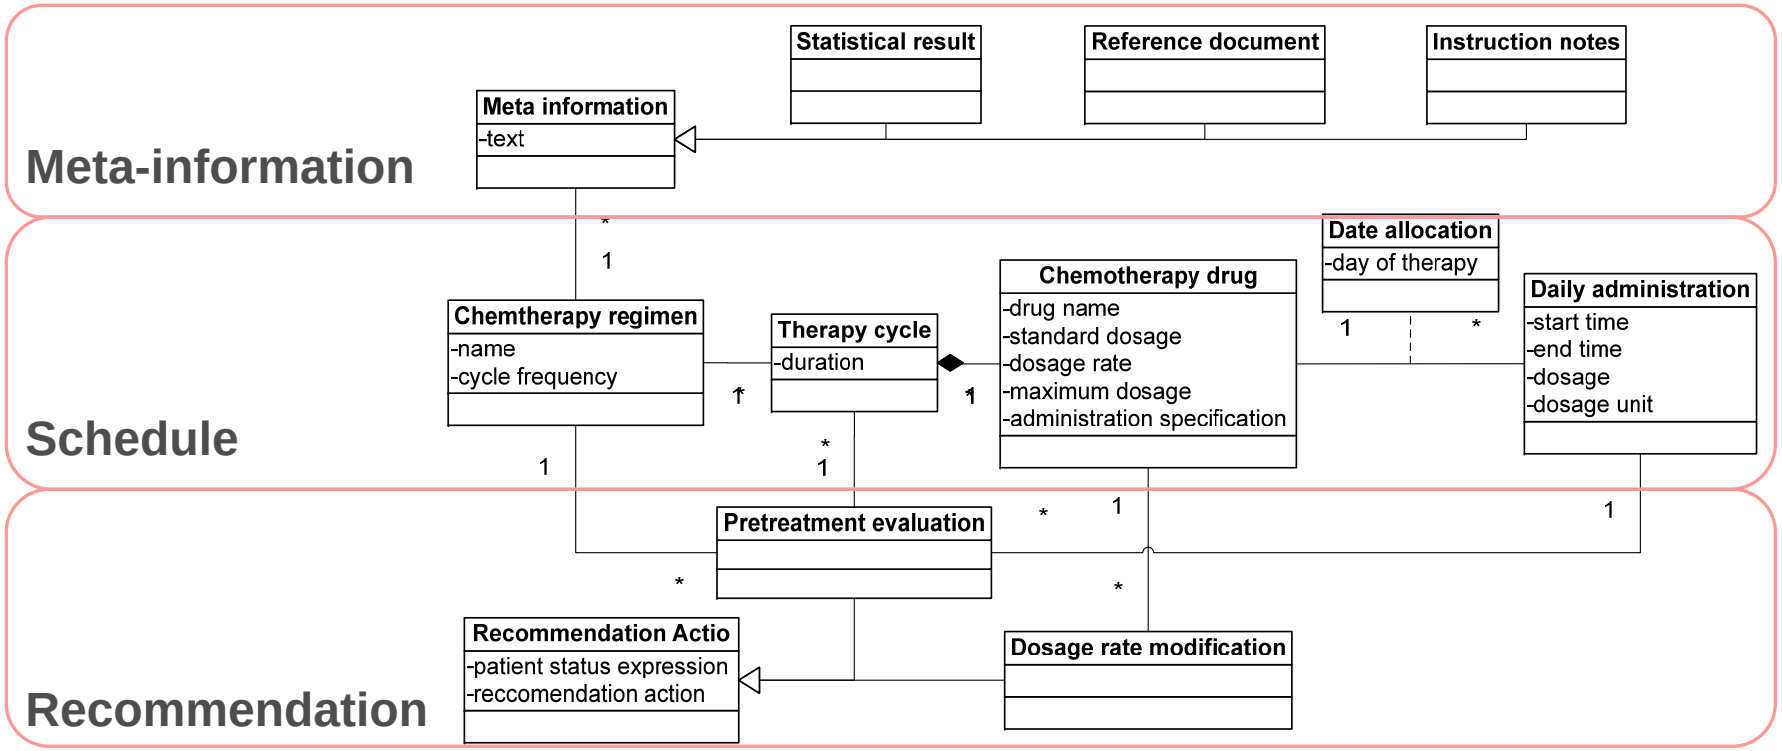
     Process model of chemotherapy work-flow.

  c. Heuristic knowledge to intervene in a chemotherapy planning.

     Model of expression language to represent decision criteria and therapy actions.

Results - a. Entity model

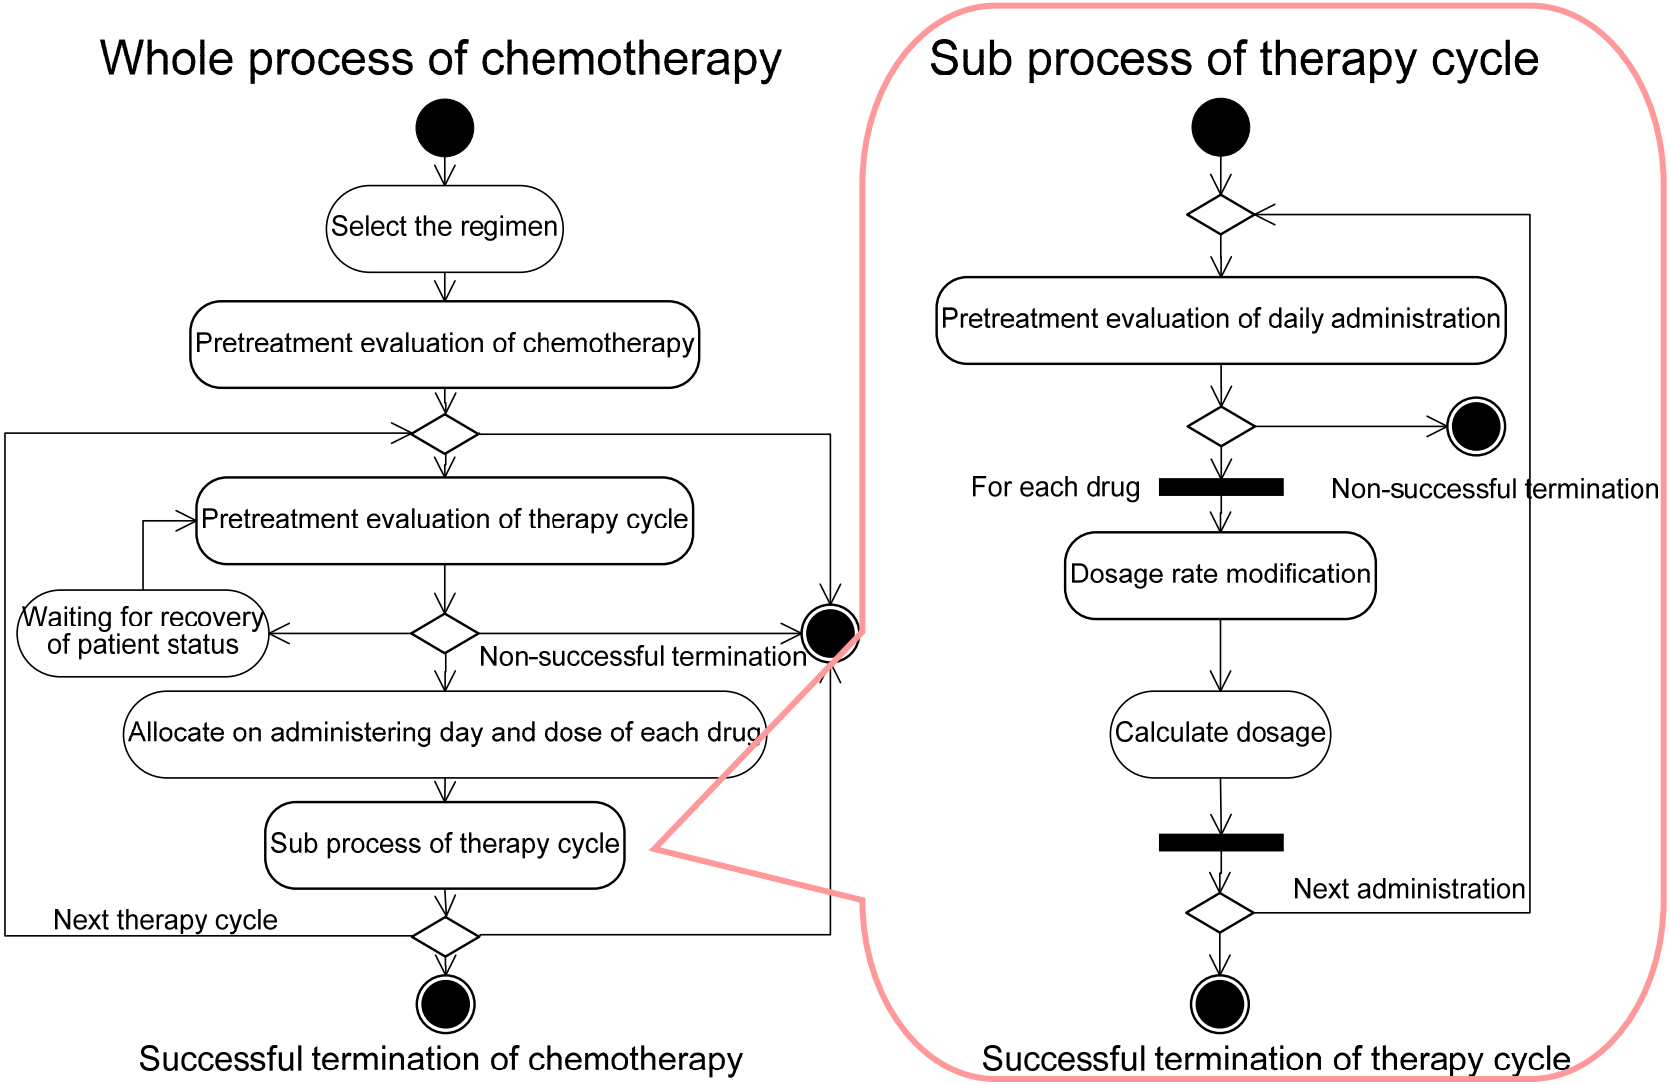
- Administration schedule of chemotherapy drug.
- Recommendation criteria of therapy actions.
- Meta-information about chemotherapy.



Results - b. Process model 1

- **Whole chemotherapy process consists of repetition of a therapy cycle.**
- **Therapy cycle consists of repetition of a daily administration.**
- **Four kinds of scenes of decision-making in those repetitions.**
  - Pretreatment evaluation of chemotherapy.
  - Pretreatment evaluation of therapy cycle.
  - Pretreatment evaluation of daily administration.
  - Dosage modification of chemotherapy drug.

Results - b. Process model 2



Results - c. Expression language

- **Recommendation criteria of therapy actions.**
  - Represented as a rule expression including classes of *Observation* and *Phenomenon*.
  - Expiration date of patient data has to be specified as *Time Context* for automated data retrieval.

Dosage Modification of Doxorubicin in CHOP

Time context: 14days

IF Phenomenon(“Leukocytes_grade”).greaterThan(3)

THEN Decrease Doxorubicin to 50% dose

Results - Knowledge base

- **Structured chemotherapy regimen.**
  - An Entity model and a model of expression language are combined.

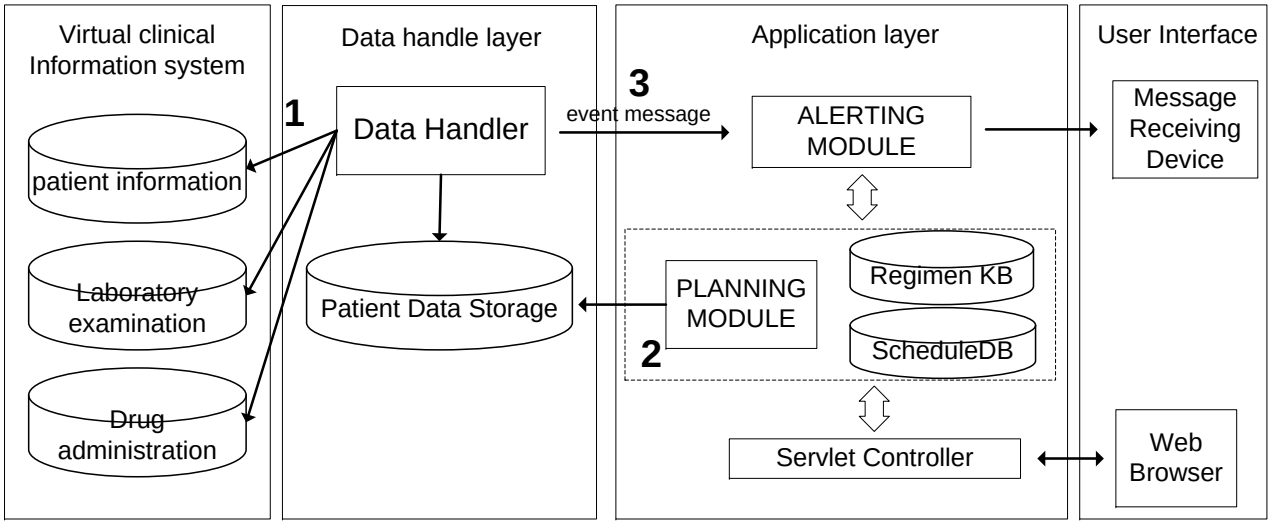
Example of a structured chemotherapy regimen of “CHOP”

```
<regimen name="CHOP" code="001" cycle_frequency="5">
  <therapy_cycle duration="21">
    <pretreatment_evaluation time_context=”14" unit=”day”>
      <lhs_expression> phenomenon(NCICTC_Leukocytes_Grade).greaterThan(3) </lhs_expression>
      <rhs_expression> Recommend beginning at the cycle to be postponed </rhs_expression>
    </pretreatment_evaluation>
    <chemotherapy_drug name="vincristine" standard_dosage="1.4" max_dosage=”2.0” dosage_unit=”mg”>
      <date_allocation> 1 </date_allocation>
      <administration_method route=”iv”>
        <division unit=”min”>60</division>
      </administration_method>
      <dosage_modification time_context=”14" unit=”day”>
        <lhs_expression> phenomenon (NCICTC_Leukocytes_Grade).greaterThan(2) </lhs_expression>
        <rhs_expression> Recommend reduce to 80% dose </rhs_expression>
    .....
```

Results - Prototype system

- **Two types of applications.**
  - **Planning module** provides a chemotherapy schedule while evaluating recommendation criteria.
  - **Alerting module** provides a notification message.

Overview of the prototype system architecture



1. Retrieve patient data from virtual clinical information system.
2. Reason about chemotherapy schedule according to the patient status.
3. Send an event message to alerting module.

Conclusion

- **We have presented the model of chemotherapy planning.**
  - Entity model of chemotherapy.
  - Process model of chemotherapy work-flow.
  - Model of expression language to represent the decision criteria and therapy action.
- **Through the implementation of the prototype system,**
  - Enables the system to support physicians appropriately in the chemotherapy work-flow.
  - Seems to be useful for preventing physicians from overlooking the information about patient.

Design of an Ontology on Cerebral Aneurysms: Representing the Conceptual Space of the @neurIST Project

Susanne Hanser[a], Martin Boeker[a], Kai Kumpf[b] and Stefan Schulz[a]

a *Department of Medical Informatics, University Hospital, Freiburg University, Germany*
b *Fraunhofer Institute for Algorithms and Scientific Computing SCAI, FhG St. Augustin, Germany*

Introduction: @neurIST

- The aim of the European project @neurIST (2006-2009)[1] is the provision of an integrated information structure related to intracranial aneurysms and subarachnoid hemorrhage. The expected benefit for clinicians and scientists includes the support of diagnosis and treatment planning, particularly with regard to aneurysm rupture risk, and an easier access to knowledge in the field, provided by a set of elaborate software tools and platforms.

Disease ontology

- A controlled vocabulary (e.g. an ontology) intends
  - To define a common vocabulary: using textual definitions, hierarchies, relations
  - To make domain assumptions explicit
  - Agreement on meaning

- Task according to DoW: “An ontology binding together the different levels of description of the disease intracranial aneurysm (e.g. from a clinicians or a geneticist’s view) and different sources of information (e.g. literature, clinical databases, image databases).”
  - Intended application contexts: text mining, semantic data mediation

„All relevant entity types …“

- Conceptual space of the project:
  - Clinical Medicine
  - Molecular Biology
  - Epidemiology
  - Simulation
  - Disease
  - Risk factor
- Classification of entities like…
  - Patient
  - Hypertensive Disease
  - Severe Headache
  - Sudden Onset
  - Intracranial Aneurysm
  - Aneurysm Rupture
  - Middle cerebral artery
  - Excessive Coffee Consumption
  - High Risk
  - Mortality
  - Shear stress

Materials and Methods

- Tools
  - Protégé ontology editor
  - OWL DL, Reasoner
- Reference ontologies and terminologies
  - Upper Level: DOLCE
  - Anatomical entity types: Foundational model of anatomy (FMA)
  - Links to Unified Medical Language System (UMLS), SWISSProt, Entrezgene
- Sources of relevant entity types (concepts)
  - clinical databases and information models (CRIM)
  - literature (high frequency domain specific terms extracted from abstracts)
  - domain experts
  - the UMLS metathesaurus and
  - open source databases (e.g. in the molecular biology field)

Ontology Design

- Descriptive Ontology for Linguistic and Cognitive Engineering (DOLCE) [2] as the basic onto-logical framework (DOLCE-Lite)
- Top-Level ”Particular” subdivided in terms of:
  - Endurants (including object- and substance-like entities, e.g. “Internal Carotid Artery”, “Blood”)
  - Perdurants (event- and state-like entities, e.g. “Angioplasty”, “Hypertensive Disease”)
  - Qualitys (individual attributes, e.g. “Blood Pressure”, “Sex”) and
  - Abstracts (mainly conceptual “regions” for structuring attributes – “values”, e.g. “Male” as a possible value for the quality “Sex”)

Results

- Coverage
  - 2000 entity types, which mostly belong to the realm of clinical medicine, throughout classified according to DOLCE top level categories
  - 86 properties (relations, e.g. part-of, participates-in)
  - Mapping to Unified Medical Language System in 51%
- Model of the conceptual space
  - see next slide for an exemplary model of a possible clinical situation in the project:
  - a “patient”, for example, participates in a disease (“Intracranial aneurysm state” which is the pathologic state of bearing an aneurysm), an “intracranial aneurysm (which is an anatomical abnormality) participates, too. The patient suffers from polycystic kidney disease; a fact which according to epidemiological knowledge leads to an increased probability for aneurysm development (i.e “triggers” the disposition to develop an aneurysm).
- Usability supported by:
  - “Particular in Context”: additional hierarchy for the representation of entity types in certain application-related contexts of human knowledge, including the possibility to extract ontology subtrees according to user’s needs, for example for text mining purposes
  - synonym database provides lexical information
  - Web Browser provides easy access to ontology content

Version Info

Different views on entities

- Representation of entity types in certain application-related contexts of human knowledge:
  - Clinical
  - Epidemiological
  - Biomolecular
  - Simulation
  - Risk Factor

- Classification of “Tobacco Smoking”?
  - “Tobacco Smoking” is a consumption habit.
  - What was discovered later:
    - “Tobacco Smoking” has a certain influence on the state of the human body
    - “Tobacco Smoking” is associated with certain pathological states (diseases)
    - “Tobacco Smoking” causes certain pathological states (diseases)

- “Tobacco Smoking” is a risk factor for aneurysm rupture” <=> View on a consumption habit as “risk factor” – in epidemiological and clinical context!

Conclusion

- The @neurIST ontology provides a structured representation of the conceptual space using DOLCE:
  - the use of the DOLCE upper level categories facilitated a classification of the @neurIST entity types in the difficult field of clinical terminology with its often vaguely defined vocabulary
  - substantial coverage of the @neurIST conceptual space is already achieved
- The ontology is currently used for text mining purposes
  - application for semantic mediation discussed

Design of an Ontology on Cerebral Aneurysms: Representing the Conceptual Space of the @neurIST Project

Susanne Hanser[a], Martin Boeker[a], Kai Kumpf[b], Stefan Schulz[a]

[a] *Department of Medical Informatics, University Hospital, Freiburg University, Germany*
[b] *Fraunhofer Institute for Algorithms and Scientific Computing SCAI, FhG St. Augustin, Germany*

Abstract

Ontologies are designed to represent knowledge, and to support the semantic interoperability among heterogeneous, distributed sources (e.g. databases or web sites) by providing machine-readable descriptions of entity types (concepts) in a domain. We describe our approach to a domain ontology which is currently under development within the scope of the European project @neurIST, intended to serve as a module in a complex architecture aiming at the provision of a better understanding and management of intracranial aneurysms.

Keywords

Medical Informatics Applications; Ontology design; Intracranial aneurysm; Terminology

Introduction

The aim of the European project @neurIST [1] is the provision of an integrated information structure related to intracranial aneurysms and subarachnoid hemorrhage. The expected benefit for clinicians and scientists includes the support of diagnosis and treatment planning, particularly with regard to aneurysm rupture risk, and an easier access to knowledge in the field, provided by a set of elaborate software tools and platforms. In this paper, we describe our approach to the design of an ontology binding together the different levels of description of the disease intracranial aneurysm (e.g. from a clinicians or a geneticist's view) and different sources of information (e.g. literature, clinical databases, image databases).

Materials and Methods

Following the current state of the art of Semantic Web technology we use the ontology editor Protegé and OWL DL as a description language. The logical consistency of the ontology during the editing process is ensured by the RacerPro OWL reasoner . In the first place, we intend to reuse existing terminology sources (as the UMLS) and widely acknowledged ontologies like the Foundational Model of Anatomy.

Acquisition of types and relations

The first step to the identification of relevant entity types ("concepts") consists in collecting terms, terms describing disease and patient as well as terms related to technical devices and data structures used in the process of description, therapy and prognosis. Sources of relevant entity types in the domain were 1. clinical databases and information models (CRIM), 2. literature (high frequency domain specific terms extracted from literature), 3. domain experts, 4. the UMLS metathesaurus, and 5. open source databases (e.g. in the molecular biology field)

Ontology Design

Top level: Particular

We chose the *Descriptive Ontology forLinguistic and Cognitive Engineering (DOLCE*) [2] as the basic ontological framework of our ontology and included its DOLCE-Lite-Plus version via the OWL import mechanism. The root of DOLCE's top level ontology is named "particular". This reflects a consensus among top-level ontologies: The ontology is a system of semantic types which define classes of particulars (individuals or instances), and not of concepts in the sense of entities of mind. According to DOLCE, "particulars" are further subdivided in terms of:

- Endurant (including object- and substance-like entities, e.g. "Internal Carotid Artery", "Blood")
- Perdurant (event- and state-like entities, e.g. "Angioplasty", "Hypertensive Disease")
- Quality (individual attributes, e.g. "Blood Pressure", "Sex") and
- Abstract (mainly conceptual "regions" for structuring attributes – "values", e.g. "Male" as a possible value for the quality "Sex")

Results

Coverage

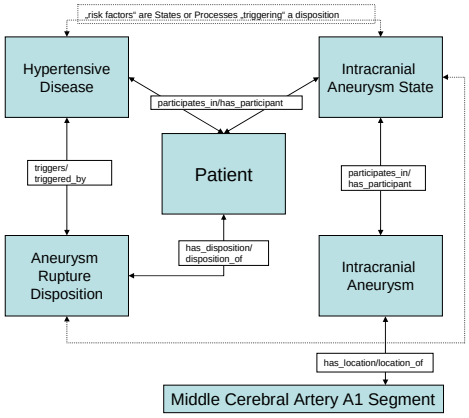
The actual representation of the domain covered by the @neurIST project includes over 2000 entity types, which

mostly belong to the realm of clinical medicine. They are classified throughout as perdurants, endurants, qualities and value ranges. Logical descriptions link nodes from different branches of the taxonomy, for example: The relation "participates_in/ has_participant" links e.g. patient ("human"), pathologic anatomical entity, and disease.

Model

Fig.1 shows a model of an exemplary clinical situation: A "patient", for example, participates in a disease ("Intracranial aneurysm state" which is the pathologic state of bearing an aneurysm), an "intracranial aneurysm (which is an anatomical abnormality) participates, too. The patient suffers from hypertensive disease; a fact which according to epidemiological knowledge leads to an increased probability for aneurysm rupture and subarachnoid hemorrhage.

Fig. 1: Model of a possible clinical situation in the project



Usability

A synonym database linking to the ontology classes provides a variety of names and acronyms used by partners in their own research areas. - We introduced a second hierarchy for the representation of entity types in certain application-related contexts of human knowledge (Particular in Context), including the possibility to extract ontology subtrees according to user's needs, for example for text mining purposes. - Finally, a web browser is under development which will provide easy access to the ontology content.

Discussion

Are top level categories necessary? In contrast to 'lightweight' ontologies, which focus on a minimal terminological structure (often just a taxonomy) fitting the needs of a specific community, the main purpose of foundational ontologies like DOLCE is to *negotiate* meaning, either for enabling effective cooperation among multiple artificial agents, or for *establishing consensus* in a mixed society where artificial agents cooperate with human beings. It is our experience that the use of the upper level categories facilitated a classification of the @neurIST entity types in the difficult field of clinical terminology with its often vaguely defined vocabulary. Our choice to use DOLCE depended on the estimation that an ontology with a "cognitive bias" was more appropriate for the representation of a conceptual space covering several scientific domains with their different views on the disease, than the more realistic, fundamental approach of the BFO (Basic Formal Ontology). While DOLCE aims at capturing the ontological categories underlying natural language and human commonsense, BFO claims that "each ontology (*SNAP* and *SPAN*) represents some partition of reality" [3]. In addition, DOLCE has been applied in the restructuring of the WordNet Lexicon with good results. [4]

Conclusion

In our opinion, a classification of the entity types from the @neurIST CRIM (describing mainly the clinical aspects of intracranial aneurysms) according to the Descriptive Ontology for Linguistic and Cognitive Engineering results in a sound classification of the domain, while a the separate presentation of human knowledge meets user's needs of a classification and concept representation in certain contexts.

A Data Structure For Decision Support Systems, Medical Expert Systems and Clinical Decision Making

Bassøe, Carl-Fredrik

The Norwegian Center for Electronic Medical Records, Institute of Neuroscience, Faculty of Medicine, University of Trondheim, the PROMED Institute, Bergen, Norway and the Department of Information Science and Media, Faculty of Social Sciences,University of Bergen, Norway

Abstract

The International Classifications of disease (ICD10) is normalized the into a relational containing tables for the etiology, body regions, organs, pathogenesis, cells, subcellular organelles, direction of change, time course and degree. Functions and morphology of different organs are abstracted into the general organ. The hierarchal structures of the etiology and anatomy are implemented. The database enables the construction of diagnoses according to the equation d:=e+o+p, where d, e, o and p each is a variable holding names of a diagnoses, etiology, organ and pathogenesis, respectively. Together, the data structure and the equation d:=e+o+p allow structured clinical decision making and a combinatorial classification.

Keywords:

classification, database normalization, clinical decision making, computer decision support system, medical expert system, education

Introduction

Computerized medical decision support systems (CDSS) and medical expert systems (MES) need to be based on a clear and versatile data structure. Both CDSS and MES require a knowledge base containing the etiology, organs and their parts, and the pathogenesis. However, etiology and pathogenesis are used differently in different settings and their meaning overlaps. A clear concept of a general organ as an object, that abstracts functions and morphologically different components, are also lacking.

The present study aims to extract etiology and pathogenesis from dependencies in ICD10 and ICF and normalize ICD10 into a database. The dependences were identified semiautomatically using an application crafted for the goal. The database is used to create a combinatorial classification and construct diagnoses.

Materials and methods

Hardware and software

The programs and databases were run on ordinary PC's. MS Access 97® was used as database. The applications were implemented in MS Visual Basic 6® (VB6) using ADO to connect to the database [1]. All work on the classification was done interactively.

Normalization of ICD10

An English version of ICD10 was downloaded from WHO [2], and a Norwegian version from KITH [3]. ICD10 was converted it into Boyce Codd Normal Form (BCNF) [4,5] by identifying the entities and attributes of diseases in ICD10. An Entity-Relationship model (ER) was built from the entities, their attributes and relationships [4,5], storing the entities in separate tables.

The lists containing codes and diagnoses in ICD10 were automatically transferred from the sequential text files into a database table with fields for tagging. A VB6 application was developed to identify words with standard medical prefixes and suffixes associated with the etiology, pathogenesis, morphology and direction of change. The collection of tables is called a combinatorial classification

Results

Functional dependencies in ICD10

ICD10 shown to contain dependencies such as 'due to use of', 'due to' and 'of presumed'. Altogether 76 different dependencies were identified. The dependencies were used to automatically parse and display dependenciesand transfer them to the appropriate tables combinatorial tables. The process iterated until the whole ICD10 had been examined for dependencies.

The etiology is defined as all agents that cause disorder and are external to the individual in time (heredity) or space. Nymerous etiological agents were detected in ICD10. Anatomical regions were identified >184 diagnoses. The direction of change is given by the prefixes a, hypo, normo, hyper, dys, meta and neo. A total of 173 diagnoses with the direction of change were identified. Names organs and organ parts were common in ICD10 diagnoses. The general organ is an abstraction of features common to all organs: the parenchyma, tube systems, cavities or slits, and the functions and morphology of these three parts. Mechanical, electrical, chemical and optic functions were described in ICD10. Thus, the entities eti-

ologi, region, direction of change, organ (part), general organ functions, degree, time course are required for a combinatorial classification created from ICD10. In addition, morphological deviations require a separate entity. Surprisingly, ICD10 contained only six diagnoses related to organelles, but this is sufficient to require an organelle entity.

The pathogenesis is defined as a relation between organs and between cells. The pathogenetic mechanisms were identified by suffixes, disorders of mesenchyme, intercellular metabolism and regulators immunological reactions, disturbances of coagulation and psychic reactions. These elements were allocated to the pathogenesis entity.

Diseases and dagnoses as ternary relations

Causal connectives between the etiology, organs or cells and the pathogenesis were identified. In particular infection can be seen as a ternary complex consisting of microorganisms (etiology), functional and/or morphological disorder in the primary affected organ or cell, and immunological reactions (pathogenesis). Allergy also becomes a ternary concept where the etiology is some allergen, and the organ and pathogenesis are the same as in infection. All the above entities give rise to the entity-relationship diagram (Fig. 1).

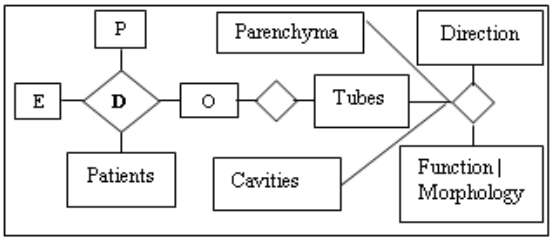

Figure 1 - Entity-relationship (ER) diagram modeling diagnoses or diseases (D), showing the relations of d to the etiology (E), organs (O) and pathogenesis (P). Organ is decomposed into the organ parts cells, tubes and cavities. These subcategories combine with the direction and function or morphology to make out a diagnosis. Diagnoses D are also related to patient

Since pre- and suffixes are recovered with the name of the elements in the entities they were used to construct diagnoses by the equation **d:=e+o+p** where d is the diagnosis, and e, o and p holds names from the etiology, organ and pathogenesis entities, respectively. A typical example is e:='bacterial ', o='endocard' and p='itis', which gives d='bacterial endocarditis'. An extended version of (1) generated diseases using all the entities described above allows the construction of about 10^{15} diagnoses (not shown).

Discussion

The present study shows that ICD10 can be normalized into a relational database. The entities (tables) can be used in a combinatorial classification and used to construct diagnoses according to the equation d:=e+o+p. This allows the construction of diagnoses simultaneously with the classification of a clinical case. The data structure is devoid of redundancy and seems well adapted to classification..

The clinical findings associated with different entities are largely disjunctive (not shown). Thereby, the prominent overlap in clinical findings between different diseases is eliminated. The combinatorial approach is therefore well suited to clinical decision making, decision support and medical expert systems.

In conclusion, ICD10 can be normalized into a relational database which allows a combinatorial classification that is easy to extend, fast and systematic, and allows the construction of diagnoses.

A data structure for decision support systems, medical expert systems and clinical decision making

Carl-Fredrik Bassøe

The Norwegian Center for Electronic Medical Records, Institute of Neuroscience, Faculty of Medicine, University of Trondheim, the PROMED Institute, Bergen, Norway and the Department of Information Science and Media, Faculty of Social Sciences, University of Bergen, Norway.

ABSTRACT

- The International Classifications of disease (ICD10) is normalized.
- The emerging relational database containing disjunctive entities.
- The hierarchal structures of the etiology and anatomy are implemented.
- The database enables the construction of diagnoses according to the equation d:=e+o+p, where e, o and p are variables holding names of a etiology, organ and pathogenesis, respectively, and d is the emerging diagnosis.
- The data structure and d:=e+o+p implement a combinatorial classification and allow structured clinical decision making.

NORMALIZATION OF ICD10

- A text file containing the ICD10 classification was used.
- ICD10 was normalized semiautomatically.
- Normalization is based on the identified functional relationships between words in the diagnoses, prefixes and suffixes.
- Diagnoses are tagged.
- Word stems are extracted using pre- and suffixes.

CREATING ENTITIES

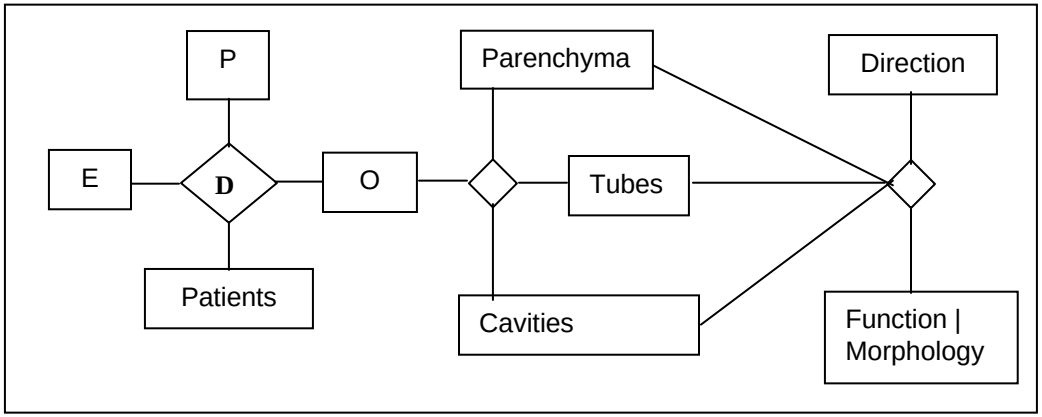
- The words are sorted onto entities related to the standard clinical curriculum: (pathological)anatomy, (patho)physiology, clinical chemistry, etc.

- This led to a database schema called a combinatorial classification which is implemented in a Microsoft Access database.

ENTITIES IN THE COMBINATORIAL CLASSIFICATION

- Etiology
- Regions
- Functions and morphology of the general organ divided on
  - parenchyma
  - tubes
  - slits and cavities
- Organs
- Pathogenesis
- Cells
- Subcellular organelles
- Direction of change
- Time course
- Degree

ENTITITY RELATIONSHIP DIAGRAM FOR THE COMBINATORIAL CLASSIFICATION



Entity-relationship (ER) diagram modeling diagnoses or diseases (D), showing the relations of d to the etiology (E), organs (O) and pathogenesis (P). Organ is decomposed into the organ parts cells, tubes and cavities. These subcategories combine with the direction and function or morphology to make out a diagnosis.

In the combinatorial classification diagnoses D are also related to patients.

THE EQUATION FOR CONSTRUCTING DIAGNOSES

- Let
  - e=“bacterial “
  - o=“myocard”
  - p=“itis”
- Then the equation d:=e+o+p gives rise to the diagnosis:

d=“Bacterial myocarditis”

USING THE COMBINATORIAL CLASSIFICATION TO CONSTRUCT DIAGNOSES

1. An application was developed to construct diagnoses.

2. The combinatorial classification gave access to the names and word stems of a wide variety of etiological agents, pathogenetic mechanisms, organs, etc.

3. Elements from the combinatorial classification were assigned to the variables in an extended version of d:=e+o+p.

4. Diagnoses were automatically constructed from elements in the entities and d:=e+o+p.

Accordingly, by steps 1-4 construction of diagnoses is algorithmic.

CLINICAL DECISION MAKING (CDM)

- Symptoms and signs from elements within each entity are (largely) disjunctive from each other (unpublished observation).

- Using d:=e+o+p to guide CDM largely eliminates the problem of overlapping sets of symptoms, signs and laboratory findings.

FUTURE OF THE COMBINATORIAL CLASSIFICATION

- Standard classifications (ICPCs, ICDs, SNOMEDs, DSMs) are steadily revised and clinical results using them are difficult to compare over years.
- The combinatorial classification is directly based on a socio-psycho-biological model of healthy and diseased individuals.
- The combinatorial classification needs no alphanumeric codes.
- A huge number of diagnoses that can be constructed by d:=e+o+p. The emerging diagnoses cover all the above mentioned classifications.
- The combinatorial classification needs to be continuously extended as medical knowledge increases, but will not require revision.
- Accordingly, the combinatorial classification is a promising tool for future clinical decision making and medical classification.

Piecewise Synonym Construction Using WordNet for UMLS Source Integration

Kuo-Chuan Huang[a], James Geller[a], Michael Halper[b]

[a] *Department of Computer Science, New Jersey Institute of Technology, Newark, NJ 07102 USA*
[b] *Department of Computer Science, Kean University, Union, NJ 07083 USA*

Abstract

Source vocabulary integration forms the basis of the UMLS's content and its planned continued growth. When integrating a new term, it is essential to recognize situations where the concept expressed by that term already exists in the UMLS, even if it is represented by a different term (i.e., a synonym). A preliminary study has shown that even when using the UMLS's rich set of synonyms, a new term for an existing concept may not match any of them. A process for automatically constructing additional, potential synonyms from multi-word source terms is presented. This process consists of decomposing the source term into words, finding separate synonyms for each in WordNet, and then recombining those synonyms into multi-word terms. We call such synonyms piecewise synonyms, and we present a precise formulation for their construction. The methodology is tested in the context of a (partial) reintegration of the "Minimum Standard Terminology" into the UMLS. The results show that additional "source term/ UMLS term" matches are gained.

Keywords:

UMLS, vocabulary integration, terminology integration, WordNet, synonym

Introduction

The Unified Medical Language System (UMLS) comprises a large terminological database covering the biomedical and health-related fields. This database has been populated via the integration of a variety of source vocabularies, e.g., SNOMED CT , LOINC , and RxNorm . Currently, the number of sources is over 100. Plans call for integration of more terminologies in the future . At present, the Metathesaurus, the UMLS's concept repository, contains over 1,000,000 concepts and over 5,000,000 terms .

The overall process of integrating a new source terminology into the UMLS is defined by the National Library of Medicine to comprise four major phases: (1) analysis and inversion, (2) insertion, (3) human editing, and (4) quality assurance . In general, the process tends to be labor-intensive and error-prone. As such, facilitating source-vocabulary integration is a critical issue facing the UMLS curators. Many algorithmic aides have been developed in this context .

In this paper, we present a methodology for increasing the effectiveness and efficiency of the insertion phase of the integration process. One of that phase's major subtasks is the identification of terms and associated concepts from the source that already exist in the UMLS. Unfortunately, the same concept may be known by several different terms. Thus, it is a distinct possibility that a new source uses a term that differs from the UMLS term for an existing UMLS concept. This problem is exacerbated for terms that consist of several words.

In a preliminary study, we found a surprisingly small number of matches for the terms of a "new" terminology with terms in the UMLS. This is surprising when one considers the large number of terms already in the UMLS. One may conclude that the UMLS is missing valid synonyms for its concepts.

Our methodology automatically generates new synonyms for multi-word terms of a source vocabulary. It does so by first decomposing a term into its constituent words. It then gathers all synonyms for the individual words. These individual synonyms are found in the widely used WordNet , a lexical database for English. Finally, a set of novel, multi-word synonyms, called *piecewise synonyms*, is created for use in a term-matching algorithm. A precise formulation of this synonym-construction process is presented.

To test the effectiveness of our methodology, we utilize it in the process of reintegrating an existing source, called the "Minimum Standard Terminology" into the UMLS. The results show that our algorithmic lexical manipulation offers gains in "source term/UMLS term" matches.

Background

In order to create a baseline for evaluating our methodology, we chose to use a set of terms (a) that had already been included in the UMLS in previous research by other authors, and (b) for which a published record on the integration process exists . The chosen set of gastro-intestinal (GI) terms is known as the Minimum Standard Terminology (MST) . The version of the MST included in the UMLS is designated "MTHMST2001," though we will continue to refer to it simply as "MST."

The MST's designers set out to devise a "minimal" list of terms that could be included within any computer system used to record the results of GI endoscopic examinations. Overall, it comprises 1,944 such terms, which represent 1,636 unique concepts. Of the terms, 289 have explicit synonyms. The concepts also exhibit relationships, e.g., *part_of* (85 concepts), *has_location* (198), *manifestation_of* (235), and *treats (*2).

The concepts of the MST, as integrated into the UMLS, are assigned a total of 29 semantic types out of the UMLS Semantic Network's 135 semantic types. The MST was originally integrated into the 2002AA release of the UMLS, as described in . Since the MST is not a terminology but rather a standard (given in a group of tables) for reports involving GI endoscopy, the major effort in focused on creating a terminology reflecting the MST's content. That terminology then became the actual source of the integration.

Using the data rich format of the UMLS , we were able to remove the MST to derive what we call the UMLS⁻, which is the UMLS with the MST entirely excluded (Figure 1). Naturally, a number of terms from the MST were also introduced into the UMLS by other terminologies. We call this overlap of MST terms with pre-existing UMLS terms the UMST. In creating the UMLS⁻ and the MST, we used the 2006AC release of the UMLS, installed in our Oracle database server. The UMST has 390 terms with 328 concepts in this release. The goal of our larger research project is to reintegrate the MST (as algorithmically as possible) into the UMLS⁻ and compare the results with those of .

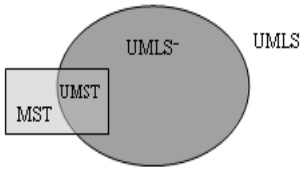

Figure 1 - The relationships between UMLS, UMLS⁻, MST, and UMST

A major step in the reintegration of the MST into the UMLS⁻ is the identification of the concepts of the UMST. Due to the addition of new sources and the update of old ones, there may be more such concepts now than in 2002, when the original integration took place. Thus, as a first step, we concentrated on the problem of finding all concepts residing in the UMST.

In a preliminary study, we found a surprisingly low number of matches between terms from the MTHMST2001 and terms in the UMLS⁻. Only 216 out of 1,944 terms matched (11.11%). Even syntactic transformations, such as removing dashes, did not improve matching results in any significant way.

The low rate of matches between the MST and the UMLS⁻ is surprising because the area of GI diseases is a core medical subject that should be well covered by the UMLS. We hypothesized that many MST terms may exist in the UMLS expressed by their synonyms. Thus, the problem to be solved was to discover new synonyms of terms that already exist in the UMLS. The complex relationships between concepts, terms, and strings in the Metathesaurus are elucidated by Table 1. Each bold number in this table is a unique identifier. As the table shows, one unique concept may correspond to several lexical terms, which are synonyms of each other.

Table 1 - Example of the relationships between Concepts, Terms, Atoms, and Strings in the UMLS

Concept (CUI)	Lexical Terms (LUI)	Strings (SUI)	Atoms (AUI)
C0009375 Colonic tumor Colonic Neoplasm Colonic Neoplasms	**L1834866** Colonic tumor	**S2142448** Colonic tumor	**A0027665** Colonic tumor (MTHMST) **A7591481** Colonic tumor (NCI)
	L0009375 Colonic Neoplasm Colonic Neoplasms	**S0363987** Colonic Neoplasm	**A0401918** Colonic Neoplasm (MSH) **A7576442** Colonic Neoplasm (NCI)
		S0026544 Colonic Neoplasms	**A0041001** Colonic Neoplasms (MSH)

For finding synonyms of individual words, we used WordNet 2.0 and JWNL (Java WordNet Library) 1.3 , a WordNet API. This API (Application Programming Interface) makes it possible to access WordNet from Java programs. Terms in WordNet are grouped into sets of cognitive synonyms, called *synsets*, used to express distinct concepts. Synsets are interlinked by conceptual-semantic and lexical relations such as hyponym, hypernym, etc. The newest version of WordNet is 2.1; however, the JWNL API was so far only implemented for WordNet 2.0. As shown in Table 2, WordNet 2.0 contains 152,059 strings. WordNet 2.1 contains 155,327. This increase is relatively small. Therefore, we found it acceptable to use the data from Version 2.0, allowing us to take full advantage of JWNL.

Table 2 - Statistics of WordNet 2.0

POS	Unique Strings	Synsets	Total Word-Sense Pairs
Nouns	114648	79689	141690
Verbs	11306	13508	24632
Adjectives	21436	18563	31015
Adverbs	4669	3664	5808
Totals	152059	115424	203145

Methods

Every MST term that is to be integrated into the UMLS⁻ is processed in several steps. Figure 2 contains a flow chart, comprising only the steps discussed in this paper. Step 1: Look for perfect matches and for matches of simple lexical variants, e.g., transformation of all letters into lowercase. Step 2: If the term consists of a single word, use synonyms from WordNet. Step 2 is not a new approach. Such a technique has already been used by Mougin *et al.*, while solving a slightly different problem . Step 3: Employ our novel matching methodology based on "piecewise synonyms."

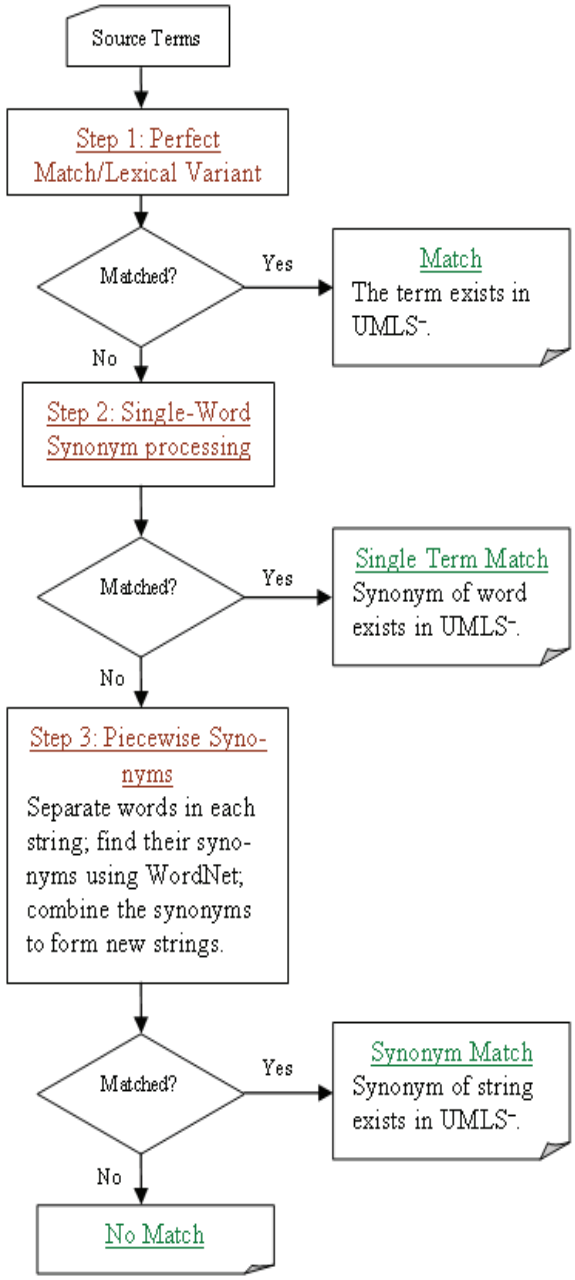

Figure 2 - Partial flowchart for string matching

Our method of constructing *piecewise synonyms* works as follows. If a medical term consists of two (or more) words, our algorithm looks in WordNet for synonyms of each individual word. Then the algorithm reconstructs two-word phrases from these individual synonyms. Then it looks for matches in the UMLS. To provide an intuitive, non-medical example, one might have a term "car insurance" and not find a match for it. Looking for synonyms

of "car" we find "automobile." Let us assume that we do not find any synonyms for "insurance." Now we reconstruct a two word term "automobile insurance" from the synonym of "car" and the original term "insurance" and attempt to find a match for it.

Our example was intentionally the simple case where only one of the two words in a two-word term has a synonym. The situation becomes more complicated if both of the terms have one or more synonyms. In this case, several piecewise synonyms are constructed. If T is a two-word term, we denote its set of piecewise synonyms as Piecewise_Synonyms(T).

We will formalize the Piecewise_Synonyms function using the Cartesian product. In simple terms, a Cartesian product creates every possible combination of members from one set with members of a second set, while maintaining the order between members. Thus, the Cartesian product ($\times$) of the set $\{a, b\}$ and the set $\{c, d\}$ would be:

$$\{a, b\} \times \{c, d\} = \{(a, c), (a, d), (b, c), (b, d)\} \quad (1)$$

In the following, we use the notation "word(T, n)" to be the n^{th} word of the term T. The WordNet synset of a word w will be denoted synset(w). The operator $\cup$ is set union.

$$\text{Piecewise\_Synonyms}(T) = \{\text{“}w_1\ w_2\text{”} \mid (w_1, w_2) \in (\text{synset}(\text{word}(T, 1)) \cup \{\text{word}(T, 1)\}) \times (\text{synset}(\text{word}(T, 2)) \cup \{\text{word}(T, 2)\})\} - \{T\} \quad (2)$$

In (2), "$w_1\ w_2$" stands for the string (i.e., potential synonym) consisting of w_1 as its first word and w_2 as its second word, such that (w_1, w_2) is an element of the Cartesian product of the synonyms of the two words in T. Note that the words of T are also utilized in the construction of the piecewise synonyms, as indicated by the two set union operations. For example, a potential synonym for T consists of its second word preceded by a synonym for its first word. This case was demonstrated above with "automobile insurance." Therefore, the complete term T must be excluded as a potential synonym of itself. This is done with the explicit use of the "set difference" operator (denoted "–") applied to the singleton set $\{T\}$ at the end of (2).

If any of the piecewise synonyms of T match an existing term in the UMLS$^-$, then we say that T is a newly discovered synonym of an existing UMLS$^-$ term. Our above approach may be easily extended to terms consisting of n (≥ 3) words. In that case, (2) would comprise an n-way Cartesian product. Its result would consist of n-tuples of words, instead of pairs of words.

One may be concerned that computing piecewise synonyms will result in nonsensical terms. For example, if "New York" is passed to the Piecewise_Synonyms() function, it might find that "Novel" is a synonym for "New" and return "Novel York." However, this is not a problem, for the following reason. We do not use a resulting piecewise synonym unless it is found as a matching term in the UMLS. Thus, we are using the UMLS itself as a filter to exclude nonsensical combinations. Any piecewise synonym that is found in the UMLS is by definition meaningful. Of course, it is recommended that a human expert review all results.

We now present a medical example. Table 3 shows the results of computing piecewise synonyms for "biliary tumor." This MST term was not found in the UMLS$^-$. However, one of the piecewise synonyms, "biliary neoplasm," was indeed found in the UMLS$^-$. Thus, we have now identified biliary tumor as a new, valid (after human review) synonym of biliary neoplasm.

Table 3 - Piecewise Synonyms of "Biliary tumor"

Original term	Biliary tumor	
Synonyms of separate words, including the words themselves	Biliary	tumor
	Bilious	neoplasm
		tumour
Piecewise synonyms, excluding the original term	Bilious tumor	
	Biliary neoplasm	
	Bilious neoplasm	
	Biliary tumour	
	Bilious tumour	

The UMLS contains many long terms. For example, "absence of bleeding of edematous duodenal mucosa" consists of seven words. Terms of more than eight words and terms with more than 100 characters occur. This would result in excessive computational runtimes. For example, the term "Ischemic colitis as reason for lower g.i. examination" would produce more than half a million potential piecewise synonyms ($2 \cdot 2 \cdot 20 \cdot 11 \cdot 1 \cdot 37 \cdot 2 \cdot 8$ = 520,960 combinations). To avoid this explosion of synonyms, our program only processes terms with fewer than six words. Even with this limitation, it takes hours to compute all potential piecewise synonyms and to check each of the generated piecewise synonyms against the whole UMLS list of terms, to verify a match.

Results

We have generated 785,155 synonyms from the MST with word length less than six. Table 4 shows the results of

matching piecewise synonyms against the UMLS. The "Matched Synonyms" column indicates how many synonyms were found. The "Matched Terms" column expresses the number of MST terms that generated these synonyms. As seen in the table, there are 132 synonyms, which came from 91 different MST terms, matched in the UMLS⁻. Of these 132 synonyms, 78 are piecewise synonyms from 65 different MST terms. The other 54 synonyms consist of one word.

Table 4 - MST matches based on synonyms

	Matched Synonyms	Matched Terms
Single-word Synonyms	54	26
Piecewise Synonyms	78	65
Total:	132	91

Table 5 shows the results of applying the matching process of Figure 1. The first and second rows (with two and three sub-rows, respectively) give the results of Step 1, i.e., perfect matches and lexical-variant matches, as defined by a transformation to lowercase letters only. For example, there were 142 perfect matches involving multi-word terms. (This number represents 3.81% of the total number of terms in the MST.) This number increased to 164 with lowercase letters only. Overall, the lexical-variant matching had an improvement of 10.19% over perfect matching. The third row in the table presents the results of Steps 2 and 3 in its first two respective sub-rows. For single-word terms, 26 matches (1.34%) were found. Finally, the main results show that the piecewise-synonyms match yielded 65 matches (3.34%). Of those 65, six are brand-new discoveries. That represents a 3.66% improvement over the results of the multi-word lowercase match.

Table 5 – Matching results

		# Matched Terms	% Matched
Perfect Match	**Single-Word**	74	3.81
	Multi-Word	142	7.30
Lower-case Match	**Single-Word**	74	3.81
	Multi-Word	164	8.43
	Improvement over Perfect	22 (10.19%)	
Synonym Match	**Single-Word**	26	1.34
	Piecewise	65	3.34
	Piecewise improvement over Lowercase	6 (3.66%)	

Table 6 shows the number of matched terms with respect to the number of words per term. Because the UMLS is concept-oriented as opposed to term-oriented, we also present the corresponding numbers for concepts. For example, two-word terms in the MST matched a total of 38 terms in the UMLS⁻. (They also matched 38 concepts.) In total, two-word terms matched 50 synonyms.

Table 6 - Matched terms with respect to number of words

	Matched Terms	Matched Concepts	Matched Synonyms
Single-Word	26	25	54
Two-Word	38	38	50
Three-Word	20	20	20
Four-Word	5	4	6
Five-Word	2	2	2
Total:	91	89	132

Table 7 shows all new matches for MST terms achieved by the piecewise synonyms methodology (Step 3). For example, the piecewise synonym "Biliary neoplasm" was used to find a match for the term "Biliary tumor" in the UMLS⁻.

Table 7 - New terms found by generating piecewise synonyms

MST Term	Piecewise Synonym
Biliary tumor	Biliary neoplasm
Colo-rectal cancer	Colorectal cancer
2nd part of the duodenum	Second portion of the duodenum
Bile ducts stone	Bile duct stone
Modification of bowel habits	Change of bowel habit
Extravasation of contrast medium	Extravasation of contrast media

Discussion

As in , we are using WordNet to improve matching of terms with the UMLS. The approach in used "Data Elements" as input and WordNet to either validate a match or select between several matches. In our approach, WordNet matching is used as one step in a larger terminology integration project, with the focus of this paper on the generation of piecewise synonyms. The key positive result of this research was the ability to generate 78 *new, valid, multi-word terms* (new from the point of view of the MST). "Validity" means that meaningful multi-word terms, which exist in the UMLS, were found, as opposed to terms such as "Novel York."

We generated these 78 new terms from 65 MST source terms; 59 of these source terms already existed in the UMLS; however, six terms did not exist. Thus, six genuinely new mappings were found. While this may appear to

be a small number, one needs to keep in mind three points: (i) The MST is fairly small, as medical terminologies go, and the 78 new terms have to be considered in relation to that fact; (ii) the UMLS is a huge repository of terms, and finding *any* new terms in a core area such as GI is important; (iii) only 216 out of 1,944 MST terms were found in the case of perfect matching, which was unexpectedly low. Thus, even a small absolute improvement by other methods of matching is meaningful.

Limiting ourselves to terms with at most five words appears acceptable, as our results show that the longer a term is, the less likely it is that its synonym has a match. We found only two matched synonyms for five-word terms, but 50 synonyms matched two-word terms. Among the 65 matched source terms, we found piecewise synonyms with matches in the UMLS^{-}, which were semantically wrong, because they belonged to concepts outside the GI domain. This reinforces the need for human review of all results.

Another unexpected result was that "subdivision of pancreas" and its piecewise synonym "branch of pancreas" belong to two different UMLS concepts, which should not be the case. This suggests a new method for auditing UMLS terms.

Conclusions

In this paper, a new methodology for enhancing automated term matching between a source vocabulary and the UMLS was presented. The methodology avails itself of the WordNet lexical database in the construction of new, potential synonyms for multi-word terms. These piecewise synonyms were shown to be another useful tool in the toolbox of medical terminology integrators and curators. Additionally, we found that our approach can have an impact on auditing the UMLS. The work described herein suggests a number of directions for future research: (1) increased use of syntactic categories (adjectives versus nouns); (2) use of one-word synonyms from the UMLS itself for constructing piecewise synonyms; (3) use of WordNet subclasses (hyponyms) and superclasses (hypernyms) of given terms; (4) use of piecewise mapping with synonyms of partial multi-word terms; and (5) use of piecewise-synonym generation as part of a complete algorithm for integrating a terminology into the UMLS.

Abstract

One goal of many clinical information systems is to capture as much data as possible in structured form. This allows significant flexibility in using the data after it has been captured. While progress data standardization efforts are making this goal more achievable, the realities of clinical information present constant challenges. We present some of the challenges that we have encountered as we create clinical data representations using the Clinical Element Model. The majority of these challenges are due to either differences in information granularity or incompatible data types. We have devised strategies for dealing with these challenges. These strategies revolve around the use of two constructs within the Clinical Element Model. The Aggregate construct is used to address issues related to information granularity differences. The Alternative construct is designed to assist in situations where data types are not consistent.

Keywords:

clinical data models; information storage and retrieval

Introduction

Providing optimal care for patients in a modern healthcare setting requires the integration of many different types of information from many different sources. Assimilating large quantities of information and determining the role this information should play in caring for a patient is a demanding task for clinicians and those who support them [1]. Clinical information systems are designed to assist in this task by helping to capture and organize much of this information. When properly implemented, the organization of information in a clinical information system enables presentation and review of the stored information in a temporal and spatial arrangement that enhances a clinician's ability to provide appropriate care in a timely fashion. In addition to presenting back to the user useful arrangements of stored information, clinical information systems may also perform higher-level functions on the information such as making inferences about the state of a patient's health or recommending tasks for managing a disease.

Regurgitation of previously stored information in useful arrangements does not generally require much structurally from the information being handled. However, as a clinical information system strives to provide higher-level functionality, the structure of the underlying data becomes more important. Although natural language processing techniques can be applied to assist in the effort, it is generally more difficult to generate meaningful and accurate alerts on unstructured, textual documents than on well-structured information.

Clinical elements

We have previously described the Clinical Element Model [2], the data modeling formalism that we employ for structuring our clinical information. The Clinical Element Model defines a highly flexible and recursive data model. The foundational unit of the model is called a Clinical Element. A Clinical Element can primarily either (1) be assigned a data type and contain one piece of information conforming to that type, or (2) contain a group of other Clinical Elements. For example, in modeling vital signs, we would define a Clinical Element for respiratory rate with a data type of "physical quantity", likely named "RespiratoryRate". We would similarly define Clinical Elements for other components of a vital signs assessment such as heart rate, blood pressure, and temperature. We would then define a Clinical Element that would contain the components of the vital signs assessment and name it something like "VitalSignsPanel". Thus, the "VitalSignsPanel" Clinical Element would contain, amongst others, the "RespiratoryRate" Clinical Element. Clinical Elements can thus be represented as a simple tree structure with all internal nodes containing other Clinical Elements, and all leaf nodes containing data of an assigned type.

The data types that we use in the Clinical Element Model are derived from the data types that Health Level Seven (HL7) has defined for their Reference Information Model (RIM) [3]. They include types such as "time stamp", "coded concept", "physical quantity", "binary", and "string". While we have made a few changes to the HL7 versions of these types to support our needs, we strive to maintain a high level of compatibility to support semantic interoperability with other systems via HL7 messaging.

Within the Clinical Element Model, in addition to the primary type of data that a Clinical Element contains, every Clinical Element may also contain a set of qualifiers. Qualifiers are data items that provide additional informa-

tion relevant to the primary data. For example, the "RespiratoryRate" Clinical Element may contain a qualifier for the time at which the respiratory rate was measured. Structurally, the data captured in qualifiers is no different from other data in the model, and thus qualifiers are modeled as specializations of Clinical Elements. Therefore every qualifier may either be assigned a data type or may contain a group of other Clinical Elements. Likewise, qualifiers may contain other qualifiers. Although the decision as to whether a piece of data should be modeled as primary data or as a qualifier is not always straightforward, in practice these cases are the exception and do not pose significant problems for this modeling approach.

A fundamental aspect of our data management approach using the Clinical Element model is that we define a single standard representation for each type of clinical information that we use in our system. We then map all incoming information to these standardized structures. In developing the Clinical Element Model, we put significant effort into structuring the information such that it will support many higher-level functions that we deem to be of value. These functions included advanced clinical decision support and semantically interoperable exchange of information with other clinical information systems.

Differently structured data

Despite the effort that we put into modeling and mapping information appropriately, we recognize several situations where real-world concerns present us with information that does not fit neatly into our ideal models. When managing a system that receives clinical information from a large number of external sources, it is nigh impossible to have the power and influence necessary to ensure that all of the information that is received comes in a format that maps well into a standardized structure. Even when an enterprise strives to require high standards of data structure when negotiating with potential data sources, the realities of legacy data, unresponsive vendors, and lack of bargaining power often leave the enterprise with less than optimally structured inbound information.

Furthermore, even when external sources of information are cooperative, enterprises will encounter relevant and accurate clinical information that does not fit well in their internal data structures. The result of these situations is source data that is of different granularity than that of the target model, or that is of a form that is not compatible with the data type in the target. In the Clinical Element Model, we have developed several constructs that allow us to gracefully handle clinical information that does not fit nicely into the standard structures that we have defined.

Methods

Handling granularity issues with aggregate

The first construct we will consider is called Aggregate. As may be inferred from its name, Aggregate is used in situations when the granularity of the source information is not consistent with that of the target model. Specifically, we use aggregate when the inbound information is less granularly structured than the target Clinical Element. In these situations we use a system that we have created for decomposition of composite information into more granular pieces. Description of this decomposition system is beyond the scope of this paper, but the output of this system is information of appropriate granularity for use in the target Clinical Elements.

For example, in our inbound interface for an external microbiology system, we receive information about the body location, from which the relevant specimen was collected, in a single, unstructured, text field. The contents and format of the data in this field vary significantly between messages. In contrast, the model for body location defined in the Clinical Element Model is highly structured, with the ability to independently specify features such as body part, laterality, proximity, superiority, depth, and lesion type.

When the decomposition system is successful, it generates an appropriately populated set of Clinical Element instances containing the information from the source text. We have found it helpful, when capturing and storing these decompositions of clinical information, to store the original composite with each piece. It is useful to have this information available when we need to present back to the user what was originally received. One reason is that although a proper decomposition should contain all of the information content from the original source data, putting all of the pieces back in an order and format that is natural for a human to consume is not a simple task. In addition, we find it useful to have the original source data closely linked when we are verifying the results of our decomposition process.

The Aggregate structure in the Clinical Element Model is the place where we store the composite source information. Aggregate is a foundational part of the model, and therefore is available to all instances of Clinical Elements. Enhancing our description of Clinical Elements above, every Clinical Element will contain a primary data item (either a field of an assigned type, or a group of Clinical Elements), and may also contain qualifiers and an Aggregate. Since all information in the Clinical Element Model is stored as Clinical Elements, any piece of information can have an associated Aggregate. In addition to the textual source data in the microbiology interface use case described above, we have either real or expected use cases

for binary data and coded concepts as source data types. Thus, the Aggregate construct consists of an exclusive choice between a "coded concept" value and a "binary" value. These two data types support all of the used cases that we are aware of for composite data in our enterprise. Following the conventions of the HL7 data types, the "string" data type is a specialization of "binary", and is thus supported by Aggregate.

An example of when we would store binary data in Aggregate is when we receive information from an outside source as a document in a format such as Adobe Systems' Portable Document Format (PDF). If the PDF document contained relevant information that we would benefit from storing in a structured format, we would extract the information, creating and storing the appropriate Clinical Elements. Each of these Clinical Elements would be associated with the original PDF by placing the PDF in the binary value field of Aggregate.

We recognize that, in many cases, storing the original composition with each Clinical Element derived from it may result in large amounts of redundant data being stored and unnecessarily wasting space. To mitigate this condition, we have devised two strategies for referencing a single instance of the source data contained in Aggregate rather than copying it multiple times.

One of the properties of qualifiers in the Clinical Element Model is that they can be inherited by containment. This is similar to "context conduction" in the HL7 RIM. To illustrate how this works, consider two Clinical Elements, A and B, and a qualifier, C. In this example, Clinical Element A contains Clinical Element B (e.g. A may be a chemistry panel and B may be a serum sodium measurement). If the definitions of both A and B reference qualifier C, then we only need to specify C for A, and it automatically applies to B unless specifically overridden. For example, in a chemistry panel, we may define a qualifier for the specimen both at the panel level and within each individual chemistry in the panel. We can then specify the specimen at the level of the panel, and each of the individual chemistries will inherit this specimen unless they explicitly specify a different one. If the composite source data decomposes nicely into a series of Clinical Elements contained within a common parent, this same mechanism can be used with Aggregate to avoid repeating the composite source data multiple times.

Within the Clinical Element Model we have also defined a mechanism for specifying a link or reference from one data instance to another. Using this mechanism, we can store the composite source data as an independent, undivided, Clinical Element. We can then, from within the Aggregate, reference this composite Clinical Element by an indexed unique identifier rather than by inclusion of the source data directly.

Handling type discrepancies with alternative

Another construct within the Clinical Element Model which we use to manage data that doesn't fit well is called Alternative. In contrast to Aggregate, which was developed for managing granularity mismatches, Alternative was designed to handle data type mismatches.

As we develop our clinical models, we evaluate each piece of relevant data, define a Clinical Element for that data, and assign that Clinical Element a type. In most cases, assigning a data type is relatively clear-cut. Most laboratory data with numeric result values is handled nicely with the "physical quantity" data type. Points in time are represented with the "time stamp" type. And so forth. However, even when the assigning of data types appears simple, the realities of clinical data present interesting challenges.

The "physical quantity" data type consists of a numeric value and a coded concept representing the units of measure. Although most of the results for a given laboratory test may fit well in this structure, sometimes we will receive a result such as "below detectable limit". In a situation like this, the value we received does provide an answer to the question posed by the laboratory test, "how much of a given substance is present in the sample", but it does not fit nicely into our "physical quantity" data type.

To handle such cases, we use the Clinical Element Model's Alternative construct. Like Aggregate, Alternative is a foundational part of the model. It is available to any Clinical Element. Also like Aggregate, its structure consists of a choice of several data types. In the case of Alternative, the available data types are "coded concept", "binary" (which includes "string" as mentioned above), and "physical quantity".

Strictly speaking, to be appropriate for use in the Alternative construct, the source data must fulfill two requirements. First, the granularity of the source data must match that of the target Clinical Element. If there is a granularity mismatch, then Aggregate should be used instead of Alternative. Second, the source data, while structurally incompatible with the target data type, should be semantically consistent with the target Clinical Element. Expanding on the laboratory example above, "below detectable limit" answers the question of "how much" in a manner similar to a physical quantity of "2 mg/dL". However, if the value we received were "specimen hemolyzed", indicating that the test could not be performed because of an unfit specimen, this value does not answer the question of "how much" and therefore should be recorded elsewhere, leaving the value in the target Clinical Element null. In practice however, determining the semantics of data received in an alternative format is frequently a difficult task. Therefore information that this

stored in Alternative is not always as semantically congruent with the expected data as we would desire.

The reason for these requirements on the use of Alternative is that we want all of a given kind of information stored, and thus retrievable, in a common manner, even if the data type is not what is expected. When querying for a given laboratory test, we do not want our users to have to remember to query both for those stored in the expected "physical quantity" format as well as for those stored in other formats. Rather, we feel that is important that a query for a given kind of information retrieve all instances of that information regardless of data type. We recognize that this places an additional burden on the applications that receive the information to handle unexpected data types, but ultimately we are more comfortable forcing these issues to be dealt with up front rather than letting this useful information fall between the cracks.

The common scenarios for using the Alternative construct include data at the extremes of possible ranges, and data from unusual, infrequent, or uncontrolled sources. In addition to "below detectable limit", other examples of the use of Alternative include:

- We receive an optically scanned SOAP note from a referring physician when we have internally defined a well-structured model for a SOAP note.
- We receive a quantitative heart rate of "140 bpm" for the APGAR pulse component which is designed to contain one of the coded concepts for "no heart rate", "heart rate less than 100 bpm", or "heart rate at least 100 bpm".

We do not use the Alternative construct when the source data is of the expected data type, but needs to be translated, such as when we receive a concept from a different coding system than that which we use internally or when we receive a physical quantity with units that differ from our enterprise standard. For these cases, the "coded concept" and "physical quantity" data types, respectively, have built in mechanisms for handling translations.

Since the information captured in Alternative should be semantically compatible with the target Clinical Element, that information may sometimes be directly transformable to the target data type. For example, in the case of APGAR scores mentioned above, would could accurately generate a concept of "heart rate at least 100 bpm" from the physical quantity that we received. In situations where this is possible, and doing so would provide enough additional value, we would develop processes – either automated or manual – to populate the primary data field in addition to the Alternative construct, allowing the data to be handled more consistently with other instances of that kind of information.

Discussion

The Aggregate and Alternative constructs provide us with practical mechanisms for handling differently structured data. Some the principles behind this approach include:

- We want our data structured in ways that support robust clinical decision support and semantically interoperable data exchange.
- When transforming data into more useful, structured forms, we want to maintain the original form of the data.
- Even when data is not structured as expected, we do not want any data to be stored using obscure methods or constructs that make it easy to overlook.

The focus or our modeling efforts is largely on the common internal data models needed to support our traditional, "best-of-bread" approach. As described above, this approach, while addressing some concerns, creates its own set of challenges, particularly for applications that use the information stored as Clinical Elements. For applications over which we have influence, we are building in mechanism to support the capture, manipulation, and display of this differently structured data. For other applications, we have to address the difficulties on a case-by-case basis and choose the best solution for each.

Conclusion

The use of the Aggregate and Alternative constructs allows us to manage relevant data that doesn't fit our data model definitions in close proximity with its expected target. This enables us to maintain the integrity of the source data, support derivations into forms consistent with other data in the system, and keep the semantics of our data models well defined.

Representing Clinical Knowledge as Archetypes

Knut Bernstein[a], Mette Rosendal Darmer[b]

[a]*MEDIQ, Copenhagen, Denmark*
[b]*Clinical Content Unit, Department of Informatics, Copenhagen Region, Denmark*

Abstract

The Copenhagen Region has developed an extensive set of clinical content specifications to be used in EHR systems. A clinical content specification is a standard plan linking a clinical problem/diagnose with predefined, detailed plans/ activities and the expected outcomes. In order to achieve a more coherent structure of the clinical content specifications and to link terms to SNOMED CT, a part of the specification has been transformed into archetypes. In this trial, archetype tools and terminology tools were used and assessed. The trial indicated that by using the tools the quality of the clinical content specifications was improved and the specifications became more suitable for incorporation into EHR-systems.

Keywords:

archetype, clinical knowledge, SNOMED CT,
electronic health record

Introduction

The "Clinical Content Project" was established in the Copenhagen Region in 2004 as part of the EHR implementation plans. The purpose of the project is specifying the clinical content of a highly structured EHR, based on the National Basic Model for EHR. This model supports a problem-oriented, longitudinal and cross professional EHR for the purpose of continuity of care [1]. The Clinical Content Project aimed at contributing to improved quality of the clinical documentation, re-use of data in an interdisciplinary contexts, and enabling use of EHR data for quality improvement.

The clinical content specifications are similar to structured clinical guidelines or clinical care pathways [2], and supports clinical decision-making. It has been shown that clinical guidelines provided as real time decision support systems' in daily clinical workflow will improve patient care significantly [3] and are an effective instrument to decrease undesired practice variability [4].

The Clinical Content Project has produced an extensive, detailed set of specifications of what to document in various clinical situations. However, the project identified a need for reducing redundancy, improving the consistency of the structure, linking the clinical content specifications to SNOMED CT, and documenting the clinical content in a format more suitable for use in EHR systems. Therefore, a trial was set up to transform a part if the clinical content specifications into archetypes.

The archetypes discussed in this paper are based on the openEHR reference model [5]. This is equivalent to the CEN pre-standard 13606 (EHRcom), which is currently under revision [6]. OpenEHR describes archetypes as "… reusable, structured models of clinical information concepts that appear in EHRs". Archetypes are described in a formal language and concepts in the archetypes may be linked to a terminology.

The templates discussed are based on the openEHR concept where archetypes can be adjusted to local needs and connected to entry forms. OpenEHR describes archetypes as "a selection of archetypes, terminologies, language and other details relevant to the particular local use of archetypes"

Methods

The clinical content specifications have a diagnosis or clinical problem, as a starting point. For each diagnose/ problem the standard plan describes in detail, a number of activities normally carried out, what expected observations are connected to the activities, and what data to enter for each observation.

It is estimated that clinical content developed in the Copenhagen Region is covering more than 75 % off the clinical documentation need, containing more than 600 standard plans.

The material is currently documented in MS Word tables and Visio flow-charts. The clinicians are comfortable with using these programs, but the specifications produced cannot easily be imported into or integrated with EHR systems.

The trial was attempting to show that using archetype tools the clinical content specifications could be made more suitable for incorporation into EHR-systems and the quality of the clinical content specifications could be improved.

The tools used were the openEHR archetype editor and the template tool and the terminology server from Ocean

Informatics, i.e. software supporting the openEHR architecture [7].

The archetype editor is an open source authoring tool for expert clinicians to create and edit archetypes. The tool was used in the trial to transform the clinical content into an archetype format and to link elements to SNOMED CT.

The template tool is an authoring tool for templates supporting design of archetype-enabled data entry. The tool was used for combing archetypes, creating variants of one archetype, and generating examples of data entry forms.

The terminology service in combination with a terminology query editor was used to create subsets of SNOMED CT – linked to the archetype. In the entry forms the subsets provided the set of selectable terms for a given data field.

Results & discussion

The selected areas from the clinical content documentation had a relatively simple structure. Areas were selected in which archetypes already existed in the openEHR repository [8].

For the clinical content specifications transformed to the "observation" archetypes, there were in generally good coherence between the two representations.

The "observation" archetype distinguishes between the list of data about the observation, the patient state, the protocol (i.e. measuring methods), and the temporal aspects. By applying this structure to the clinical content specifications, the ambiguity could be reduced and it became clearer if parts of the specification were missing or omitted.

However, the following challenges were encountered when comparing archetypes with the clinical content specifications:

- In some cases the lists of data about the observation or the protocol list needed to be extended. Since the archetype is meant to be the "maximum data set", this calls for a change of the archetype.
- Allowable values of observations may be represented as a list. However, some professionals would need a larger classification in addition to the list. The archetype editor seems only to offer functionality to hold either a list or a link to a classification.

The "section" structure was tried out for a few specifications, and the functionality seemed to be sufficient. This structure mainly groups archetypes into a larger, compound archetype.

The archetype editor could be improved by integrating it with a data dictionary. In this way the author could get an overview over terms used as well as their definitions, and this would support the re-use of terms or parts of archetypes

The template editor was used to develop templates and entry forms for doctors and nurses respectively – based on the same archetype. This functionality seemed to be sufficient.

The terminology server was tried out with only a few examples. It was relatively easy to define a subset of SNOMED CT based on the clinical content specifications; the main challenge being to identify the correct terms in SNOMED CT based on the terms in the clinical content specifications. The terminology query editor has a good facility for creating a search tree where parts of the tree are for navigation only and other parts can be selected by the user.

The linking of the SNOMED CT subset to the archetype element did also function well. An URL pointer was introduced instead of a value list in the archetype. However, sometimes i.e. doctors and nurses in principle can share the same template but require different terminology subsets. This requires an option to make further restrictions of the SNOMED subset at the template level, which is currently not possible.

Conclusion

The archetype editor helped structuring the clinical content specifications. There was generally good coherence between the two representations. Using archetypes made the linking to SNOMED CT more manageable, and made the clinical content more suitable for incorporation into EHR-systems.

It is a challenge to manage a large number of the archetype components, templates and entry forms. A link to a data dictionary could be considered to ease the re-use of the elements.

It is a large advantage that the clinical content specifications can be stored and exchanged in a standardised format. However, it is still an outstanding issue if EHR vendors are able to handle the archetype concept and import the archetype format.

Many clinical areas are not covered by existing archetypes, and some archetypes needs to be extended. This calls for an improved strategy and tools for managing the development, maintenance and approval process at an international level.

Ontology Model of CRF for Clinical Research in Traditional Korean Medicine

Jinseok Moon[a], Kyungmo Park [b], Yoosik Yoon[c], Sunmi Choi [a]

[a] *Korea Institute of Oriental Medicine, Korea*
[b] *Dept of Biomedical Engineering, University of Kyunghee, Korea*
[c] *Dept of Medical School, University of Jungang, Korea*

Abstract

Multicenter trials progress in oriental and western medicine. The CRF for stroke clinical trial in oriental and western medicine is made up of syndrome differentiation, etiologic items and blood serum test, etc. To represent systematic and structural knowledge of CRF, we design stroke clinical ontology by Protégé 3.1. The result is just on stroke domain, afterward, it will be extended to the framework of the other specific disease. And it could be developed for decision supporting system.

Keywords:

ontology, traditional medicine, oriental medicine,
Case Report Form (CRF), clinical trial

Introduction

The Case Report Form (CRF), which is essential to clinical research, is a printed, optical, or electronic document designed to record all of the protocol-required information to be reported to the sponsor for each trial subject. However, it is a fact that writing the paper-based CRF claims takes many hours and causes errors. To solve such problems, the electronic Case Report Form (eCRF) has emerged as an alternative way to reduce risk of errors in filling out and send data from hospitals to research centers on a real-time basis. The trend toward multi-center clinical studies is also pushing the demand for web-based eCRF.

We suggest that the electronic CRF based on the ontology. That could be systematically collect and analyze clinical data.

Methods

This study established the conceptual model of CRF on oriental and western medicine, and developed ontologies. The CRF applied in this study is a draft through consensus of experts for stroke research at the Korea Institute of Oriental Medicine. The conceptual model is made up of syndrome differentiation, diagnosis, blood test, dietary life and history et al. This model was referenced ISO TC 215 22789 Patient Findings[1]. The OntoCRF(CRF based Ontology) is based on the conceptual model using Protégé 3.1. Ò°

Results

The OntoCRF builds on the standard CRF by domain experts. It organizes classes and properties and their relationships. Therefore preparation based ontology is more systematically than that based RDBMS at representing the knowledge. The ontology of CRF consisted of Label, ControlType and Value classes and hasControl, hasValue and hasSymptoms properties. The Label is the class of question items groups, so it could have CRF questionnaire instances. The ControlType is the class that expresses controls such as checkbox, text, etc in the HTML script. The Value class represents selections for each items.

Discussion and conclusion

This ontology model is developed in stroke domain. Furthermore it could use to construct the other disease diagnosis and clinical decision or reasoning by ontology.

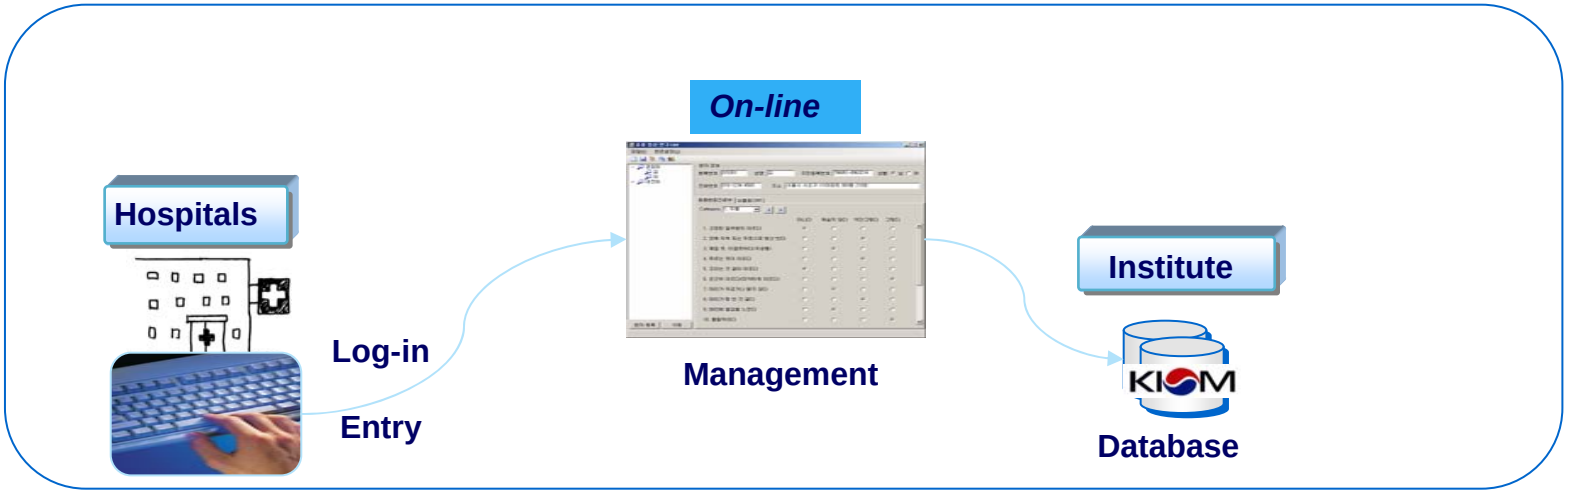
Background

- Multicenter trials progress in oriental and western medicine. A Case Report Form(CRF) is a questionnaire specifically used in clinical trial research. The CRF is the primary data collection tool from the investigator site. As a nowadays, as using electronic CRF, it decreases the errors that was generated for inputting data and be convenient to sending the clinical data.



- We suggest that the electronic CRF based on the ontology. That could be systematically collect and analyze clinical data.

Methods

- The conceptual model is made up of syndrome differentiation(辨證), diagnosis, blood test, dietary life and history et al. This model was referenced ISO TC 215 22789 Patient Findings.

- The OntoCRF(CRF based Ontology) is based on the conceptual model using Protégé 3.1.

A Framework to Extract, Interpret and Structure Clinical Information From Free-Texts

Gisele Azambuja [a], Tatjana Zrimec [a], Andrew Hopkins[b]

[a] *Centre for Health Informatics, University of New South Wales*
[b] *Cardiology Department, The Liverpool Hospital*

Abstract

The major barrier in existing hospital information systems is that most information is stored in free-text medical narratives and is unavailable for decision support and research. Our aim is to develop a general medical text processing system to extract clinical information from different types of free-text clinical records. We propose a framework to encode and represent clinical information relying on UMLS Knowledge Resources.

Keywords:

natural language processing, medical records

Introduction

For more than three decades physicians, computer scientists and linguists have addressed Natural Language Processing (NLP) techniques in medicine. Applications include extracting selected types of information from free-text clinical notes and automatic coding of patient information in the terms of a controlled medical vocabulary [1, 2]. When referring to natural language commonly used in medicine, NLP systems are also called Medical Language Processing (MLP) systems [3]. When adequate processing of texts is achieved, MLP systems can make clinical information available for a variety of applications and still preserve the knowledge integrity while offering freedom of expression to physicians.

Conventional medical narratives are commonly stored in existing electronic medical records as free-text clinical notes. We propose a method and provide a framework to automatically process clinical free-text reports from different medical domains in order to extract and represent relevant clinical information. This information can then be easily accessed for other computer applications. In this paper we focus particularly on creating a structure to represent information from free-text clinical notes.

Materials and methods

We based the development of our system on the assumption that, when reading free-text clinical notes, physicians want to know what, when, where, and why health care activities were performed as well as their outcomes. These questions are related with general categories of information as follows: “Event”, “Time”, “Place”, “Reason” and “Outcome”. In our schema, designed to represent information from the free-text, we used the translation of above mentioned categories into semantic types from Unified Medical Language System (UMLS). In this way, “Event” was mapped to “Health Care Activity”, “Time”, to “Temporal Concept” and “Place” became “Health Care Related Organization”. The category “Reason” was mapped to both, “Disease or Syndrome” and “Sign or Symptom”. Since, in our schema, most classes and sub-classes are based on UMLS semantic types they can be related with each other by predicates existing in the UMLS Semantic Network. Thus, assertions such as, “Health Care Related Organization *carries_out* Health Care Activity” and “Diagnostic Procedure *is_a* Health Care Activity” are represented in our structure. However, the UMLS semantic types do not cover all classes of information necessary to represent and structure free-text clinical notes. Therefore, we added other classes to the schema, like “Outcome”. Similarly, we also added some relationships between classes that are well known as existing in free-text medical narratives, even though they do not exist in the UMLS Semantic Network. An example is the relation *occurs_in* between the classes “Health Care Activity” and “Temporal Concept”.

Results

We have created a schema to represent information from clinical notes. The idea here is to represent sentences from a clinical text using an expandable structure which consists of classes of information, relationships among them and a set of attributes for each class of information. At this stage we are evaluating the schema and applying automated techniques to discover rules for the processing task. To date, we have defined some hypotheses which have the potential to develop into these rules.

"For better or worse, most clinical data accessible to computer processing is still in the form of unstructured natural language."

(Peter Szolovits 2006 http://groups.csail.mit.edu/medg/projects/text/)

Reasons for having clinical data as free text

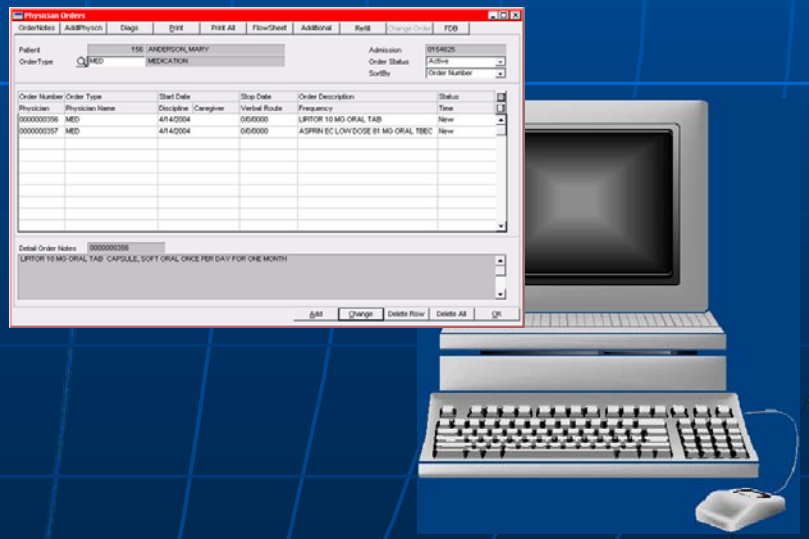
- Original paper-based medical records have been transferred to electronic systems;
- Lack of formalization and standardization;
- Textual Literature – main source of knowledge;
- Computerized Clinical Systems failed to provide structures for clinical information with same degree of expressiveness than free-text.

Some facts about the problem

Conventional medical narratives are commonly stored in existing electronic medical records as free-text clinical notes.

Searching for information in free-text is labour-intensive and demanding task

Computer applications require electronic data to be available in a structured format



To provide a framework and devise automatic methods for extracting relevant clinical information from clinical free-text reports.

Requirements

The system should be applicable to different medical domains

Extracted information should be represented in a form that can be easily accessed by

- medical professionals and
- other computer applications

Approach

We assume that physicians have 5 major questions in mind when reading free-text clinical notes:

What?

Where?

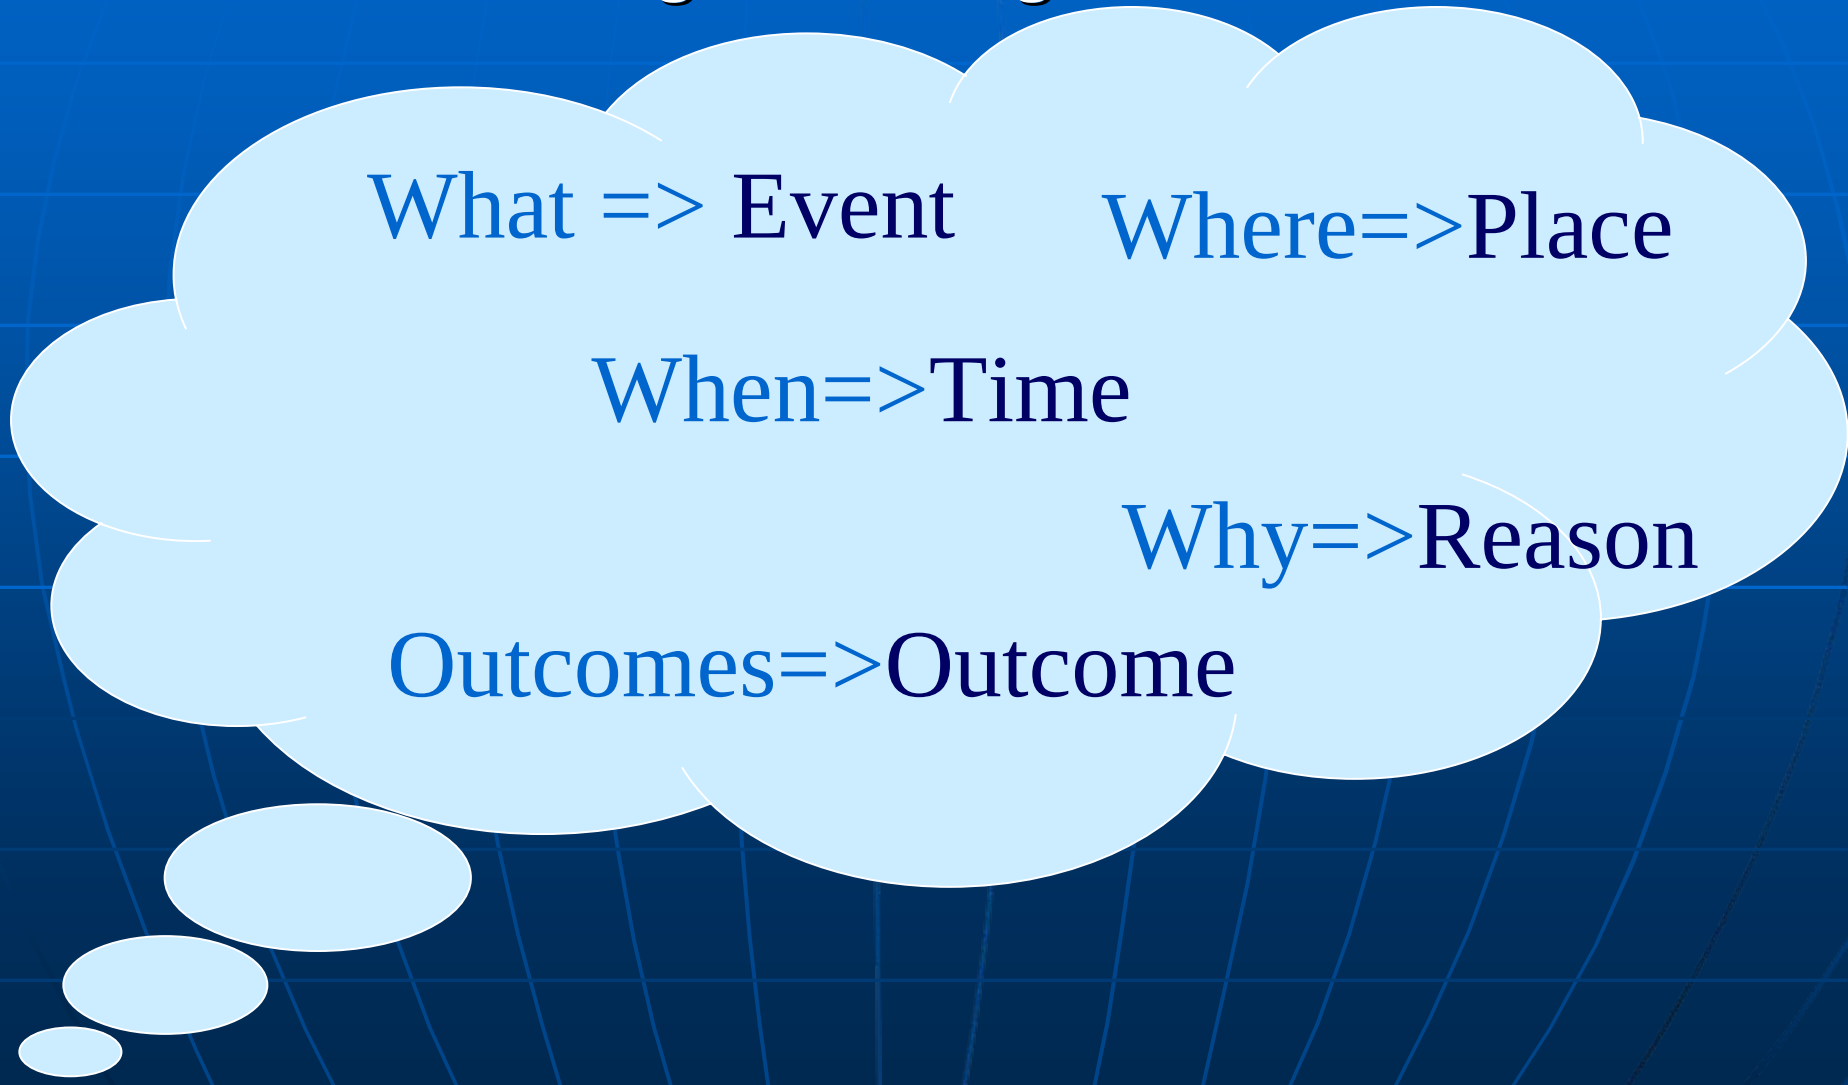
When?

Why?

Outcomes?

Approach

In our schema for representing clinical information, these questions are related to general categories of information.



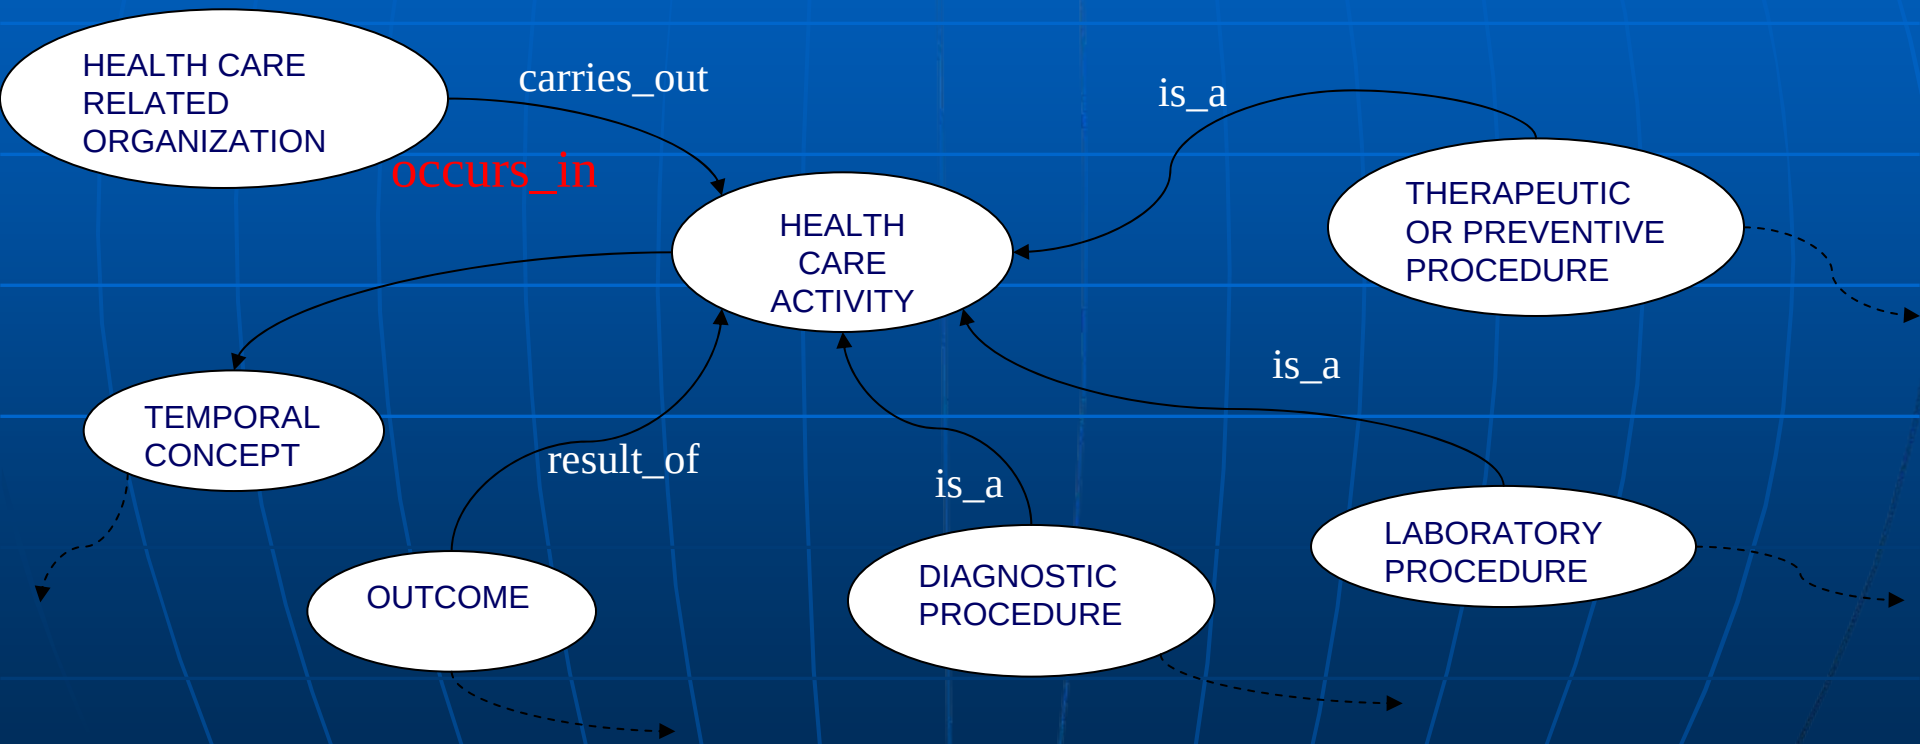
We translated the categories into semantic types from Unified Medical Language System (UMLS).

Event=>"Health Care Activity"
Place=>"Health Care Related Organization"
Time=> "Temporal Concept"
Reason=> " Disease or Syndrome " and "Sign or Symptom"
Outcome=> …..

Some classes like "Outcome" are not related to UMLS semantic types.

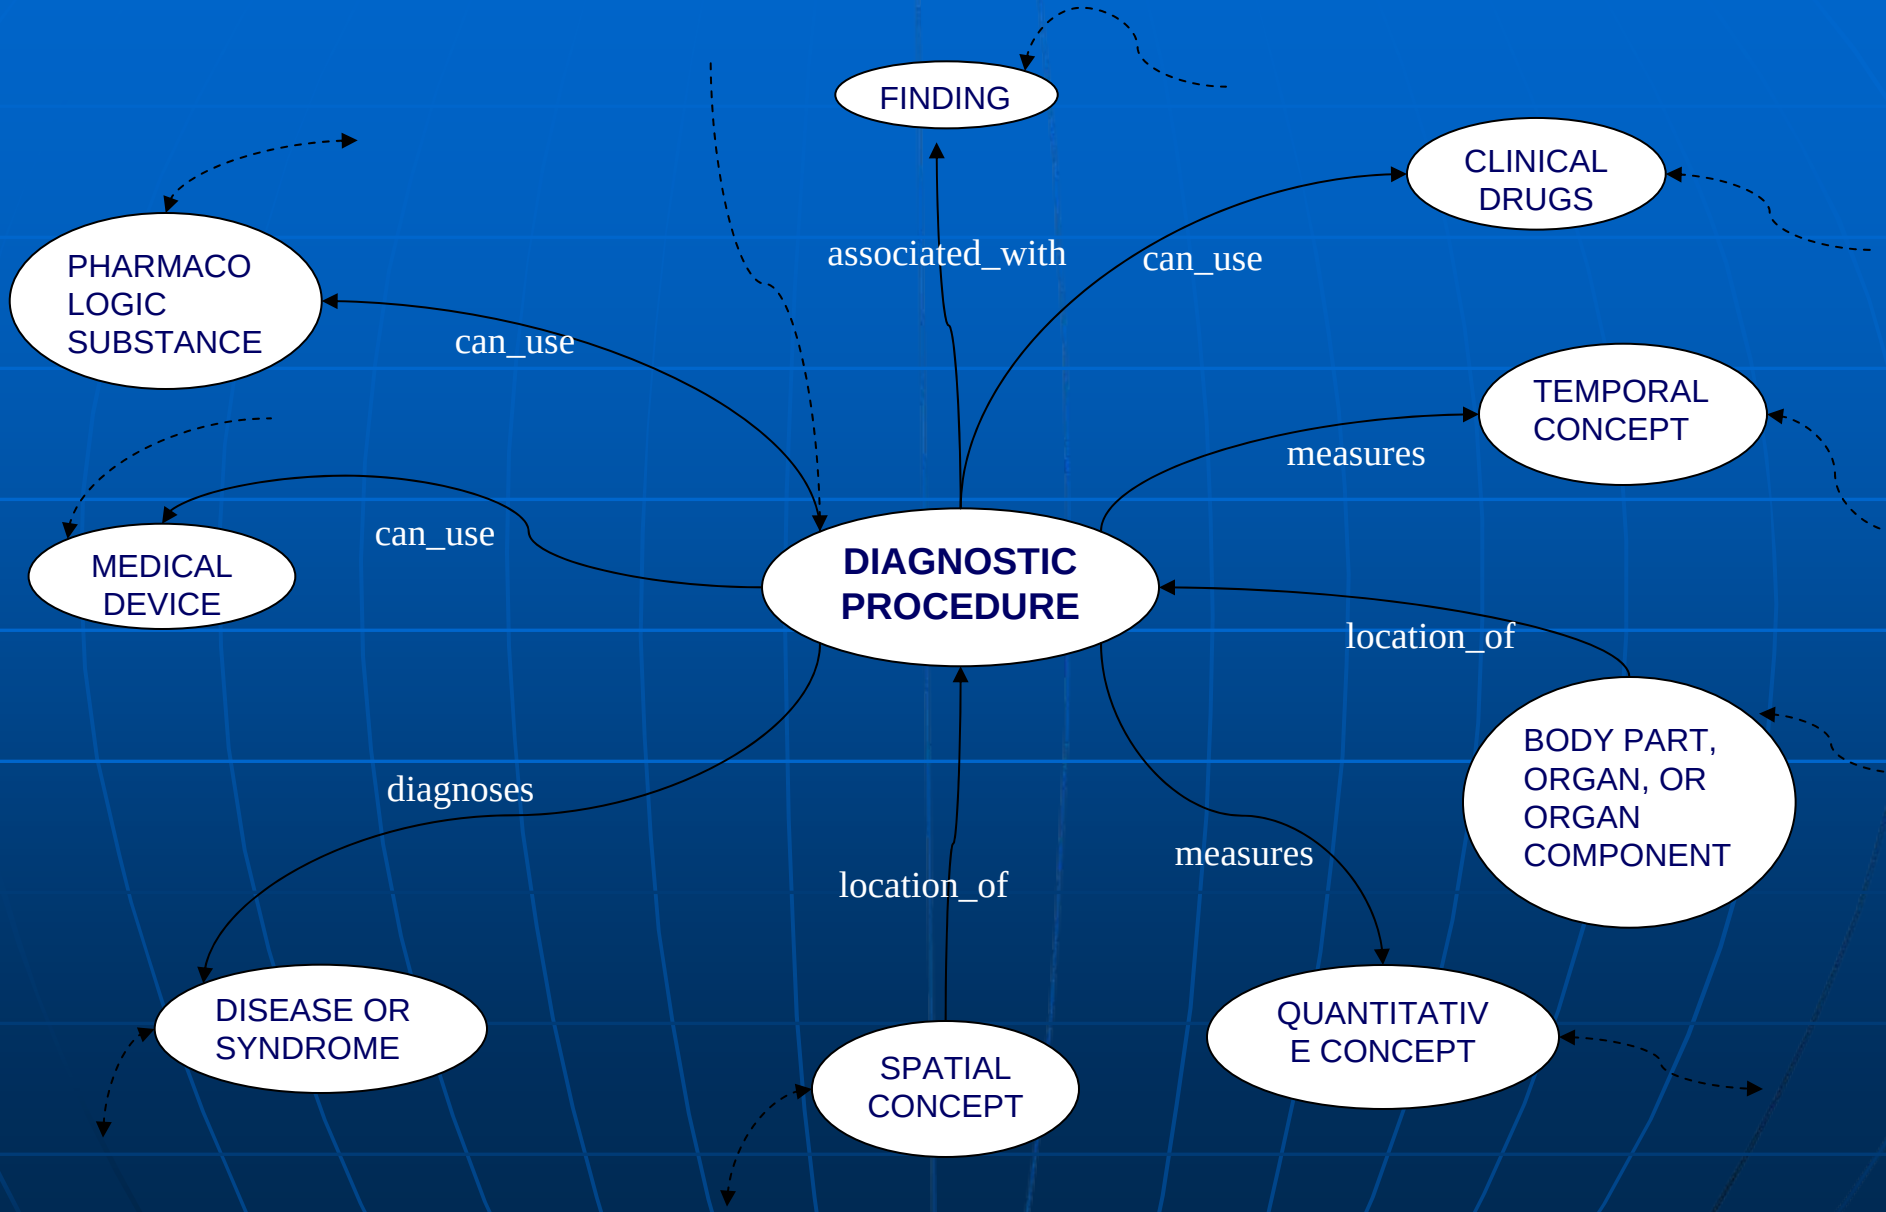
A structure for representing information from free-text clinical notes

The schema inherited predicates existing in the UMLS Semantic Network for classes related to UMLS semantic types.



We also added some relationships between classes that are well known as existing in free-text medical narratives, even though they do not exist in the UMLS Semantic Network.

Diagnostic Procedure - component



Results

Created a schema for representing information from clinical notes using an expandable structure which consists of

- classes of information,
- relationships among them and
- a set of attributes for each class of information.

[HEALTH CARE ACTIVITY]
(*occurs_in)* [TEMPORAL CONCEPT]
[HEALTH CARE RELATED ORGANIZATION] (*carries_out)*
[LABORATORY PROC] | [DIAGNOSTIC PROC] | [THERAPEUTIC OR PREVENTIVE PROC] (*is_a)*
[OUTCOME] *(result_of)*

[DIAGNOSTIC PROCEDURE]
[BODY PART, ORGAN, OR ORGAN COMPONENT] (*location_of)*
[SPATIAL CONCEPT] (*location_of)*
(diagnoses) [DISEASE OR SYNDROME]
(measures) [TEMPORAL CONCEPT]
(measures) [QUANTITATIVE CONCEPT]
(can_uses) [CLINICAL DRUGS]
(can_uses) [PHARMACOLOGIC SUBSTANCE]
(can_uses) [MEDICAL DEVICE]
[FINDING] *(associated_with)*

[BODY PART, ORGAN, ORGAN COMPONENT]
[SPATIAL CONCEPT] (*location_of)*
[QUALITATIVE CONCEPT] *(associated_with)*

[DISEASE OR SYNDROME]
[BODY PART, ORGAN, ORGAN COMPONENT]
(*location_of)*
[SPATIAL CONCEPT] (*location_of)*
[QUANTITATIVE CONCEPT] *(associated_with)*
[FINDING] [FIND] *(associated_with)*

Examples of the schema components

Current status

- Implementation - the schema represents 19 different entities and 34 relationships among them
- Representation - evaluating the schema
- Information extraction - applying automated techniques to discover rules for the processing task

Constructing Evaluation Corpora for Automated Clinical Named Entity Recognition

Philip V. Ogren, Guergana K. Savova , Christopher G. Chute

Division of Biomedical Informatics, Mayo Clinic College of Medicine, USA

Abstract

We report on the construction of a gold-standard data set consisting of annotated clinical notes suitable for evaluating our biomedical named entity recognition system. The data set is the result of consensus between four human annotators and contains 1,556 annotations on 160 clinical notes using 658 unique concept codes from SNOMED-CT corresponding to human disorders. Inter-annotator agreement was calculated on annotations from 100 of the documents for span agreement (91% as positive specific agreement). For annotations found to be a match with respect to span, agreement was calculated for concept code (82% as positive specific agreement), context (85% as Kappa), and status (89% as Kappa). Complete agreement for span, concept code, context, and status was 75% as positive specific agreement. We consider this to be a conservative estimate for the upper bound for total system performance evaluated with the gold-standard. We found that creating a consensus set based on annotations from two independently created annotation sets can reduce inter-annotator disagreement by 32.3%. Surprisingly, we found little benefit to pre-annotating the corpus with a third-party named entity recognizer.

Introduction

The text analysis group at the Mayo Clinic College of Medicine has built and deployed a text analysis system that processes the entire repository of clinical notes in Mayo's electronic medical record. The system identifies, among other things, mentions of disorders and the context and status of those mentions. This output provides a concept-based index of the clinical notes repository used for retrieval purposes by researchers. We have anecdotal evidence based on browsing system output and end-user feedback that gives us a rough idea of the quality of our system. However, there has not yet been a formal evaluation of the final output of the system. By creating a gold-standard data set that represents complete and accurate system output, it becomes possible to measure the performance of actual system output in a way that is automated and comparable across multiple versions of the system. To this end, we have created a gold-standard corpus of annotated clinical notes for the disorder concepts that our system attempts to identify. In this paper we describe how we constructed this gold-standard corpus and evaluated its quality.

[1] provide a survey of gold-standard corpora that are available for the biomedical domain. They are few in number and vary widely in size and quality and none of them were designed with clinical data in mind. There have been no such publicly-available resources for the clinical domain until very recently[1]. This is due to the sensitive nature of patient data and the strict confidentiality laws designed to protect them[2]. Unfortunately, the development of gold-standard corpora is difficult and expensive because of the tedious and detailed nature of the work and the domain expertise required. Some of the well known challenges are outlined in [2]. Absent shared community resources for the medical domain, we are faced with the choice of creating our own or doing without. As we took up the challenge to build our own gold-standard data set, a key consideration was to determine the feasibility of creating a very high quality corpus with limited resources. Thus, the process of building our gold standard was designed so that we could measure the expense of additional review of the annotations against gains in quality of the data set. We also explored one way to potentially speed up annotation: pre-annotation with a third party system, MetaMap.

Materials and methods

Clinical notes corpus

The Mayo Clinic has a repository of approximately twenty million clinical notes that consist of documents dictated by physicians that are subsequently transcribed and filed as part of the patient's electronic medical record. The notes consist of sections such as *Chief Complaint, Current Medications,* and *Impression/Plan,* among others. The repository contains outpatient notes, discharge summaries, and inpatient service notes. From this repository we ran-

1 See https://www.i2b2.org/NLP/.

2 For this reason, our corpus will not be made publicly available in its current form. Contact chute@mayo.edu further information.

domly selected 160 notes for the corpus used for the gold-standard data set. The total number of words in the corpus is 47,975 with a median word count of 249 words per note.

Table 1 - UMLS Semantic types corresponding to disorders

TUI	type name
T019	Congenital abnormality
T020	Acquired abnormality
T037	Injury or Poisoning
T046	Pathologic Function
T047	Disease or Syndrome
T048	Mental or Behavioral Dysfunction
T049	Cell or Molecular Dysfunction
T050	Experimental Model of Disease
T190	Anatomical Abnormality
T191	Neoplastic Process

Annotation schema

The annotation task performed by the annotators consists of creating labeled spans of text that correspond to mentions of disorders found in the clinical note. Each annotation has one or more spans of text, a concept code, a context, a status, and a flag that indicates whether the mentioned disorder is related to the patient or not. An annotation's concept code is a string attribute that contains a concept identifier from a controlled vocabulary, in this case SNOMED-CT. The context of an annotation is an attribute with one of the following values: *current, history of, and family history of*. The status of an annotation is an attribute with one of the following values: *confirmed, possible,* and *negated*. Any combination of context and status values is permitted for an annotation. For example, the combination of the context *family history of* with the status *negated* means that the patient has no family history of the mentioned disorder. An annotation may also be flagged as unrelated to the patient if the mentioned disorder has little or nothing to do with the patient's health (e.g. an organization's name as in "Diabetes Clinic"). When an annotation is flagged as unrelated to the patient, the context and status are both automatically given the value *unrelated to patient.*

We created a subset of SNOMED-CT that contains only those concepts corresponding to disorders by leveraging the Unified Medical Language System[3] (UMLS) and its Semantic Network. The UMLS assigns to each concept in SNOMED-CT one or more semantic types defined in the Semantic Network. The subset of SNOMED-CT we used was created by selecting only those SNOMED-CT concepts assigned one of the semantic types shown in Table 1. This list was derived from [3][4]. The resulting subset of SNOMED-CT consists of 82,813 concepts and was provided to the annotators via an interface that provides keyword search and hierarchical navigation[5].

Annotators

Four clinical data retrieval experts performed the annotation task. All of them have been in their current work positions since 2002 and have prior experience in the medical coding of patient records. Each of the annotators has experience with various medical terminologies (e.g. ICD-9). However, none of them had prior experience with SNOMED-CT and no SNOMED-CT specific training was conducted.

Annotation software

Knowtato[6]r is a general purpose text annotation tool for creating gold-standard training and evaluation corpora for Natural Language Processing (NLP) systems described in [4]. The annotation schema described above was easily instantiated in Knowtator without any task-specific software development. Knowtator provides a mechanism to aggregate multiple sets of annotations into a single annotation project and various inter-annotator agreement (IAA) metrics for comparing multiple sets of annotations. Additionally, Knowtator provides a consensus set creation feature that provides a mechanism for resolving differences between two sets of annotations.

Table 2 - Annotation summary

set	description	count	hours
A1	MMTx pre-annotated	1105	53.5
A2	not pre-annotated	1142	53
A3	MMTx pre-annotated	1054	38
A4	not pre-annotated	1113	21
C1	consensus of A1 & A3	1125	8
C2	consensus of A2 & A4	1193	11
GS	consensus of C1 & C2	1164	13
MMTx	created by MMTx	664	<1

6 See http://bionlp.sourceforge.net/Knowtator

Pre-annotation of the corpus with MMTx:

We pre-annotated all 160 notes in the corpus using the MetaMap Transfer (MMTx)[7] tool. MMTx provides mappings from natural language text to UMLS concepts. The MMTx distribution provides a set of scripts that can build a customized target set of concepts to map to. Using these scripts we were able to provide MMTx with the set of SNOMED-CT concepts described in §2.1. Each annotation that MMTx presents has a span, a concept code, and a relevance score. We used only those mappings with a relevance score of 900 or greater (out of a possible 1000) in order to reduce the number of spurious matches. The resulting annotations were imported into Knowtator and were made available to two of the annotators as described below.

Annotation workflow

Each of the 160 notes was annotated individually by all four annotators, referred to as A1, A2, A3, and A4 (see Table 2). Two of the annotators, A1 and A3, were given MMTx annotations and were encouraged to use, discard or add to the provided annotations as they saw fit. The other two annotators, A2 and A4, were given the clinical notes without any MMTx annotations provided. Other than the presence or absence of MMTx annotations, all four annotators had exactly the same annotation task using the same annotation guidelines. After a note was annotated individually by A1 and A3, a set of pair-wise consensus annotations, C1, was created by A1 and A3 using the annotations they created individually and having them work together to resolve all differences. Similarly, a consensus set, C2, was created from A2 and A4's annotations. When both consensus sets were created for a document a master consensus set, GS, was created by all four annotators working together to resolve the differences between C1 and C2. The set GS is considered our final gold-standard set of annotations.

Sixty of the notes were annotated during a trial phase during which the annotation schema was finalized, the annotation guidelines were completed, and the annotators were trained. Frequent meetings were held during this phase to provide instruction, review examples, and receive feedback about the task. IAA results reported here exclude annotations from this set of 60 notes. However, we included these annotations into our final gold-standard data set because the annotation schema and guidelines were completed before a final round of four-way consensus annotation was performed as described above. During the annotation of the remaining 100 notes the annotation schema and guidelines were not changed, no meetings were held, and the annotators were given a strict prohibition from communicating with each other about the annotation task. IAA results reported below are only for these 100 notes.

Annotation guidelines

[5] show that careful consideration of annotation guidelines can have a marked impact on IAA. Therefore, we took care to create detailed and complete guidelines for the annotators. The annotation guidelines given to the annotators consist of about 3900 words and contain over 40 examples. The guidelines have the following four overarching principles:

1. *A mentioned disorder should be assigned the most specific concept code named by the span of text*. The text covered by the span of an annotation should be a reasonable synonym of the names associated with the concept. Descriptions of disorders should not be annotated, i.e. there should be little or no inference performed by the annotator.
2. *All mentions of disorders in each note are to be annotated.* Every disorder mentioned by name in the text of the clinical note should be annotated regardless of its relevance to the patient. If the disorder is not related to the patient's health, then the corresponding annotation should be flagged as *unrelated to patient*.
3. *A disorder is defined as any concept that appears in the subset of SNOMED-CT that has been provided.* This rule provides an unambiguous and clear definition of what a disorder is.
4. *There should be only one annotation per mentioned disorder.* In some cases a mentioned disorder could reasonably be assigned to more than one concept code. Always, choose the most specific concept that is named by the text.

The remainder of the guidelines consist of a detailed description of the annotation schema, Q&A styled instructions, and examples. Some example questions answered in the guidelines were: *How do I decide what the most specific concept is? Are nested annotations allowed? Are overlapping annotations allowed? Can the spanned text of an annotation be more specific than the assigned concept code?*

Calculating IAA

We report IAA as positive specific agreement described in [6] given by:

$$Ppos = \frac{2a}{2a + b + c} \quad (1)$$

7 See http://mmtx.nlm.nih.gov/

where *a* is the number of cases where the annotators agree and where *b* and *c* are non-matches from each annotator, respectively. Positive specific agreement is reported for match criteria requiring span selection agreement because negative instances are not easily counted and expected chance agreement is vanishingly small. We also report the Kappa statistic described by [7] and [8] given by:

$$\kappa = \frac{P(A) - P(E)}{1 - P(E)} \quad (2)$$

where P(A) is percentage agreement and P(E) is expected chance agreement. Kappa is reported for match criteria that compare only annotations that already agree with respect to span selection for the features concept code, context, and status. The procedure that we used for calculating Kappa is described in detail by [9].

IAA for annotation of texts in the biomedical domain have been reported as Kappa as in [10, 11] and as F-measure described in [12] by [5, 13, 14]. [6] show that positive specific agreement, balanced F-measure, and Kappa are equivalent as P(E) approaches zero. The calculation of IAA for a set of annotations can be varied in many ways by defining different match criteria. We report on the following match criteria: spans are identical, spans overlap, spans overlap and concepts match, spans overlap and contexts match, spans overlap and status's match, and spans overlap, concepts, contexts, and status's match.

This selection of match criteria reflects our attitude towards exact span matching versus approximate span matching. We consider the agreement of concept code, context, and status assignments to be far more important than having exact span agreement. By relaxing the span matching criteria to require only an overlapping span match we get a better idea of how well the annotators agree with respect to the other attributes.

Results

The final gold-standard data set consists of 1556 annotations from the master consensus sets from the trial and experimental sets of notes. A total of 658 unique concept codes were used in the concept code assignments of the annotations. Because sixty of the notes were annotated under uncontrolled circumstances (i.e. the annotators communicated with us and each other) we report only results on the annotations for the remaining 100 notes. Table 2 provides a summary of the annotation sets that were created for these 100 notes including the number of annotations in each annotation set and the number of hours it took the annotators to create them. Because it took a total of 185 hours to create A1, A2, A3, A4, C1, and C2 we conclude that the annotator time to create a single pairwise consensus set for 100 documents is about 92 hours or roughly one document per hour. Table 3 provides the IAA results as positive specific agreement and Table 4 shows the IAA results as Kappa for only those annotations that are considered matches with respect to overlapping span for the attribute's concept code, context, and status. A1, A2, A3, and A4 are compared as average 2-way IAA in both tables.

An estimate on the upper bound of system performance

One would not expect an NLP system to agree with a human generated gold-standard data set better than the humans agree with each other. As such, the IAA numbers reported here represent upper-bounds on system performance as measured against the gold-standard. The most important datum that best represents the overall consistency of the gold-standard on the entire annotation task is the agreement between C1 and C2, 74.6%, for the match criteria that requires the spans to overlap and the concept code, context, and status values to match shown in Table 3. Because the final gold-standard data set is the result of an additional consensus step based on C1 and C2 we would expect that the consistency of GS to be better than C1 and C2. Thus, we conclude that 74.6% is a conservative upper bound for complete system performance.

Table 4 - IAA as Kappa

	A1,A2,A3,A4			C1,C2		
	K	P(A)	P(E)	K	P(A)	P(E)
concept	82.6	82.7	0.5	89.9	89.9	0.5
context	75.4	90.0	59.2	84.5	93.4	57.1
status	82.8	92.2	54.3	88.8	94.7	52.3
concept + context + status	71.0	71.1	0.3	82.1	82.1	0.3

Another datum of importance is the positive specific agreement, 81.7%, between C1 and C2 for the match criteria that requires the spans to overlap and the concept codes to match. A related datum appears in Table 4 that reports Kappa on concept code agreement for those annotations that match with respect to overlapping spans for C1 and C2, 89.9%. However, this represents an inflated measure of concept code agreement because this computation of Kappa removes annotations that disagree with respect to span. This effectively removes annotations that disagree with respect to concept code because the tasks of span selection and concept code assignment are very closely related per the annotation guidelines. It follows that measuring concept code agreement on only those annotations that agree with respect to exact span matching is even

higher (= 95.0% between C1 and C2). Therefore, we believe 81.7% to be a more reasonable estimate of the upper bound for system performance on the task of normalized named entity recognition.

Because the tasks of assigning context and status to annotations is much less related to the task of span selection, we consider the Kappa results in Table 4 to be a better indication of how well the annotator's agree than the corresponding percentage agreement results in Table 3. Thus, we consider 84.5% and 88.8% as Kappa agreement between C1 and C2 for context and status, respectively, to be the fairest measure of annotator agreement for those attributes. However, the absolute percentage agreements of 93.4% and 94.7% probably represent a more appropriate upper bound on system performance.

Table 3 - IAA as positive specific agreement

compared annotation sets	compared attributes					
	spans exact	spans overlap	spans overlap +			
			concept	context	status	concept + context + status
A1, A2, A3, A4	75.7%	87.9%	72.7%	79.0%	80.9%	62.5%
C1, C2	81.4%	90.9%	81.7%	84.8%	86.0%	74.6%
C1, MMTx	42.3%	47.0%	42.3%	n/a	n/a	n/a
C2, MMTx	38.2%	44.1%	37.3%	n/a	n/a	n/a
GS, MMTx	39.8%	45.7%	39.5%	n/a	n/a	n/a

The effect of creating a pair-wise consensus set

We hypothesized that having two individuals annotating independently and creating a consensus set would result in a much more consistent set of annotations. For every match criteria that we examined, there is a marked improvement in IAA between pair-wise IAA of individuals and the corresponding pair-wise consensus-level IAA. Table 3 shows that the average pair-wise IAA for the match criteria that requires spans to overlap and the concept code, context, and status rises from 62.5% for individual annotation sets to 74.6% for consensus annotation sets, a 32.3% disagreement reduction.

The effect of pre-annotating with MMTx

We hypothesized that providing the annotators with annotations from a third party system, MMTx, would be a good way to improve the speed and consistency of the annotation task without introducing bias that favors our system. Unfortunately, Table 2 shows that the annotators given the MMTx annotations, A1 and A3, annotated slower than the other two annotators, A2 and A4. Both A1 and A3 complained that the existing annotations slowed them down because spurious annotations and multiple mappings for the same span made them consider more concept codes than they would have otherwise. There was also no clear trend that the MMTx annotation improved pair-wise IAA between individuals. Also, MMTx did not have any measurable impact on the final assignments made in the master consensus set. If MMTx was providing "better" concept codes, then one would expect this to be reflected in the agreement between GS and MMTx. Table 3 shows the percentage agreement with respect to overlapping spans and concept code matching for C1 and MMTx to be 42.3% and 37.3% for C2 and MMTx. The agreement between GS and MMTx is about halfway between these two points at 39.5%. This is the case for every other IAA number reported for MMTx in Tables 3 and 4. Thus, we conclude that while the MMTx annotations seemed to influence the annotations in C1, there was no clear benefit to introducing this bias.

Acknowledgments

We acknowledge annotators Barbara Abbott, Debra Albrecht, Pauline Funk, and Donna Ihrke for their fine work, and Tanya Hoskin, Serguei Pakhomov, and James Buntrock for their input.

MedinfoParser: A Semantic tool for Information Extraction

Hee Kyong Park[a], Jinwook Choi[a], Elizabeth Liddy[b]

[a] *Department of Biomedical Engineering, Seoul National University, South Korea*
[b] *Center for Natural Language Processing, Syracuse University, U.S.A.*

Abstract and objective

We have developed a semantic tool (MedinfoParser) for the information extraction of medical documents. The main role of the parser is to parse medical sentences and extract key information. It puts Part-of-Speech (POS) tags and conceptual tags for the extraction. The parser consists of a Korean parser, an English parser, a numeric detector, and a noun phrase detector. For the semantic extraction, it gets conceptual id from the UMLS knowledge server.

Keywords:

MedinfoParser, information extraction, medical document

Introduction

In the era of the electronic medical record (EMR), huge amount of medical documents are produced electronically. EMR provides many kinds of templates for the coded data entry, but most clinical notes are still written in free text. To catch the patient's clinical status in a short period of time, EMR should provide a neat tool for summarizing medical records. We have developed MedinfoParser which is a semantic tool for information extraction.

Methods

MedinfoParser consists of a Korean parser, an English parser, a numeric detector, and a noun phrase detector.

Korean parser: Korean parser breaks a document into sentence fragments and tokenizes sentences. It provides POS tags of words and those of morphemes. As a Korean parser we have used KLT parser[1]. We modified the numeric module of KLT parser in order to provide more sophisticated analysis. Numeric expressions are more distinctly denoted by separating the numeral tokens from the alphanumeric combined words. And numeral words are converted into Arabian numbers. A new tag of 'NB' and 'M' are introduced to annotate numeric expressions more precisely.

English parser: In general, Korean medical records are written in Korean and English mixed. However, most medical expressions are written in English. In order to parse those key medical expressions, English parser detects medical terms written in English. By sending queries to UMLS knowledge server, it gets UMLS cuis. Then it puts a 'MED' tag and a UMLS cui at the end of each medical term. Medical documents contain lots of abbreviations and locally defined terms which are used only in a specific institution. As these terms are not searched through UMLS, we designed user dictionaries.

Numeric detector: As the numeric expression contains very important meaning in medical records, we have improved the numeral identification function. Especially in order to extract key information in the chronological order, the identification of the temporal expression is the most significant. For the Numeric detector we designed a rule pattern based on data frames for the semantic extraction. Each data frame works as a unit concept. It has various methods to evoke functions. The numeric detection rule contains data frames which are necessary to extract numeric expressions from the medical records.

Noun phrase detector: Noun phrase (NP) detector identifies medical concepts that are consisted of more than two words. NP boundary can be identified in many ways according to the reviewer's view. Therefore we made principles to clearly identify noun phrases. About one hundred NP lists were extracted from the discharge summaries in Seoul National University Hospital. We analyzed the context of each NP occurrence and have been developing rule patterns for NP detection.

Discussion and conclusion

We have developed a semantic tool for the information extraction of medical documents. The implemented Korean parser and English parser generate the highly readable XML files that can be used for other medical applications. For the future work, we will display the output of MedinfoParser onto the timeline to make a chronological summary. We hope that MedinfoParser will be a promising tool for the information extraction in medical field.

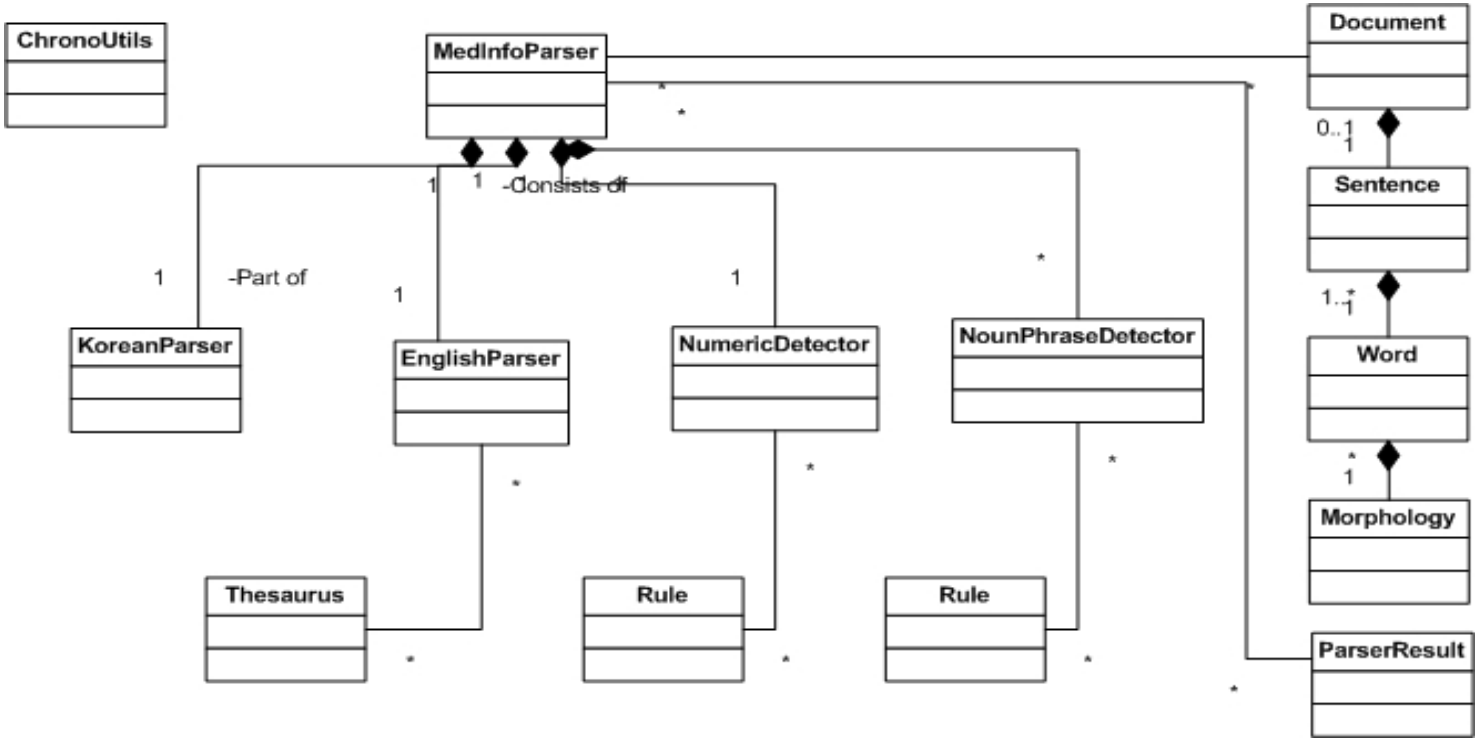
Introduction

- Background
  - Era of the electronic medical record (EMR)
  - Huge amount of medical documents are produced electronically
  - Most clinical notes are still written in free text
  - Difficulties in catching a patient's clinical status in a short period of time
  - Needs for a neat tool for summarizing medical records
- Purpose
  - Develop a semantic tool for summarizing medical records
- We have developed MedinfoParser

MedinfoParser

- A semantic tool for information extraction
- Role
  - Tokenization
  - POS tagging
  - Concept recognition
    - medical concept
    - numeric concept
    - noun phrase identification
- Components
  - Korean parser
  - English parser
  - Numeric detector
  - Noun phrase detector

A Classdiagram of the MedinfoParser



Korean Parser

- Tokenizes and parses Korean medical documents
  - Breaks a document into sentence fragments
  - Tokenizes sentences
  - Puts POS tags after the each parsed word and morpheme

An example of Korean parser output

English Parser

- Characteristics of Korean medical records
  - Written in Korean and English mixed
  - Most medical expressions are written in English
  - Contain a lot of abbreviations and locally defined terms
- Parses key medical expressions
  - Detects alphabetic words
  - Sends queries to UMLS knowledge source server
  - If any UMLS CUIs are returned, puts ‘MED’ tag and a top ranked UMLS cui
- To detect medical terms that are not searched from UMLS, we designed user dictionaries

<s>
<ins>Child C LC Chronic PSE Supportive care 위해 입원함</ins>

followed by drugUnit;
;;
```

A sample numeric detection rule for *'medication'*

Rule patterns

- Designed based on data frames (David W. Embley, 2004)
  - Representational frame that encapsulates the essential properties of everyday data items
- Each data frame contains functions, other concept classes, relations, expressions to extract single concept
- Each data frame works as a unit concept. It has various methods to evoke functions

Noun Phrase Detector

- Identifies boundaries of the medical noun phrases (NPs) which are consisted of more than two words
- Made principles to clearly identify boundaries of ambiguous cases
  - The main idea of the principles : the longest noun phrase which has an atomic medical concept should be identified as a NP
  - E.g., *'… Child C liver cirrhosis …'*
    - Possible NPs : *'liver cirrhosis', 'Child C liver cirrhosis'*
    - Noun phrase detector identifies *'Child C liver cirrhosis' as a NP*
- Have been developing rules for NP detection

An example of noun phrase tagged output

Discussion and Conclusion

- Have developed a semantic tool for the information extraction of medical documents
- Each module produces a highly readable XML file as an output
- Easily adoptable to other medical applications
- Future work
  - Display the output of MedinfoParser onto the timeline to make a chronological summary

Collecting Presenting Problems From Patient Records by Text Mining

Anders Thurin

Sahlgrenska University Hospital, Göteborg, Sweden

Abstract

The presenting problem in emergency care largely determines the direction of activities and thus the workload of parts of the hospital. To determine the mixture of presenting problems in the emergency department of a teaching hospital we analysed text in patient records, using a set of regular excpressions to extract the patients' presenting problem/reason for encounter. Such a problem could be extracted in about 84% of cases, and suggests that such methods can be useful for creating statistics. Among anticoagulated patients, bleeding related problems were overrepresented, suggesting that this method could also be used to find adverse drug effects.

Keywords:

natural language processing, data mining, reason for encounter, adverse drug reactions, anticoagulant therapy

Introduction

A majority of the patients treated at our hospital present as non-planned emergency visits and are initially admitted through the emergency ward. When a patient is discharged the final diagnosis is reported for national statistics, but no information is collected routinely on the reasons for encounter. The distribution of patient problems in the emergency ward to a determines a large part of the workload and activities at the hospital. Manual coding of patients' reasons for encounter is time consuming, and no optimal coding system is available.

The aim of this study was to analyse the distribution of reasons for encounter in general as well as among patients treated with the anticoagulant drug warfarin. Data extracted this way could be aggregated to describe the case mix of actual patients, and help in planning the work and activities at the hospital. One hypothesis was that conditions related to bleeding would be more common with anticoagulation.

Materials and methods

Materials

All records from 1994-2005 of the database Melior[1], Departments of Surgery and Internal medicine, Östra Sjukhuset, Sahlgrenska University Hospital, Göteborg, Sweden, were analysed. We have no access to the database tables containing patient identity, which helps preserve patient integrity. The method of data collection has been approved by the local ethics committee and those responsible for security at the hospital.

Text in the patient record is sorted in the database under different record headings, and for this study only text under the heading "besöksorsak" (reason for encounter) from the physician emergency note was analysed. This text can consist of a single word, like "buksmärtor" (abdominal pains), or it can be made up of anything from a few words to several sentences, e.g. "patienten söker på grund av illamående och buksmärtor" (the patient seeks help because of nausea and abdominal pains). In addition to the reason for encounter text under this heading often describes other conditions of patients' admission, such as from where patient is referred (other hospital, GP, other clinic), or how patient comes to the emergency ward (by ambulance/brought in by relative…).

Methods

Text paragraphs were collected from the database by SQL queries, giving a relatively homogeneous set of text paragraphs, most of which contained a reason for encounter. The average length of each text line in medical and surgical notes were 38.7 and 38.3 characters, respectively. The longest text string was 1444 characters and the shortest 1 character. The result set was saved in a text file consisting of 49918 lines from surgery, 87037 from internal medicine, with text from one medical record on each line. Similar text files of 1035 lines from surgery, 8791 from internal medicine was produced with the additional criterion that the medical record somewhere contained the string "Waran", the trade name for Warfarin in Sweden.

The search method was developed using only the surgery material, and later applied to the internal medicine text. First analysis was made using a concordance (a list of all the words in the text presented with their closest context) was created from the larger text file using the software package Concordance 3.0[2], which count the number of instances of every unique word, and allows concordance lists to be sorted by the context that appears around the word - the word before or after, two words before or after, and so on.

1 Siemens Health Solutions

2 R.J.C Watts. http://www.concordancesoftware.co.uk/

S0rting the words by number of appearances made it possible to see which reasons for encounter were the most common. By looking at the concordance of a common reason for encounter with the context sorted in different ways it was easy to see in which surroundings the word often appears. Patterns in the text that were often associated with a reason for encounter were determined by manual analysis of concordances, and guided by these identified patterns, customized Perl[3] scripts could identify and count phrases matching reasons for encounter according to the patterns determined in the concordance analysis. The method of doing this was divided into two steps. In the first step, a Perl script reads through the text file one line at a time, trying to match each line with a pattern such as:

- a single word, like buksmärtor (abdominal pains) or skalltrauma (head trauma).
- two or a few words, or comma separated lists of such word groups, like commotio cerebri or svårighet att gå, buksmärtor (difficulties to walk, abdominal pains)
- a comma separated lists of single words, like buksmärta, illamående, diarreer (abdominal pains, nausea, diarrhea) or hematemes, melena samt buksmärtor (hematemes, melena and abdominal pains).

Table 1 - Reasons for encounter in surgery

Surgery - total		Occurrences	
Reason for encounter		*n*	%
Buksmärtor	abdominal pains	9036	18,0
Buksmärta	abdominal pain	4224	8,43
Kräkningar	vomiting	1455	2,90
Misshandel	abuse	953	1,90
Sårskada	wound	834	1,66
Illamående	nausea	813	1,62
Feber	fever	712	1,42
Falltrauma	fall	609	1,22
Trafikolycka	traffic accident	585	1,17
Diarreer	diarrhea	512	1,02
Skalltrauma	head injury	412	0,82
Melena	melena	409	0,82
Hematemes	hematemesis	402	0,80
trauma skalle	head trauma	383	0,76
Diarre	diarrhea	344	0,69
Förstoppning	obstipation	268	0,54
Obstipation	obstipation	264	0,53
epigastralgier	epigastralgia	257	0,51
Urinstämma	urinary obstruction	209	0,42
trauma thorax	thorax trauma	181	0,36

- longer text strings where keywords or keyphrases indicate the reason for encounter, like ...frågeställning om appendicit (suspected appendicitis) or ...söker pga högersidig buksmärta, illamående och kräkningar (seeking care due to abdominal pain, nausea and vomiting). In these cases only the rest of the sentence after the keyphrase (here frågeställning om and söker pga) is regarded as the reason for encounter, even if there is more text after that sentence.

In the second step another Perl script reads through the hashtable to further split and analyze the phrases identified in step 1, often containing long strings of text or comma separated lists of words, by pattern matching.

Some examples of patterns handled in step 2 are:

- Words in lists and enumerations separated by commas, full stops and conjunctions are regarded as separate reasons for encounter, like buksmärta, illamående, diarreer (abdominal pain, nausea, diarrhea) which result in three reasons for encounter.
- Lists or enumerations of word groups consisting of a few words separated by commas, full stops and conjuctions are regarded as separate reasons for encounter, like svårighet att gå, högersidiga buksmärtor (difficulties to walk, abdominal pains on the right side). Here svårighet att gå is one reason for encounter, högersidiga buksmärtor is another.

Results

The Perl scripts were able in the surgery material to identify a reason for encounter according to the patterns in 42961 of the 49918 lines in the text file (86.1 %). In all, 50093 occurrences of any of 10459 different reasons for encounter were found. 406 reasons for encounter were identified 10 times or more, accounting for 35934 occurrences (72% of all). 8283 reasons for encounter only appear once (16% of occurrences, 79% of types) some of which may be e.g. spelling errors or in need of further processing. The most common reasons for encounter consist of one or two words, like illamående (nausea) or trauma skalle (head trauma). 3387 (32% of types) of the reasons for encounter consist of one or two words, and most of these seem to be correct and relevant.

Table 2 - Reasons for encounter in surgery among warfarin patients

Surgery - Waran		Occurrences	
Reason for encounter		*n*	%
buksmärtor	abdominal pains	158	14,74
buksmärta	abdominal pain	58	5,41

anemi	anemia	8	0,75
blödning per rektum	rectal bleeding	7	0,65

3 ActivePerl 5.8 http://www.activestate.com

In the Waran text file a preliminary reason for encounter was identified in 883 of the 1035 lines (85.3 %). 1072 occurrences of 502 different reasons for encounter were found. 411 of the reasons for encounter were only found once (38% of occurrences, 82% of types) and 264 consist of one or two words.

The most common reasons for encounter in surgery, in both the total material and the Waran text file is buksmärtor (abdominal pains). The most common reasons for encounter in each file is shown in tables 1-2. Among patients of internal medicine, however, stated reasons for encounter are quite different. The most common all over is chest pain, and bleeding related disorders are rare, reflecting the different patient panorama in internal medicine – thus it can be expected that bleeding complications are presented at the dept of surgery even

falltrauma	fall	12,16	23,32	1,92
urinretention	urinary retention	2,04	3,73	1,83
smärtor under höger arcus	pain upper right abdomen	1,04	1,87	1,80

Table 6 - Frequency ratios (warfarin/total) among internal medicine patients

Medicine - ratio		number tot al	war an	Ratio W/ Total
nyupptäckt förmaksflimmer	new AF	15	15	7,5
sviktsymtom	heart failure	5	5	7,5
fladder	atrial flutter	4	4	7,5
högt inr	high INR	3	3	7,5
högt pk-värde	high PK	3	3	7,5
nydebuterad förmaksflimmer	new AF	3	3	7,5
recidiverande förmaksflimmer	recurring AF	3	3	7,5
smärta i vä skulderblad	shoulder pain	3	3	7,5
smärtor vänster underben	Pain left calf	3	3	7,5
susp cerebral insult	Suspected stroke	3	3	7,5
waranblödning	warfarin blee-ding	3	3	

To assess which reasons for encounter were more frequent among warfarin patients, we calculated the ratio of frequencies between the two patient groupsgroups, and the highest ratios are presented in table 2, in falling ratio – larger ratio means this problem is more common among warfarin treated patients. It is quite clear in the surgical material that bleeding related reasons for encounter are much more common among the warfarin patients than in the whole patient. In internal medicine, however, this is not so clear – there are many overfrequent problems but here the more frequent problems are rather related to indications for anticoagulation, such as atrial fibrillation and stroke, and no obvious relation to adverse effects can be seen.

Discussion

We have developed methods to identify and extract reasons for encounter from plain text in patient records of a department of general surgery at a teaching hospital. We find a reason for encounter in about 85 % of the records, suggesting that the method could be useful for example in statistical calculations and studies of patient groups. As a separate group we considered patients where "Waran" is mentioned. This is the trade name of warfarin in Sweden, the only oral anticoagulant currently on the market. Mention in the text does not necessarily imply that the patient is treated with warfarin before hospital admission, and this is a weakness in the design, but at least it suggests that patient has some condition where warfarin is discussed. Methods to ascertain whether current treatment includes warfarin would be very interesting, but this adds a lot of complexity to the information retrieval strategy. Experience from other authors suggest that general negation-detecting methods {{c:\fo\refs\ir.ref #120; Chapman et al., 2005}} can be used to distinguish "Waran" from "not Waran" which seems hopeful.

The possibilities of text data mining is getting a lot of recent attention within biomedicine, but most of the work is done in the domain of identifying genes and biochemical entities in published literature, much less work is focused on patient data[4]. Also coding of "chief complaint" has been attempted[5],[6],[7] . In Sweden, we also need to adapt all methods to our language, and we are not aware of any similar work done in Swedish.

Many of the reasons for encounter identified with this method are only found once and consist of long text strings. These reasons for encounter often result from a string matching where the rest of the sentence after words like inkommer för (comes because of?) is saved. Some of these lines and the lines where no reason for encounter was found need to be further analyzed and perhaps handled in a different way to make it possible to decide which the actual reasons for encounter are.

The result of the study could probably be improved by adding more patterns to the string matching scripts and by improving the already existing patterns. Analyzing the lines where a reason for encounter have not been found might help in doing this. A thorough analysis of the identified reasons for encounter is also needed to see what kinds of mistakes are made during identification, and what can be done to improve the precision and remove incorrect reasons. A larger text material would probably make the

numbers and calculations more accurate and would also be a way of further improving the results.

Many of the reasons for encounter are different morphological forms of the same word and should be considered synonyms, like buksmärtor and buksmärta (abdominal pain/pains). Natural language processing techniques, like part-of-speech tagging and stemming, can be applied to the material to help joining morphological forms. Work to accomplish this improvement has begun.

Grouping and categorizing the reasons for encounter could be achieved by looking for certain indicators of for example location, laterality or time. These indicators can then be used to search for reasons for encounter that are synonymous but not variants of the same word, like "hematemes" and "blodiga kräkningar" which refer to the same health condition. To accomplish this we hope to use medical morphemes from the Morphosaurus project[8], where we have been participating in entering Swedish morphemes.

It would be interesting to apply this method to different kinds of medical text and some work on this has already been started. The initial tests show that some modifications of the method are needed, and the pattern matching algorithm might have to be changed according to the text at hand.

Supplementing the UMLS with Acronym/Abbreviation Knowledge for Natural Language Processing Applications

Manabu Torii, Hongfang Liu

Department of Biostatistics, Bioinformatics and Biomathematics
Georgetown University Medical Center, USA

Abstract

Background: *With the widespread use of acronyms/abbreviations (denoted as short forms, abbreviated as SFs) in biomedical domain, a terminology knowledge source that associates SFs with their descriptive expressions (denoted as long forms, abbreviated as LFs) needs to be supplemented further for the improvement of natural language processing (NLP) systems in the biomedical domain.* ***Objectives:*** *We investigate a framework to supplement the UMLS, a terminology knowledge source, with information of SFs and LFs extracted from text.* ***Method:*** *Given a pair of (SF, LF) automatically collected from text using certain patterns such as parenthetical expressions, there will be three (exclusive) scenarios: (1) LF and SF are listed in the UMLS as synonyms, (2) only LF is listed in the UMLS, and (3) LF is not included in the UMLS. For the second scenario, we can safely supplement the UMLS with SF and mark SF with the annotations associated with LF. For the third scenario, even though we are unable to associate SFs with existing concepts in the UMLS, we can annotate LFs and SFs with UMLS semantic groups under the assumption that the UMLS semantic classification system is comprehensive. Utilizing a collection of (SF, LF) pairs obtained previously using five months' worth of Medline abstracts and also a semantic group assignment system constructed based on headwords and suffixes, we evaluate the framework.* ***Results:*** *We found that approximately 18k of SFs could be newly marked with existing concepts in the UMLS, and furthermore 40k of (SF, LF) pairs could be assigned with UMLS semantic categories with an average precision as 79%. Supplementing the UMLS with such acquired acronym/abbreviation knowledge would be critical for NLP applications that depend on the UMLS for their terminology needs.*

Keywords:

medical informatics; natural language processing; vocabulary, controlled

Introduction

From healthcare news to journal articles in medicine, acronyms/abbreviations have been widely used to provide concise presentations for domain-specific concepts. However, they pose a great challenge to automated text processing systems as well as to human readers. Unlike their corresponding full forms, acronyms/abbreviations are usually not descriptive representations of their referred concepts. For example, when skimming through paper titles at PubMed, one may have difficulty in understanding the meaning of acronyms such as VHA[1] and HIT[2] in the title *"An HIV collaborative in the VHA: do advanced HIT and one-day sessions change the collaborative experience?"* (PMID: 16776387). Since most acronyms/abbreviations represent important domain-specific concepts, and they are highly ambiguous, associating them with the correct concept is a critical task for building natural language processsing (NLP)-based systems for clinical decision support (CDS) or Evidence-Based Medicine (EBM) (see, e.g., [1]). A comprehensive terminology knowledge source that lists all possible full forms associated with an acronym/abbreviation is needed for the task. In the following, for simplicity, we call acronyms/abbreviations as short forms (SFs) and the corresponding full forms as long forms (LFs).

In the UMLS, SFs and their corresponding LFs are considered as synonyms, but the coverage of the UMLS regarding to acronym/abbreviation is not comprehensive. In this paper, we propose a framework for supplementing the UMLS with the acronym/abbreviation knowledge [2]. The framework consists of two steps: (i) automatic extraction of SFs and their corresponding LFs from text, and (ii) assignment of semantic categories with SFs. Both tasks in these steps have been tackled in this domain (e.g., [3, 4]), and the automatic supplementation of terms to the UMLS has also been considered (e.g., [5]). In this work, we aim to integrate theses two tasks and propose a framework specialized in supplementing the UMLS with SF knowledge and evaluate the framework utilizing results from two previous studies: one is to compare different SF definition detection systems, and another is to build a UMLS semantic category assignment system based on headwords and suffixes [6].

1 "VHA" = "Veterans Health Administration"
2 "HIV" = "health information technology"

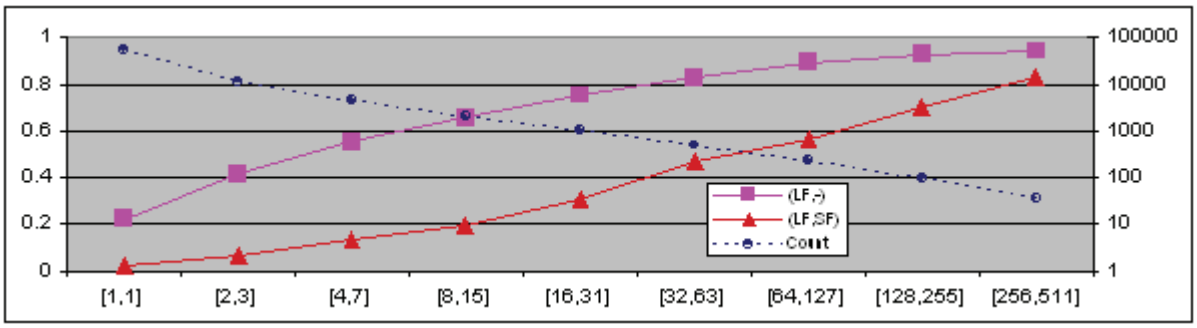

Figure 1 - X-axis represents bins of SF.LF pairs with different frequency ranges. A dotted line shows the number of pairs in each bin (read the right axis). Two solid lines show (i) the coverage of LF, i.e., (LF,-), and (ii) the coverage of LF.SF pairs, i.e., (LF,SF), in UMLS (read the left axis)

Resources and previous work

The UMLS

The UMLS, developed and maintained by National Library of Medicine (NLM), is an extensive terminology knowledge source in the medical domain. We used two components of the UMLS for this study, Metathesaurus (META) and SPECIALIST lexicon. In META, terms referring to the same biomedical concept (i.e., synonyms) are assigned with the same concept ID, e.g., "human immunodeficiency virus" and "HIV" are assigned with a concept ID C0019682. Moreover, in META, each concept (represented by a concept ID) is associated with UMLS semantic types, e.g., C0019682 is associated with a type Virus. As for SPECIALIST lexicon, we used one of its tables LRABR that records SF and LF phrase pairs. We also used another table LRAGR for normalizing noun tokens.

The SF definition detection comparison study

In this study [7], we used three independent systems ([8-10]) to extract pairs of SF and LF from *parenthetical expressions*, e.g., given a sentence "An electronic medical record (EMR) is a …", the systems will extract phrases "electronic medical record" and "EMR" as LF and SF. The three systems were applied to Medline abstracts published between January and May 2006 (210k records), and we collected 224k pairs (denoted as SF.LF) that are recognized by all of the three systems. After merging identical pairs[3], we obtained 74,428 unique SF.LF pairs. We manually inspected over 500 pairs randomly sampled from the obtained SF.LF, and found that all the pairs were valid SF and LF pairs.

Given this set of SF.LF pairs, we repeat the procedure described in [7] and summarized below to show the coverage of the UMLS over SF.LF pairs. We first grouped SF.LFs according to the frequency of their occurrences in their corpus to several bins. We then reported (i) the coverage of LF in the UMLS, and (ii) the coverage of both SF and LF in UMLS. The result is shown in Figure 1 where X-axis indicates bins according to frequency and Y-axis indicates the percentage. From Figure 1, we can see that (i) the coverage of SF.LF pairs lags behind that of LF (i.e., the gaps between the two solid lines), and (ii)even for frequent pairs, LFs may not be included in the UMLS

Semantic group assignment based on headwords and suffix

Headwords and suffixes of headwords are the two most effective features for automatic semantic group assignment (see, e.g., [4-6]). For example, a headword "virus" as in "Human Immunodeficiency Virus" strongly implies the semantic category of the concept referred. Similarly, a suffix "cyte" as in "Acanthocyte" implies that the referred entity is a cell. Hence, as in our previous work [6], we built a simple assignment system that assigns semantic groups to name phrases using headword/suffix information. In short, the system first extracts headwords/suffixes from a category-annotated list of name phrases (e.g., META), and then associate each headword/suffix with the most prevalent semantic category assigned to the phrases bearing the same headword/suffix.

Methods

Framework for supplementing the UMLS

- Our framework to supplement the UMLS consists of the two major subtasks (shown in Figure 2):
- Automatic extraction of SF.LF pairs from biomedical text
- Development of a semantic category assignment system

3 Identity of pairs is tested after the normalization of LF, which includes normalization of upper/lower cases, singular/plural forms, hyphen/blanks, etc.

After extracting SF.LF pairs in the first subtask, there would be three scenarios in terms of our objective:

1. Both SF and LF are recorded as synonyms in the UMLS
2. Only LF is in the UMLS but SF is not in the UMLS as a synonym of LF
3. LF is not in UMLS.

In the first scenario (1), we do not need to do anything because both SF and LF are already in the UMLS as synonyms. In the second scenario (2), we can safely mark SF with the concept ID of the paired LF. In the third scenario (3), we cannot associate LF with an existing concept ID, but we can assign the UMLS semantic category to SF and LF based on headwords and suffixes of LF.

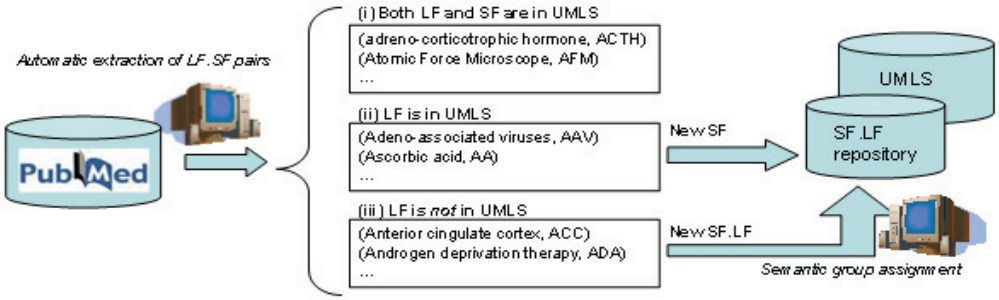

Figure 2 - Overview of the framework to suppplement UMLS

Evaluation method

For step 1, we used the collection of SF.LF pairs obtained in the comparison study to evaluate the framework (see the section Resources and Previous Work)[6]. For the semantic assignment step, instead of using the entire META for obtaining headwords and suffixes, we used only LFs from the collection that can be looked up in META through a procedure that normalizes textual variants (i.e., ignoring punctuations and normalizing using the Specialist lexicon). Similarly to [6], we used 15 semantic groups to provide reasonable granularity for the assignment system. After extracting headwords/suffixes from those LFs, we recorded them together with semantic groups assigned to the source name phrases, e.g., ”leukemia” appears as a headword in 39 phrases in META, of which 39 are annotated as Disorders, but one is annotated as Genes (note that a phrase can be annotated with more than one semantic type in the UMLS). When these headwords/suffixes are used for semantic group assignment, only the majority group is considered for assignment. For example, given a phrase “chronic mylogenous leukemia”, it is annotated with Disorders because the majority group of its headword “leukemia” is associated with Disorders. The system is then applied to pairs where LFs are not in the UMLS. Similarly to the comparison study in the previous section, we report the results with respect to different frequency bins. In order to investigate the precision of the semantic group assignment system, from each bin of LF.SF pairs (where bins from [32,63] to [256,511] were merged as [32,511]), we randomly picked as many as 100 LF.SF pairs where the assignment rules are applicable to LFs.

Results

Assignment of semantic groups to novel SFs

Of 74,428 unique SF.LF pairs automatically extracted from five month’ worth of Medline, approximately 5% of them were recognized as synonyms using the UMLS. However, in 30% of the cases, LF could be found in the UMLS. Therefore, by incorporating the SF.LF relations automatically recognized, SFs in 25% (30-25) of the pairs (i.e., 18k SFs) could be associated with existing concept IDs in the UMLS.

For the remaining 52,348 pairs where LFs cannot be found in the META, the semantic group assignment system was applicable to 81% of them. Among pairs where the system was applicable, the distribution of assigned semantic groups varied much: some with higher percentage (e.g., Chemicals & Drugs 18%, Procedures 16%, Disorders 13%), and some with lower percentage (e.g. Occupations 0.2%, Geographic Areas 0.1%). Given this highly skewed distribution, we looked into the performance of the five significant semantic groups, Procedure, Chemicals & Drugs, Disorders, Anatomy, and Organizations. The results about these five semantic groups are shown in Table 1. The first row of the table indicates that there are 42,579 pairs occurring once in the text. Around 80% of them can be automatically associated with UMLS semantic groups with a precision of 86%. There is a slight

increasing trend of percentage of pairs where the assignment system was applicable based on the third column of table 1, but not significant.

Discussion

As for 19% of the pairs where the assignment system was not applicable, we observed several reasons, e.g., typos (e.g., 12-lipoxygeanse), or adjectival phrases (e.g., single-stranded).

Though we found that the system achieved the precision of 80% or more for the most of the semantic groups, we concern the poor performance for the important and distinct semantic group Disorders. After looking at the error cases for the group Disorders, we found some of the shortest suffixes are used in the error cases, e.g., "sion" which is extracted from "hypertension", "occlusion", "convulsion", etc. In our previous study, short suffixes were not the major problem: those short suffixes are not used often because there are longer suffixes and headwords that have precedence over them. For example, given a phrase "rapid maxillary expansion" (RME), the phrase can be properly associated with a group Procedure owing to phrase entries with the headword "expansion" or even "maxillary expansion" in the UMLS. We can easily resolve the problem by increasing the amount of source name phrases when building the assignment system. For example, we can use the whole collection of Medline abstracts to have a large collection of LF.SF pairs or use all META phrases that appear in text at least once.

Freq. Range	Num. pairs	Type assigned	hand-checked	Procedures	Chemicals & Drugs	Disorders	Anatomy	Organizations	All
[1,1]	42,579	80%	100	95% (20)	88% (25)	68% (19)	90% (10)	100% (3)	86% (100)
[2,3]	6,712	81%	100	95% (13)	100% (14)	52% (21)	86% (14)	100% (2)	74% (100)
[4,7]	1,990	82%	100	72% (29)	85% (20)	47% (15)	75% (8)	100% (2)	70% (100)
[8,15]	698	82%	100	96% (23)	93% (14)	53% (17)	100% (4)	0% (1)	85% (100)
[16,31]	252	84%	100	79% (33)	88% (16)	75% (12)	100% (7)	100% (2)	83% (100)
[32,511]	117	83%	97	81% (16)	85% (26)	59% (13)	86% (7)	100% (3)	75% (97)

Table 1 - precision of semantic group assignment for five semantic groups

Conclusion

In this study, we proposed a framework to supplement a biomedical thesaurus with SFs as well as LFs. In general, SFs can be highly ambiguous semantically and it is difficult to determine their semantic categories. In our framework, SFs are annotated with semantic categories through the corresponding LFs. Another idea employed was that, in building a semantic category assignment system, we did not use the entire META, but we used only those phrases that are actually used in text so as to identify viable name phrases in biomedical text.

In sum, from the five month's worth of Medline records, approximately 18k SFs are newly associated with existing concept IDs in UMLS, and furthermore, 40k SFs and LFs are supplemented to the UMLS, where these phrases were assigned with semantic categories with the over all precision of 79%.

While we investigated the framework over the five month's worth of Medline records, the framework can be extended to a larger set of records. With a larger corpus, we could not only supplement the UMLS further, but we might incorporate more source name phrases in building a semantic category assignment system, which may improve the performance of semantic category assignment system further.

Implementing Literature-Based Discovery System using Semantic Relations

Dimitar Hristovski[a], Carol Friedman[b], Thomas C. Rindflesch[c]

[a] *Institute of Biomedical Informatics, Medical Faculty, University of Ljubljana, Slovenia*
[b] *Department of Biomedical Informatics, Columbia University, New York*
[c] *National Library of Medicine, Bethesda, Maryland*

Abstract

Literature-based discovery (LBD) is a method for automatically generating hypotheses from the research literature. Current LBD systems depend on co-occurrence for finding relations between concepts. In previous research we proposed an enhanced method using semantic relations supplied by two natural language processing systems, BioMedLEE and SemRep. The use of these relations reduces the number of hypotheses proposed and simplifies their evaluation. Here, we describe an implementation (based on BITOLA LBD system) of our methodology using semantic relations.

Keywords:

literature-based discovery, natural language processing, text mining, Medline, UMLS, knowledge discovery

Introduction

Current literature-based discovery systems (for example [1]) use concept co-occurrence as their primary mechanism. No semantic information about the nature of the relation between concepts is provided. The use of co-occurrence alone has several drawbacks, since not all co occurrences underlie "interesting" relations: (a) Users must read large numbers of Medline citations when reviewing candidate relations; (b) systems tend to produce large numbers of spurious relations; and, finally, (c) there is no explicit explanation of the discovered relation.

In our previous research [2] we proposed a theoretical methodology to address the deficiencies of using co-occurrence only, which involved augmenting co-occurrences with explicit predications obtained through use of two natural language processing systems: SemRep and BioMedLee. Here we report on the implementation of LBD system based on the methodology described in [2].

Methods and results

We implemented the *Maybe_Treats1* discovery pattern which can be used to find new treatments for a disease or to find new therapeutic applications for an existing drug. *Maybe_Treats1* is satisfied when there is a change in a substance, body function, or body measurement (concept Y) associated with the starting disease X, and there is also an opposite change in concept Y associated with the drug or substance Z; additionally, drug or substance Z should not be already used to treat disease X. The *change* relations were extracted by BioMedLee and the *Treats* relations by SemRep.

The new web interface (Figure 1) that we developed integrates the co-occurrence-based interface of the BITOLA LBD with the semantic relation extracted by BioMedLee and SemRep. We take a top-down approach. We consider co-occurrence of two concepts as an indication of a relation, however then we present in an aggregated fashion the semantic relations extracted from the Medline citations. At the next level the user is shown as evidence the sentences from which the semantic relations were extracted (Figure 2). In other words, we go from concept co-occurrence to semantic relations to sentences supporting these relations.

The user first selects a starting disease X (Parkinson disease in Figure 1). All co-occurring Y concepts are provided in the blue area; information about those that have a semantic relation is also given, so that the user can select concepts that are changed in relation to the starting disease (for example, gamma-Aminobutyric Acid in Figure 1). Further use of the interface displays drugs Z that cause an opposite change to the intermediate concepts Y. The sentences from which the semantic relations were extracted are also accessible (Figure 2). The new interface, enriched with semantic relations, makes it easier for the user to evaluate a smaller number of proposed hypotheses.

Abstract

Personalization—adaptivity to the individual—is becoming an essential component of any computer-based system. In e-health systems, personalization of health information is emerging as a key factor in the trend to patient-centric care. Patient-centric healthcare aims to engage patients in their treatment to promote greater compliance and satisfaction with their therapeutic regimens, resulting in both better patient outcomes and reduced healthcare costs. We have developed a prototype Web-based Natural Language Generation system for the authoring and subsequent personalization of patient education materials. Our initial domain of application is reconstructive breast surgery, but our Natural Language software tools and authoring methodologies are generally applicable to all medical interventions.

Keywords:

patient education; personalized e-Health; natural language generation; artificial intelligence

Introduction

E-health services are playing an increasingly important role in health-care management by providing relevant and timely information to patients about their medical care. An important factor in the rapid growth of online health services is the trend in health management to *patient-centric* health care: patient-centric care aims to involve the patient directly in the medical decision-making process by providing better access to the relevant information that patients need to understand their medical condition and to enable them to make more-informed decisions about their prescribed treatment.

An important new approach in patient-centric care is through 'Information Therapy': prescribing the right information to the right person at the right time. Ideally, Information Therapy promises to deliver specific medical information to individual patients at just the right time to assist with decision-making or behaviour changes [5]. So far, however, the kinds of information delivered through specific patient portals or other individualized 'information prescriptions' is still quite generic (Claudette DeLenardo, Program Director, My CARE Source Patient Portal, Grand River Hospital, personal communication).

An effective means of providing patient-centric healthcare would be through the personalization of health information: with individually tailored information, the patient would be both better-educated about their specific condition and better able to make informed decisions. As a key element in e-health services, personalized health education has great potential to provide relevant, patient-specific information that would integrate the clinical process with 'anywhere, anytime' healthcare delivery to produce both better-informed patients and enhanced patient outcomes. Some improvements in patient outcomes we may hope to see: greater compliance and satisfaction with therapeutic regimens, fewer complications, shorter hospital stays, and fewer return visits.

Natural Language Generation System for personalized health information

The fundamental problem in personalization of patient education is that the process involves much more than just producing each brochure or leaflet in half a dozen different versions for different audiences. Rather, the number of different combinations of factors can easily be in the tens or hundreds of thousands. It is impossible to produce and distribute, in advance of need, the large number of different editions of each publication that is entailed by individual tailoring of health information. Recently, researchers in Natural Language Generation have begun to apply methods from Artificial Intelligence and Computational Linguistics to develop automated systems for tailoring health information to individual patients (e.g., [1][4][6]).

The key components in our health information tailoring system are:

- Creation of corpora of content variants written in language that will engage the patient and address individual concerns.
- A *Physician's Authoring Tool* that assists the physician in mapping from the various options at each stage of a medical intervention to corresponding content variations.
- *A Natural Language Generation Tailoring Engine* that will automatically select, assemble, and revise content from a library of reusable text to produce a customized version for an individual patient [2].

Project team roles and competencies

The HealthDoc Project (1994-present) [3] involves team members from the University of Waterloo, the Waterloo Institute for Health Informatics Research, the University Health Network of the University of Toronto, and the University of Southern California. Our project team includes a wide variety of academic, clinical, and health IT professionals fulfilling the following roles:

Health IT Leader: A professional who provides strategic leadership regarding all aspects of IT/IM for health organizations.

Healthcare Providers: Clinicians who provide specifications for design of our technology based on their day-to-day practices and who evaluate our systems and software tools.

Patient Education Providers: Experts in patient education are available to our project as advisors and evaluators through the University Health Network (University of Toronto) and Grand River Hospital (Kitchener-Waterloo).

Health Portal Developers: Experts in development of health portal systems and software tools.

Computational Linguists: Researchers in theory and design of Natural Language Generation systems.

Linguists: Researchers in rhetoric of medical language, physician/patient communication, and communication design.

Software Manager: Professional software developer who oversees all aspects of system design and development.

A pilot tailoring system

The initial stage of our project focused on the creation of a corpus of patient-specific educational content by our surgeon team members covering a selected subprocedure of reconstructive breast surgery. We developed an initial Web-based authoring environment that allows the medical domain expert to interact directly with the system from any provider location.

To demonstrate the results of our research so far, we implemented a pilot Web-based delivery system for generating tailored health information materials. The pilot system integrates the main components of our project—the corpus of content variants, the Authoring Tool, and the Natural Language Generation Tailoring Engine—with a Web-based framework for delivery of tailored health education, i.e., a 'personal patient portal'. Several sample domains for tailored health information (e.g., smoking cessation, reconstructive surgery) have been tested with the pilot system.

Preoperative Education

The Problem:

Patients only retain approximately 15% of information discussed prior to surgery

Preoperative Education

Possible solutions:

- "Take-away" information
- Brochures, booklets, etc
- Online information

How to take care of your wound from the operation

- Keep the bandage clean and dry at all times.
- Leave the bandage on until you return for your follow-up appointment.
- If your surgeon has told you to remove the bandage, do so as instructed.
- If you have Steri-strips® under the bandage (small white tapes), leave them in place. When they start to peel off, remove them and throw them away. Keep your arm or foot covered until the wound heals or the stitches have been removed (usually 7 to 10 days after the surgery).
- If you have stitches, they will be removed at your next follow-up appointment.

Preoperative Education

Potential benefits of improved information:

- Reduced anxiety
- Higher patient satisfaction
- Improved outcomes, therapy compliance

Our solution: Tailored information:

- Previous studies on tailoring:
  - Nutrition
  - Smoking cessation
  - Diagnostic testing (mammography)
- However, surgical literature sparse

The HealthDoc Approach:
'Generation-by-selection-and-repair'

– Contains all text snippets needed for any patient

– Specific choices for individual patient

– Automatic restoration of good style

Authoring of the Master Document

Three levels of authoring:

- Knowledge level
  - Knowledge engineer
- Content level
  - Domain expert = Physician
- Deep-linguistic level (for repairs)
  - Computational linguist

Authoring: Knowledge level

- Knowledge engineer defines high-level structure of the master document.
- Goal: Map patient and physician concerns, components of surgical procedure, to organization of master document.
- Ideal: Authoring tool should maintain cognitive model to guide mapping of complementary, sometimes conflicting, concerns.

Authoring: Content level

A new model of composition

- Surgeon fills in raw ‘medicalese’ blocks of content in spreadsheet-like format.
- Rhetorician shapes content using models of argumentation:
  - Physician wants to *engage* patient, ensure *compliance*.
  - Patient wants *adaptivity* to preferred style of learning.
- Creation of stylistic variations:
  - By the physician.
  - By the rhetorician.
  - Automated?
- On-going: Modification by individual surgeon.

An Authoring Tool for Creating Tailorable Content

The Basic Tool: Specifications

- Domain expert directly enters textual variations, accompanied by Boolean selection conditions.
- Gradual editing at any re-entry point, by multiple authors.
- Automated checking of conditions for consistency and completeness.
- Displaying sets of text variations for validation.
- Many regular text-processing features:
  - cut-and-paste, spell-checking, thesaurus.

An Authoring Environment for Physicians: What would it look like?

- Both *push* and *pull* content authoring:
  - Physician directly enters procedure-specific text components (*push*).
  - Wizard-like query engine prompts author for details (*pull*).
- Reuse of discourse structure, text passages from similar surgical procedures.
- Natural Language Generation text-repair engines
  - Relieve physician of worrying how selected text will go together.
  - Need for both stylistic and semantic repair.

A Web-based Delivery System

- Automated transformation creates customization form from Master Document: Fill in form, press a button, display customized document.
- Can progressively update Master Document as add/refine surgical procedure, re-invoke transformation, view results.
- Using “Web Informatics Development Environment” (WIDE): wizard-like development of Web-based system that supports databases, shared virtual spaces, rich multimedia content.

Application of Multiple Neural Networks to Time Sequence Data - Prediction of Nosocomial Infection in Intensive Care Unit Patients

Machi Suka[1], Shinichi Oeda[2], Takumi Ichimura[3], Katsumi Yoshida[1], Jun Takezawa[4]

[1] Department of Preventive Medicine, St. Marianna University School of Medicine, Japan
[2] Department of Information and Computer Engineering, Kisarazu National College of Technology, Japan
[3] Faculty of Information Sciences, Hiroshima City University, Japan
[4] Department of Emergency and Intensive Care Medicine, Nagoya University Graduate School of Medicine, Japan

Abstract

We have invented the method of modeling time sequence data for prediction using multiple neural networks (NNs). In this study, we examined whether multiple NNs outperforms logistic regression and single NN in the prediction of nosocomial infection in intensive care unit patients (n=16,584). The three predictive models were developed using the 80% training subset and their predictive performances were assessed using the 20% testing subset in terms of classification accuracy and the area under a receiver operating characteristics curve. Overall the highest predictive performance was found in multiple NNs, followed by logistic regression and single NN. The predictive performance of multiple NNs was kept at a constant level, whereas that of logistic regression and single NN decreased with increasing a follow-up period.

Keywords:

Comparative study, predictive model, time sequence data, neural networks, nosocomial infection, intensive care units

Introduction

Multivariate regression models, particularly logistic regression, have commonly been used to estimate probabilities of outcome events. The predictors are usually selected from baseline data. Accordingly, the developed predictive models take no account of subsequent events, which may affect the patient's outcome.

We have invented the method of modeling time sequence data for prediction using multiple neural networks (NNs). The model was designed to use baseline data and subsequent events for estimating the probability of the outcome event - nosocomial infection in intensive care unit patients. We compared the predictive performance of multiple NNs with that of logistic regression and single NN using the cross-validation method.

Methods

A large cohort database was accumulated from the Japanese Nosocomial Infection Surveillance System. In the cohort of 16,584 eligible patients aged 16 years, hospitalized in 28 intensive care units for 2 days, there were 915 patients (5.5%) who had at least one episode of nosocomial infection during the first 10 days. After stratification by the outcome event, the original data set was randomly divided into 80% training and 20% testing subsets. The three predictive models - logistic regression, single NN, and multiple NNs were developed using the training subset and their predictive performances were assessed using the testing subset in terms of total classification accuracy (TCA) and the area under a receiver operating characteristics curve (AUC).

Logistic regression and single NN incorporated the following baseline data: sex, age (16-39, 40-69, 70+), severity of illness (0-10, 11-20, 21+; APACHE II), operation (none, elective, urgent), ventilator (yes, no), urinary catheter (yes, no), central venous catheter (yes, no). Multiple NNs incorporated subsequent events (ventilator, urinary catheter, and central venous catheter used at a specific period after admission) in addition to the baseline data.

As shown in Figure 1, multiple NNs consisted of 4 three-layer networks, which were responsible for predictions at four periods (Day 3-4, 5-6, 7-8, and 9-10 after admission), respectively. Two neighboring networks were connected in series to represent dependencies of subsequent periods. As shown in Figure 2, estimates for period t_a, $P(t_a)$ were passed forward to a subsequent network as inputs and used to enhance estimates for the following period t_b, $P(t_b)$. The first network with 13 input, 10 hidden, and 1 output neurons was used to input baseline data (sex, age, severity of illness, operation, ventilator, urinary catheter, and central venous catheter) to estimate the probability of the outcome event at Day 3-4 after admission. The second network with 4 input, 10 hidden, and 1 output neurons was used to input the output of the first network and subsequent events (ventilator, urinary catheter, and central venous catheter used at Day 3-4 after admission) to estimate the probability of the outcome event at Day 5-6 after admission. The third and

fourth networks followed the second network in a similar fashion (Figure 1). Each network employed back propagation learning with the momentum of 0.8. The learning rate was 0.01.

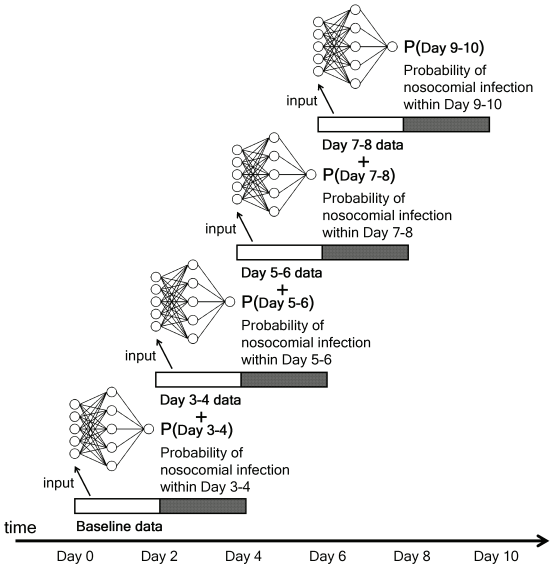

Figure 1 - Multiple NNs

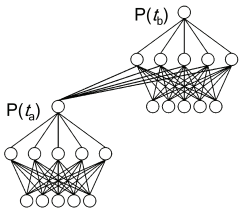

Figure 2 - Connection of two neighboring networks

Results and discussion

Table 1 shows the classification accuracy of the three predictive models. Multiple NNs showed the highest classification accuracy for total (TCA), positive (sensitivity), and negative (specificity) cases among the three predictive models.

Table 1 - Classification accuracy

	Total (TCA)	Positive (sensitivity)	Negative (specificity)
Logistic regression	0.63	0.71	0.62
Single NN	0.37	0.85	0.35
Multiple NNs	0.73	0.92	0.72

The receiver operating characteristics curve nearest to upper left corner was found in multiple NNs, followed by logistic regression and single NN. The AUCs of multiple NNs, logistic regression, and single NN were 0.83, 0.73, and 0.60, respectively. These results suggest that multiple NNs may be superior to logistic regression and single NN in terms of the discriminatory ability at a threshold level (indicated by TCA) and also the overall discriminatory ability independent of the setting of threshold level (indicated by AUC).

Table 2 shows the predictive performances of the three predictive models by period. Multiple NNs showed no significant change in TCA or AUC, whereas logistic regression and single NN showed noticeable declines in TCA and AUC. This result suggests that multiple NNs may be useful for improving predictive performance especially at later periods.

Table 2 - Predictive performance by period

		Day 3-4	Day 5-6	Day 7-8	Day 9-10
Number of patients (positive cases)		1625 (68)	610 (51)	292 (34)	612 (21)
Logistic regression	TCA	0.75	0.61	0.52	0.38
	AUC	0.79	0.73	0.67	0.62
Single NN	TCA	0.43	0.37	0.33	0.25
	AUC	0.63	0.58	0.55	0.55
Multiple NNs	TCA	0.73	0.66	0.79	0.77
	AUC	0.86	0.77	0.84	0.82

Conclusion

Multiple NNs outperformed logistic regression and single NN in the prediction of nosocomial infection in intensive care unit patients. The predictive performance of multiple NNs was kept at a constant level, whereas that of logistic regression and single NN decreased with increasing a follow-up period.

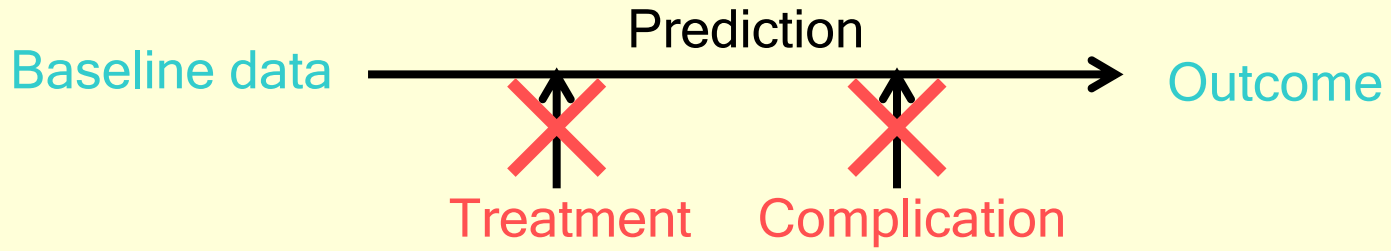
[4] *Nagoya University Graduate School of Medicine, Japan*

Background

- Multivariate regression models, particularly logistic regression, have commonly been used to estimate probabilities of outcome events.
- The predictors are usually selected from baseline data.
- Accordingly, the developed predictive models take no account of subsequent events, which may affect the patient's outcome.

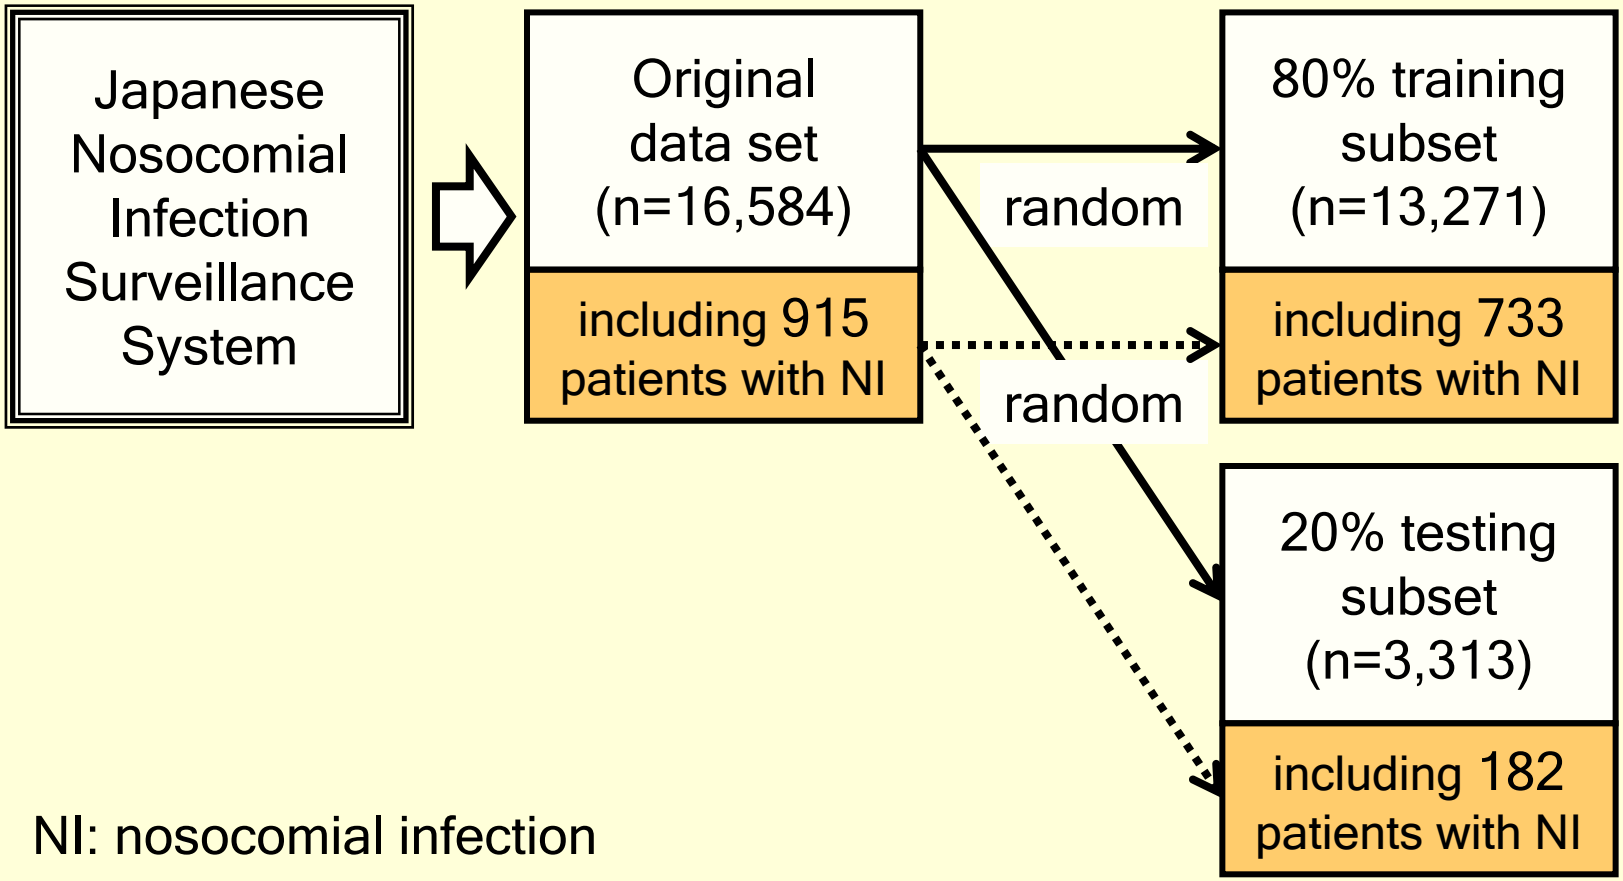


Objective

- We have invented the method of modeling time sequence data for prediction using multiple neural networks (NNs).
- The model was designed to use baseline data and subsequent events for estimating the probability of the outcome event - nosocomial infection in intensive care unit patients.
- We compared the predictive performance of multiple NNs with that of logistic regression and single NN using the cross-validation method.

Methods (1)

- Preparation of data sets (cross-validation)



NI: nosocomial infection

Methods (2)

- Development of three predictive models
  - Logistic regression
  - Single NN

  - Multiple NNs

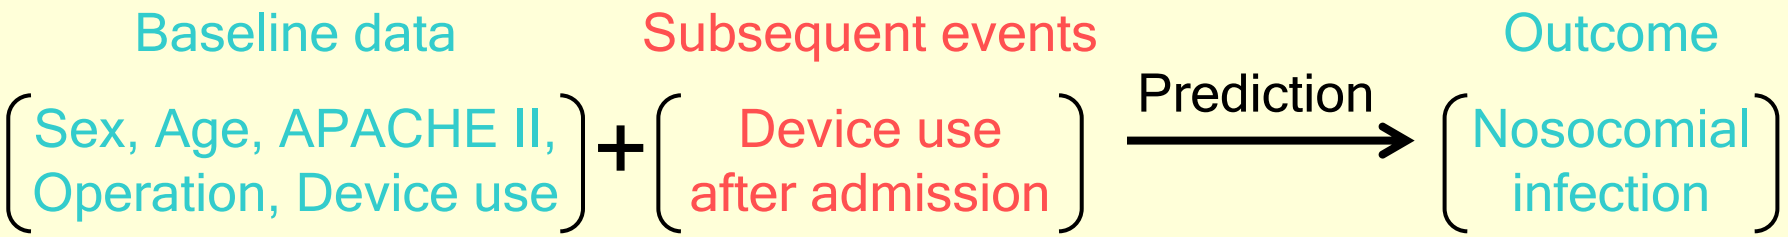


Figure 1 - Multiple NNs

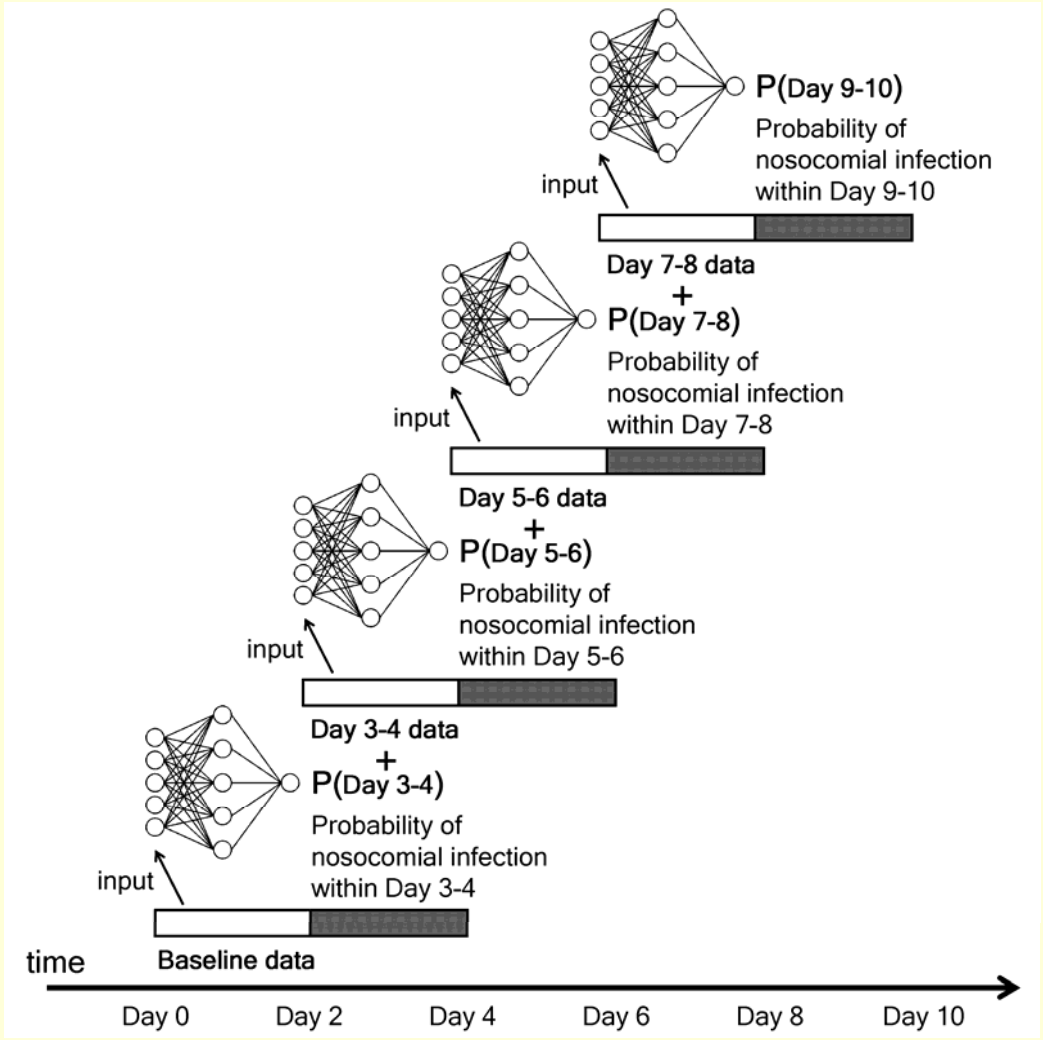
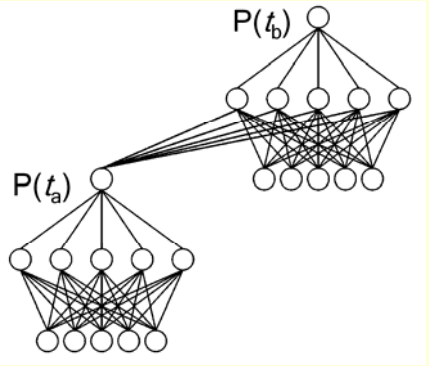




Estimates for period t_a, P(t_a) were passed forward to a subsequent network as inputs and used to enhance estimates for the following period t_b, P(t_b).

Methods (3)

- Assessment of predictive performance
  - Total classification accuracy (TCA)

    A proportion of correctly classified cases.
  - The area under a ROC curve (AUC)

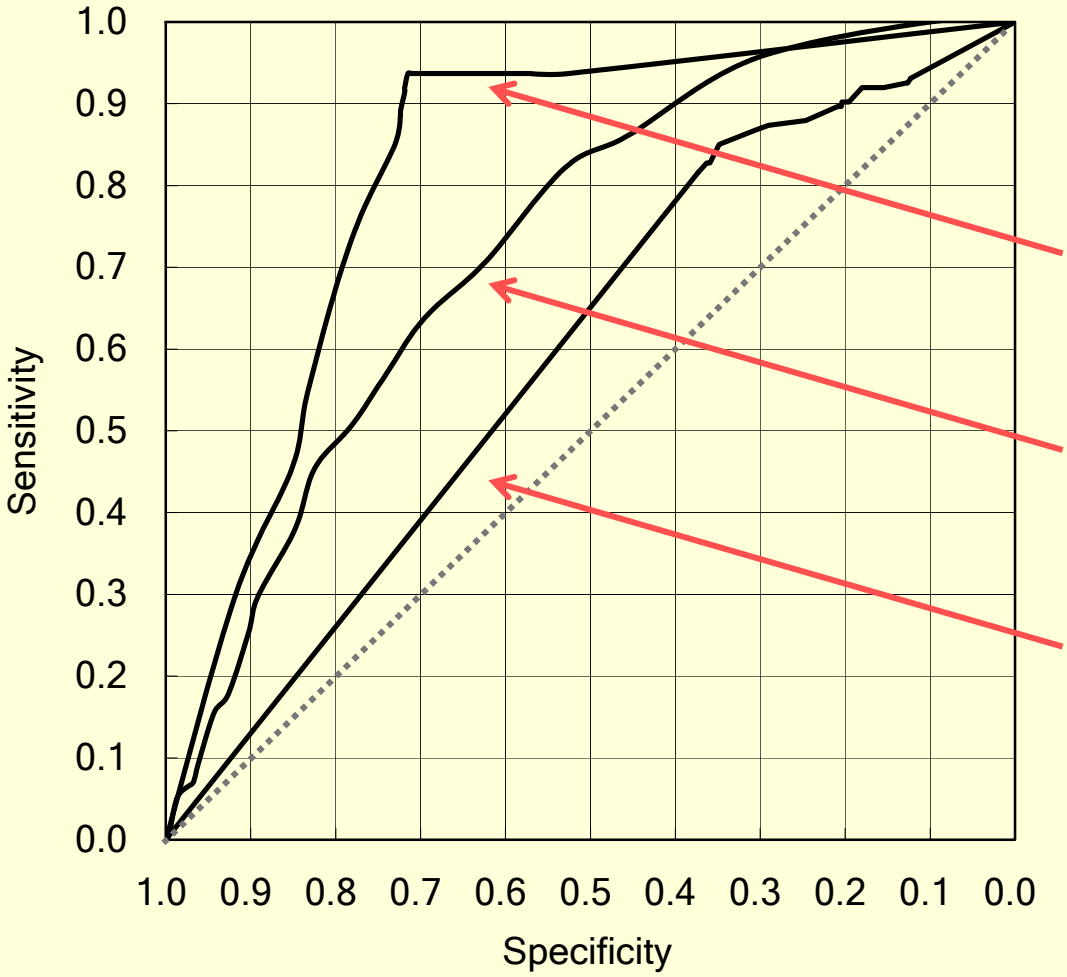
    A trade-off between sensitivity and specificity.

Table 1 - Classification accuracy

	Total (TCA)	Positive (sensitivity)	Negative (specificity)
Logistic regression	0.63	0.71	0.62
Single NN	0.37	0.85	0.35
Multiple NNs	0.73	0.92	0.72

Multiple NNs showed the highest classification accuracy for total (TCA), positive (sensitivity), and negative (specificity) cases.

Figure 2 - ROC curves



Multiple NNs
(AUC=0.83)

Logistic regression
(AUC=0.73)

Single NN
(AUC=0.60)

Table 2 – Predictive performance by period

		Day 3-4	Day 5-6	Day 7-8	Day 9-10
Number of patients (positive cases)		1625 (68)	610 (51)	292 (34)	612 (21)
Logistic regression	TCA	0.75	0.61	0.52	0.38
	AUC	0.79	0.73	0.67	0.62
Single NN	TCA	0.43	0.37	0.33	0.25
	AUC	0.63	0.58	0.55	0.55
Multiple NNs	TCA	0.73	0.66	0.79	0.77
	AUC	0.86	0.77	0.84	0.82

Multiple NNs showed no significant change, whereas logistic regression and single NN showed noticeable declines in TCA and AUC.

Conclusion

- Multiple NNs outperformed logistic regression and single NN in the prediction of nosocomial infection in intensive care unit patients.
- The predictive performance of multiple NNs was kept at a constant level, whereas that of logistic regression and single NN decreased with increasing a follow-up period.

Abstract

At nearly every patient visit, medical documents are produced and stored in a medical record, often in an unstructured form as free text. The growing amount of stored documents increases the need for effective and timely retrieval of information. We developed a multi-label text classification system to categorize free text medical documents (e.g. discharge letters, clinical findings, reports) written in German into predefined classes. A random sample of 1,500 free text medical documents was retrieved from a general hospital information system and was manually assigned to 1 to 8 categories by a domain expert. This sample was used to train and evaluate the performance of 4 classification schemes: Naïve Bayes, k-NN, SVM, and J48. Additional tests of the effect of text preprocessing were done. In our study, preprocessing improved the performance, and best results were obtained by J48 classification.

Keywords:

machine learning, classification, medical records, multi-label

Introduction

At nearly every patient contact with healthcare-providers, medical documentation is generated and stored in medical or nursing records, often as free text. With the increasing amount of stored, unstructured free text information, the need for effective and timely retrieval of relevant information is growing. In this work, we describe the development and the evaluation of an information system for multi-label classification of medical documents into predefined classes.

Methods

A random sample of 1,500 unstructured, free text documents written in German was extracted from an electronic medical record (EMR) of a general hospital in Austria. A domain expert (physician) manually classified the retrieved documents into one or more of the following classes: surgery, vascular surgery, casualty surgery, internal medicine, neurology, anesthesia and intensive care, radiology and physiotherapy. In average, 1.47 labels were assigned to a document. We built an automated multi-label text classification system in Java based on Weka [1], an open-source machine-learning framework. Four different kinds of classification schemes were compared: Naïve Bayes, k-NN, SVM and J48. 10-fold cross validation was used for evaluation. Moreover, the influence of text preprocessing (e.g. stop-word-removal, stemming, lowercasing) was studied.

Results

Evaluation results for the F-measure [2] with and without text preprocessing are illustrated in Figure 1.

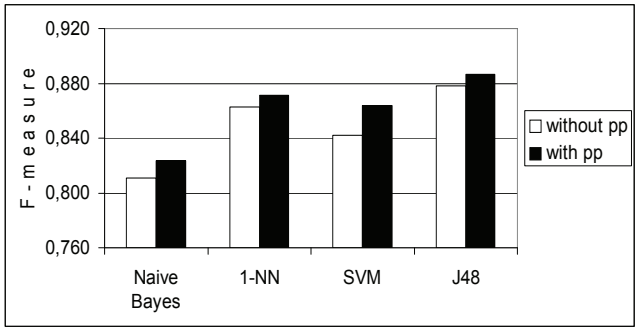

Figure 1 - F-measure with and without text preprocessing (pp)

Evaluation results *without* text preprocessing:

J48 classification model achieved best results with an F-measure of 0.877. The F-measure of the 1-NN model is 0.864 and SVM obtained a value of 0.850. Naïve Bayes achieved the worst result with a value of 0.811.

Evaluation results *with* text preprocessing:

Best result achieved again the J48 classification model with an F-measure of 0.886. 1-NN and SVM are middle-ranking models with values of 0.871 and 0.864. Naïve Bayes achieved an F-measure of 0.824, which was again the worst result of the models. Table 1 and shows the

improvement of the F-measure in percentage caused by text preprocessing

Table 1 - Improvement of the F-measure in percentage caused by text preprocessing (pp).

F-measure	Naïve Bayes	1-NN	SVM	J48
without text pp	0.811	0.864	0.850	0.877
with text pp	0.824	0.871	0.864	0.886
improvement	**+ 1.53** %	**+ 0.83** %	**+ 1.61** %	**+ 1.05** %

In order to compare classification models regarding their achieved F-measures more clearly, differences are given in Table 2. For this comparison F-measures are calculated for classifications with text preprocessing. For example, the 1-NN model achieved an F-measure better by 5.76 % than Naïve Bayes and the F-measure of Naïve Bayes is 4.66 % worse than the F-measure achieved by the SVM model.

Table 2 - Differences in percentages of F-measures achieved by evaluated classification models for classifications with text preprocessing

	Naïve Bayes	1-NN	SVM	J48
Naïve Bayes	0.00 %	**- 5.45** %	**- 4.66** %	**- 7.07** %
1-NN	**+ 5.76** %	0.00 %	**+ 0.84** %	**- 1.72** %
SVM	**+ 4.88** %	**- 0.83** %	0.00 %	**- 2.53** %
J48	**+ 7.61** %	**+ 1.75** %	**+ 2.60** %	0.00 %

Discussion

Evaluation results indicate that J48, SVM and 1-NN are preferable to Naïve Bayes. This finding corresponds to the results of [3]. Text preprocessing increased F-measures for all models. A reason for the rather small effect of text preprocessing on the evaluation results might be medical language. Medical language is quite specific with its own grammar and terms. Hence, for example standard stop word removal or stemming might not be that effective. [4] states that the result of text preprocessing strongly depends on the underlying terms. Thus, text preprocessing might be improved by using domain specific stop word lists and adapted stemming algorithms.

Conclusion

Results show that it is possible to classify medical documents written in German originating from a general hospital with automated machine-learning classification schemes with promising results, comparable with [5].

The classification system is used in a prototype of an information retrieval system for score-calculation, thus influencing the display order of search results. Further studies are needed to evaluate the accuracy of the developed system in other hospitals as well as the user-perceived benefits of this prototype.

Trial Evaluation of Automatic Lung Cancer Staging from Pathology Reports

Darren Moore[a], Iain McCowan[a], Anthony Nguyen[a], Mary-Jane Courage[b]

[a]CSIRO e-Health Research Centre, Brisbane, Australia
[b]Queensland Cancer Control Analysis Team (QCCAT), Queensland Health, Brisbane, Australia

Abstract

This paper presents a system that classifies lung cancer stage using automatic text categorisation of free-text pathology reports. The system has been evaluated in a trial where its output was compared to that of two clinical experts for 179 lung cancer cases. The system achieved 77% accuracy for T staging and 87% for N staging. Inter-expert agreement was also studied.

Keywords:

cancer staging, lung cancer, machine learning,
Clinical Decision Support Systems

Introduction

Evidence-based treatment guidelines for lung cancer treatment are informed by analysis of patient outcomes, where data is first stratified into comparable cases according to the AJCC TNM (tumour, nodes, metastases) staging standard [1]. The preferred method for staging lung cancer is through multi-disciplinary team (MDT) conferences. In Queensland, the Integrated Lung Cancer Outcomes Project (QILCOP) collects formal stage data from MDTs. However, due to the resource- and time-intensive nature of MDTs, the state-wide coverage of QILCOP stage data is approximately 50-60% of all lung cancer cases.

The purpose of this study was to develop a prototype system to automatically determine a T stage (TX, T1-T4) and N stage (NX, N0-N2) for lung cancer patients from free-text pathology reports stored in clinical information systems. As metastatic lung cancer is defined as involvement of other organs, it is not usually assessable from pathological studies of the lung, and therefore the current system does not attempt to determine the M stage. The system uses automatic text categorisation techniques to detect individual observations within reports that are relevant to staging, and to automatically assign a stage. Such a system could be used to obtain stage data for patients not formally staged by an MDT, allowing more comprehensive population-level analysis of lung cancer outcomes.

This paper reports findings from a trial comparing automatic staging to that of two clinical experts on a set of 179 lung cancer cases.

Method

The system architecture is illustrated in Figure1. The input to the system is the set of lung cancer related pathology reports for a patient. All report text is first standardised (spelling, acronyms, numbers, removal of punctuation, etc.) and sentence boundaries are identified using a set of search and replace regular expressions. Sequences of words are then transformed into codes from the UMLS Specialist Lexicon using a dynamic programming search for optimal allocation. Phrases implying negation are identified and associated with surrounding terms using the NegEx algorithm [2]. Each transformed report is then classified for relevance to T and N staging by support vector machines. Reports deemed irrelevant are omitted from further processing. If all reports for a patient are classified as irrelevant to T or N staging then the patient is assigned a stage of TX or NX respectively (i.e. stage cannot be assessed). Support vector machines were implemented using the SVM^{light} package [3].

Each sentence of each relevant report is then input to a series of sentence level classifiers corresponding to specific factors from the staging guidelines (e.g. extension of primary tumour into the visceral pleura, involvement of mediastinal lymph nodes, etc). A broad keyphrase filtering step first disregards completely unrelated sentences. Remaining sentences are then passed to the classification step. For factors that were sufficiently well represented in the training set, the classification step is implemented as a two level support vector machine (SVM). The first level binary SVM classifies a bag-of-words representation of each sentence as relevant (or not) to the factor in question. Relevant sentences are then classified as supporting either a positive or negative finding by the second level SVM. For staging factors that were not well represented in the development data set, manually coded rule-based classifiers make a decision based on the proximity of specific sets of words or phrases. The final stage assignment is the highest stage associated with any of the factors classified as positive across all sentences for that patient.

The system was developed on a set of pathology reports for 710 lung cancer patients. Gold standard T and N stages were obtained from a database of pathological TNM stages previously assigned by expert pathologists or multidisciplinary team meetings. Unbiased accuracy results of

77.6% and 81.8% for T and N staging respectively were obtained across the complete development set.

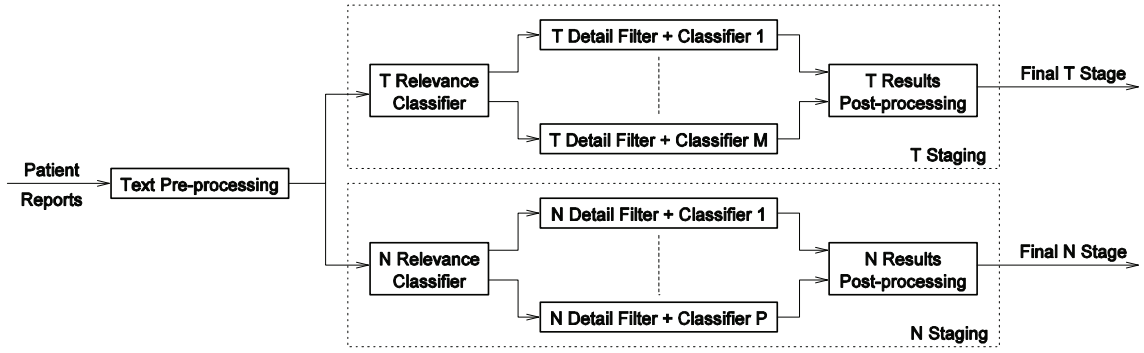

Figure 1 - Automatic staging system architecture

The system was then validated in an independent trial, where automatically assigned T and N stages were compared with stages assigned by two pathologists with expert knowledge of the TNM staging guidelines for lung cancer. The trial set consisted of pathology reports for 179 lung cancer patients previously unseen by the development team. The two main objectives of the trial were:

1. To study the level of agreement in expert staging decisions, and use this to establish a consistent gold standard for evaluating the automatic system.
2. To evaluate the reliability of the automatic staging system.

A post-trial meeting was convened with the clinical experts in order to discuss cases where different stages had been assigned. A consensus stage decision was assigned for as many cases as possible. Where a consensus could not be reached, both stages were retained as the gold standard for evaluating the automatic system performance.

Results

The main trial findings were:

1. On the 179 case trial set, the inter-expert agreement was 89.9% (18 disagreements) and 97.8% (4 disagreements) for T and N staging respectively. Most disagreement was due to ambiguity in the reporting, which resulted in experts applying different assumptions and interpretations to reach a final decision. In the post-trial meeting with the clinical experts, a consensus decision was reached on all but 8 T staging decisions.
2. The automatic system was evaluated against the expert-assigned T and N stages. T staging performance was 75.4% and N staging performance was 87.4%, corresponding to the confusion matrices in Table 1. The observed results are similar to those obtained during system development, and the difference in T and N staging performance mirrors the difference in expert agreement levels.

Table 1 - Trial set confusion matrices for automatic staging

Experts \ System	T1	T2	T3	T4
T1	**39**	10	0	1
T2	5	**81**	2	13
T3	1	7	**2**	0
T4	1	4	0	**13**

Experts \ System	NX	N0	N1	N2
NX	**10**	6	1	0
N0	2	**105**	0	1
N1	0	8	**27**	1
N2	0	3	2	**13**

Conclusion

The prototype system for automatically staging lung cancer was validated against expert decisions in a trial setting with promising results. Future work will focus on improving the current system and adapting the automatic techniques for staging other cancer types and staging protocols.

Cost-Sensitive Decision Trees Applied To Medical Data

Alberto Freitas[a,b]

[a] *CINTESIS – Center for Research in Health Information Systems and Technologies Portugal*
[b] *Department of Biostatistics and Medical Informatics, Faculty of Medicine, University of Porto Portugal*

Abstract

Classification plays an important role in medicine, especially for medical diagnosis. Health applications often require classifiers that minimize the total cost, including misclassifications costs and test costs. In fact, there are many reasons for considering costs in medicine, as diagnostic tests are not free and health budgets are limited. Our aim with this work was to define, implement and test a strategy for cost-sensitive learning. We modified an algorithm for decision tree induction to consider costs, including test costs, delayed costs and costs associated with risk. Then we applied our strategy to train several cost-sensitive decision trees in medical data. Built trees were tested following some strategies, including group costs, common costs, and individual costs. Using the factor of "risk" it is possible to penalize invasive or delayed tests and obtain decision trees patient-friendly.

Keywords:

classification, costs and cost analysis, artificial intelligence, cost-sensitive learning

Introduction

In medical care, as in other areas, knowledge is crucial for decision making support, biomedical research and health management [1]. Data mining and machine learning can help in the process of knowledge discovery. Data mining is the non-trivial process of identifying valid, novel, potentially useful and ultimately understandable patterns in data [2]. Machine learning is concerned with the development of techniques which allow computers to "learn" [3].

Classification methods can be used to build models that describe classes or predict future data trends. It generic aim is to build models that allows predicting the value of one categorical variable from the known values of other variables. Classification is a common, pragmatic tool in clinical medicine. It is the basis for finding a diagnosis and, therefore, for the definition of distinct strategies of therapy. In addition, it plays an important role in Evidence-Based Medicine. Machine learning systems can be used to enhance the knowledge bases used by expert systems as it can produce a systematic description of clinical features that uniquely characterize clinical conditions. This knowledge can be expressed in the form of simple rules, or decision trees [4].

The majority of existing classification methods was designed to minimize the number of errors. Nevertheless, real-world applications often require classifiers that minimize the total cost, including misclassifications costs (each error has an associated cost) and test (attribute) costs. In medicine a false negative prediction, for instance failing to detect a disease, can have fatal consequences; while a false positive prediction may be less serious (e.g. giving a drug to a patient that does not have a certain disease). Each diagnostic test has also a cost and, for deciding if it is worthwhile pay the costs of tests, it is necessary to know both misclassification and tests costs. There are many reasons for considering costs in medicine. Diagnostic tests, as other health interventions, are not free and budgets are limited.

Misclassification and test costs are on the most important costs, but there are also other types of costs [5]. Cost-sensitive learning (also known as cost-sensitive classification) is the area of machine learning that deals with costs in inductive learning.

Our aim with this work was to study and implement a strategy for learning and testing cost-sensitive decision trees, considering several costs, and with application to medical data.

The rest of this paper is organized as follows. In the next section we expose the main types of costs. Then we review the related work. After that, we explain our cost-sensitive decision tree strategy. Next we present and compare some experimental results. And finally, we conclude and point out some future work.

Types of costs

Turney [5] presents a taxonomy for many possible types of costs that may occur in classification problems. From his enumeration, misclassification and test are on the most important costs. Costs can be measured in many distinct units as, for instance, money (euros, dollars), time (seconds, minutes) or other types of measures (e.g., quality of life).

Misclassification costs

A problem with n classes is normally associated with a matrix $n*n$, where the element in line i and column j represent the cost of classifying a case in class i being from class j. Usually the cost is zero when $i = j$. Typically, misclassification costs are constant, that is, the cost is the same for any instance classified in class i but belonging to class j. The traditional error rate measure occurs when the cost is 0 for $i = j$ and 1 for all other cells.

In some cases, the cost of misclassification errors could be conditional, that is, it could be dependent of specific features or dependent of the moment in time. The cost of prescribing a specific drug to an allergic patient may be different than prescribing that drug to a non allergic patient.

The cost of misclassification can be associated with the moment it occurs. A medical device can issue an alarm when a problem occurs and, in this situation, the cost is dependent simultaneously on the correctness of the classification and on the time the alarm is issued, that is, the alarm will only be useful if there is time for an adequate action [6]. Misclassification costs can also be dependent on the classification of other cases. In the previous example, if one alarm is correctly and consecutively issued for the same problem, then the benefit of the first alarm should be greater than the benefit of the others.

Cost of tests

In medicine, the majority of diagnostic tests have an associated cost (e.g., an echography or a blood test). These costs can be highly distinct between different tests (attributes).

The costs of tests may be constant for all patients or change according to specific patient features. A bronchodilatation test, for instance, have a higher cost for children under 6 years, which means that the feature age have influence in the test cost.

Medical tests can also be very distinct when considering their influence in the "quality of life". A range of tests are completely harmless for patients (e.g., obstetric echography), others can be dangerous and put patient life at risk (e.g., cardiac catheterism), and some can be (only) uncomfortable (e.g., digestive endoscopy).

Some tests can be cheaper (and faster) when ordered together (in group) than when ordered individually and sequentially (e.g., renal, digestive and gynecological echography). Some tests can also have common costs that can be priced only once. Blood tests, for instance, share a common cost of collecting the blood sample. There is not only an economic reduction but also a non-economical reduction in the cost of "worry" the patient.

A number of tests might depend of the results of other tests. The test "age", for instance, may influence the cost of the bronchodilatation test. Some tests can have an increased price as result of secondary effects. Other tests can have patient specific, time dependent or emergency dependent costs.

In general, tests should only be ordered if their costs are not superior to the costs of classification errors.

Related work

In inductive learning (learning by examples), the majority of the work is concerned with the error rate (or success rate).

Nevertheless, some work has been done considering non-uniform misclassification costs, that is, different costs for different types of errors [7, 8]. Other literature is concerned with the cost of tests, without taking into account misclassification costs [9, 10].

And there is also some work concerned simultaneously with more than one type of costs, including the work of Turney [11], Zubek and Dietterich [12], Greiner et al. [13], Arnt and Zilberstein [14], and Ling et al. [15-20]. At this level, the work of Turney [11] was the first to consider both test and misclassification costs. Next, we give a brief overview of this work considering both costs.

Turney [11] implemented a system, the ICET system, that uses a genetic algorithm for building a decision tree that minimizes test and misclassification costs. The ICET system was robust but very time consuming.

Several authors associated the cost problem to a Markov decision process that has the disadvantage of being computationally expensive. Zubek and Dietterich [12] used an optimal search strategy, while. Arnt and Zilberstein [14] included a utility cost for the time necessary to obtain the result of a test.

Greiner et al. [13] analyzed the problem of learning cost-sensitive optimal active classifiers, using a variant of the probably-approximately-correct (PAC) model.

Chai et al. [15] proposed a cost-sensitive naïve Bayes algorithm for reducing the total cost. Ling et al. [16] proposed a decision tree algorithm that uses a cost reduction splitting criteria during training, instead of minimum entropy. After that, Sheng et al. [17], presented another approach where a decision tree is built for each new test case. In another paper, Sheng et al. [18] proposed a hybrid model that result from the integration of a decision tree sensitive to costs with a naïve Bayes classifier. Zhang et al. [19] compared strategies for checking if missing values should be or not obtained and stated that, for tests with high costs or high risk, it should be more cost-effective to not obtain their values. Recently, Ling et al. [20], updated their strat-

egy for building cost-sensitive decision trees, with the inclusion of sequential test strategies.

Our cost-sensitive strategy

Next, we briefly describe our strategy for implementing a cost-sensitive decision tree. Our aim was to implement a tool for building decision models sensitive to costs, namely test costs, misclassification costs and other types of costs.

We opt to use decision trees because they have several interesting characteristics for health professionals. They are easy to understand and use, and present an intuitive and appealing structure. Their structure is congruent with decision making methods that physicians normally use in daily routine, when they try to understand which is the best diagnostic test or the best treatment for one patient [21].

We modified the C4.5 algorithm [22] to contemplate costs and, consequently, to generate cost-sensitive decision trees. Specifically we used de j48 class, implemented in the open source package for data mining Weka [3].

Cost function

We adapted the decision tree splitting criteria to contemplate costs, through the following cost function (1):

$$\frac{\Delta I_i}{\left(C_i \phi_i\right)^{\omega}} \tag{1}$$

Where ΔI_i is the information gain (or gain ratio) for attribute i, C_i is the cost of attribute (test) i, ϕ_i is the factor of "risk" associated with attribute (test) i, and ω is the factor of power.

When building a tree, for each node, the algorithm will select the attribute that maximizes the defined heuristic for the cost function. The cost function does not consider misclassification costs, as these costs do not have influence in the decision tree splitting criteria [22].

Attributes without cost, as age and gender, are assigned the value 1. Attributes with higher costs lead to lower results in the cost function and have, consequently, fewer chances to be selected.

The factor of "risk" is an influent piece in the cost function. This factor was introduced to penalize attributes that might be invasive, may cause discomfort and disturb, or could somehow contribute to low patient quality of life (e.g., the invasive test "coronary angiography"). The value 1 means absence of influence and is equivalent to a completely innocuous test, while values higher than 1 means that exists influence. Higher factors leads to lower results in the cost function and, therefore, to lower possibilities for and attribute to be selected.

If both test cost and factor of "risk" are equal to one, then their participation is neutral and, thus, the cost function is basically the traditional information gain function. The cost of the attribute can be adjusted in two ways. It can increase or decrease considering the inoffensiveness of the test (factor of "risk"), or it can be modified by the factor of power. The factor of power is a general parameter that is equally applied to all tests, reducing or increasing the influence of costs in attribute selection.

The factor of "risk" can also be used to penalize delayed tests. A longer test can have consequences in the patient quality of life and may increase other costs, as those related to staff, facilities and increased length of stay. Between two similar tests, but with one longer than the other, it makes sense that the faster test should be preferred. Hence, considering the average length of tests, an adjustment can be made through the factor of "risk".

The factor of power regulates the influence of costs, as it can make trees more (or less) sensitive to costs. This factor may also be used to adequate the cost function to the used scale. An inexpensive test, such as the "age" test, has the same cost for any scale. But, tests with real costs have clearly different values in different scales. If a test "A" cost 10 in the Euro scale then it costs 1000 in the centime scale, that is, the ratio between the tests "age" and "A" are 1 to 10 in the Euro scale and 1 to 1000 in the other. To avoid that a change in the scale could benefit some attributes, it is important to adjust it with the factor of power.

For a factor of power of 0 the costs are not considered as the denominator of the cost function became 1. This situation is equivalent to consider the original information gain. With an increase in the factor of power, the costs of tests will have more influence and less expensive tests will preferred. The factor of power typically will assume a value between 0 and 1.

For making our model sensitive to misclassification costs, we used a meta-learner implemented in Weka, CostSensitiveClassifier [3].

Decision tree test and usage strategies

After building cost-sensitive models, we want to test and use them. For that, we have a test strategy where we consider the cost of a test individually or in a group. Within groups of tests it is possible to distinguish between (i) tests ordered simultaneously or (ii) tests that have a common cost.

Sometimes (i), there is a big difference between the cost of a group of tests and the sum of individual tests costs. Many medical tests do not have an immediate result and there-

fore it also important to consider the length of time for the group against the total delay of the individual tests. When a medical doctor is at a node of the decision tree, and have the first of a group of tests, he must decide if he will ask for a group of tests or only for the node test. If he orders a group of tests, then the cost considered will be the group cost, even if some tests in the group are not used.

In the other situation (ii), it is possible to separate a common cost for a group of tests. In a group of blood tests, for instance, the cost of collecting blood is a common cost for all tests in the group. Only the first test of the group will be priced for that common cost.

Delayed tests are considered in the training phase of the decisions tree. Slower tests will, therefore, have tendency to be tested only after faster ones.

Individual costs

Our strategy also allows (a) to consider specific patient characteristics, (b) to modify test costs in situations where their values are already known (tested previously), and (c) to consider availability and slowness of certain tests.

The cost of each test can be conditional on the characteristics of the patient, that is, it is possible to have a variable cost associated with specific features of the patient. As seen before, the age can change the cost of the test "bronchodilatation" (higher for children less than 6 years). The comorbidity index of a patient is another example, as it can influence the cost of some tests and, therefore, could be used to adjust the cost of the test. For a specific test, different patients may require additional tests, consequently with an increase in costs.

In other circumstances (b), some tests might have been obtained previously and, logically, their original costs should not be considered again. Consequently, we adopt another approach for building trees where, for each new instance (patient), tests with known values are considered without cost and without "risk". For each new vector of distinct costs a new decision tree is built.

Resources are not infinite neither are always available. A specific test may be conditional on the availability of a medical device in a specific time period. In these cases, it is possible to exclude that test and build a new tree. Optionally, it is possible to increase de factor of "risk" of that test, decreasing it probabilities of being selected. As the availability is not constant over time, this problem should be analyzed for each case (patient); this is a circumstantial cost and not a cost intrinsic to the patient.

Experiments

We tested our cost-sensitive decision tree with several datasets, including the Pima Indians Diabetes. This dataset contains 768 instances and a class that assumes 2 values, "healthy" (500) or "diabetes" (268)[1]. In Table 1 we can see test costs (all attributes are numeric).

Table 1 - Attribute costs for Pima Indians diabetes

Test	Cost ($)	Group cost ($)
a. Number of times pregnant	1	
b. Glucose tolerance test	17.61	b+e=38.29
c. Diastolic blood pressure	1	
d. Triceps skin fold thickness	1	
e. Serum insulin test	22.78	b+e=38.29
f. Body mass index	1	
g. Diabetes pedigree function	1	
h. Age (years)	1	

Tests "glucose tolerance" and "serum insulin" are not immediate and have a distinct cost (other attributes have a symbolic cost of $1). Moreover they share a common cost, $2.1, from collecting blood. As these attributes are not immediate, when using the tree it is necessary to decide if both tests will be ordered together (in group) or not.

We ranged the factor of power from 0.0 to 1.0 and induced decision trees using 10-fold cross-validation. After that, we considered cost zero for cases classified correctly and varied misclassification costs, from $10 to $1000, with equal costs for false negative and false positives. In Table 2 we can see the results of the evaluation of five decision trees for that range of misclassification cots. Notice that for factor of power equal to zero, the model is equal to the obtained by the traditional C4.5.

1 UCI Repository Of Machine Learning Databases, ftp://ftp.ics.uci.edu/pub/machine-learning-databases/

Table 2 - Average costs in the evaluation of 5 decision trees, for a range of misclassification costs and factors of power

fp:	**0.0**	**0.1**	**0.2**	**0.5**	**1.0**	**95% IC var.**
Accuracy (%):	73.8	73.7	72.3	68.5	68.2	
$10	23.4	21.9	19.5	6.4	5.7	±0.5
$20	26.0	24.5	22.2	9.5	8.8	±0.8
$50	33.8	32.4	30.6	19.0	18.4	±1.7
$100	46.9	45.5	44.4	34.7	34.2	±3.3
$200	73.1	71.8	72.2	66.2	66.0	±6.5
$500	152	151	155	161	161	±16
$1,000	283	282	294	318	320	±32

In this example, for low misclassification costs, the best results are obtained for a factor of power between 0.5 and 1.0. In these situations, average costs are much lower when compared with C4.5. For high misclassification costs, compared to test costs, best results occur with factor of power equal to 0.0 (C4.5) and 0.1, but without substantial differences for the other models.

As misclassification costs rise, test costs tend to be negligible. That is, for sufficiently higher misclassification costs and considering equal cost for false negatives and false positives, a higher accuracy rate corresponds to a lower average cost.

In this evaluation we distinguished between individual and group costs, and realized that results considering group costs always had higher average costs. This happened because the serum insulin test, which shares group costs with the glucose tolerance test, only intermittently appeared in the decision trees and, therefore, there was an extra imputed cost nothing or little used.

We also tested the factor of "risk" with other datasets and obtained interesting results. Sometimes, with minimum increase in the total cost it is possible to obtain models that are more patient-friendly.

Conclusions

In this paper we present approaches to build cost-sensitive decision trees, considering different aspects of test costs, where are included economic and non-economical costs. Our framework integrates also a cost-sensitive meta-learner to consider the situations where misclassifications costs are different. Results show that it outperforms the traditional, non cost-sensitive, C4.5.

As technologies became more expensive, it is even more rational to consider all the cost involved. A big challenge is to have better healthcare using less money. The factor of "risk" is an important item of the proposed framework as it can induce models patient-friendly. Decision trees represent a natural representation for classification problems (for diagnosis or prognosis) that includes costs.

In our future work we will continue to evaluate our strategies, with new experiments in other datasets, with real data and real costs. We will try to incorporate other costs associated with delayed tests, emergency situations, staff, facilities, and increased length of stay. The cost function will also be refined and tested for different scenarios. We will also study other methods for building and testing decision trees with the application of a cost-sensitive pruning strategy.

Linking and Analysing Health Data with Appropriate Privacy and Security

Norm Good[a], David Hansen[b], Christine M O'Keefe[c]

[a] *E-Health Research Centre and Mathematical and Information Sciences, CSIRO, Australia*
[b] *E-Health Research Centre, CSIRO, Australia*
[c] *Preventatative Health National Research Flagship and Mathematical and Information Sciences, CSIRO, Australia*

Abstract

In this paper we discuss current approaches for linking and analysing sensitive health data for research, and discuss associated security and privacy risks. We also provide an overview of two CSIRO tools, HDI™ and PPA®, developed for enabling secure access to personal health data for research while providing the required privacy protection, in some situations.

Keywords:

medical record linkage; privacy; statistics; health research

Introduction

The increasing number and size of health data repositories can provide the health and medical research communities with information which is important to clinical treatment and medical research. There is a need not just to access the data, but to locate records relating to the same patient in multiple databases and bring the records together for analysis and research.

Various approaches and protocols have been developed for attempting to simplify the linkage and provision of separate data sources to end users for analysis and research whilst preserving the privacy of individuals, including two and three party protocols and blind record linkage algorithms [1]. The technological approaches differ in their architecture and software/hardware platforms, and there are differences between the applicable legislative and policy frameworks.

Model architectures range from single large databases[2], separate databases linked only as required[3], chains of links type data systems[4], and federated databases[5]. In most cases access to the data is controlled by ethical review boards and the released data is usually in de-identified format, with names, addresses and dates of birth removed.

The role of data custodians in the provision of health data to users varies: with some custodians releasing the data completely and others entrusting third parties to manage the privacy and security issues. As the number of data sources increases, the complexity of privacy and security agreements will obviously increase, placing a substantial amount of responsibility upon the parties involved [6].

Once a linked data set is available, usually in de-identified format, the analysis of the data is generally carried out using statistical or reporting software. In some cases results of subsequent statistical analyses are assessed for disclosure risk prior to publication [2], whilst in others the burden resides upon the trusted third party undertaking the analysis. Whilst ethics agreements may contain clauses governing how results of statistical analyses may be disseminated, there remains a real risk of disclosure [7].

In this paper we propose one solution for linking and analysing health data that may reduce the risk of identifying individual records in some situations.

Health data integration™ (HDI™)

The core functionality of HDI™ enables linking of patient records from different data repositories whilst maintaining the privacy of the patients. It is a virtual repository, and external release of the data is controlled by the data custodian, and can be stopped at any time. HDI™ provides support in software for data custodians to develop a strong governance framework providing rules for: release of data for use in projects; management of the HDI™ installation; support for the separation of identifying and clinical information, and the building of a virtual linked data set by Project Administrators for Users to access linked data. HDI™ offers this data on-line, allowing real time query and retrieval without using a data warehouse.

The HDI™ model allows data custodians to release demographic information to HDI™. As HDI™ is installed locally there is also the provision for third party software to link directly to HDI™ and the data. Within the governance framework provisions can be made that only certain types of analyses may be performed on sensitive data.

Privacy-preserving analytics® (PPA®)

Privacy-Preserving Analytics® (PPA®) is a menu-driven web-based software package for conducting statistical analysis on raw microdata in a secure computing environment. Outputs of an analysis are filtered before

presentation, with the aim that no individual unit record is disclosed or can be inferred.

Reducing the risk of disclosure is achieved in several ways:

- Variable names that are a privacy risk are de-identified
- Some models are fitted on subsamples of the dataset to limit attempts at re-engineering
- Some data transformations are restricted
- Some parameter estimates are rounded, standard errors and exact significance values are not produced, and
- Some higher order interactions are limited.

PPA™ can be used as a knowledge discovery tool for testing hypotheses before developing a full research proposal.

The use of PPA™ may reduce (though will not entirely remove) the administrative burden of consent provisions, custodian security compliance, ethics committee processes and address the requirements of HIPAA (Health insurance Portability and Accountability Act 1996 (US)).

Analysis of health data in an HDI™ and PPA® framework

As an example of HDI™ and PPA® working together, consider that in the HDI™ environment, data custodians may allow HDI™ access to sensitive information such as individual demographic details, surgeon, and hospital. In that case, a flag may be attached to a sensitive field to inform HDI™ that this field may be used as an explanatory variable in an analysis using PPA® but no estimate may be published. PPA® can then use that information for constructing and running a full statistical model to gain reliable information about other explanatory variables, where the estimates can be published. In a knowledge discovery context a researcher can test hypotheses regarding the effect of factors such as age, gender and comorbidities on clinical outcomes, for example, while having the effect of the surgeon modeled but not released.

Conclusion

A data custodian has responsibility to ensure that no identifiable information is released to an unauthorised third party. Project agreements normally require that data is used only for the specific aims of the project for which it was released, and that the data is destroyed at the end of the project. The release of results from the project must also satisfy privacy agreements. This is the limit of control a data custodian has over their data once it has been released. The HDI™/PPA™ model may support the fulfillment of a significant amount of the responsibility of the data custodian by significantly reducing the risk that identifiable information is publicly released from a project. Similarly, researchers may benefit by being able to use more sensitive and valuable information for testing hypotheses, though without actually seeing the data. The HDI™ and PPA™ tools may also allow less authorised third-parties such as graduate students, and other researchers to conduct analysis on raw data without having to modify existing data agreements with data custodians.

Acknowledgments

HDI™ and PPA® are projects of the CSIRO Preventative Health National Research Flagship. HDI™ is being developed by researchers at the e-Health Research Centre, a collaboration between CSIRO and the Queensland Government and PPA® is being developed by researchers in CSIRO Mathematical and Information Sciences.

Comparison of Perceptions of Patients' Information Privacy in Dealing with Nurses in Japan

Hiroko Iguchi[a], Katsumasa Ota[b]

[a]*Department of Nursing, College of Life & Health Sciences, Chubu University, Japan*
[b]*Department of Nurisng, School of Health Sciences, Nagoya University, Japan*

Abstract and objective

It has become very important to maintain the proper balance between protecting the privacy of patients' information while adequately sharing their information in the era of ICT. This study aimed to compare perceptions regarding patients' information privacy between patients and nurses to discuss appropriate ways of future interdisciplinary communication. A self- administered survey was conducted to obtain perceptions on patients' information privacy among 595 patients and 1770 nurses from 37 hospitals in 3 prefectures in Japan. A factor analysis was performed to clarify the concept of patients' information privacy, and t-test was performed to compare the level of perceptions. As a result, the concept of patients' information privacy was almost the same between patients and nurses, while nurses were more aware of patients' information privacy than the patients themselves. This indicates the importance of asking patients their intentions with regard to information sharing among healthcare professionals in order to protect the patient's right to information privacy.

Keywords[1]:

interdisciplinary communication, privacy, information sharing

Introduction

In Japan, an electronic medical health records system has been rapidly implemented to facilitate interdisciplinary communi- cation through information sharing. At the same time, a debate has ensued over whether information privacy is properly protected among healthcare professionals. Maintaining the proper balance between protecting the privacy of patients' information and adequately sharing patients' information has become a critical issue. The aim of the study was to compare perceptions on patients' information privacy between patients and nurses to discuss appropriate ways of future inter- disciplinary communication.

Methods

A self-administered survey was conducted to obtain current perceptions of patients' information privacy among a total of 595 patients and 1770 nurses from 37 hospitals in 3 prefec- tures in Japan. The questionnaire contained 26 items that related to information privacy, such as "diagnosis," "name," "toilet habit," "history of family disease," and so on, that were scored using a 6-point Likert scale (1:high sensitivity to 6: low sensitivity). Patient surveyed were asked to complete an anonymous self-administered questionnaire. Also, nurse par- ticipants were asked to recall one specific patient, and reply to the questionnaire by assuming how the patient would respond to each question. The survey was conducted in accordance with a certain ethical procedure.

Results

The valid response rate was 40.2% (n=239) from patients and 51.4% (n=909) from nurses. As a result of a factor analysis for patient responses, four common factors were extracted, "Treatment-Related Information," "Identification-Related Information," "Daily Life Behavior-Related Information," and "Personal Life-Related Information," as shown in Table 1. The result of factor analysis for nurse responses showed ex- traction of four common factors, whose components were almost the same as the result of patients as shown in Table 2. By analysis of the score differences between patients and nurses, nurses responses were significantly lower to most questions than patients ($p<0.05$). No differences were found among three questions; "name," "birthday," and "allergy," as shown in Table 3.

Discussion

As a result of factor analysis for patient responses (Table 1), patients' perceptions of information privacy were confirmed to be composed of four factors. The items included in each extracted factor are considered very important information in the range of care provided by all healthcare professionals. In particular, nurses not only use medical information, but also various other types of information related to life at home in order to provide nursing care. Therefore, the proven four factors relating to information privacy are considered to be very meaningful for the col-

1 A part of this research was funded by a Grant-in-Aid for Scientific Research (B)(18390571) from the Ministry of Education, Cultures, sports, Sciences and Technology

lection, use, and sharing of patients' information for treatment as well as protecting the hospitalized patients' information privacy.

Also, the result of factor analysis for nurse responses showed extraction of four common factors, whose components were almost the same as the result of patients. This result indicates that both patients and nurses shared virtually the same views about patients' information privacy.

However, the score differences between patients and nurses, nurses responses were significantly lower to most questions than patients, which means nurses are more sensitive to patients' information privacy than patients-selves. According to Ota's study[1)] conducted in 2002, nurses considered their own privacy more important than patients' privacy. Compared to Ota's result, Japanese nurses' concern for patients' infor- mation protection is growing. This may be influenced by the Personal Information Protection Law enacted in Japan in April 2005.

Conclusion

The study was conducted to compare perceptions on patients' information privacy between patients and nurses to discuss appropriate ways of future interdisciplinary communication.

This study revealed that both patients and nurses shared vir- tually the same views about patients' information privacy, but their level of awareness was the different. Therefore, it is important to ask patient themselves how they want healthcare professionals to share their privacy related information to protect their right to information privacy.

Abstract

The financial analysis is needed to evaluate efficiency in hospitals. A prototype using rule-based engine was developed and the results of the user evaluation suggested the effectiveness of the system.

Keywords:

financial management, computer reasoning, rule-based engine

Introduction

The financial analysis is a method to analyze the financial status of companies. It is used both for external analysis and for internal analysis to evaluate the status of one's own company. Hospitals, which are non-profit organizations, are required to manage efficiently these days, and the financial analysis in hospitals is needed. Financial analysis by computer systems is expected to save cost and time for hospitals. The objective of this research was to develop a financial status analysis system for hospitals.

Methods

Requirements

The mandatory functions to analyze financial status in hospital are to be segmented as follows: 1) Define Indices 2) Calculate Index Values 3) Evaluate Index Values 4) Find Root Cause. Rule-based engine and forward chaining was thought to be suitable for the financial analysis, because of the characteristics of the financial data which can be obtained as a group of data, and the characteristics of the financial analysis of which the knowledge system is relatively simple.

Prototype system

A prototype using a rule-based engine and forward chaining was developed. Figure 1 shows the architecture of the prototype.

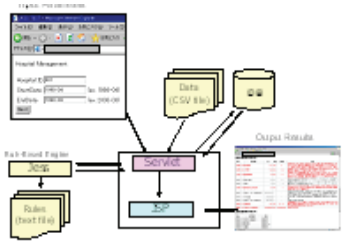

Figure 1 - Architecture of the Prototype

Jess[1], a rule-based engine described in Java was adapted. 16 financial indices were selected and defined in rules. Rules to calculate and evaluate the index values were also set in rules. Decision tree analysis was developed to infer the reasons why the operating profit was less than the threshold value by using the relationships between the indices.

Evaluation

5 end-users joined the evaluation of the prototype. All 5 subjects agreed to the evaluation item "Evaluation of the index values are reasonable". 2 subjects chose "I agree" and 3 chose "I agree a little" for the item "the system can analyze the financial status comprehensively." It showed that the results analyzed by the prototype suit the results analyzed by users.

Results

A possibility of the hospital financial analysis system using rule-based engine was shown. Rule-based engine is expected to solve the root problems in hospitals.

Abstract

The financial analysis is needed to evaluate efficiency in hospitals. A prototype using rule-based engine was developed and the results of the user evaluation suggested the effectiveness of the system.

Keywords

- Financial Management
- Computer Reasoning
- Rule-Based Engine

Backgrounds

- Financial analysis
  - a method to analyze the financial status of companies
  - used both for external analysis / for internal analysis

- Demand for efficient management to hospitals

  → Demand for financial analysis in hospitals

- Financial analysis system for hospital managers is possible to save cost and time.

Objective

To verify the effectiveness of financial analysis system for hospital managers by developing a prototype system and evaluating it.

Methods(1) - Requirements

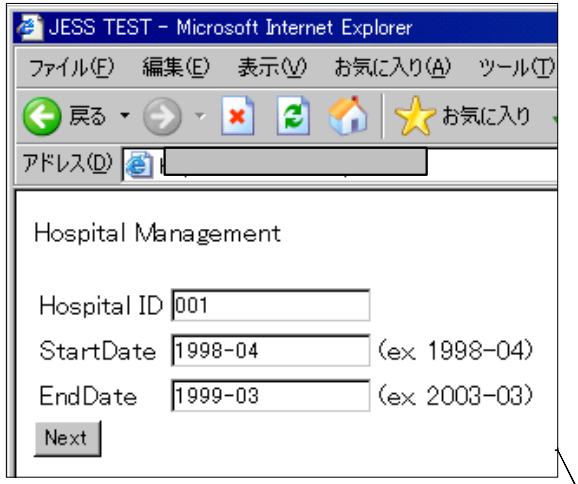
- Mandatory functions
  1) Define indices
  2) Calculate index values
  3) Evaluate index values
  4) Find root cause.

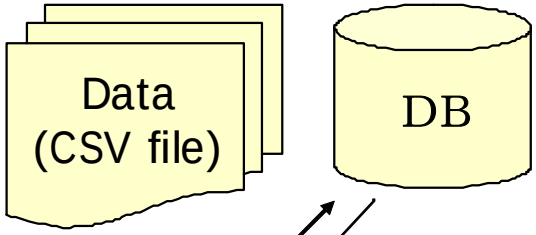
- Development methods
  - Rule-based engine
  - Production system and knowledge representation using frames
  - Forward chaining

  (from the characteristics of the financial data and financial analysis)

Methods(2) - Prototype System

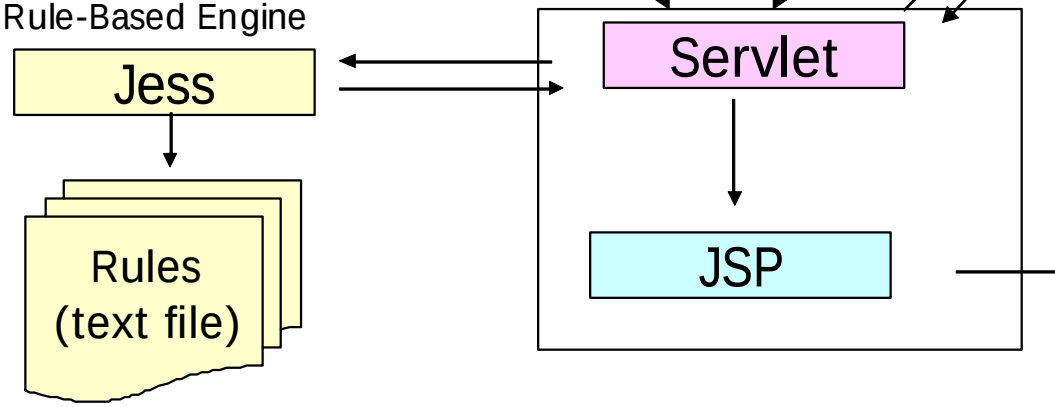
Input Parameters





Output Results

Rule-Based Engine



System Output (Examples)

- Financial Indices Evaluation

Viewpoint	Index	Value	Evaluation	Standard	Explanation
Stability	Labor Productivity per person	8,301,128.21	--	-	This index shows ....
Stability	Labor's Share	94.57	NG	60 - 70	This index shows .... When it is too low, it will.... and when it is too high, it will...

- Profit Tree Analysis

Operation profit does not meet the standard because...
=> Operation cost does not meet the standard
Operation Cost does not meet the standard because...
=> Personnel expense does not meet the standard
Personnel expense does not meet the standard because...
=> Personnel expense per labor does not meet the standard

Methods(3) - Evaluation

- Levels of agreements to the analyzed results
  - By 5 end-users (medical doctors)
  - By 5 professional consultants
- Required functions for financial analysis
  - By 5 professional consultants

Evaluation Results
(Levels of Agreement)

	End-users					Consultants				
	1	2	3	4	5	1	2	3	4	5
a. Index items are enough for practical use	0	**2**	**3**	0	0	0	0	**1**	**4**	0
b. election of the index items are reasonable.	0	**2**	**3**	0	0	0	**2**	**2**	**1**	0
c. Evaluation of the index values are reasonable	0	**5**	0	0	0	0	**1**	**4**	0	0
d. Explanation of the evaluation is enough	0	**2**	**2**	**1**	0	0	**1**	**3**	**1**	0
e. From the synthetic viewpoint, the financial status is analyzed.	0	**2**	**3**	0	0	0	0	**2**	**3**	0

[Levels of Agreement] 1: I agree a lot. 2: I agree. 3: I agree a little. 4: I don't agree. 5: I have no idea.

- All Evaluation result by end-users is in the affirmative.
- Evaluation result by consultants is not positive, but not completely negative.

Possibility of hospital financial analysis system using rule-based engine was shown.

Evaluation Results
(Required Functions for Financial Analysis)

#		Number of subjects to check each item
	(Input Data)	
1	Input of non-financial data (ex. years after foundation)	1
2	Input of financial data for longer period	2
	(Output)	
3	More detailed explanations	**3**
4	More variety of representation (ex. graphical interface)	**4**
5	Comprehensive evaluation (not only evaluation of each index)	2
	(Analysis Methods)	
6	Adjustment of standard value by characteristic of hospitals	**4**
7	Evaluation by multiple steps (ex. Good / Fair/ Bad)	2
8	Comparison with best-practice facilities	**4**
9	Analysis over consideration of external environment change	2
	(Others)	
10	Others	2

Discussion

#3 More detailed explanations
#4 More variety of representation (ex. graphical interface)

→ Additional functions are required for better comprehension.

#6 For adjustment of standard value by characteristics of hospitals
#8 Comparison with best-practice facilities

→ Additional input data are required.

Ex.
- Years after foundation
- Type of the organization (private / public)
- Size of the organization (number of beds etc.)

Conclusion

- A prototype system for hospital financial analysis using rule-based engine was developed.
- Possibility of hospital financial analysis system using rule-based engine was shown.
- It is suggested to add :
  - More functions for better comprehension
  - More input data for adjustment of standard value by characteristic of hospitals and for comparison with best-practice facilities

By equipping those functions and data...

It is expected to increase end-users' satisfaction and to reach the level enough for practical use.

Risk Analysis – A Tool for IT Development and Patient Safety
A Comparative Study of Weaknesses Before and After Implementation of a Health Care System in the County Council of Ostergotland, Sweden

Annica Öhrn[a], Gunilla Eriksson[b]

[a]*Patient safety office of county council of Ostergotland, Sweden*
[b]*Laboratory medicine unit of county council of Ostergotland, Sweden*

Abstract

There is a lack of tools to secure patient safety considering information security and health care systems. Risk analysis can be used as a systematic method for identifying risks before a medical error occurs. In healthcare is this type of analysis uncommon use. An indicator for this need of systematic proactive work is the amount of adverse advents that are reported in the deviation system .In this comparative study of a health care system during 2004 and 2006, one of the results is an reduction in the numbers of risks due to technique & equipment and in the area of training & competence. This study gives an indication of that risk analysis helps the health care organisation to develop and manage routines for reducing possible risks.

Keywords:

information system, safety management, risk management/methods, medical errors, systems analysis, quality of health care

Introduction

In the county council in Ostergotland, Sweden has a supporting system for requests and laboratory reports, called LR, and been implemented during the last year and a half. A risk analysis has been performed before and after implementation and is planned to continue regulary for the coming years. The aim of this study was to perform a comparative risk analysis for a recently implemented health care system.

Methods

Risk analysis has been performed before and after the implementation of the system. Risk analysis is a systematic tool, including: process mapping, risk identification, determination of the severity and probability of each risks and action plans. The analysis has a patient safety perspective and has been performed with a trained risk analysis team including members from different roles/specialities. The risks were categorised in areas of six potential sources; technique & equipment, rules/policies/procedures, environment, training & competence, barriers and communications & information.

Results

The risk analysis shows that the total risk points are lower during 2006 for the areas technical solutions and procedures compared to the points of the same areas during 2004.

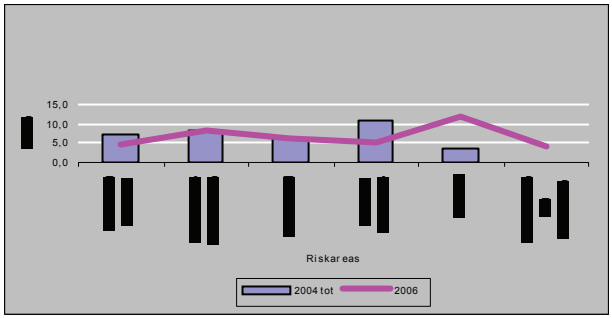

Figure 1 – Risk profile, comparison 2004-2006 LR

Discussions

The risk analysis performed demonstrated differences between the results obtained prior and after the implementation. This was especially true within the sources; technique & equipment, training & competence as well as for barriers. The risk profile within technique & equipment demonstrated that most of the risks prior to the implementation have been dealt with. Training of the personal drastically decreased the risk profile within training & competence. However, increased risks were found for the source barriers as a consequence of the introduction of new barriers, which reduced the accessibility of laboratory results. This was a consequence of the Swedish legislation for patient related information in medical records, which prevents full access of a patient's laboratory test data without the patient consent.

The risk profile for the source; rules/policies/procedures is unchanged. The numbers of risks have decreased but the

risks with a high score, which were identified prior to the implementation, were never dealt with.

Conclusion

Risk analysis is a useful method for identifying and managing possible patient safety risks and also a method for proactive work in health care organisations. Systematic and regular risk analysis is preventive of managing new routines. This may be a constructive tool for the patient safety work.

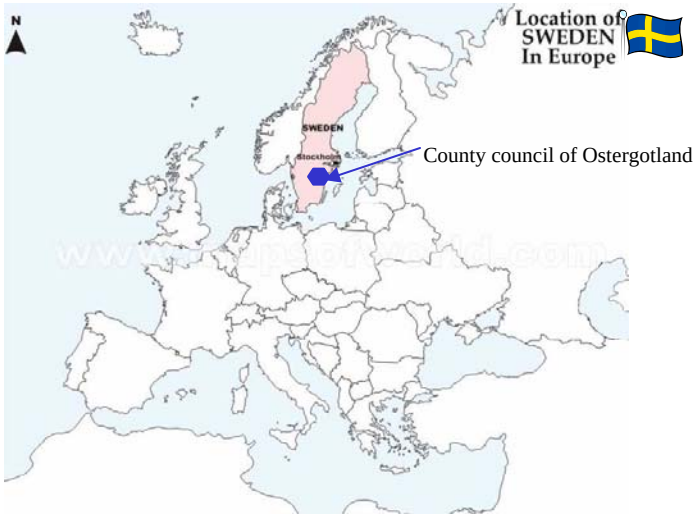
Risk Analysis
– a tool for IT development and patient safety



Annica Öhrn[a], Gunilla Eriksson[b]

[a] *Patient safety office of county council of Ostergotland, Sweden*

b Laboratory medicine unit of county council of Ostergotland, Sweden

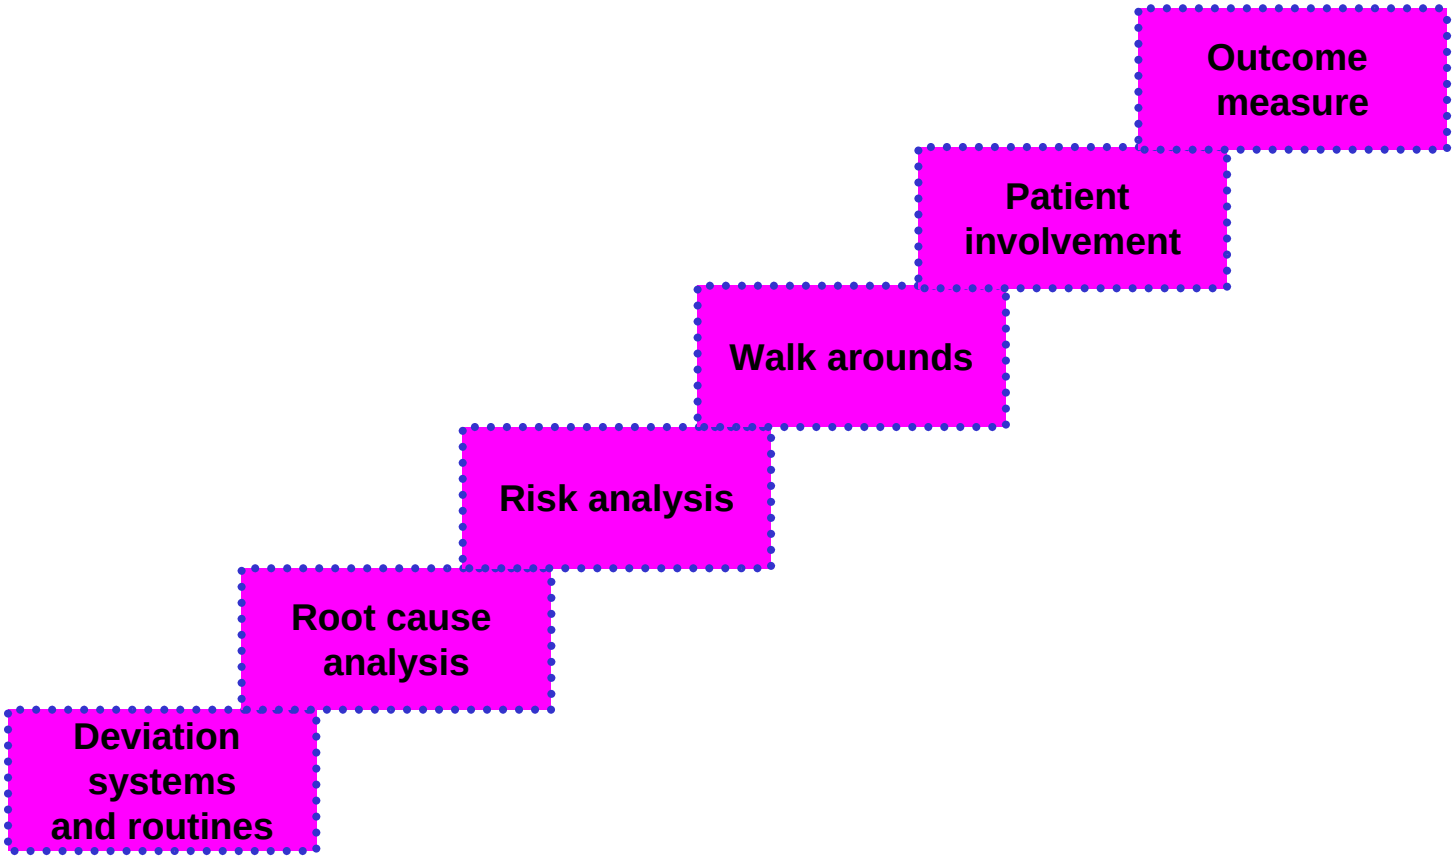
Aim

A comparing study of weaknesses before and after implementation of a health care system

Introduction

- The county council in Ostergotland, Sweden
  - work systematic and structure with patient safety since year 2000
  - has implemented a supporting system for requests and laboratory reports during the last year and a half.

Introductions



The model for patient safety in county council of Ostergotland, Sweden

Methods

- Risk analysis has been performed before and after the implementation of the system

- Risk analysis is a systematic tool, including:
  - process mapping
  - risk identification
  - determination of the severity and probability of each risks
  - action plans

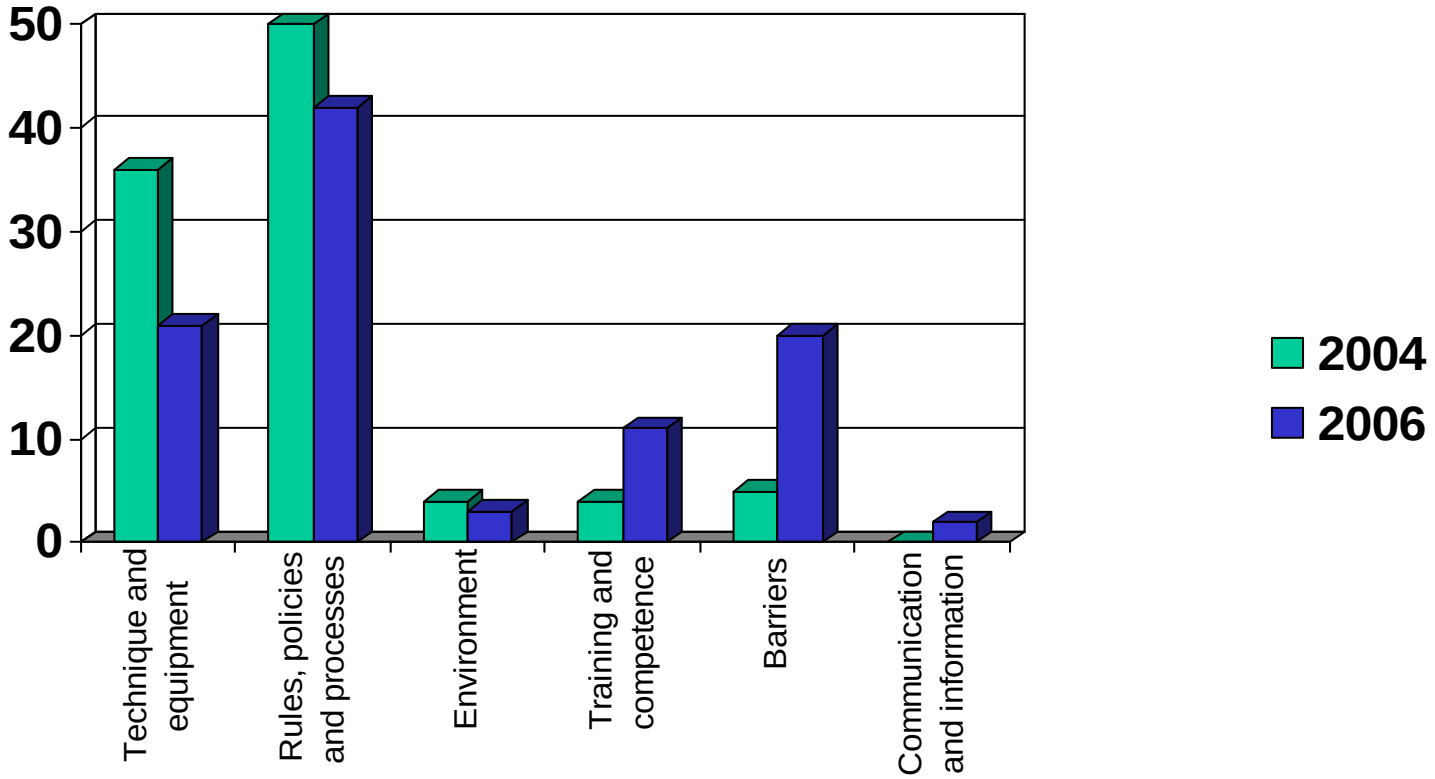
Methods

- The analysis has a patient safety perspective
- Team with trained risk analysis team including members from different roles/specialities.

Methods

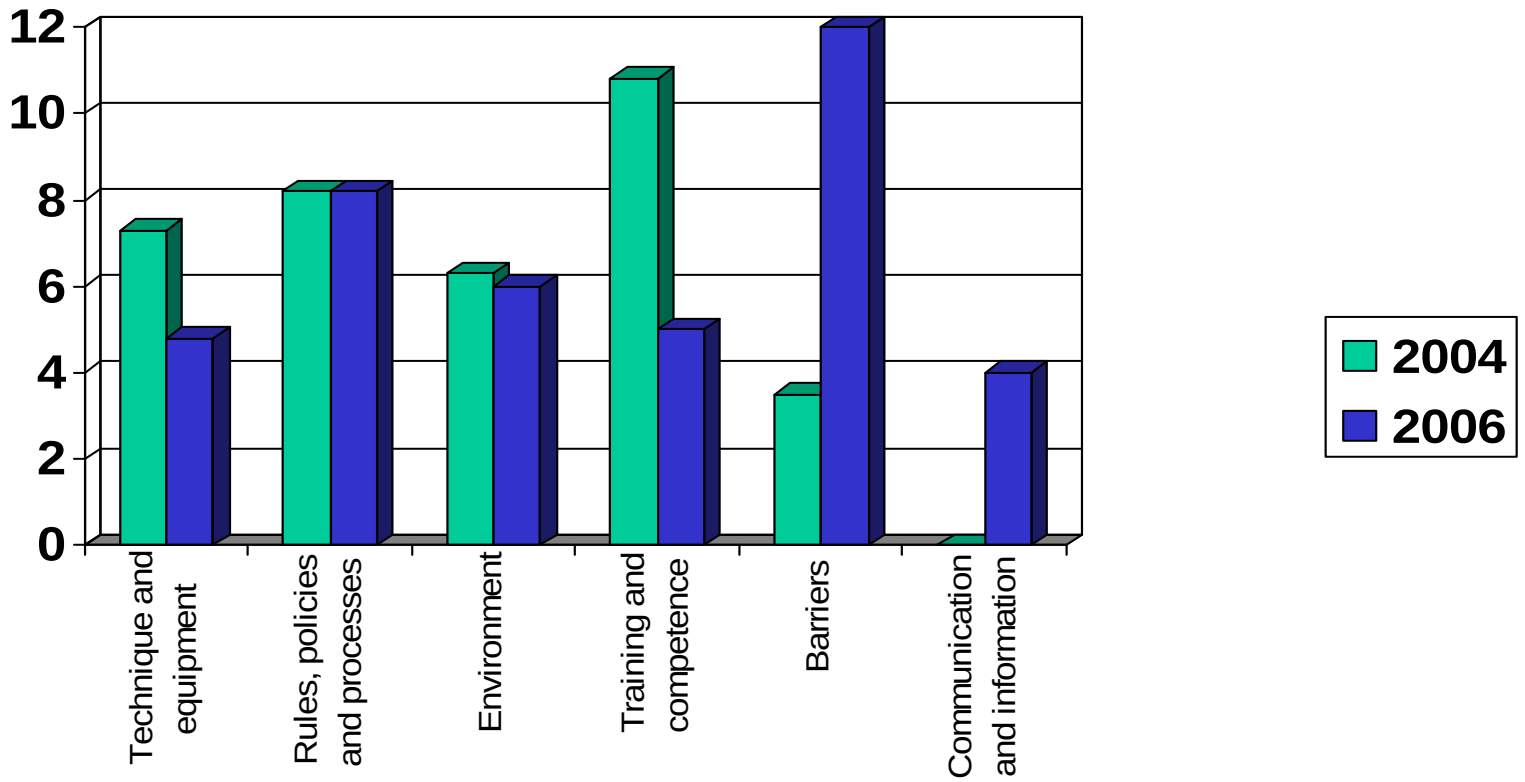
- The risks were categorised in areas of six potential sources;
  - technique & equipment
  - rules/policies/procedures
  - environment
  - training & competence
  - barriers
  - communications & information

Results



The risk share/risk areas. A decrease in the number of risks in technique & equipments and rules, policies/procedures shows but the risks in training & competence and barriers has increase between the year 2004 and 2006.

Results



The risk profile/risk areas.
A decrease in the risks severity in technique & equipments and training & competence shows but the severity in barriers has increase between the year 2004 and 2006.

Results

- The risk profile within technique & equipment demonstrated that most of the risks prior to the implementation have been dealt with.

- Training of the personal drastically decreased the risk profile within training & competence.

Conclusion

- Risk analysis is a useful method for identifying and managing possible patient safety risks and also a method for proactive work in health care organisations.
- Systematic and regular risk analysis is preventive of managing new routines.
- This may be a constructive tool for the patient safety work.

Discrete Event Simulation Analysis for Optimization of Outpatient Flow

Ohta S[a, b, c], Aoki N[a, b, d, e], Kikuchi N[a, b, f], Mariko Oishi[a, g]

[a]*Center for Health Service, Outcomes Research and Development – Japan (CHORD-J), Tokyo, Japan*

[e]*University Hospital Medical Information Network (UMIN) Center, The University of Tokyo Hospital, Tokyo, Japan*
[f]*Okabe Clinic Regional Palliative Care Program, Natori, Japan,* [g]*Oishi Clinic, Kyoto, Japan*

Abstract

The Okayama Central Clinic is a community hospital located in a city with a population of 680,000. A routine customer-satisfaction survey showed that the most important and critical issue of the clinic is "long waiting-time." The purpose of this study was to utilize discrete simulation analysis to optimize outpatient flow and resource allocation.

Discrete simulation analysis (DES) using Simul8 software (Simul8, Inc., Boston, MA) was used to model a work flow of the clinic, and to identify the bottlenecks of the model. Time data was derived from the time survey at the clinic.

Baseline data showed that the average waiting time before examination by a physician was 35.3 minutes, and only 1.6% of the patients waited for less than 10 minutes. The physician's examination was identified as the bottleneck of this model. The DES demonstrates that setting up warm-up time is an efficient way to decrease average patient time spent at the clinic without increasing the physician's workload.

Keywords:

discrete event simulation, process optimization, outpatient

Introduction

The Okayama Central Clinic is a community hospital located in a city with a population of 680,000. A routine customer-satisfaction survey has demonstrated that the most important and critical issue of the clinic is the "long waiting-time." The "long waiting-time" is also a critical issue at hospital emergency rooms in the U.S.A. [1]. The patients' satisfaction is one of the factors constituting to the quality of care, and it is clear that the long waiting-time will lead to the degradation of quality of care.

Systematic problem solving of ambulatory care is needed for a long time. Identification of bottlenecks and planning countermeasures may have been considered in hospitals, however, it seems that practical applications of improvement plans are difficult.

Simulation is one of the most widely used operation research and management science techniques for evaluating systems. Discrete Event Simulation is one of the simulation techniques, that has been used to analyze ambulatory care [2, 3]. Improvement plans for ambulatory care can be inspected by the simulation, and it can prevent risks attending application of the improvement plans directly to the real world.

The purpose of this study is to simulate outpatient flow in a primary care clinic, identify the bottleneck of the flow, and develop a quality improvement plan.

Materials and methods

Figure 1 shows a work flow of the Okayama Central Clinic.

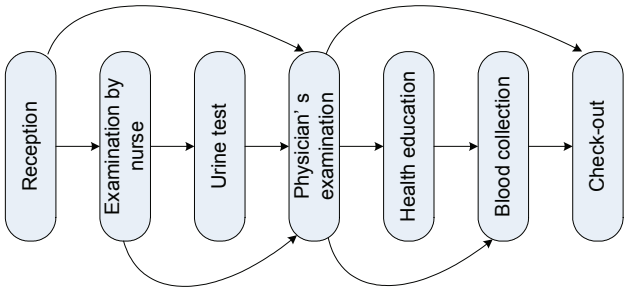

Figure 1 – Simplified Work flow at the Clinic

All patients were required to check-in at the reception desk. There were two types of patients: those with and without an appointment with the physician. Depending on the patient conditions, patients would receive (1) an initial interview by the nurse, (2) a urine test, or (3) both. Subsequently, all patients see a physician for examination. Some patients would have blood collected, and others may need health education for diet and exercise. Finally, all patients were required to check out.

We used Simul8 software (Simul8, Inc., Boston, MA) for the discrete simulation. Time data was derived from the time study at the Okayama Central Clinic.

Prerequisites

1. Table 1 shows the time data from the time study at the Okayama Central Clinic

Table 1 – Simulated Patients' time Spent at the Clinic

Name of Work Station	Patient's Time spentminutes
Reception 1	8
Reception 2	5
Nurse's Inquiry with urine test	10
Nurse's Inquiry without urine test	15
Urine examination	20
Physician's examination	10
Blood collection	5
Blood examination at Laboratory	30
Check out	10

2. Patients

   According to the average distribution at the clinic, 70% of patients received the nurse's inquiry with urine examination, 20% received nurse's inquiry without urine examination, and 10% passed through the steps of nurse's inquiry.

3. Resources

   One doctor, three nurses, four receptionists, and four laboratory technicians were used in this model.

4. Operation time of clinic

   The opening time of the clinic is 9:00 AM. Patients were accepted until 12:00 PM. Patients arrived at the clinic every 10 minutes.

Results

Baseline data show that the average waiting time before the physician's examination was 35.3 minutes, and patients waiting less than 10 minutes were 1.6%. The physician's examination is identified as a bottleneck of this model.

The time pattern used by the physician shows that the doctor did not work for 40–45 minutes after the opening time of the clinic because the patients had not been ready to have physician's examination at that time.

Table 2 reveals the result of the simulation. Average time spent at the clinic can be decreased without increasing physician's time (which is more important) if we set-up a one-hour warm-up time (i.e., the first patient is asked to visit the clinic at 8:00 AM, although the scheduled time is 9:00 AM). However, little difference was observed in number of patients who visited the clinic.

Table 2 – Simulated Patients' time Spent at the Clinic

Patients' time spent at the clinic	Average Time Spent(minutes)	Number of Patients
Open at 9:00 AM	99.9	23
Open at 9:00 AM with 1 hour warm-up	85.5	24
Physician start work at 8:45 AM	81.5	24

Conclusion

This analysis demonstrates that we could increase the efficiency without increasing the bottle-neck or the physician's workload. Further analysis is needed to identify the optimal resource utilization to improve the availability of the doctor and throughput of the system.

g *Oishi Clinic, Kyoto, Japan*

Introduction

- "Long waiting-time" was the most important and critical issue for ambulatory care. (*Annual consumer satisfaction survey at Okayama Central Clinic*)
- To identify the bottleneck of the outpatient flow and plan the countermeasures against them is the possible way to solve the systematic problem.
- Discrete Event Simulation is one of the simulation techniques, that has been used to analyze ambulatory care. Improvement plan for ambulatory care can be inspected by the simulation.

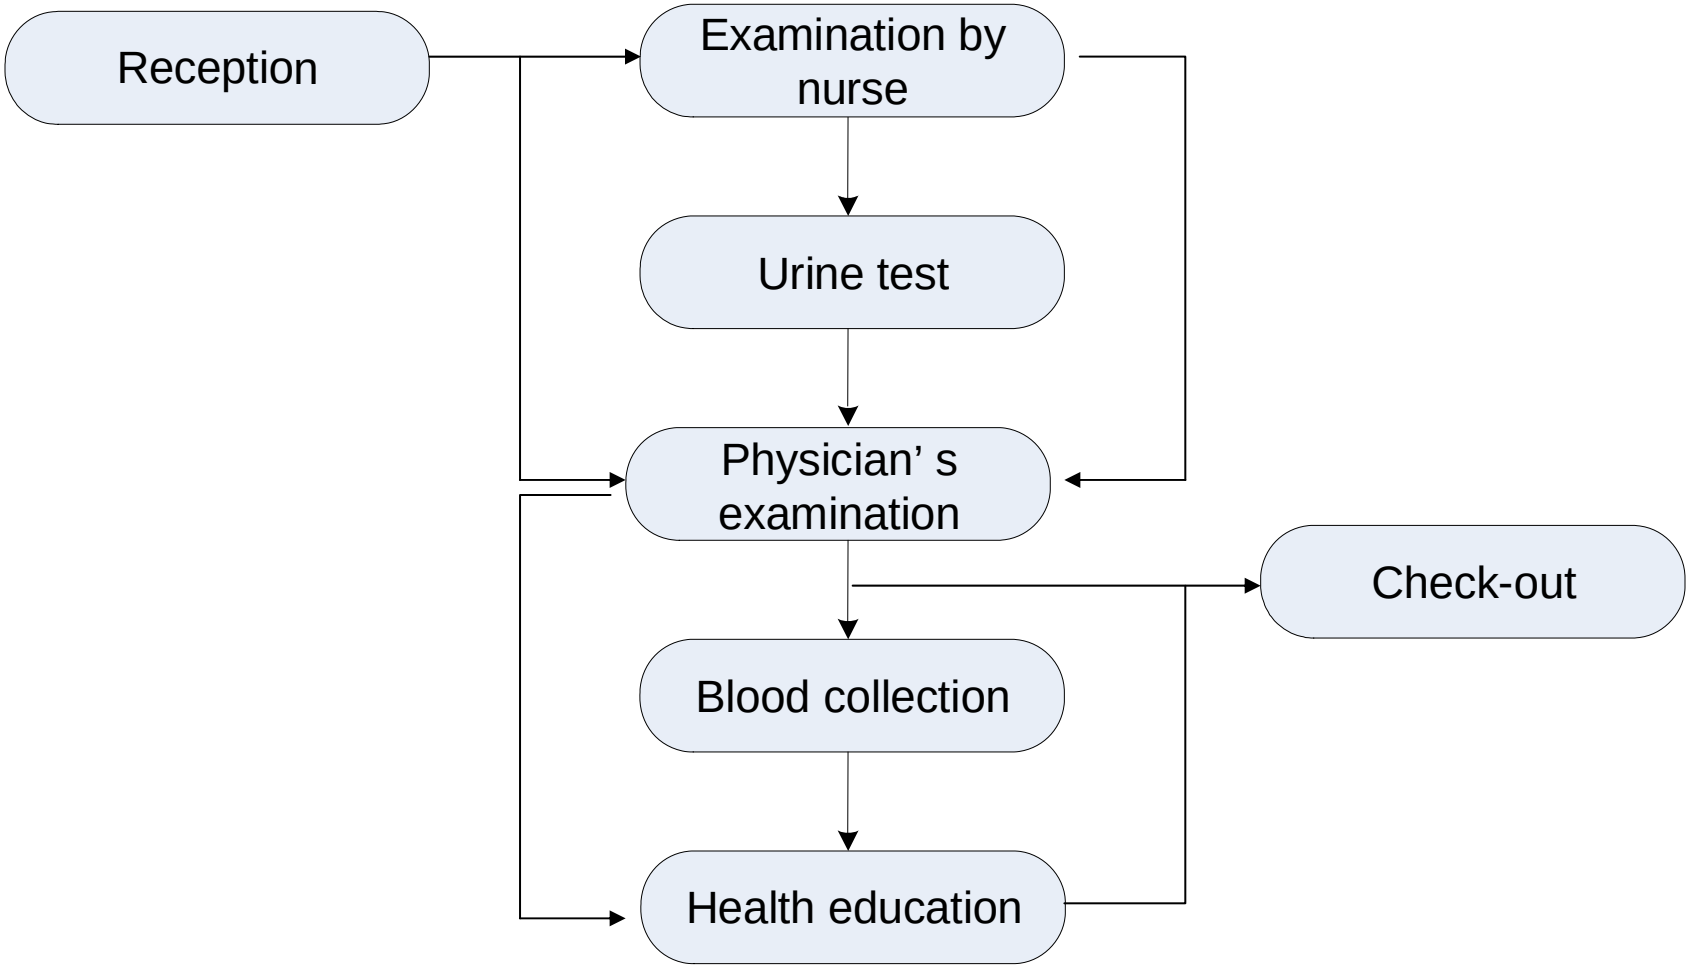
Purpose

Simulate the outpatients flow in a primary care clinic to develop a quality improvement plan

Methods

- Identify the process main activities from start to end – Used SIMUL8 software to model the process
- Apply time data derived from the time study undertaken at the Okayama Central Clinic
- Analyze and identify potential problems and suggest improvements
- Implement the changes and analyze the impact on the overall process

Simplified Work Flow at the Clinic



Prerequisites

- Data of time spent in each work station

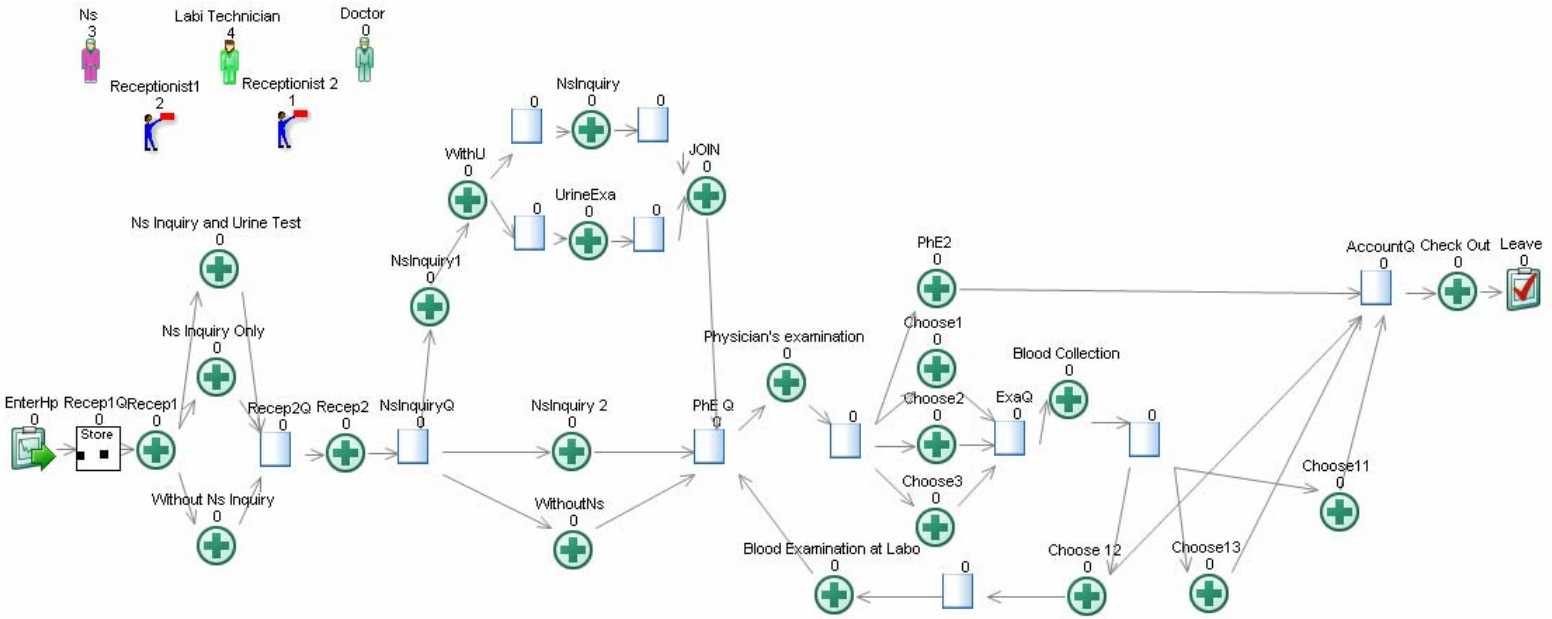
Name of Work Station	Patient's Time spent (Minutes)
Reception 1	8
Reception 2	5
Nurse's Inquiry (Patients with urine test)	10
Nurse's Inquiry (Patients without urine test)	15
Urine examination	20
Physician's examination	10
Blood collection	5
Blood examination at Laboratory	30
Check out	10

Prerequisites

- Item (patient)
  - Label 1 (70%); Who has nurse's inquiry with urine test
  - Label 2 (20%); Who has nurse's inquiry without urine test
  - Label 3 (10%); Who passes nurse's inquiry and urine test
- Resources

  Doctor; 1 Nurse; 3 Receptionist; 4 Lab Technician; 4
- Operation Time
  - The opening time of the clinic is 9:00A.M.
  - Acceptance of the patient; until 12:00

The model on Simul8



Base line data

The number of Patients completed 23

Average time spent in the model 99.9 min

Work Station	Average Time Waiting (minutes)	patients waiting less than 10 minutes (%)
Reception 1	0.2	100.0
Reception 2	0.1	98.1
Nurse Inquiry	0.8	98.1
Physician's examination	35.3	1.6
Check Out	9.0	60.3

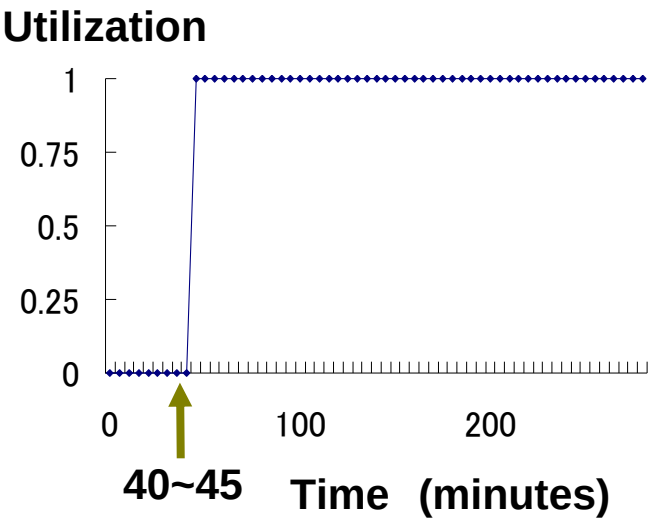


Fig. Time trend of utilization of the physician

Implementation of improvements

- Suggested Improvement area

  The bottleneck in the model; physician′s examination

- Results of the simulation

Simulation Requirements	Average Patients' Time Spent (minuts)	Number of Patients	Availability of doctors (%)
Open at 9AM (similar to real clinic)	99.9	23	98.8
Open at 9AM with 1 hour warm-up	85.5	24	95.8
Physician start work at 8:45AM	81.5	24	95.8

Conclusion

- This analysis demonstrates that we could identify the bottleneck of the system using Discrete Event Simulation.
- The simulation proved that the improvement plan increase efficiency without increase bottle-neck capacity, physician workload.
- Further analysis is needed to identify the optimal resource utilization to improve availability of the physician and throughput of the system.

WorkWeb: Enhancing Collaboration and Communication in Community Based Clinical Research through Innovative Uses of Wikis

Sharib A. Khan[1], Meir Florenz[2], Rita Kukafka[1], J. Thomas Bigger[2], Stephen B. Johnson[1]

[1]Department of Biomedical Informatics, Columbia University, New York, NY
[2]The Clinical Trials Network, Columbia University, New York, NY

Abstract

*The NIH Roadmap Initiative aims to re-engineer the clinical research enterprise in the United States. The **InterTrial** project at Columbia University is re-engineering clinical research in community practice settings by improving collaboration and communication. Our intervention, informed by numerous studies of needs and workflow, is an online, collaborative space, named the WorkWeb that brings together many different stakeholders (such as clinical research coordinators [CRCs] and investigators) and resources to facilitate clinical trials. The WorkWeb includes tools to support several research tasks and allows stakeholders to create peer-to-peer support groups. The WorkWeb has been built entirely using the wiki philosophy and thus represents a paradigm shift in providing its end-users almost full control over the content and features.*

Keywords:

clinical research, workflow, software, Wiki

Introduction

The National Institutes of Health (NIH) Roadmap Initiative is a landmark development in the area of clinical and translational research informatics [1]. This initiative aims to significantly increase the clinical research capacity in the US. Such an increase in capacity is contingent on the development and successful adoption of information technology (IT) to improve efficiency, communication and collaboration among the diverse and distributed research networks and patient communities.

Methods

The InterTrial project has focused its re-engineering efforts on clinical research in community practices and particularly on the CRCs, who are the main hub of work and information. The requirements for our intervention have emerged from extensive empirical studies that were conducted in community practices through surveys, interviews, focus groups and onsite observations to elucidate the needs and workflow [2].

Results

Two over-riding themes from our studies motivated the development of our collaborative space, which we call the WorkWeb. One was the need to enhance *collaboration*, especially between research sites and the other to provide users more *control* over the systems they use. The WorkWeb provides a platform for coordinators and investigators in a research network to share information and experiences and it provides various tools to support daily tasks in clinical research. Our innovation has been to build the entire system using wikis. A wiki is a web page or online resource that allows users to add or edit the resource collectively [3]. Wikis in conjunction with other social collaborative content generation methods like forums and blogs are emerging as viable alternate means of online content creation and management. Also, wiki-based systems give their users a greater degree of control than conventional software, an important element towards promoting end-user adoption.

The WorkWeb is presented to the user as a number of different internal webs. Each web is a collaborative workspace that can contain topics (pages) created by the users, files (MS Word, Excel, etc.) that can be attached to topics to provide a shared document repository, links to other topics or to any Internet URL, or external components that embed functions from other components (applications to support routine clinical research work like a to-do list, calendar or a services and patient tracking system). The webs presented to a user are organized in an onion-like manner, with the innermost webs being the private web of the user and the outermost to the entire InterTrial Community. The WorkWeb includes forums, blogs (used to build a support community) and features to broadcast news or announcements to its community wide users. The initial feedbacks to the prototype have been very positive and we expect to begin a phased roll out in the beginning of 2007.

Conflict Resolution Tactics in Participatory Design of Health Information Systems

Magnus Irestig[a], Toomas Timpka[a,b]

[a]*Department of Computer and Information Science*
[b]*Department of Health and Society Linköping University, Linköping, Sweden*

Abstract

During the development of health information systems, different types of conflicts arise, and are addressed with suitable conflict resolution tactics. This study examines the tactics used to cope with the antagonisms that occurred during the design of an information system for 175 000 users in an occupational health context. Discourse analysis methods were used for data collection and interpretation. The results display differences in selected resolution tactics based on the nature of the conflict and a preference for low risk tactics associated with an ambition to keep decisions clearly within the given mandate of the design group Further studies comparing conflict resolution tactics and their implications in health service settings are warranted.

Keywords:

information systems development, participatory design, discourse analyses, organizational studies.

Introduction

Health information systems (HISs) are extending their scope towards regional networks and health IT infrastructures. Accordingly, integration, interoperability and interaction design are today's core problems. To produce viable IT solutions, each critical attribute needs to be specifically addressed and prioritized. Recent studies indicate that traditional methods used to derive these requirements and attributes are often inadequate and the risks that are faced in ensuring a safe and secure system are highly application dependent and dynamic [1]. In response to this situation, contextual design methodology in conjunction with participatory design have been introduced for HIS development and showed to be promising tools in several settings [2]. However, there is little knowledge available about the practical use of these methods.

The aim of this study is examine decision-making tactics during participatory design of HISs. The research was performed in an occupational health setting.

Methods

The theoretical approach to the data collection and analysis used in this study was discourse analysis (DA). DA focuses on the interactional accomplishment of specific social activities. Accordingly, the methodology combines a contextual sensitivity of language use with analyses of talk as a means for social action [3]. DA can be performed at different levels, where the lowest levels include lexical choice and turn design. The present analysis was performed at the level of social epistemology and social relations. In the case study setting, conflicts occurring during the system design process and the tactics used to resolve them were identified in the interaction during the design group meeting and thereafter integrated into a strategic framework.

Data collection

All 20 design-meetings in the case study project were videotaped, and the audio track, 65 hours in all, was transcribed. The transcript was detailed with a close-to-verbatim match between audio track and transcripts. The four meetings where the design specification was discussed (no. 7-10) were selected for specific analysis in this study.

Data analysis

Data were first examined to identify conflict instances during the design group meetings. A conflict instance during a meeting was defined as one or a series of utterances that addressed a particular conflict involving the future system.

The technological conflicts identified during the prototype evaluation meeting (n=86) were used for the final analysis of conflict resolution tactics. Specific tactics were first identified as interaction patterns using DA, and these patterns were thereafter associated and aggregated. A second order of analysis was then performed to validate the issue descriptions and associate them to the development of an overall strategy for conflict resolution during health information system design meetings. The last phase of the analysis focused on integrating the micro- and macro-level analyses. Correspondingly, specific attention was paid to the points of passage between the micro- and macro-level findings. The results from these were compared, discussed, and integrated in order to identify specific implications for design method development.

Results

The analysis reconstructed a strategy for conflict resolution used by the design group during the design specification processes. The strategy displays that problem-solving in HIS design is shaped by control, power, and the relationships between interest groups. In order to be permitted access to the important design decisions, a participatory design group has to successfully accommodate the interests of the critical stakeholders. Two basic tactics to resolve conflicts and resume a balance in the design process were identified; change of the design specification and acceptance (and acknowledgement) of the conflict.

Primary tactic: Change design

In accordance with that the nature of system design being construction of artefacts, the natural tactic to resolve conflicts was to change the actual specification at hand. This tactic was further specialized by the case study group into deciding to adjust the design of the actual system, and to stipulate adjustments of conditions external to the system. The latter adjustments were characterized by that they could not be implemented or directly controlled by the design group.

Subtactic 1: system adjustments

The most common way to deal with conflicts was to decide adjustments to the system. These adjustments were in the analysis divided into deletions and modifications,

Subtactic 1.1: Deletion of system component

Design implications: A design group is in total control of the deletion tactic, which also brings immediate closure to a conflict. One negative aspect is that the decision is hard to reverse if it is proven to be wrong.

Subtactic 1.2: Modification of system component

Design implications: A design group is in control of the modification tactic, but the effect may be difficult to evaluate. The decision is less difficult to reverse if shown to be wrong.

Subtactic 2: Adjust organizational environment

Design implications: A proposal to adjust the organizational environment is out of control for a design group, and therefore associated with high risk. If the adjustment fails, serious problems may occur downstream in the design process.

Subtactic 3: Adjust technical environment

Design implications: Also this tactic is associated with risks. Even though the tactic solves the conflict for the design group responsible for the design and implementation of the system, it may endanger the effectiveness of the system if not all potential users can conform to the requirements.

Alternative tactic: Accept conflict

The second, and less common, tactic to resolve conflicts in the system design was to accept and acknowledge the identified antagonisms as a limitation of the design.

Subtactic 1: Allow conflict in system

Design implications: The design group is in control of a decision to allow conflicts in the system design. Verification of the conflict is essential in order to avoid secondary problems for users and during later design stages.

Subtactic 2: Allow conflict between system and organization

Design implications: This tactic is associated with an extremely high risk, due to that the design group cannot control the actions of the organization in conflict with the system. Verification of the conflict is essential

Discussion

The aim of this study is examine decision-making tactics during participatory design of HISs. Previous research has suggested that participatory design of HISs may be less feasible in centralistic environments [4]. Our results display that, given the existing power relations, the continuous engagement with interest groups is a central aspect of decision-making during participatory design in HIS settings. The users that contribute to a design have to be associated to groupings both within and outside the actual design group. We suggest that existing optimistic expectations of user participation in HIS development inhibit acknowledgement of the troubling work of balancing power relations. Rather than denying such power relations, participatory design projects should be expected to plan for them.

User Participation in Design of a Process Oriented Medical Record – When and How?

Pia H. Kopke, Niels R. Larsen, Kirsten Bredegaard

Department of Informatics, Capital Region of Denmark, Denmark

Abstract

User participation is crucial to the success of a project but the challenge is to determine how and when to involve the users. Our experience from a project designing a Process Oriented Medical Record (POMR) is that choice of user participation methods must be based on the degree of expected organizational change and the type of design questions to be answered.

Keywords:

electronic health record, user participation

Introduction

When implementing EHR systems, changes are introduced in the organization. It is therefore crucial to the success of a project to have the users participating in all the phases of the project [1]. The purpose of involving the users differs in the phases of the project, for instance system specification, system assessment, designing user interfaces or facilitating end user ownership to the system. One of the challenges of involving users in the design of clinical systems is to determine which methods to use and when to use them.

Materials and methods

The EHR project intended to purchase an interdisciplinary POMR for about 25.000 clinical users in the Capital Region of Denmark. Before project initiation it was decided that the EHR should:

- be interdisciplinary
- be problem oriented
- contain the concept of period of care
- contain highly structured data
- make it possible to reuse data for different purposes, for example quality assurance, management information, research and billing

The vast majority of the region's hospitals use monodisciplinary, chronological paper based records and the designed interdisciplinary POMR would therefore introduce a new concept for clinical documentation and thereby the introduction of Second-order changes in the organization [2].

The clinical users participated right from the beginning of the project and during the design phase more than 100 clinical users were involved in the project. Being able to support the users in making decisions about an interdisciplinary POMR required different methods based on the type of questions to be answered.

In the early phases of the project the methods were primarily based on textual descriptions of the IT-system's functionality that were reviewed by the users and later discussed on follow-up workshops. Later in the project more visually based methods were used and in total we used four fundamentally different methods of user participation in the design of the system:

1. Focus groups - Review and discussions of the system specification documents
2. Scenario based approach – designing data presentation facilitating clinical overview of the POMR
3. Use case[3] – describing process oriented data capture
4. Prototyping and usability testing – deciding principles for data capture

Results

The focus groups were used to review and discuss system specifications. The specifications consisted of textual descriptions of the POMR functionality complemented with user interface sketches. The review process resulted in hundreds of comments from the clinicians including

- comments to the documents wording
- rejections of functionality
- proposing new functionality
- concerns about the described functionality

Focus groups reviewing and discussing system specifications often left users in great uncertainty of whether the POMR could support the clinical workflows.

In the next phase of the project *the scenario method* was introduced to design the user interface for obtaining overview of the POMR. Relevant articles about the subject 'reading the medical record' were initially examined, discussed and combined with clinical practice resulting in nine generic clinical scenarios.

The method had the advantage of relating the known daily workflow to the needs of data presentation and thereby linking the two concepts of clinical documentation (chronological based record and process oriented record).

The Use case method was introduced to focus on the system's necessary workflow support in capturing data. The result was long textual structured descriptions of data capturing processes. The clinicians found the production of new long textual descriptions difficult and time-consuming and the use case method wasn't suitable for a large involvement of clinicians. Nevertheless applying the use case method in small interdisciplinary groups answered several questions about how the system should support clinical workflows.

Prototypes and their usability testing were considered the most inspiring method by the clinicians, visualizing the new concept of clinical documentation and facilitating concrete decisions about the user interface. The prototypes were tested for usability by clinicians and the principles for documentation in the POMR could be decided on this background.

The prototype method established the best conditions for the clinicians making decisions about the new system's functionality. The vendor agreed in this observation, but considered this method the most demanding as regards the use of resources.

Discussion

It was evident that many of the 100 clinicians who were involved in the project found it difficult to relate the textual descriptions of the POMR system to the future clinical practise. The POMR would introduce a second order change in the organization and the need for a more sophisticated method to visualize the system's impact to the future clinical practice was identified.

The scenario method made it possible for many of the clinicians to see how the EHR could change and actually support clinical work. Thereby the clinicians could more precisely express their need for different surveys of the data in a patient's EHR. The scenario method doesn't contain elements to structure and detail the steps in work practise and therefore this method was found most suitable for answering generic questions about data presentation.

The use case method was difficult to use for the clinicians, but made it possible for the IT consultants from the customer and the vendor to gain a common understanding of the need for process support by the system. Searching for and piecing together the information to make a clinical survey of the relevant data in the patient record is not a logical step by step procedure and the use case method was therefore primarily used to describe data capturing processes.

Finally and on the background of the above mentioned methods it was possible for the vendor to make prototypes that were understood and accepted by the coming users. The prototypes could visualize the system functionality and the support of the future clinical documentation process but still the visualisation of the consequences for the future clinical work practise were missing. In case of second order changes to the organization it could be necessary to test the prototypes in medical settings or in medical simulation environments.

In summary the total design phase using four methods for user participation was a protracted and time consuming process that could have been conducted better if the understanding of the purpose of user participation and the complexity of the questions to be answered had been better described in advance.

The possibilities and limitations of the four user participation methods are well described in the literature[3][4][5] but in addition our project identified a need for a reflective approach to choose between the different methods based on the degree of organizational change and type of design questions. Examples of questions to be answered before choosing the method to user participation could be:

- Which degree of organizational change will the system implementation cause?
- How many end users are to be involved in decisions about the system design?
- Are the questions about data capturing or data presentation?
- Are the questions about principles or detailed functionality
- Is the purpose to facilitate end user ownership or to capture detailed information about clinical practise?

Conclusion

Our experience regarding the development of an interdisciplinary POMR shows that one universal method of user participation in system design does not exist. Decision about methods of user participation must be based on the degree of organizational change and the concrete system design questions to be answered (data presentation or data capturing) in the design process.

The Capital Region of Denmark

REGION

User participation in design of a Process Oriented Medical Record

- when and how?

Pia H. Kopke, Niels R. Larsen, Kirsten Bredegaard

Department of Informatics, The Capital Region of Denmark, Denmark

MEDINFO 2007

Introduction

- The described EHR project was aimed at developing a Process Oriented Medical Record (POMR) for about 25.000 clinical users in the Capital Region of Denmark
- We knew that an it-project's success depends on user participation
- And we learned that you must clarify from the beginning:
  - What is the purpose of user participation in this phase of the project
  - Which methods of user participation are the best to use in this phase of the project

Materials

The EHR project was based on the following principles. The POMR should:

- Be interdisciplinary
- Be problem oriented
- Be based on the concept of period of care
- Contain highly structured data
- Make it possible to reuse data for different purposes like:
  - Quality assurance and quality development
  - Management information
  - Research
  - Billing

Meaning that the POMR would introduce a second order change in the organization

Methods

Four fundamentally different methods of user participation were used in different phases of the design process:

- Focus groups – in review of system specification
- Scenario based approach – in design of data presentation
- Use case – in design of process oriented data capture
- Prototyping and usability testing – in design of principles for data capture

Results – Focus groups

- Were used to review and discuss system specifications consisting of textual descriptions
- Resulted in a lot of comments including:
  - Comments to the wording of a specification
  - Rejections of functionality
  - Proposals of new functionality
  - Concerns

➢ Users were often uncertain whether the functionality described could support the clinical workflows

Results – Scenario based approach

- Was used to design the user interface for obtaining overview of the POMR
- Nine generic clinical scenarios were designed based on a combination of literature and knowledge of clinical practice

➢ The method helped relating the known daily workflow to the needs of data presentation i an EHR – linking together the known chronological based record to the new and unknown process oriented record

Results – Use Case

- Was used to focus on the application's workflow support in capturing data
- Resulted in long and very detailed textual descriptions

- The users in general found the method difficult and time-consuming
- But several questions of how to support clinical workflow were answered
- The vendor developed prototypes based on the use cases

Results – Prototyping

- Was used to design the user interface
- Facilitated the users' decision-making
- The prototypes were usability tested

- The users preferred the use of prototypes for designing system functionality and user dialogues
- The vendor recognized the benefit of prototyping, but found it time-consuming and expensive regarding the need of resources

Discussion

- Focus groups
  - Many users have difficulties in visualising a future system when descriptions are solely paper-based and textual
- Scenario based approach
  - Less useful for designing detailed workflows, but suitable for answering generic questions of data representation
- Use case
  - Difficult to use for ”ordinary” users, but very useful in designing data capture processes
- Prototyping
  - Facilitate users ability to make decisions about the system design, but even more useful if tested in medical simulation environments

Discussion - Which user participation method?

- Which degree of organizational change will the system implementation cause?
- How many end users are to be involved in decisions about the system design?
- Are the questions about data capturing or data presentation?
- Are the questions about principles or detailed functionality?
- Is the purpose to facilitate end user ownership or to capture detailed information about clinical practise?

Conclusion

- The development of an interdisciplinary POMR means second order change in Danish clinical work
- There is no universal method for user participation
- Methods must be chosen based on the degree of organizational change
- The more organizational change a project implies the more the need of using visualizing methods for system design
- You must distinguish strictly between designing functionality for data presentation or data capture and let your choice of method of user participation depend hereon

Spatial Analysis of Referrals from Secondary Care and to Aftercare in a Tertiary Care University Hospital in Japan

Shin-ichi Toyabe, Kouhei Akazawa

Department of Medical Informatics, Niigata University Medical and Dental Hospital, Japan

Abstract

All Japanese citizens are covered by the national insurance system, which provides universal free access to healthcare services. We studied the pattern of referral of inpatients from secondary care hospitals to a tertiary care university hospital and the pattern of reverse referral in Japan using a geographic information system (GIS). The results showed that 55.7% of the patients were directly admitted to the hospital without referral from other hospitals or clinics and that 89.1% of the inpatients were referred to the outpatient department of the hospital to which they had been admitted. GIS analysis for the inpatients service area showed that the tertiary care university hospital functions also as a primary and secondary care hospital for patients living near the hospital. There were several foci of inpatients with prolonged length of hospital stay. These results suggest that the function of university hospitals in Japan is unspecialized and that the referral route from a university hospital to aftercare is also ill equipped.

Keywords:

geographic information systems, university hospitals

Introduction

In Japan, all citizens are covered by the national insurance system, which provides universal free access to healthcare services. There are no general physicians or "gatekeepers" in the Japanese healthcare system. Patients in Japan can freely choose between going to a physician's office or a hospital [1]. Hospitals are popular because of their prestige and high quality of care. On the other hand, there is no clear differentiation between large and small or public and private hospitals or between hospitals and private practices in the healthcare system in Japan [1]. Functional differences between hospitals and nursing homes for the elderly are also not clear despite the introduction of long-term care insurance [2]. Hospitals often function as nursing homes for the elderly, which is one of the main reasons for the extraordinarily long hospital length of stay (LOS) in Japan. LOS is very long in Japan compared with that in other Organization for Economic Co-operation and Development (OECD) countries [3], particularly for the elderly. The government has tried to address the issue of undifferentiated functions of health care facilities. A system of fees for referral was introduced in 1988, and outpatient consultation fees for university hospitals were increased if more than 30 percent of their new ambulatory care patients came with referrals [4]. Since 1996, patients who visit a large hospital without referral from a primary care physician have had to pay an extra charge [5]. In 2003, an inclusive payment system for acute inpatient care was introduced in university hospitals [6]. These systems are based on a policy of facilitating functional differentiation of health care facilities. However, little is known about the actual patterns of referral from secondary care hospital to tertiary care university hospitals and the reverse referral in Japan. We therefore studied the pattern of referral form secondary care hospitals to a tertiary care university hospital and the pattern of reverse referral in Japan.

Materials and methods

Data

Niigata University Hospital had 810 inpatient beds, 23 clinical departments and medical staff of 818 in 2004. The service area of the hospital as a tertiary care hospital covers all districts in Niigata Prefecture, which has a population of 2,400,000. The size of the hospital is typical for a Japanese university hospital. Data were analyzed for all patients who had received inpatient care at Niigata University Hospital during the period from April 2004 to March 2005. Data on patient age, sex, residential address, route of referral to Niigata University Hospital, discharge diagnosis classified by Japanese case mix classification for inpatients (diagnosis procedure combination, DPC) [5,6], length of hospital stay (LOS), outcome of admission and route of referral from Niigata University Hospital were obtained from the hospital information system. In the DPC system, patient discharge is classified into 16 major diagnostic categories (MDC) and 1,727 case-mix groups. Data on average and standard deviation (SD) of LOS of the patients in Japan, who were assigned to each DPC, were obtained from the Ministry of Health, Labor and Welfare. Spatial analyses were performed using GIS software ArcView GIS 3.1a and ArcGIS 9 (Environment Systems Research Institute Inc., CA, USA). Road network data (Pasco, Tokyo, Japan) also contain codes for different classes of roads, average car speed and rules of the roads in order to calculate how long it would take to drive along a particular road segment [7].

Referral from clinics and other hospitals

To study the geographic distribution of patients admitted to Niigata University Hospital, the geographic distributions of all inpatients were geo-coded by residential addresses to a GIS map. Empirical Bayesian estimates for the rate of inpatients per population at risk were plotted on a GIS map with 2 km meshes [8]. To study the relationship between spatial accessibility to Niigata University Hospital and the distribution of patients, the number of inpatients who lived within an area that is a certain time by car from Niigata University Hospital was calculated by using Network Analyst (ESRI Japan). The same procedure was performed for other hospitals in Niigata Prefecture in order to compare the inpatient service areas of Niigata University Hospital and general hospitals. The distribution of patients referred from other medical facilities was plotted on GIS maps using the kernel density method [9,10].

Referral to aftercare

Aftercare was defined as referral to an aftercare program, such as outpatient care and transfer to inpatient wards of other hospitals, not including foster care, a group home or a nursing home [11]. Distributions of patients referred to the Outpatient Department of Niigata University Hospital, patients referred to outpatient care of other medical facilities and patients transferred to paediatric wards of other hospitals were plotted on GIS maps. Since delay in referral of a patient to aftercare prolongs LOS of the patient, spatial differences in LOS of inpatients might reflect the spatial differences in accessibility to aftercare. To estimate the spatial differences in accessibility to aftercare, LOS of each patient was scored and plotted on a GIS map. The SD scores for LOS (LOSSDS) of a patient who was assigned to a DPC were calculated as follows:

$$\frac{\left[\left(actual\ LOS\ of\ the\ patient\right)-\left(average\ LOS\ of\ the\ DPC\right)\right]}{SD\ of\ the\ LOS\ of\ the\ DPC}$$

Contour maps of LOSSDS of the patients were produced by interpolation using the ordinary Kringing method [12].

Results

Referral from clinics and other hospitals

During the study period, a total 8,545 patients were admitted to Niigata University Hospital (Table 1). Among them, data for 8,177 patients living in Niigata Prefecture were used for analysis in this study. The empirical Bayesian estimates for the rate of inpatients per population at risk were plotted on a map with 2 km meshes. Although these patients were predominantly distributed around Niigata City, the capital of Niigata Prefecture, there were some meshes with large numbers of inpatients far from Niigata City. This indicated that patients visited Niigata University Hospital from a broad area of the prefecture. In addition, there were marked spatial differences in the distribution of residences of inpatients living in or near Niigata City, suggesting competition with other primary and secondary care hospitals to get inpatients.

Table 1 – LOSSDS of all inpatients

Major Diagnostic Category	Number of patients	LOSSDS Average (SD)
Nervous system	646	-0.19 (3.70)
Eye	743	0.36 (2.11)
Ear, nose, mouth and throat	413	0.90 (5.65)
Respiratory system	444	0.48 (6.26)
Circulatory system	547	0.83 (4.44)
Digestive and hepatobiliary system	1,273	0.04 (2.28)
Musculoskeletal system	715	-0.05 (1.91)
Skin and subcutaneous tissue	250	-0.35 (1.65)
Breast	48	-0.53 (1.36)
Endocrine, nutrition and metabolic system	362	-0.06 (2.21)
Kidney and urinary tract	634	-0.04 (3.76)
Female reproductive system and pregnancy	1,202	-0.41 (2.20)
Blood and immunological disorders	135	2.31 (6.00)
Newborn and other neonates	640	-0.71 (1.69)
Children	76	-0.17 (5.27)
Injury, poison and burns	417	0.36 (7.68)
Total	8,545	0.06 (3.67)

The number of patients admitted to Niigata University Hospital without referral from other hospitals and clinics was 4,524 (55.3%), which differed remarkably by MDC or clinical department from 38.8% to 63.0% (median 55.7%). Detailed information on referral was obtained by analyzing data for inpatients admitted to the Pediatric Department. The rate of the inpatients referred from other medical facilities was found to be 38.8%. Only 19.0% of patients admitted to Niigata Hospital lived in an area 30 min from the hospital by car, suggesting that even patients living far from the hospital are often admitted to the hospital without referral from other medical facilities. Results obtained by using the kernel density method indicated that pediatric inpatients living near Niigata City tended to be admitted directly to Niigata University Hospital, whereas inpatients living far from Niigata University Hospital tended to be referred from other medical facilities (Fig. 1). This tendency was the same for other clinical departments. These results suggest that a tertiary care university hospital in Japan has characteristics of both a primary care hospital and a secondary care hospital for inpatients living near the hospital.

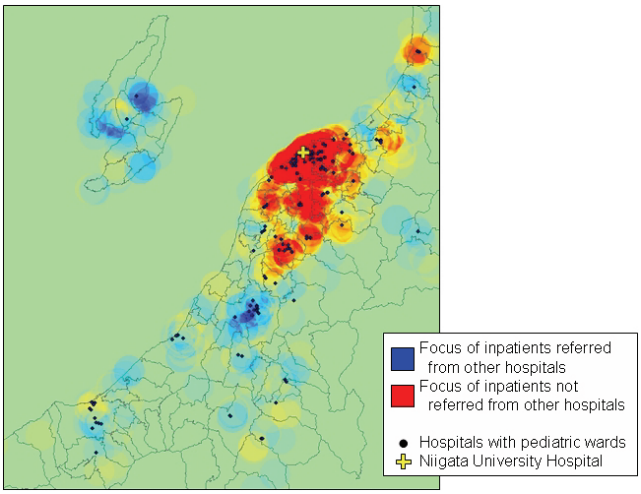

Figure 1 - Focus of inpatients referred from other medical facilities

Referral from clinics and other hospitals

Almost all of the inpatients (7,745 out of 8,177, 94.7%) received referral to aftercare, and 6,907 (89.1%) of them received care in the Outpatient Department of Niigata University Hospital after discharge. Only 838 patients (10.2%) were referred to clinics or outpatient departments of other hospitals, and 199 patients (2.4%) were transferred to other hospital wards after discharge from Niigata University Hospital. The patients referred to clinics or outpatient departments of other hospitals and the patients transferred to wards of other hospitals tended to be distributed far from Niigata City and in Sado Island, which is located 40 km away from Niigata City. The situation was the same for pediatric inpatients. Almost all of the pediatric inpatients (96.4%) received referral to aftercare, and 82.8% of them received aftercare in Niigata University Hospital. Only 11.6% of them were referred to clinics or outpatient departments of other hospitals, and 2.0% of the pediatric patients were transferred to other hospital wards after discharge from the hospital.

Next, we investigated spatial difference in trends of referral using LOSSDS in order to ascertain whether there were barriers to referral to aftercare in each district. The LOSSDS of each MDC of Niigata University Hospital is shown in Table 1. There were also remarkable differences in LOSSDS among clinical departments. Figure 2 shows the data for pediatric inpatients. There were some foci with high LOSSDS near Niigata City (A and B), where there might be some barriers to referral to aftercare. We paid special attention to one of the foci (A) and investigated why the patients who lived in that focus showed high LOSSDS. There were no problems in spatial or physical accessibility in the focus, because the focus was located over arterial roads. The focus was located within an area 30 min by car from two hospitals. Although these hospitals had beds for children, each hospital had only one pediatrician. Therefore, shortage of pediatric manpower is one of the reasons for the clustering of patients.

Discussion

The results of our study indicate that about half of inpatients visited a tertiary care hospital in Japan without referral from other medical facilities and that more than 80% of inpatients were referred to the outpatient department of the hospital. Most of the inpatients received outpatient care, inpatient care and aftercare in the same hospital. Patients living near the hospital tended to use the hospital as a secondary care hospital or were admitted without referral from other medical facilities. As a secondary care hospital, the hospital was in competition with other secondary care hospitals to get inpatients. On the other hand, patients who lived far from the hospital tended to use the hospital as a tertiary care hospital and were referred to the hospital from other medical facilities.

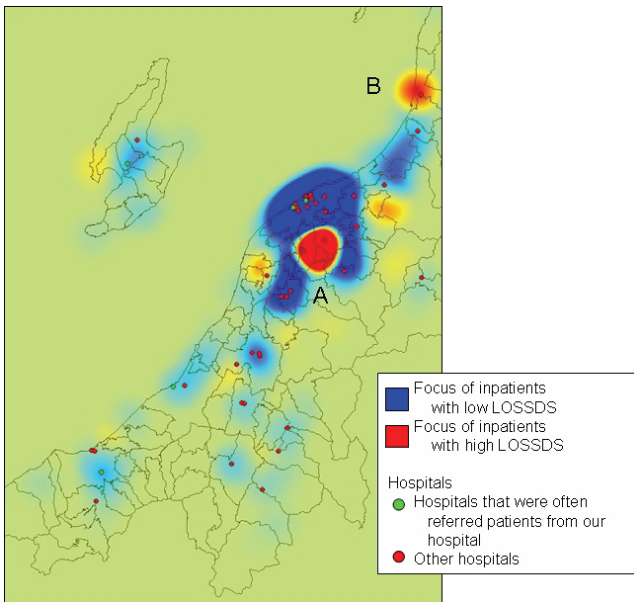

Figure 2 - Focus of inpatients with high and low LOSSDS.Our results showed that even a tertiary care university hospital functions as a secondary care hospital, especially for patients living near the hospital. Moreover, acute care hospitals in Japan usually provide care that is usually provided by nursing homes and home caregivers in other countries such as the USA and UK. The undifferentiated functions of acute care hospitals in Japan make LOS of inpatients extraordinarily long compared with that in other advanced countries [3]

Although the care provided by so-called acute care hospitals in Japan is a mixture of various kinds of care, there are trends toward differentiation and specialization in these

hospitals. One such example is the introduction in 2003 of a new inclusive payment system for acute inpatient care in the eighty main hospitals at universities and national centers to replace the traditional fee-for-service payment system [6]. Under this payment system, hospitals can obtain medical fees more efficiently as the LOS decreases. Actually, the LOS of inpatients in these hospitals has become significantly shorter after the introduction of the new payment system [13]. Reduction in LOS leads to a new incentive to acquire new patients to fill the unoccupied inpatient beds. This can be accomplished by an increase in referrals from other medical facilities, and the reduction in LOS needs a close partnership between medical facilities participating in aftercare. The results of our study clearly showed spatial differences in partnership between other medical facilities in terms of both referral to the hospital and referral from the hospital. By using GIS, we could easily find districts where the hospital had not established a strong partnership with medical facilities. The results of analysis of LOSSDS provided a hint as to why inpatients living in a region stay in the hospital for a long time. The methodology described in this article can be used to study regions in which a partnership between medical facilities has not been established and why a partnership has not been established in the regions [14-16]

Conclusion

The results of our study suggested that the function of university hospitals in Japan is unspecialized and that the referral route from a university hospital to aftercare is also ill equipped.

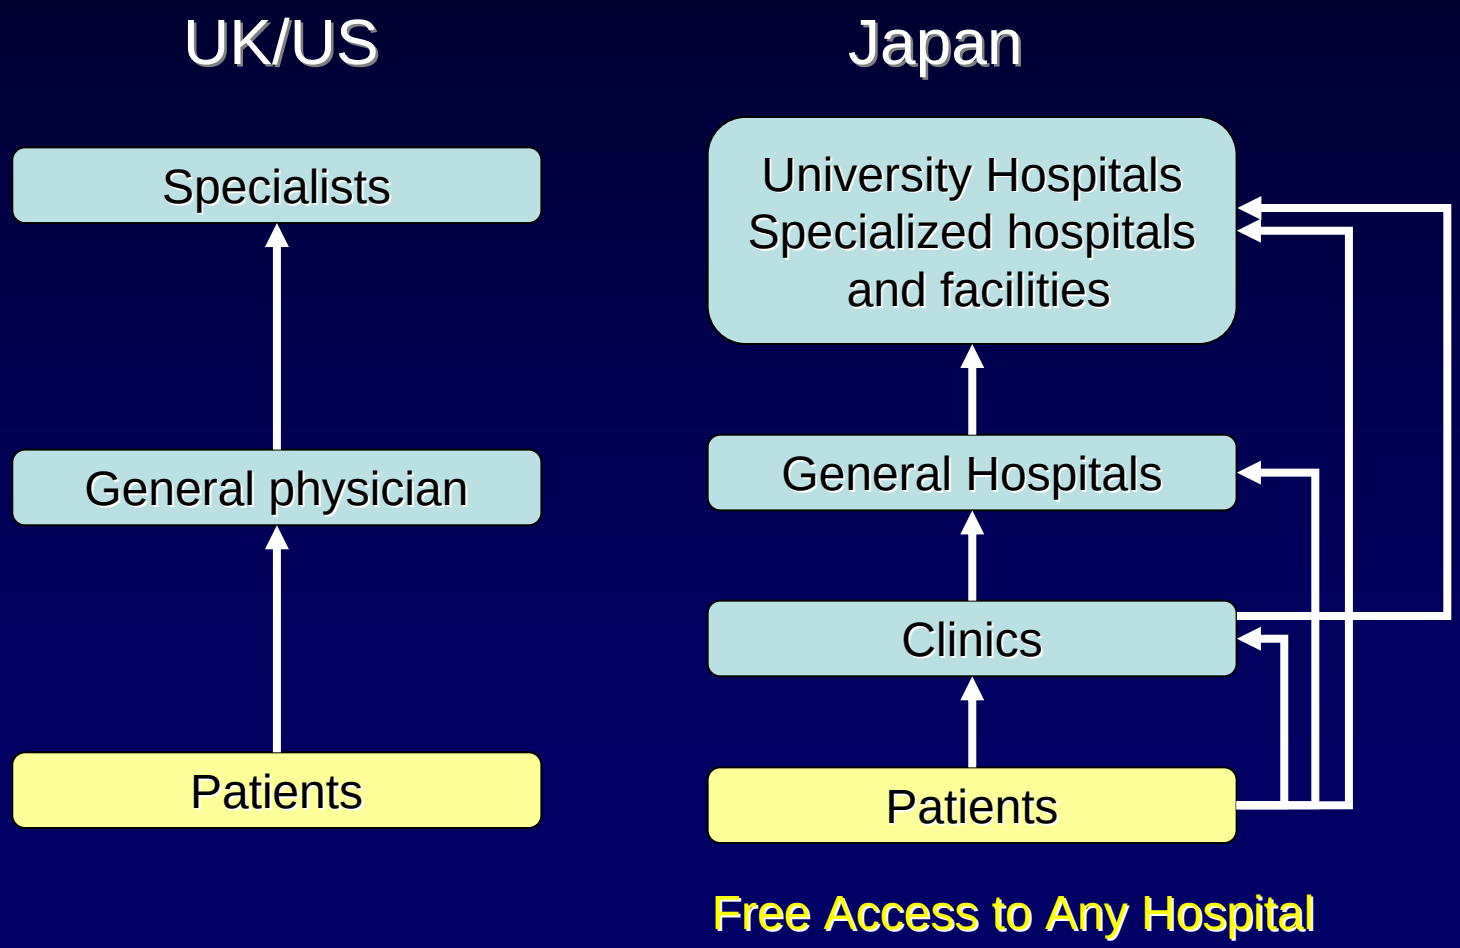
Spatial Analysis of Referrals from Secondary Care and to Aftercare in a Tertiary Care University Hospital in Japan

Shin-ichi Toyabe, Kouhei Akazawa

Department of Medical Informatics, Niigata University Medical and Dental Hospital, Japan

Background #1: Free access to hospitals in Japan leads to undifferentiated functions of university hospitals



Background #2: Policies to facilitate functional differentiation of university hospital in Japan

- Outpatient Consultation Fees (1988)
- Extra charges for patients without referrals from primary care physicians (1996)
- Inclusive payment system for acute inpatient care in university hospitals: higher payment to hospitals with more advanced functions (2003)

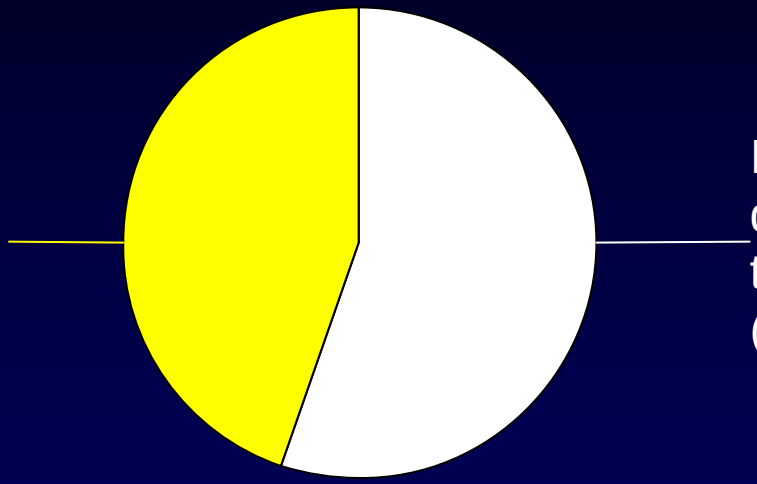
Objectives

- To study actual condition of referrals from secondary care hospitals to university hospital in Japan
- To study actual condition of referrals to aftercare from university hospital in Japan
- To study spatial difference in trends of the referrals using geographic information system (GIS)

Methods

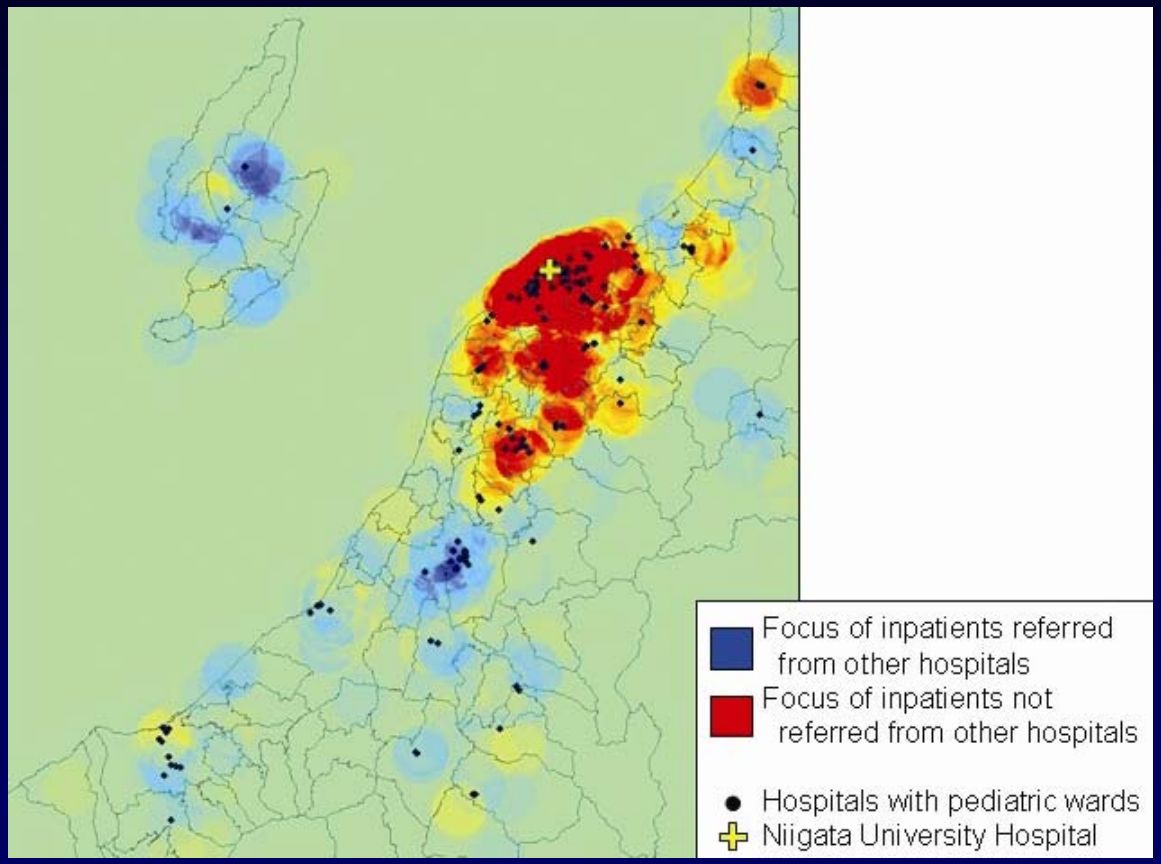
- All patients who received inpatient care in Niigata University Hospital from April 2004 to March 2005
- Data on age, gender, residential address, route of referrals, diagnosis (Japanese case mix classification)
- Spatial analysis
  - Geocoding of all patients
  - Empirical Bayesian Estimates for rate of inpatients
  - Medical service area for secondary and tertiary care
  - Spatial difference in trend of referrals: kernel density method, ordinary Kriging

Referrals from other hospitals



- The rate of inpatients who directly admitted to the hospital differed by disease (major diagnostic category) from 38.8% to 63.0% (median 55.7%)

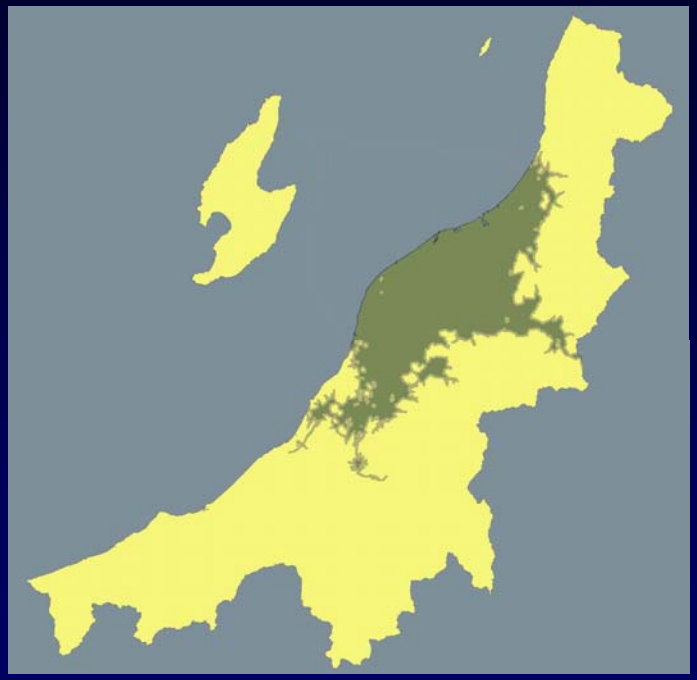
Spatial distribution of inpatients who referred from other hospitals



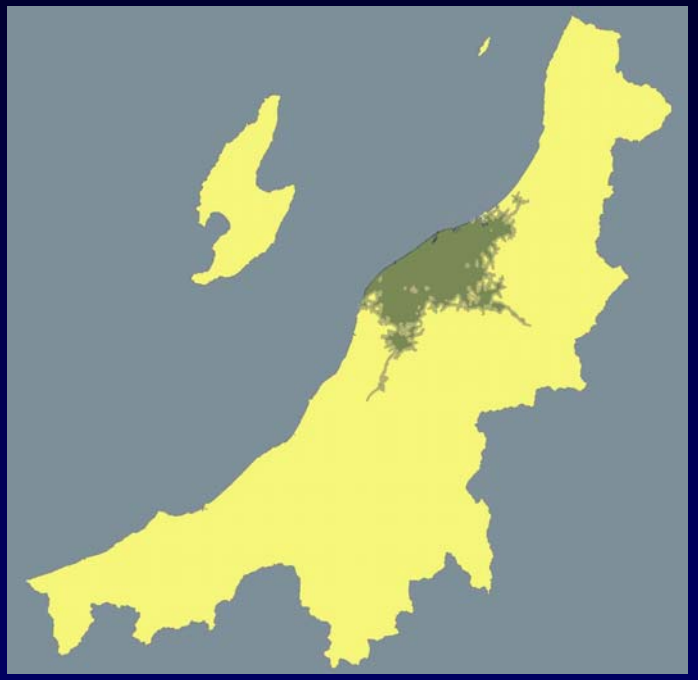
Patients who lived near the hospital have tendency to directly admit to the university hospital

University Hospital has two different kinds of medical service area

For tertiary care

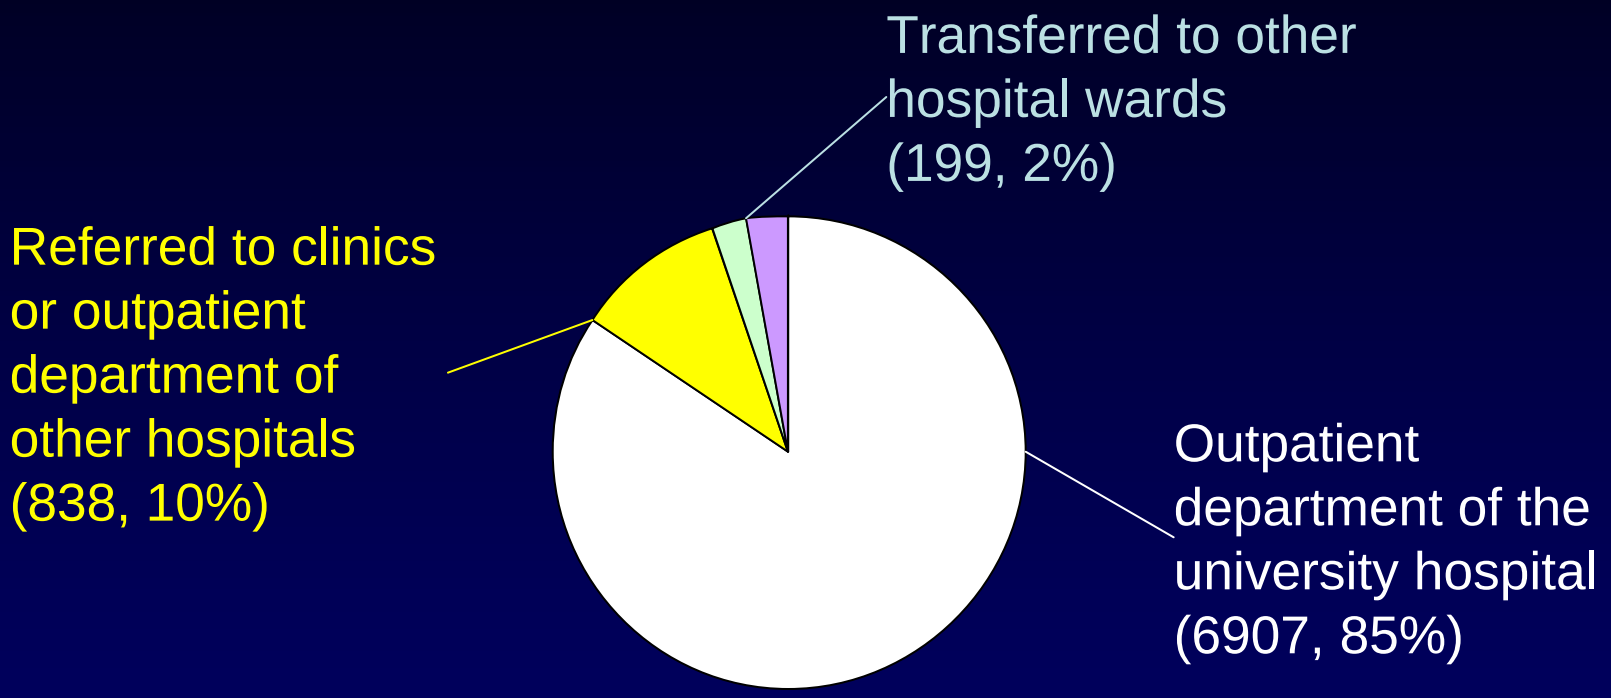


For secondary care



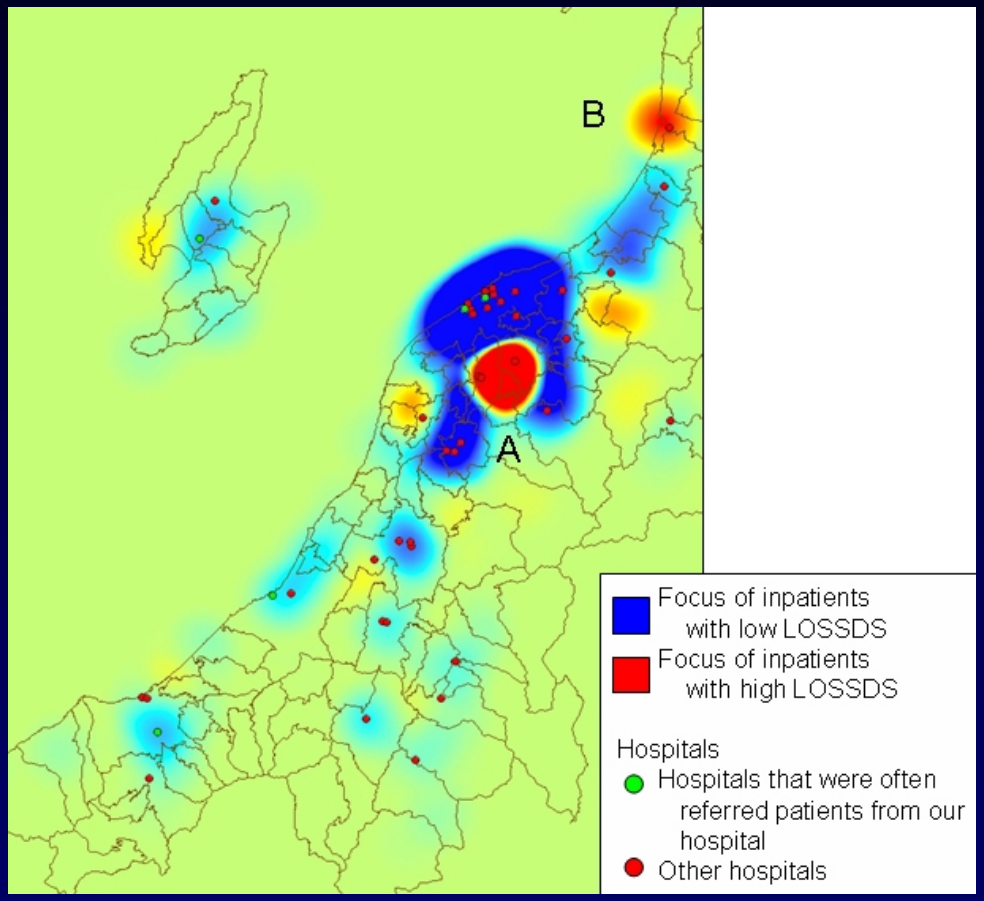
- Medical service areas covering 80% of inpatients belonging to the case-mixes with or without complicated clinical courses (coma, surgical operation, invasive treatment and complications)

Referrals to aftercare



- 89.1% of the patients who referred to aftercare received care in the outpatient department of the university hospital

Spatial focus of inpatients with long and short length of stay



There are barriers to referrals to aftercare in focus A and B. In these foci, there are hardly any hospitals which have good cooperation with the university hospital.

Summary

- 55% of inpatients admitted to the university hospital without referrals from other hospitals
- The university hospital is in competition with neighborhood general hospitals to acquire inpatients
- The university hospital has two types of medical service areas for secondary and tertiary care
- 89% of inpatients who referred to aftercare received care in the outpatient department of the university hospital
- There were several foci of inpatients with prolonged length of stay, which originated from lack of hospital-to-hospital cooperation

A Qualitative Study to the Telemedicine System in Taiwan: The Views of Medical Profession

Jer-Junn Luh[a], Po-Hsing Cheng[b], Heng-Shung Chen[c], and Jin-Shin Lai[d]

[a]*School and Graduate Institute of Physical Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan*
[b]*Office of Information, National Taiwan University Hospital, Taipei, Taiwan*
[c]*School of Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan*
[d]*Department of Physical Medicine and Rehabilitation, College of Medicine, National Taiwan University, Taipei, Taiwan*

Abstract

Taiwan launched a telemedicine service for rural area since 1995. In this study, a qualitative evaluations of Taiwan's telemedicine was performed to assess various measures of effectiveness (e.g., diagnostic accuracy), efficiency (e.g., cost), and participant's altitudes to determine its success. Qualitative data were collected from semistructured interviews with thematic analysis. Basically the system was successful to perform tele-consultation. However, network quality improvement, special instruments for different disease, and more specified training were also need for further telemedicine services.

Keywords:

telemedicine, qualitative study

Introduction

The use of telemedicine is beginning to change the health care industry[1-2]. The challenge now is to integrate these new technologies into the delivery of high quality health care. Patient and provider satisfaction is critical to the success of any health care delivery system. Costs and conveniences of telemedicine are critical issue for the Taiwan's telemedicine service.

Taiwan launched a telemedicine service for rural area since 1995. Four medical centers connected with remote medical organizations and, provided essential telemedicine services to the rural area [3]. However, lack of quality survey about the Taiwan's telemedicine project. Using qualitative research methods, we tried explored the experiences of users of Taiwan's telemedicine system.

Materials and methods

Telemedicine system in Taiwan

A low cost telemedicine system which constructed with inexpensive, commercially available parts and used SDSL network was developed for teleconsultation. This system contains two important devices: a videophone (TIA-8000, Tatung Inc, Taiwan) was used to provide video and audio communication; and a integrated platform which written by LabVIEW (National Instruments, TX) was used to provide heart and breathing sound, blood glucose, O2 saturation, and vital sign via SDSL network (512kbps). Figure 1 shows the function block diagram of this integrated platform.

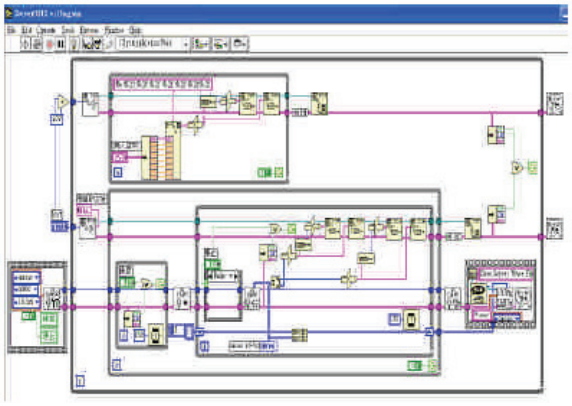

Fig 1 Block diagram (in Labview®) of the integrated platform

We cooperated with two national medical centers, two regional hospitals, and five remote native tribes which are all located inside Taiwan Central Mountain Area. This telemedicine communicated with internet to National Taiwan University Hospital (NTUH). The same data could also transmit to Puli Christian Hospital at mid-Taiwan. Meanwhile, National Cheng-Kung University Hospital which was a national medical center located at south Taiwan, is fully participating and connected with other four rural villages.

Study design

Qualitative data were collected from semistructured interviews with thematic analysis. First we used a questionnaire based to identify further respondents for the study, than we conducted in-depth interviews to collect additional free text data from the participants[4]. Our goal was to evaluate how the participants felt about the system in general..

Results

Nine healthcare professionals, including three family physicians, one physician of physical medicine and

rehabilitation, one general surgeon, one dermatologist, one obstetrician-gynecologist, one dietitian, and one physiotherapist, received our interviews. All the participants had at least two year experience about teleconsulting before this study. We reviewed efficiency, convenience of Taiwan telemedicine system, and attitudes towards telemedicine.

Efficiency of Taiwan's telemedicine system

To evaluate the efficiency of the system, the key point was to find out the medical profession felt that they could make medical decision by the telemedicine system. This was dependent on the quality of the video images and the high fidelity of the physiologic signals.

All of the participants mentioned that the telemedicine facilities were relatively simple and easy to be operated. However, special instruments should be included for special patients. Lung sounds were not clear to determine the tiny features of different diseases. They also hoped to have ultrasound image for liver and abdominal diseases screenings.

Beside the qualities of instruments, quality of network communication was also criticized by all participants. When it is in use, unstable bandwidth in the distance resulted in blurred vedio. Increasing the bandwidth and its stability can solve this problem.

Convenience of Taiwan's telemedicine system

Another question was lack of proper training to use the telemedicine facilities although all the participants were familiar with using a personal computer, webcam, internet, and other IT products. They also felt they need more training to perform teleconsulting.

Attitudes towards telemedicine

We also interviewed our participants about the attitudes towards telemedicine. All of our participants felt the telemedicine emerges mainly because people in rural area were inaccessible to quality services, so it should not be compared with traditional face-to-face medical services.

One major limitation of telemedicine was also mentioned by the surgeon and the obstetrician-gynecologist: No emergency procedure could be taken by internet.

However, one family physician suggested the telemedicine should be the screening system for the emergency case.

Discussion

It is clear that participants are more than willing to discuss their feelings about telemedicine, and that in general, they perceive telemedicine in a positive manner. Initial qualitative findings from this study will provide a valuable assessment of satisfaction with the system as it is being implemented.

All of the participants mentioned that the telemedicine facilities were relatively simple and easy to be operated. However, special instruments should be included for special patients.

As for special cases, telemedicine system should have the functions of real time diagnosis, long-term observation, and acute complication prevention, thus improve the quality of medical services, narrow the gap between doctors and patients, and build up the patients' confidence in the system.

Our participants' attitudes towards telemedicine were positive. Lack of patients' view points was a major limitation of this study. We only presented perceptions of health providers who were participate the telemedicine project. However, patient satisfaction was an important issue.

Conclusion

The Taiwan's telemedicine system was evaluated by an quantitative methods in the study. Basically the system was successful to perform teleconsultation. The medical profession that joined this telemedicine project suggested that this telemedicine system can provide suitable services for primary healthcare. This system might be able to improve the health care quality for the rural residents by a comprehensive medical service.

Restricted by environment differences, geographical distances, cost and time, the future development of the telemedicine system should be to satisfy the special need of different medical specialists, gain the patients' confidence, and provide more training about how to use the telemedicine instruments.

Acknowledgments

This research, "Mountain and Island Telemedicine: NTUH Cross-domain Telemedicine Project for Aboriginal Area," is fully supported by the DOH Taiwan and NTUH.

Measuring Race and Ethnicity in SNOMED Patient Records

Mary E. Campbell[a]

[a] *Department of Sociology, University of Iowa, United States*

Abstract

One of the challenges facing informatics today is the collection of useful data on racial and ethnic background. The collection of these data is complex and problematic. The current system for coding racial and ethnic data in patient records is often inconsistent and confusing, as an examination of the example of SNOMED illustrates. Principles drawn from the social science research on the topic can be used to improve our methods of collecting racial and ethnic data.

Keywords:

race, ethnicity, Systematized Nomenclature of Medicine (SNOMED), computerized patient record

Introduction: The complexity of "race"

Although "race" and "ethnicity" are social, not biological, constructs, it is nonetheless important that these social groups be measured appropriately in medical informatics. Developing coding systems that use racial and ethnic concepts in a logically consistent way is challenging. Our ideas about measuring race and ethnicity developed in an often haphazard response to nation-specific historical ideas about racial and ethnic difference. We have no internationally comparable or systematic nomenclature for capturing race and ethnicity in health contexts [1-2]. In an effort to contribute to the development of a valid method of coding racial and ethnic groups, I discuss ways that the social scientific evidence on measuring race and ethnicity could be incorporated into informatics systems.

Accurately categorizing "race" and "ethnicity" is not simple. Variation in how these data are collected can significantly change our understanding of the relationship between ethnicity and health. First, some datasets identify patients by appearance, while others allow patients to self-identify. In vital statistics data in the United States, for example, death certificates are often completed based on the appearance of the deceased or other observable factors, which leads to an undercount of Latinos and other minority groups [3].

Second, small differences in the way questions about race and ethnicity are worded or formatted lead to large differences in how individuals identify. For example, many U.S. surveys separate Latino "ethnicity" from the question on "race" [4]. This results in higher rates of identification as "Latino" than questions that include all of the groups in a single question [5]. Survey respondents are also strongly influenced by the examples they are given and the placement of the question [6].

Third, some ethnic groups are simply left out of many data collection efforts. Individuals of Middle Eastern or Arab descent, for example, typically cannot identify that heritage on U.S. health surveys, despite significant health disparities [7].

Results: Racial/ethnic categories in SNOMED

I use SNOMED as an example of a comprehensive clinical terminology to illustrate how race and ethnicity are currently being captured in medical informatics. The January 2006 release of SNOMED [9] codes "ethnic group" and "racial group" data as part of a patient's social context.

The list of "ethnic groups" included in SNOMED is extensive and detailed, ranging from nationalities (e.g. Germans, Dutch), ethnic groups within national boundaries (e.g. Basques, American Indian tribes), religio-ethnic groups (e.g. "Oriental Jews"), panethnic groups that refer to skin color (e.g. "Black") and region of the globe (e.g. "Asian"). Major "racial groups" in SNOMED are based in part on Census terminology [1]. These lists are not based on a single, consistent set of criteria. They include categories based on geography, skin tone, national boundaries, and cultural distinctions.

The separation of "racial groups" from "ethnic groups" is also a potential source of confusion. In the absence of claims based on biological racism, it becomes more difficult to articulate why the categories should be separated in health data [10-11]; for patient records, we simply need to be able to accurately identify the social groups to which the patient belongs.

Discussion: Principles for racial and ethnic data

The social science research on racial and ethnic identification suggests several principles for race and ethnicity vocabulary.

First, *self-identification should be preferred over observer identification*; staff and clinicians should be reminded to *ask* individuals about their ethnicity directly. Self-identifi-

cation is preferable to create consistency across datasets, give clinicians information about the social group that influences the patient's actions, and eliminate the strong influence of observer bias [12-13]. Ethnic self-identification is related to the selection of peer groups, communities, media and cultural outlets. If observer identification is used, it should be identified as such.

Second, *the dichotomy of "race" and "ethnicity" found in the SNOMED classification of ethnicity should be discarded*. Instead, "ethnic origins" should be collected together. As noted above, the inconsistent use of the terms makes their separation nonsensical in most contexts. Racial and ethnic questions that are formatted differently from how patients and staff think have higher rates of inaccuracy and nonresponse [4].

Third, *patients should be allowed to choose more than one ethnic origin*. Multiracial identification is increasing rapidly, increasing the importance of understanding the multiple ethnic origins that influence patients.

Fourth, *patients should also be asked to choose a single ethnic category that they find **most** representative of their ethnicity.* At times it is necessary to cluster patients into larger groups; it is more meaningful to do this by asking patients about their identification than by arbitrary allocation rules [8, 14-15].

Finally, *patients must be allowed to select from a list of ethnic categories that includes **all** of the groups that face ethnic discrimination or inequality.* If we hope to target populations that are facing increased health risks due to persecution or differences in socioeconomic opportunities, we cannot exclude meaningful categories. In this respect, the 2006 SNOMED categories are admirable in their level of detail; they include, for example, not simply panethnic categories (e.g. "American Indian") but a detailed list of ethnic categories (e.g. tribes). Conversely, terms that are not socially meaningful for any groups today should be dropped from the list.

It is wise to periodically reassess the ethnic data collected for patients, both because popular understandings of ethnicity change, and because identities are fluid over time [16]. The examples we give patients influence their identification, so it is also important to administer in the questions in a consistent way. National and regional differences will also influence how ethnic labels are understood and interpreted [2].

Conclusion: Recommended question format

I recommend asking patients:

"What are your ethnic origins or ancestry? Please select all the groups that apply." The entries currently found on the detailed list of ethnic and racial groups in SNOMED could be used as the potential answers to the question, once those categories have been pared down to include only categories that are socially meaningful to patients. (For example, the term "Mongoloid" is generally not used as an ethnic group identifier today.) In order to make this rather lengthy list comprehensible to users, it could be organized geographically, by region of ethnic origins.

Individuals who identify more than one ethnic group should also be asked a follow-up question: "Which one of these groups would you say BEST represents your ethnic origins or ancestry?" The same list of potential answers can be used.

The advantages of this format are many. First, questions that combine "ethnic" and "racial" categories into one question have lower rates of nonresponse, improving data quality [4]. The current SNOMED "racial groups" allow Hispanics to belong to a white or black subgroup, but do not do the same for any other "racial group," leading to potential confusion. Second, the level of detail found in the SNOMED ethnic categories is crucial, since panethnic categories such as "Hispanics" and "Asians" mask a tremendous amount of heterogeneity that is important to health outcomes. Third, the follow-up question asking each respondent to choose a single category is essential. Allocating multiracial respondents arbitrarily leads to grouping highly disparate individuals together and incorrectly identifies the category they would have chosen on a single-race survey [8, 14-15]. Using this follow-up question for allocation leads to much better information, since multiracial individuals tend to most resemble the single-race group they choose for themselves.

Measuring Race and Ethnicity in SNOMED Patient Records

Mary E. Campbell
Department of Sociology, University of Iowa

Measuring Race and Ethnicity

- *How might the social science evidence on the measurement of race and ethnicity be useful for the design of informatics systems?*
  - This study uses SNOMED as an example of a comprehensive clinical terminology to illustrate how race and ethnicity are currently captured in medical informatics, and discusses how recent research on the measurement of race and ethnicity can be distilled into five useful principles that can guide measurement of race and ethnicity, leading to better data quality.

The complexity of classifying "race" and "ethnicity"

- Measurement of race and ethnicity is very sensitive to question format
  - We have no internationally comparable or systematic nomenclature for capturing race and ethnicity in health contexts [1-2].
  - Self-reported race & ethnicity is different from the race & ethnicity that observers assign to patients [3-5].
  - Minor differences in the wording of questions leads to major differences in self-identification [6-8].

Racial and Ethnic Categorization in SNOMED

- The January 2006 release of SNOMED codes "ethnic group" and "racial group" data as part of a patient's social context.
  - The list of "ethnic groups" is extensive, ranging from nationalities (e.g. Germans, Dutch), ethnic groups within national boundaries (e.g. Basques, American Indian tribes), religio-ethnic groups (e.g. "Oriental Jews"), panethnic groups that refer to skin color (e.g. "Black") and region of the globe (e.g. "Asian").
  - Major "racial groups" in SNOMED are based in part on Census terminology [6, 8]. They are: African, American Indian/Alaska Native, Asian or Pacific Islander, Australian Aborigine, Caucasian, Hispanic, Indian, and Mixed Racial Group (with subgroups included under several of these groups).

Racial and Ethnic Categorization in SNOMED, continued

- Measurement of race and ethnicity has important implications for health data [9-10].

- These lists of groups are not created based on a single, consistent set of criteria. They include categories based on geography, skin tone, national boundaries, and cultural distinctions [11-12].

- These contradictions are potentially confusing. For example, the “racial groups” allow Hispanics to belong to a white or black subgroup, but do not do the same for any other “racial group” [6].

Principles for racial and ethnic data

1. *Self-identification should be preferred over observer identification*; staff and clinicians should *ask* individuals about their ethnicity. This is preferable for several reasons:
   a. Creates consistency across data sources,
   b. Gives clinicians information about the social group that actually influences the person's identity and actions, and
   c. Eliminates the strong influence of observer bias [3-5]. (An observer's own racial identification strongly influences estimates of another person's ethnic group.)

Principles for racial and ethnic data, continued

2. *The dichotomy of "race" and "ethnicity" found in the SNOMED classification of ethnicity should be discarded*.

"Ethnic origins" should be collected together. The separation of "racial groups" from "ethnic groups" is often a source of confusion. In the absence of claims based on biological racism, it becomes difficult to articulate why the categories should be separated in health data [11-12]; for patient records, we simply need to be able to accurately identify the social groups to which the patient belongs. Racial and ethnic questions that are formatted differently from how patients and staff think of themselves have higher rates of inaccuracy and nonresponse [6].

Principles for racial and ethnic data, continued

3. *Patients should be allowed to choose more than one ethnic origin*.

   Multiracial identification is increasing rapidly, increasing the importance of understanding the multiple ethnic origins that influence patients.

4. *Patients should also be asked to choose a **single** ethnic category that they find **most** representative of their ethnicity*.

   At times it is necessary to cluster patients into larger groups; it is more meaningful to do this by asking patients about their identification than by arbitrary allocation rules [10, 13–15].

Principles for racial and ethnic data, continued

5. *Patients must be allowed to select from a list of ethnic categories that includes **all** of the groups that face ethnic discrimination or inequality*.

   If we hope to target populations that are facing increased health risks due to persecution or differences in socioeconomic opportunities, we cannot exclude meaningful categories [9]. In this respect, the 2006 SNOMED categories are admirable in their level of detail.

Recommended question format

- “What are your ethnic origins or ancestry? Please select all the groups that apply.”

- Individuals who identify more than one ethnic group should also be asked a follow-up question: “Which one of these groups would you say BEST represents your ethnic origins or ancestry?”

Advantages of this format

1. Questions that combine “ethnic” and “racial” categories into one question have lower rates of nonresponse, improving data quality [6].
2. The level of detail found in the SNOMED ethnic categories is crucial, since panethnic categories such as “Hispanics” and “Asians” mask a tremendous amount of heterogeneity that is important to health outcomes.
3. The follow-up question asking each respondent to choose a single category is essential, because multiracial individuals tend to most resemble the single-race group they choose for themselves. Allocating multiracial respondents arbitrarily leads to grouping highly disparate individuals together and incorrectly identifies the category they would have chosen on a single-race survey [10, 13-15].

Abstract

Introduction*: This paper examines a new digital divide between patients and health care professionals in the context of emerging Information and Communication Technologies (ICTs).* ***Methods:*** *Through a survey of Staff Oncologists, Fellows and Residents, this study examines how the Internet is currently being used in clinical practice, research and continuing education. This study also probes the physician's view of the benefits and barriers of the Internet as a resource for their patients.* ***Results:*** *Analysis revealed that a large majority consider the Internet as essential to their practice and see its use increasing in the future, but have reservations about adopting new paradigms for clinical care.* ***Conclusions:*** *Though nearly all physicians recognize the benefits the Internet offers to patients, few are integrating new technologies such as email communication with their patients into their clinical practice.*

Keywords:

internet, consumerisms, radiation oncology practice, information and communication technologies

Introduction

A new digital divide is emerging. This new divide is between what patients are demanding from new technologies, and what professionals and organizations are prepared to provide. Many patients are becoming sophisticated consumers of health care services and just as they utilize new technologies in almost every other facet of the life, there is an expectation that health services also adopt a paradigm appropriate for the knowledge age. At the same time, health professionals are adopting these technologies in their own lives, but are reluctant to provide care utilizing these technologies. This reluctance is creating a chasm between the health system and health consumers. It is a chasm they are not certain how to bridge and reluctant to cross.

There is little doubt that that the prevalence of Information Communication Technologies (ICTs) and a wealth of information on the Internet is having a profound effect on clinical practice. The amount of information available to clinicians and their patients can be overwhelming, confusing and difficult to process. Developing strategies for dealing with this information explosion is essential if this information is going to have a positive, rather than negative effect on the clinical encounter[1] .

Many doctors use the Internet in their own practice for a variety of uses including obtaining medical information from online journals and e-mailing colleagues.[2] Continuing education/continuing medical education (CE/CME) programs that adopt self-directed, computer-based instruction formats via the Internet or CD-ROM can ease the demands placed on clinicians who are required by licensing boards to accumulate CE/CME credits as part of their career-long learning [3]. Having CE/CME courses on the Internet creates a flexible learning environment; the information in the courses is updated easily, time away from the workplace is reduced, and the learning can happen at the individual's own pace.[3-5]

The advent of ICTs has also had a profound effect on the delivery of care; patients are accessing information and educational tools and resources that have the potential to empower them as active participants in their care. As Shaw has noted, health care professionals appear to have a great deal of trepidation about what impact the "expert patient" could potentially have on clinical practice: "The suspicion is that for many doctors, the expert patient of the imagination is the one clutching the sheaf of paper from the internet, demanding a particular treatment that is unapproved, manifestly unsuitable, astronomically expensive or all three [6]."

The discipline of radiation medicine is inherently driven by computer-based technologies that profoundly shape the ways in which care is delivered. Yet it is not clear that the experience with computer-based technologies, depended upon for the provision radiation based treatments, extends to other aspects of the clinical interaction. This study will examine the perceptions, attitudes and barriers for radiation oncologists incorporating ICTs into their practice to improve the access to and the delivery of quality patient care.

Rationale/Purpose

To conduct a study of Radiation Oncologists at a large, academic, comprehensive cancer centre to determine current attitudes towards the Internet as a component of health care delivery, and to explore attitudes related to increased integration of Web-based applications and resources into the practice and delivery of radiation medicine.

Methods and materials

This study focused on the impact of the Internet on the practice of radiation therapy from the radiation oncologists' viewpoint. Radiation oncologists were surveyed to explore to what extent they use online resources for their own professional education and their attitudes towards further integration of Web-based strategies for patient education and care delivery into their clinical practice.

Study design

The survey instrument contained 18 items as well as demographic questions pertaining to age, sex and professional status. The questionnaire was divided into three sections. 1) The impact of the Internet on the education and practice of radiation oncologists. 2) The current reliance on the Internet to provide clinical services to their patient. 3) The oncologists' perceptions of the potential impact on clinical practice of patients using the Internet for education and clinical purposes. The questionnaire was pre-tested for face validity with three oncologists. Modifications to clarify and improve questions were made based on the feedback.

All radiation oncologists as well radiation oncology fellows and residents at a comprehensive cancer centre were eligible to participate in the study; at the time the survey was administered, there were 64 potential participants. The survey was initially administered in paper-format, but was also made available through an online version.

University Health Network Research Ethics Board approval was obtained for this study.

Results

Demographics

A total of 51 respondents completed the questionnaire for a response rate of 80%. Half of the respondents 49% were staff oncologists, 31% fellows and 20% residents. Just over half 60% were male; 54% are between the ages of 21 and 40 and 44% between 41 and 60. The respondents specialized in a wide range of cancer sites; the most common sites of specialization were breast cancer (24.5%), gastrointestinal (24.5%), genital-urinary (30.6%) and head and neck (20.4%).

The Internet and clinical practice and education

Three-quarters (75%) of the respondents perceived the Internet as essential and 24% as important to their clinical practice. All respondents have network access at work and 90% have home Internet access. The majority of respondents 81% consult online practice guidelines. Only 57% of respondents reported using the Internet to research new medications; trainees, however, appear to be more likely to use the Internet for this research with 90% of the residents, 75% of the fellows and 32% of the staff oncologists reporting researching medications online (See Table 1).

The Internet was also used by respondents for collaborative activities including clinical consultation, research and the review and publication of research manuscripts. The majority (92%) stated that they email colleagues for clinical advice or referrals. Many of the respondents (69%) use online avenues for improving international collaboration, but only 22% are currently conducting online meetings or conferences. Over three-quarters (78%) use the Internet to collaborate on research projects; this includes 30% of the residents, 81% of the fellows and 76% of the staff oncologists. Online publishing of their research and reviewing manuscripts, was done by 76% of respondents.

Table 1 - How do you use the Internet?

	Oncologist	Fellow	Resident
Accessing medical journals	24 (96%)	16 (100%)	10 (100%)
E-mailing colleagues	25 (100%)	13 (81%)	9 (90%)
E-mailing patients	11(44%)	4 (25%)	1 (10%)
Checking info on Web sites	9 (36%)	10 (63%)	7 (70%)
Researching new medications	8 (32%)	12 (75%)	9 (90%)
Looking for practice guidelines	19 (76%)	13 (81%	10 (100%)

The majority of respondents believed that the Internet usage will continue to increase as part of the clinical practice (80%), research (87%) and education (80%). Over half of the respondents (60%) see themselves using the Internet for telemedicine and 58% think they will use the Internet for online training or teaching of students. Thinking to the future, 77% of respondents see themselves using the Internet for online conferences, and 67% think they will use the Internet for formal online learning and distance education. All most all the respondents (90%) believe that the Internet will continue to be important for promoting their academic activities and research.

Patient-physician communication online

The majority of oncologists do not encourage patients to communicate with them using email. Approximately one-third (31%) of respondents use the Internet to email patients and only 33% would like patients to have the ability to email them concerning their treatment: 50% of the residents want to have this ability, 25% of fellows and 32% of the staff oncologists. Email exchange was rarely or never encourage by 73% of respondents. However, half of the respondents include their email address on their business cards and 59% are interested in having a separate email account dedicated to exchanging email with patients that are related to the clinical encounter.

Patients on the Internet: Physician perspective

Respondents believe that patients benefit from accessing information online, with 81% stating the online information is somewhat helpful to patients. According to the respondents, 96% of patients sometimes (47%) or often (49%) bring information that they have found on the Internet with them to their appointments. More than half (61%) report referring patients to information on the Internet. Although a few respondents referred patients to common search engines such as Google™, the majority referred them to specific, well-known sites including the National Cancer Institute's (NCI) education database (PDQ™), the American and Canadian Cancer Societies and Cancer Care Ontario. Only 51% of respondents reported checking and/or assessing information on popular Web sites for patients.

More than half (61%) of respondents agree or somewhat agree that patients should research their condition on the Internet before they accept treatment recommendations and 78% agree or somewhat agree that patients who do Internet research before their clinical consultations are better informed about their options than those who do not. The majority (80%) also agrees that patients who come with information that they found on the Internet generally take more time during consultation and 78% agree that these patients often request treatments not offered in Canada. However, almost half of the respondents (47%) do not believe that patients who do research on the Internet have a better consultation with their physicians than those who do no research prior to the appointment. There is also general agreement that the Internet is not being used to its full advantage as a patient tool for clinical care at the cancer centre.

Limitations

Despite the fact that the Princess Margaret Hospital houses the largest Radiation Oncology program in Canada, and despite the fact that this study enjoyed an 80% response rate, the numbers dealt with in the survey (n = 51) are still quite small. Such a sample size does not allow for the accurate extrapolation of information based on professional status and demographics. This study took place at only one, academic cancer centre involving only radiation oncologists, fellows and residents. The opinions and perspectives gathered, therefore, cannot be considered representative of radiation oncology practice in general or for larger physician populations.

Discussion

Communication with patients via e-mail

An overwhelming majority of respondents in this study stated that the Internet is essential to their clinical practice and education. However, the use of the Internet for patient communication and education lags behind other aspects of online activities for radiation oncologists. Very few physicians (33%) would like their patients to be able to e-mail them directly. This reluctance to correspond through e-mail could be due to a number of factors. The most obvious of these factors is time. Other important factors may include the already large number of e-mails received daily, the inability to effectively bill for time spent e-mailing patients, the dangers of e-mail reliance in urgent cases, the lack of a system to document patient e-mails in their medical record and issues of confidentiality,.

Despite the hesitations felt in regards to patient e-mail, several factors will make the adoption of such systems inevitable: (1) these technologies are becoming common place in every other industry; (2) a growing number of patients are expecting to be able to use these technologies to manage their health care; (3) these technologies can potentially promote self-managed care in areas such as chronic diseases and (4) these technologies have the potential to improve the delivery and accessibility of health care [7, 8] .

The Internet as a patient education resource

A concern amongst physicians for patients seeking health information on the Internet is the accuracy, reliability and appropriateness of the information they receive [9]. Patients would more likely trust resources recommended by their doctor [10], but a surprisingly large number of oncologists (40%) rarely or never do so. Many staff do point their patients in the direction of reputable sites such as the Canadian Cancer Society (www.cancer.ca), the American Cancer Society (www.cancer.org) and the National Cancer Institute (www.cancer.gov), but our respondents also acknowledged that, the Internet is not being used to its full potential as an educational resource at the Princess Margaret Hospital.

Concerns about the digital divide

There is a growing concern among physicians about the possible ramifications of responding to patients' demands for online interactions. This paradigm shift could potentially create barriers to care for certain patient populations. Shaw's study *How the Internet affects patients' experience of cancer: A qualitative study* shows that significantly fewer elderly patients access the Internet for medical information (Shaw, BMJ 2004). Even those who are able to access the Internet may not wish to do so for obtaining medical information. Henwood argues that with increased information and empowerment comes increased responsibility (Henwood, Sociology of Health and Illness, 25:6, 2003) [11]. He asserts that many patients are more than happy to trust their doctors and leave decisions to them. This resistance, on the part of providers towards adopting a more wide spread use of ICTs, could in part explain the reluctance of our respondents.

While some may argue that providing communication and information options on the Internet neglects non-users such as the elderly, few would agree that withholding such options from those who could take advantage of them would be a suitable practice. The goal of any health care organization should be to provide their patients with as many options as possible to increase their understanding of their disease and treatment. The Internet should not be seen as a replacement to traditional forms of information gathering and communication but rather as a complement to them.

The Internet's role in professional development

Though not every radiation oncologist surveyed in this study supported the Internet as a means of patient communication or education, nearly all agreed on its value to their professional development. The Internet has become an integral part of professional development, research and peer communication. In fact, 75% of respondents said that the Internet was essential to their practice and education and all but one said it was at least important.

The next generation of oncologists

Although the low number of participants prevents tests of statistical significance, the trends suggest there is no difference in the way that residents and fellows are using the Internet for clinical services. However, there do appear to be a few notable exceptions. Residents and fellows appear to be searching for new medications online more than staff oncologists. They also seem to spend more time on the Internet checking or assessing information on popular websites for patients. As for their own professional development, staff and fellows are much more likely to use the Internet to review or publish manuscripts than residents and are also more likely to go online to improve international collaboration. This result is, of course, in line with regular career development for radiation oncologists. In the future, fellows and residents see themselves participating in formal online learning much more than the staff and are also more likely to involve themselves in telemedicine and online consulting. Despite these few differences, staff, fellows and residents have similar opinions on the current and future roles of the Internet in their careers and professional development.

Conclusions

While physicians have realized the potential for the Internet in their research and professional development, the potential in their clinical practice is not being realized. Although evidence shows that having better informed patients should have a positive impact on their experience, the emergence of the expert patient also means a change in the way clinicians approach a patient's clinical care. In order to better accommodate the expert patient, physicians need to take an active role in examining the information available to patients on the Internet and steer their patients towards reliable, accurate and relevant sites. New systems and approaches need to be developed to assist oncologists in bridging this new emerging gap between patient expectation and current practice.

Variation in Use of Informatics Tools Among Providers in a Diabetes Clinic

Kim M. Unertl, Matthew B. Weinger

Department of Biomedical Informatics, Vanderbilt University, Nashville, TN, USA

Abstract

Direct observation and semi-structured interviews were used to examine variability in health information technology (HIT) use among four nurse practitioners (NP) and four physicians (MD) in an ambulatory diabetes clinic. One of the goals of the study was to understand the rationale behind variability in HIT use and to assess the impact of this variability on patient care. The study provides direction for future design to improve usability and efficiency.

Keywords:

qualitative research, observation, interviews

Introduction

We investigated workflow and information flow in an ambulatory specialty clinic, the Vanderbilt Eskind Diabetes Clinic. Variability of use of HIT among providers was examined as part of the study, and analyzed for impact on patient care. The variability reveals some of the strengths and weaknesses of existing HIT and provides suggestions for modifications.

Methods

The clinic provides diabetes care to approximately 6000 patients, who typically visit the clinic at 3-month intervals. Clinic providers have been using an electronic medical record (EMR) for approximately 3 years. All 8 providers had equal access to HIT features and training except for dictation software, which was available only to the physicians. Verbal assent was obtained from staff and providers prior to direct observation in offices, work areas, hallways, and exam rooms. Patients gave verbal assent prior to observation of patient-provider interactions. We conducted 52 hours of observation in the clinic. Observational data were supplemented through the use of semi-structured interviews.

Results

Use of HIT in the clinic can be grouped into three categories. Information access included examining existing data in the EMR. Information input involved altering existing data or entering new data. Communication involved using the EMR to communicate with others. Use of HIT varied both within and between the groups of providers and variability extended across all three categories of use (Table 1).

Table 1 – Variability in HIT use

Non-secure email with patients	◢	◢	◢	◢	◢	◢	◢	◢

◢ Uses routinely
◢ Uses sometimes (not routinely)
◢ Uses rarely or never

Discussion

Variability of providers' HIT use has implications for both patient care and informatics design. Understanding the rationale for variability provides direction in the redesign of current applications and suggestions for features of new HIT. Direct observation and interviews can provide critical data about whether informatics tools are meeting user needs and supporting their workflow and can help guide design.

Variation in Use of Informatics Tools Among Providers in a Diabetes Clinic

Kim M Unertl, MS, Matthew B Weinger, MD
Department of Biomedical Informatics
Vanderbilt University, Nashville, TN, USA

Introduction

- Study conducted in the Vanderbilt Eskind Diabetes Clinic
- Examined variability of electronic medical record (EMR) use and assessed impact of variability
- Clinic: outpatient clinic providing speciality care to over 6000 patients with diabetes
  - EMR used by clinic providers for ~3 years

Methods

- Observed 4 physicians (MD) and nurse practitioners (NP) during their daily work including patient interactions
  - 52 hours of observation (18 hours for MDs, 18 hours for NPs)
- Took detailed notes during observation with focus on interaction between people, processes, and technology
- Supplemented observations with semi-structured interviews

Similarities in EMR usage

- Providers gathered information from the EMR prior to visiting patient
- Consulted EMR to clarify information or understand medical history
- None of the providers completed all of their documentation while with the patient
- All providers utilized secure messaging features

Variability in EMR usage

- EMR as information repository vs integrated tool for disease management
- A few of the providers started notes in the EMR while in the exam room, most did not
- Use of graphical displays of data
- Time to complete patient documentation varied, dependent on EMR use in exam room
- Only MDs had access to dictation software

Information Access: Examining data already in EMR

Functionality	NP				MD			
	1	2	3	4	1	2	3	4
Look up information (in exam room)	●	●	●	●	●	●	●	●
Look up information (outside exam room)	●	●	●	●	●	●	●	●
Graphical views of patient data	○	●	○	○	○	●	○	○

● Uses routinely
◐ Uses sometimes (not routinely)
○ Uses rarely or never

Information Input:
Altering existing data, entering new data

Functionality	NP				MD			
	1	2	3	4	1	2	3	4
Input note (in exam room)	●	○	●	◐	○	○	○	○
Correct data in record (in exam room)	●	●	●	●	●	◐	◐	◐
Input note (outside exam room)	●	●	●	●	●	●	●	●
Dictation software	○	○	○	○	●	●	●	●

● Uses routinely
◐ Uses sometimes (not routinely)
○ Uses rarely or never

Communication:
Using the EMR to communicate with others

Functionality	NP				MD			
	1	2	3	4	1	2	3	4
Message basket communication	●	●	●	●	●	●	●	●
Write prescriptions	●	◐	○	○	○	○	○	●
Patient portal	●	●	●	●	●	●	◐	●
Non-secure email with patients	●	●	●	●	○	○	○	○

● Uses routinely
◐ Uses sometimes (not routinely)
○ Uses rarely or never

Discussion

- All 8 providers had access to the same EMR in the same clinical environment and were treating the same disease in the same patient population
- Expectation: similar patterns of EMR adoption and use
- Observation: substantial variability in use
- Implication: providers not taking advantage of all EMR features - why not?

Contributors to variability

- Familiarity with the EMR features
- Typing ability
- Workload
- Patient needs
- Personal preferences

Implications for EMR design

- Redesign system to better fit user needs, abilities, and workflow
  - Pursue alternative approaches to data entry
  - Better match technology to workflow
- Workarounds point to need for new functionality or alternative implementation of existing functionality
- EMR modifications to promote standardization

Abstract

The purpose of the study is to use the web 2.0 concept in developing the nursing Information portal (NIP) in a large medical center with 1800 nurses. The website contents have been created and maintained by end users instead of traditional website manager. The website manager chose Microsoft SharePoint Service 2003 as the portal website developing tool to meet head nurses' information management needs, such as news, documentations exchange and survey taking. According to the study results for users' acceptance, nurses are very satisfied with the NIP.

Key words:

Web 2.0, nursing information, portal

Introduction

Nursing management is a complex work because nurses represent the largest group in hospital. Generally, nursing domain includes clinical and administrator work. As time going, there are many nursing specialist needed in the hospital. They are asked to do special nursing function such as case managers, nursing quality managers, disease control managers etc. The common need for all of them is a useful Information tool to help them deal with their work more efficiently. For example, they usually need to collect data from every unit via paper forms, E-mails and hone calls. Then they do their statistics manually. This manual data collection process is very time consuming. Furthermore, if they would like to deliver newest information to all units or to share documentations to all nurses, they often use the emails. It is important for these nursing managers to overcome these problems and help them work more efficiently.

According to the study, experts think the attitudes toward the computer are the most important computer competency for the nursing profession in Taiwan[1]. However nurses are seldom trained with the skills in computer usage and what IT tools could help them to do their work more efficiently. They often depend on IT people to design the information systems to help their work. Unfortunately, the IT people in hospital have difficulty to satisfy all users' Information needs[2]. In recent years , to solve the nurses' Information problems, some nurses try to develop Information system by themselves in nursing scheduling, discharging plan system etc.[3-5]. But these nurses are few and they still need to resolve the challenges in programming learning and organizational poor support [6]. The nurses' attitude toward developing information systems by themselves is positive[7].

In order to let the general nurses who never take any professional IT programming training, the information tools must be very easy to learn and easy to use. At the same time, collaboration is also important for them. So the web-based platform seems an important tool for these nursing managers.

In the last decade, there are numerous websites created in the world. People use internet for searching information. The creators or managers of websites know how to create and manage the websites. Website users rarely participated in the website content generation and maintenance process. In this old model, the website managers are responsible for almost all website management. The Web 2.0, a phrase used by O'Reilly Media in 2004, refers to a new generation of Internet-based services such as social networking sites, communication tools that emphasize online collaboration and sharing among users[8]. In the new model, the websites are co-managed by all interested users. Many Web 2.0 websites have successfully attracted many users to participate, like Wikipedia for free encyclopedia, YouTube for videos, Blogs for personal web diary etc.

One of the key important factors that Web 2.0 concept becomes so popular is users' participation. Users could easily edit their own information and put their documentations or multimedia materials on the websites. They could share everything to each other if they want. In this kind of sharing mechanism, websites could attract more people and all users could become the authors of the websites. If the users think the website is important for them, they will become aggressive to maintain and keep the information updated. The maintenance of the websites becomes easy and efficient. Therefore, the burden nursing website management might be improved if those who need the websites can participate to help managing the websites.

In this study, we chose Microsoft SharePoint Service 2003 (SPS) as our Nursing Portal platform. SPS is under Microsoft Windows SharePoint Services[9]. It comes with many common components that users can use right away. The web components are based on the technology of 'Web Part'. A Web Part is a modular unit of information that has a single purpose and that forms the basic building block of a Web Page. In order to incorporate the specific requirements of nurses in a user-friendly manner, this platform provides a web components based interface for integrating tailoring functionality. Based on this environment, nurses are allowed modify any application by reassembling components without programming. SharePoint Services can deliver a set of core functions that allow nurses to develop their own specific web application through the web-browser. It offers flexibility, ease of use and can enhance the productivity of applications[10].

In a 2357-bed medical center in Taipei, Taiwan, there are 88 clinical units and 1800 nurses. According to their major work, there are clinical nurses, head nurses, nurse supervisors. Among them, there are nine kinds of special functional nurses serving in this medical center. Some of them are in charge of the disease management like DM, TB, nurse managers, wound care, heart failure etc. Some of them are in charge of the administration like quality assurance, discharge plan. In the old days, they depended on the website manager, who was an information nurse, to help them to design and update the nursing website. However this was not an efficient way to maintain the website. There has been always too for a single website manager to take care of. Therefore, SPS seems a right platform for improvement. The objective of this study was to know if the nurses could accept the Web 2.0 tool like SPS to help their work and how they thought about the SPS as an easy tool for them or not?

Materials and methods

In May 2006, we started to use the SPS to build our new nursing information portal (NIP). The structure is showed in Figure1.The informatics nurse plays a role the initial role to manage and design the website. When the prototype website was created, more nursing managers were assigned to participate in the training courses. There was a 2-hour training course in the first week and 1-hour in the following two weeks. Training materials cover the introduction of the NIP and demonstration of the functions, like how to upload and download files, to created documentations base, to create photo base, and to create a survey etc. After a total of 4-hour training, they were asked to design and to manage their assigned website and if there were any problem they could ask the informatics nurse's for help. Three months later, the NIP was formally for open to all nurse members. The NIP is showed in Figure 2. We introduced the website to all head nurses and clinical nurses in one hour speech to teach them how to use the NIP. After another three months, one questionnaire (5-Point Likert scale) was designed to nursing managers to ask for their acceptance.

Results

We totally created 28 sub-sites in NIP. There are 24 nursing managers assigned to manage the website, including 13 nurse supervisors, 8 special functional nurses, 3 administrators. After the training course, 7 special functional nurses design their assigned website on their own. Nurse supervisors were too busy to design by themselves and to supply the materials and to ask the informatics nurse to help them in beginning. However, they sometimes needed to collect data form units so they would ask informatics nurse to teach them how to create a survey in NIP. With this regard, the NIP became their useful tool to data collection.

There were 29 questionnaires returned with a return rate of 36.7%. The result of questionnaire survey is shown in Table 1. Overall, they were very satisfied with the NIP and its performance.

Discussion

The NIP appears to be a useful tool for nurses to meet their information needs. They could collect the data more efficiently then before. They furthermore became to ask other nurses who were not familiar with the NIP to learn how to use that. Some head nurses even asked informatics nurse to integrate more functions into NIP, like the documentation records. Some nurses did appreciate this website.

Conclusion

Within few months, the NIP has helped nurse supervisors and special functional nurses in improving different work flow and made their work more productive. The Web 2.0 concept in nursing information portal appears successful from our study. There are still many nurses afraid to use this new website. So in the future study, we would like to encourage them and continuous to integrate more easy but useful functions in NIP like document searching. Besides, we would also like to teach our head nurses to manage their unit websites to improve their wok performance then before and to increase their acceptance of NIP.

A Review of the Use of Health Technology Assessment in Relation to the Safe and Effective Use of Diagnostic Imaging Technologies in Health Care

Bernard L Crowe[a] and Peter MacIsaac[b]

[a]*Partner, Bernard Crowe & Associates, Canberra, Australia*
[b]*Principal, MacIsaac Informatics, Canberra, Australia*

Abstract

Health Technology Assessment (HTA) has become the standard methodology use by government agencies for evaluating the role and funding priorities of new Diagnostic Imaging (DI) technologies. A structured literature review of recent HTA reports concluded that there had been no major developments in assessment methods used in HTA and, therefore, no widespread spillover from the development in research methods in general to the field of HTA methodology.

Purchasing decisions of new technology are guided by a DI professional assessment of improvements in image quality, efficiency, safety and capacity for expanded range of diagnostic and procedural interventions. The implementation of a new technology in DI often precedes systematic reviews by HTA bodies of patient outcomes and may be based on data provided by manufacturers and on recent papers presented at professional conferences. This situation often leads to a clash of evaluation cultures between the DI profession and the HTA agencies charged with informing public purchasing and health policy.

As emerging DI technologies sit at the border of computer technology and social interaction between patients and clinicians, a number of authors have concluded that because of the complexities of health systems, both qualitative and quantitative data are required to resolve questions about the appropriate use of diffuse DI technologies. The authors conclude that assessment of DI technologies s should be based on qualitative methods involving surveys of the experience of practitioners and patients rather than only on traditional quantitative methods.

Keywords:

health technology assessment; diagnostic imaging; quantitative assessment; qualitative assessment

Definition of HTA

Health Technology Assessment (HTA) is a scientific and policy domain that has grown rapidly over the past twenty years. HTA is a multidisciplinary field of policy analysis. It studies the medical, social, ethical, and economic implications of development, diffusion and use of health technology. HTA seeks to inform health policy makers by using the best scientific evidence on the medical, social, economic and ethical implications of investments in health care.

HTA and priority setting

The impact of on new Diagnostic Imaging (DI) technologies on health care is seen as a major factor in the improvement in health outcomes in many developed countries. At the same time, DI is seen by critics as a driver of increases in health expenditure. While the various health professions have traditionally managed the introduction of new diagnostic imaging technology, principles of evidence based medicine are being rigorously applied to the introduction process by many government health authorities. New techniques and procedures have to be not only effective and beneficial, but also justify any increased costs and resources. It is a reality that a mechanism such as HTA is required for priority setting in government environments where there are competing calls on limited resources.

Literature review of developments in HTA methodology

A review of relevant literature has been conducted to determine trends in the use of HTA methodology for the assessment of DI technologies. Consideration is being given by academic radiologists to the issues of how to both collect evidence on the impacts of DI as well as how to deal with appraisal of rapidly changing technology [1]. A conceptual framework of a hierarchy of levels of efficacy that could guide thinking about imaging test evaluation has been developed. In particular, the framework relates the key questions; "How well does this test distinguish disease from the non-diseased state?"; "How much does this intervention improve the health of people?"; "What is the cost of that improvement?" The model describes decision analysis and cost-effectiveness analysis, which are quantitative modeling techniques usually used to answer the two core questions for imaging.

However, a structured literature review by Draborg et al [2] of 433 HTA reports from the period 1989 to 2002 by eleven leading HTA institutions worldwide found that lit-

erature reviews were still the most often used method of assessment. The authors concluded that there had been an increase in the number of HTAs but no major developments in assessment methods used and, therefore, no widespread spillover from the development in research methods in general to the field of HTA methodology.

Discussion

As a group of emerging technologies, DI sits at the border of computer technology and social interaction between patients and clinicians and thus calls for a socio-technological approach to evaluation of organizational, cultural and technological factors. An innovative qualitative approach to the assessment of DI technologies is required when seeking new directions for evaluation [3]. The conclusions of a recent workshop, Putting Evidence into Practice in Edmonton, concluded that: "In the end, evidence and information cannot be the determining factor in policy decisions. There will always be world views and values, which will help to determine when a condition becomes a problem and when the political situation is such that a decision can be made."[4]

The ability of HTA systematic reviews to keep pace with technological change in DI technologies is being challenged in environments of limited resources for research and evaluation. While both quantitative and qualitative techniques of evaluation have evolved over the last decade, the HTA paradigm of systematic review has not, yet controlled trial evidence of the outcome of DI technologies is often hard to find. It is suggested that assessment of DI technologies should be based on qualitative methods involving surveys of the experience of practitioners and patients rather than only on traditional quantitative methods.

A review of the use of Health Technology Assessment in relation to the safe and effective use of Diagnostic Imaging technologies in health care

Bernard L Crowe and Peter MacIsaac

Medinfo 2007

Brisbane 20-24 August 2007

Overview 1.

Health Technology Assessment (HTA) has become the standard methodology use by government agencies for evaluating the role and funding priorities of new Diagnostic Imaging (DI) technologies

Purchasing decisions of new technology are guided by a DI professional assessment of improvements in image quality, efficiency, safety and capacity for expanded range of diagnostic and procedural interventions

The implementation of a new technology in DI often precedes systematic reviews by HTA bodies of patient outcomes and may be based on data provided by manufacturers and on recent papers presented at professional conferences.

Overview 2

This situation often leads to a clash of evaluation cultures between the DI profession and the HTA agencies charged with informing public purchasing and health policy.

As emerging DI technologies sit at the border of computer technology and social interaction between patients and clinicians, a number of authors have concluded that because of the complexities of health systems, both qualitative and quantitative data are required to resolve questions about the appropriate use of diffuse DI technologies.

The authors of this paper conclude that assessment of DI technologies s should be based on qualitative methods involving surveys of the experience of practitioners and patients rather than only on traditional quantitative methods

Definition of HTA

Health Technology Assessment (HTA) is a scientific and policy domain that has grown rapidly over the past twenty years.

HTA is a multidisciplinary field of policy analysis. HTA studies the medical, social, ethical, and economic implications of development, diffusion and use of health technology.

HTA seeks to inform health policy makers by using the best scientific evidence on the medical, social, economic and ethical implications of investments in health care.

HTA and priority setting for DI

The impact of on new Diagnostic Imaging (DI) technologies on health care is seen as a major factor in the improvement in health outcomes in many developed countries.

At the same time, DI is seen by critics as a driver of increases in health expenditure

Principles of evidence based medicine are being rigorously applied to the introduction process of DI by many government health authorities.

New techniques and procedures have to be not only effective and beneficial, but also justify any increased costs and resources.

It is a reality that a mechanism such as HTA is required for priority setting in government environments where there are competing calls on limited resources.

Literature review of developments in HTA methodology

A review of relevant literature has been conducted to determine trends in the use of HTA methodology for the assessment of DI technologies.

Consideration is being given by academic radiologists (Sunshine et al) to the issues of how to both collect evidence on the impacts of DI as well as how to deal with appraisal of rapidly changing technology.

A conceptual framework of a hierarchy of levels of efficacy that could guide thinking about imaging test evaluation has been developed. In particular, the framework relates the key questions:

Key questions for HTA

"How well does this test distinguish disease from the non-diseased state?“

"How much does this intervention improve the health of people?" and

"What is the cost of that improvement?”

The Sunshine et al model describes decision analysis and cost-effectiveness analysis, which are quantitative modeling techniques usually used to answer the two core questions for imaging.

Literature review 2

A structured literature review by Draborg et al of 433 HTA reports from the period 1989 to 2002 by eleven leading HTA institutions worldwide found that literature reviews were still the most often used method of assessment

The authors concluded that:

there had been an increase in the number of HTAs

no major developments in assessment methods used

no widespread spill over from the development in research methods in general to the field of HTA methodology.

Discussion 1

As a group of emerging technologies, DI sits at the border of computer technology and social interaction between patients and clinicians

DI calls for a socio-technological approach to evaluation of organizational, cultural and technological factors.

An innovative qualitative approach to the assessment of DI technologies is required when seeking new directions for evaluation

Discussion 2

A workshop Putting Evidence into Practice in Edmonton, concluded that:

"In the end, evidence and information cannot be the determining factor in policy decisions.

There will always be world views and values, which will help **to determine when a condition becomes a problem** and when the **political** situation is such that a decision can be made."

Conclusion

The ability of HTA systematic reviews to keep pace with technological change in DI technologies is being challenged in environments of limited resources for research and evaluation.

While both quantitative and qualitative techniques of evaluation have evolved over the last decade, the HTA paradigm of systematic review has not, yet controlled trial evidence of the outcome of DI technologies is often hard to find.

It is suggested that assessment of DI technologies should be based on qualitative methods involving surveys of the experience of practitioners and patients rather than only on traditional quantitative methods.

Qualitative Characterization of Query Structure in the Arden Syntax

Robert A. Jenders

Cedars-Sinai Medical Center and the University of California, Los Angeles, USA

Abstract and objective

Context: Arden Syntax is an American National Standard Institute (ANSI) standard used to encode executable knowledge as Medical Logic Modules (MLMs). Consensus is elusive regarding a standard format for database queries in knowledge bases (KB). Objective: Analyze a sample of MLMs in order to characterize the syntax of database linkages. Method: A convenience sample of 331 MLMs drawn from 6 distinct clinical decision support systems (CDSS) was examined. MLM types included 42% lab, 23% clinical assessment and 14% medication. Results: Only half of the systems include the Structured Query Language (SQL) in queries. Only two used standard terminologies. Queries from all six systems contained at least some site-specific content, some of which was included only at run-time. Conclusion: Arden Syntax database linkages vary in format, and significant work remains to converge on a standard for Arden Syntax queries.

Keywords:

decision support systems, clinical; knowledge bases

Introduction

Arden Syntax is an HL7/ANSI standard for procedural knowledge representation, and the medical logic module (MLM) is the unit of representation. Nevertheless, some site-specific changes must occur in order for a KB in standard format to be transferred from one site to another—the "curly braces" challenge, named for the construct that encodes site-specific references in the Syntax. A database query is represented by a READ statement, which may contain site-specific references in the curly braces combined with standard operators such as aggregation and constraints. Key to minimizing the need for KB changes when sharing MLMs is the standardization of these database linkages. The present work qualitatively characterizes the structure of database queries from different institutions and CDSS. This will inform development of a standard for database linkages and estimation of the work needed to converge on the standard.

Methods

MLMs were obtained from six distinct source systems: sample knowledge bases of the 3 principal vendors of Arden-compliant CDSS and three academic medical centers with independently developed CDSS. The READ statements in the collected MLMs were isolated in order to characterize their structure. The analysis focused on these characteristics: the use of ANSI-standard SQL; whether query elements were added at run time that were not encoded in the MLM; the use of coded terminology; and the extent to which the query was represented entirely within the curly braces or partially in the standard component of the READ statement.

Results

A total of 331 MLMs were pooled from the 6 source CDSS, including 19 from 3 vendor KBs and 312 from the 3 academic medical centers. MLMs concerned mainly with lab tests were the most common (138/331 = 42%), followed by clinical assessment or classification (75/331 = 23%) and medication (45/331 = 14%). The remainder addressed administrative and miscellaneous topics. Each MLM contained at least one READ statement. Within the MLM cohort of each CDSS, query structure did not vary by MLM type. Half of the source systems used SQL to link to databases, while the others used proprietary expressions. Four of the six systems included the entire query in the READ statement, while the other two relied on partial run-time inclusion of query elements. Only two of the systems used coded vocabulary terms to refer to data elements. Each of the other four appeared to use a local, controlled terminology that was neither coded nor standard. All six source CDSS used the curly braces to represent at least part of the query; none used the standard parts of the READ statement exclusively. Three of the six included SQL queries in the curly braces, while two others reserved the curly braces for local terminology references.

Conclusion

A sample of MLMs drawn from a variety of Arden Syntax-compliant CDSS demonstrates the absence of a uniform query structure. Other standards such as SQL and controlled terminologies are used but do not predominate. Run-time inclusion of query elements complicates efforts to represent queries in a standard, shareable format. Considerable work remains to achieve convergence on a standard for representing database queries in the Arden Syntax.

Development of Reference Terminology in Korean Health Domain

Seung-Hee Kim[a], Yoo-Kyung Boo[a], Dong-Kyu Kim[b], So-Yong Yoon[a], Mi-Sook Kwak[a], Yoon Kim[a]

[a] *R & D Center for Interoperable EHR, Korea,*
[b] *CTO Prompt co., ltd., Korea*

Abstract

To know whether existing terminologies are applicable to our environments or not, we analyzed the structure of health information vocabularies and other terminologies. From this, we knew the necessity of reference terminology suitable for our environment. To make Korean reference terminology in health domain, we made three models— Meta, Conceptual, and Instance model— based on the structure of our terms. And we constructed database based on these models. Our work is expected to be a useful precedent to develop reference terminology appropriate for our environments.

Keywords:

vocabulary, controlled; Korean language

Introduction

Reference terminologies and terminology services permit retrospective and real-time aggregation, and sophisticated decision support. A reference terminology is a formal terminology where each term has a computer-usable formal definition supporting data aggregation and retrieval. Such formal terminologies promise to reduce maintenance and mapping effort [1, 2].

To accomplish and continually improve medical records documentation, improve care quality, promote patient safety, and reduce costs, we made reference terminology models.

Methods and results

Analyses

To know whether existing terminologies are applicable to our environments or not, we analyzed the structure of health information vocabularies which have been collected by National Health Information Standard Committee and other terminologies—UMLS and SNOMED CT.

Collected terms are being used in 12 departments (or domains)— Clinical Findings and Problems, Diagnoses, Operations and Procedures, Nursing, Laboratory, Imaging, Medical Device, Dentistry, Oriental Medicine, Drug, Public Health, and Health Statistics. The structure of these terms was domain specific and had various structures. We also analyzed UMLS and SNOMED CT to confirm applicable to our terms. According to analyses, we think that UMLS and SNOMED CT don't suitable for representing our terms. It is because existing terminologies could not reflect various structures of our terms and include needed terms sufficiently.

Modeling

We made three-level models based on the structure of our terms. The most abstract level is the Meta model. This model consists of Concept, Semantic class, Lexicon, concept relationship, semantic class relationship, term relationship, concept-term relationship (or consist_of relationship), and concept-semantic class relationship (or categorized_by relationship). The conceptual model is more specific than the Meta model. It is divided into the common conceptual model (CCM) and domain conceptual model (DCM). The CCM defines common properties which are applicable to all domains. The DCM defines domain specific properties. The most specific model is the instance model. It generates instances which have properties with real value and consists of skeleton tables and queries. From this model, we can obtain instances and see the integrated vocabulary structure.

DB construction

We made logical and physical schema based on our models, then we constructed DB using Oracle 10G based on these schema. We also developed user interface using Visual Studio C# .NET 2005. Through this, we could confirm our models.

Conclusions

The reference terminology which is used commonly and centrally is a prerequisite for meaningful exchange. For this, we went to work—terms analysis, modeling, and DB construction. In the future, we will develop integrated terminology system suitable for our environment.

Mapping of Korean Healthcare Vocabulary to the UMLS

Yoo-Kyung Boo[a], Seung-Hee Kim[a], Mi-Sook Kwak[a], So-Yong Yoon[a], Yoon Kim[a]

[a] *R & D Center for Interoperable EHR, Korea*

Abstract

The UMLS is used for research and development across wide range of different applications. In this paper, we evaluated the coverage of the UMLS as mapped with healthcare vocabularies in Korea. Of the 216,697 terms, 42% were matched with the UMLS concepts exactly. We then analyzed unmatched terms. There were various reasons why 58% of our terms were unmatched with the UMLS concepts.

Keywords:

vocabulary, controlled; Korean language; UMLS

Introduction

There is an increasing need for successful terminology mapping to achieve compatibility among terminologies and to allow clinicians and researchers familiar with one terminology to search and use other terminology schemes [1]. The Unified Medical Language System (UMLS) has incorporated over 100 sources into one database [2].

In this study, we evaluated the coverage of the UMLS as mapped our terms to the UMLS Metathesaurus (MT) using string matching tool. Then, we analyzed mapping results.

Methods and results

Mapping to the UMLS MT

The National Health Information Standard Committee collected healthcare vocabularies which are used in twelve departments (or domains)—Clinical Findings and Problems, Diagnoses, Operations and Procedures, Nursing, Laboratory, Imaging, Medical Device, Dentistry, Oriental Medicine, Drug, Public Health, and Health Statistics—for standardization of healthcare vocabulary.

We mapped 216,697 healthcare vocabularies to the UMLS MT using string matching tool which was developed by the Vocabulary Server Development team in the Interoperable EHR Center. The mapping results are provided in Table 1.

Analysis mapping results

Of the total terms, 91,056 (42%) terms matched with the UMLS MT exactly. The Diagnoses had highest mapping percentage and the Medical Device had lowest mapping percentage. Un-mapping terms were the Korean alphabets (Hangul), composite concepts, misspellings, and domain specific terms. There were some of un-mapping terms which were included conceptually in the UMLS MT, because we did only string matching. From this result, we could know coverage of the UMLS MT. The UMLS MT has many terms which are related to diagnoses, laboratory, operations and procedures, and clinical findings and problems. On the other hand, the UMLS MT has a few terms which are related to medical device, imaging, drug, and oriental medicine.

Table 1 – Mapping Result to the UMLS MT

Domain	Matched terms (%)	Unmatched terms (%)	Total
Clinical Findings & Problems	39,927 (61.0)	25,523 (39.0)	65,450
Diagnoses	24,453 (84.8)	4,381 (15.0)	28,834
Operations & Procedures	5,661 (74.7)	1,915 (25.0)	7,576
Nursing	93 (12.8)	634 (87.0)	727
Laboratory	13,256 (79.5)	3,412 (20.0)	16,668
Imaging	5 (0.1)	3,888 (99.9)	3,893
Medical Device	0 (0.0)	130 (100.0)	130
Dentistry	5,867 (27.1)	15,763 (73.0)	21,630
Oriental Medicine	76 (2.1)	3,534 (98.0)	3,610
Drug	395 (0.6)	65,045 (99.0)	65,440
Public Health	1,313 (54.0)	1,117 (46.0)	2,430
Health Statistics	10 (3.2)	299 (97.0)	309
Total	**91,056 (42.0)**	**125,641 (58.0)**	**216,697**

Conclusions

The high percentage of medically relevant unmatched terms is attributed to a variety of factors. The UMLS MT has incomplete synonyms and absent concepts. Also, healthcare vocabularies have different term structures to the UMLS MT and misspellings.

Results

Results

Diagnoses Domain

- The highest mapping rate (84.8%)
- This domain collected concepts based on the UMLS ones

Medical Device Domain

- The lowest mapping rate (0%)
- This domain has product names, but UMLS doesn't have these concepts

Results

- Unmapping concepts analysis
  - Korean Concepts
  - Composite Concepts
  - Misspelling Concepts
  - Etc.
- Because we did only string match, there were some of un-mapping terms which were included conceptually in the UMLS MT
- The UMLS MT has many terms
  - which are related to diagnoses, laboratory, operations and procedures, and clinical findings and problems
- The UMLS MT has a few terms
  - which are related to medical device, imaging, drug, and oriental medicine

[c] *Dept. of Medical Informatics Kyungpook National Univ., Republic of Korea*

Abstract

Logical Observation Identifiers Names and Codes(LOINC) set is the only publicly available universal standard for laboratory test names essential for Electronic Medical Record(EMR) system. Although Regenstrief Institute maintaining the LOINC database provide an automatic LOINC mapping tool (RELMA), It is not sufficient for applying LOINC code set to Laboratory Information System (LIS) of local hospital. LOINC code has up to six attributes and if one of six attributes has the different value, it means different LOINC code is defined. Because many local hospitals have used their own LIS with arbitrary codes witch is not followed by LOINC attributes and some does contain several same attributes, one code of LIS system would match with several LOINC codes. So we cannot help developing protocols and tools to match codes of LIS system to codes of LOINC as one to one. As we have been develop automatic tools to connect LIS system of Pusan National University Hospital (PNUH) with LOINC. Ant it may be valuable as facilities for applying of LOINC code set essential for EMR system to the local hospitals witch has their own LIS system.

Keywords:

logical observation identifiers names and codes; electronic medical record; laboratory information system

Introduction

Development of information technology is bringing many changes to our lives, and such processes of change can also be experienced in the medical environment. Developments are also being made in the public health areas so that data can be automatically retrieved and analyzed, and such data are already being used in the form of electronic documents and being integrated into the Public Healthcare Information System. The Hospital Information System (HIS), enhances information accessibility in the aspects of patient diagnosis, education, research, and heath care management and affects the medical profession in various ways. With Information Technology, HIS surpasses the scope of an automated tool and is evolving as Electronic Medical Record Systems, EMRS.

According to materials that studied status of hospital informationalization at approximately 122 large scale medical facilities including general hospitals, 88.1% are equipped with the Hospital Order Communication System and 9.2% are equipped with the Electronic Medical Records System. As a useful tool that can overcome the restrictions of time and space, access to EMRs is possible anywhere and any time a computer is available, therefore, it is being expanded into various fields such as remote diagnosis and remote education [1].

In order to provide appropriate information that is needed in many areas such as diagnosis and research using the Electronic Medical Records System, the significance and the essence of the data to be used must be communicated accurately to the user or to the user's computer. In reality, however, accurate expression and maintenance of accurate medical records of patients' conditions and their progress of treatment is something that is difficult to accomplish, and exchange of information is also impossible. The main reason is for these difficulties is because majority of hospitals independently operate and manage their HIS or EMRs of medical records. Majority of HIS or EMRs that are being utilized are being operated based on a Relational Database Management System, and because information and data are being expressed based on the relationship between specific key values that are unique to each hospital, accurate communication and transmission of information between disparate systems cannot be accomplished. In addition, since independent systems have been constructed using code switching, message exchange between Disparate Systems are impossible. In order to extract the massive information neglected in independently constructed systems for use as knowledge source and to communicate accurate meaning of medical records through information exchange and sharing between each facility, use of Standard Vocabulary is necessary. Currently, various studies on standard vocabulary systems including Unified Medical Language System (UMLS) [2], Systematized Nomenclature of Human and Veterinary

Medicine Clinical Term (SNOMED-CT) [3], Logical Observation Identifier Names and Codes (LOINC) [4], and International Classification of Diseases Version 10(ICD10) [5] are in progress.

LOINC is a general standard vocabulary system that is used for expressing medical diagnosis results, and of all forms of medical information, a medical diagnosis result is the most objective form of information that expresses and displays the condition of the patient. Also, by providing basic materials with which treatments are made, it is also extremely important in a clinical environment. Standardization of medical diagnosis results not only saves waiting period for patients when transferring to a different hospital or when sharing information between medical facilities it also serves as the basis for Evidence Based Medicine (EBM) [6].

Materials and methods

We have been mapping the LOINC for Local code of 183 blood chemistry in LIS. We need Link code's generation to connect Local code and LOINC code for Automated LOINC mapping.

Logical Observation Identifier Names and Codes

The Logical Observation Identifier Names and Codes (LOINC) code set is the only publicly available universal standard for laboratory test names [7-9]. The current version of the LOINC code set, maintained by the Regenstrief Institute, contains more than 33,000 observations. Each LOINC record corresponds to a single test result and includes fields for specifying component (analyte), property measured, timing, type of scale, and, where relevant, the method used to property measured, timing, type of sample, type of sample, type of scale, and, where relevant, the method used to produce the result. Therefore, each LOINC code has up to six attributes and belongs to a class or group (e.g., Chemistry, Microbiology). The purpose of the LOINC is to facilitate the exchange and pooling of results, such as blood hemoglobin, serum potassium, or vital signs, for clinical care, outcomes management, and research [10,11].

Local Terminology

The Local Terminology (LT) being utilized is organized in the form in which alphabetic code or acronym of classification codes are documented and expanded into a numeric code based on an independent classification system (Figure 1)

Table 1 – LOINC specimen abbreviation to available in LOINC database

Specimen code	Specimen code name	LOINC specimen abbreviation
A0	Blood, Plain tube	SER/PLAS
C0	Body fluid	FLD
C4	Cerebrospinal fluid(CSF)	CSF
C7	Body fluid, gastrointestinal	GAST
C8	Joint(synovial) fluid	SNV
CB	Peritoneal(ascetic) fluid	PRT
CC	Pleural fluid	PLR
Y0	Urine	UR

This is the form most commonly used by majority of HIS being operated based on RDBMS. LT is linked with specimen code more than one in single laboratory code [12]. However, LOINC must recognize by laboratory test that same test is different if specimen is different. Therefore, we created link code so that compose of LT and specimen code. As a result, LT could correspond with LOINC code (Fig. 1).

Lab. Code	Specimen code	Specimen code name	Tube code	tube	unit
LCLDH	A0	Blood, Plain tube	55	SST tube	IU/L
LCLDH	C0	Body fluid	37	Plain tube	IU/L
LCLDH	C4	Cerebrospinal fluid	37	Plain tube	IU/L
LCLDH	CC	Pleural fluid	37	Plain tube	IU/L
LCLDH	Y0	Urine	28	Culture cup	IU/L

LCLDHY0

Figure 1- LT of PNUH and formation of Link code for LOINC

Development tools

For the purpose of this study, in order to map and simulate the LT being used at a university hospital with the LOINC, Oracle 10g DBMS Version 10.0.2, a relational database management system by Oracle was installed on a PC. In addition, for development and management of an efficient database, Toad for Oracle Freeware Version 8.0.5.5 by QuestSoft was used as a Database Managing Tool and for development to User Interface of the application for viewing LIS (Laboratory Information System) results, Visual Basic 6.0 Enterprise by Microsoft was utilized.

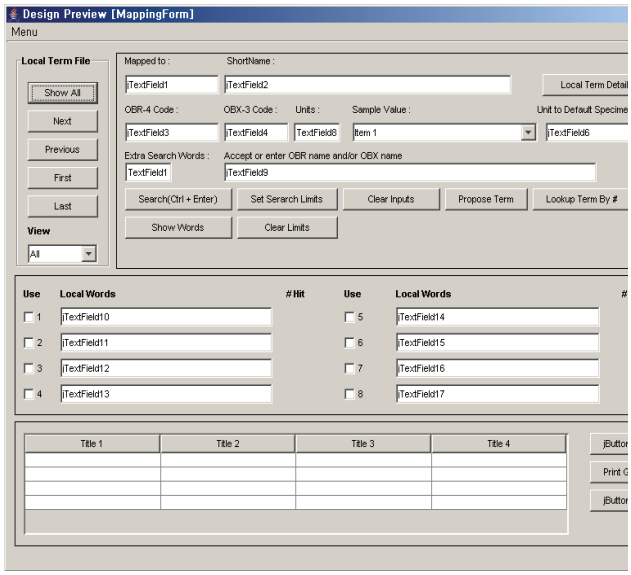

Figure 2- Screen capture of original mapping program, in mapping process

Natural Language Processing

The above figure represents the natural language processing. In this process, there are two steps such as normalization process and words index. Normalization process is get local terminology as input, it convert this string to uppercase string. And then process split string into array of words, and eliminate all of special characters such as ‘, “, ?, etc. Eventually, the process will give array of words as result [12, 13].

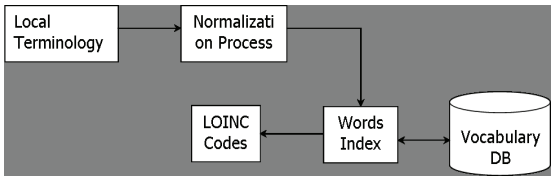

Figure 3- Natural language process

The words Index process gets result of Normalization process as input data. Each word is used in order to look for LOINC within Vocabulary database. Eventually, the output is LOINC that related to LT. In the summary, the natural language processing is used for looking for all of LOINC that related to Local terminologies.

ABY	1017-3
ABY	1018-1

Figure 4- Results of Natural language process

Vocabulary database includes LOINC table, keywords table, hierarchy data, and so on. The keywords table is called dictionary. The words index process use keywords table in order to look for LOINC.

Results

137 codes (excepted battery item of 183 Link code) did automatic mapping by results of 133 (97%). The failed Link code did Mapping in LOINC manually. Table 2 is result for automated LOINC mapping tools.

Table 2- Result for automated LOINC mapping tools

Specimen code name	**Code Link**	**LOINC**
Body fluid	LCLDHC0	22989-1
Cerebrospinal fluid(CSF)	LCLDHC4	22958-7
Body fluid, gastrointestinal	LCLDHC7	22989-1
Joint(synovial) fluid	LCLDHC8	23141-3
Peritoneal(ascetic) fluid	LCLDHCB	22989-1
Pleural fluid	LCLDHCC	23019-5
Urine	LCLDHY0	22958-7

This study was conducted in order to identify a method for efficient information exchange between disparate systems through informationalization of massive medical data that are stored in independent HIS. For the purpose of the study, 183 chemistry codes being utilized at a university hospital were randomly selected and mapped with LOINC, and as can be seen in Table 2, in a single examining room UI, independent use of LT or LOINC is possible, and mixed use is also possible. At this time, items that are displayed to the user are only partially shown, and because information that are internally hidden includes various types of information as seen possibility of efficient information exchange with a disparate system was verified.

Therefore, user convenience in an independent HIS can be secured by utilizing a LT and information exchange with disparate systems can be accomplished by utilizing the HL7 Interface Engine of the LOINC.

Discussion

In this study, by mapping diagnosis results codes and their expression methods that are currently being utilized in hospitals with standardized codes, a fundamental study for standardized information sharing of medical information and Evidence Based Medicine was conducted. Of all medical records, medical diagnosis result is the most objective information that provides reliable data. LT being independently used in hospitals can be applied and utilized various ways within each hospital, but because the vocabulary system of each hospital are completely different, diagnosis results of one facility cannot be used directly at another facility. In order to extract and exchange the massive amount of information stored within medical information systems as knowledge information, a study on a method for efficiently utilizing a standardized vocabulary system must be conducted.

An applicability of a standard vocabulary system was evaluated by mapping an LT of a hospital system with LOINC, an international standard coding system; and rather than terminating the study at standardization of codes, a database was designed to maintain their 6 axial forms so that the information to be exchanged can remain their compatibility. Driven by development of information technology and specialization of medical technology, importance and need for real time remote diagnosis and exchange of medical information between hospitals are increasing. This study is scientifically significant because it serves as substantial basic work for electronic data exchanges in the medical environment.

RxNav: Towards an Integrated View on Drug Information

Kelly Zeng, Olivier Bodenreider, John Kilbourne, Stuart Nelson

U.S. National Library of Medicine, NIH, Bethesda, Maryland, USA

RxNav[1] is a browser for *RxNorm*[2], a controlled vocabulary of normalized names for clinical drugs. *RxNav* displays links from clinical drugs, both branded and generic, to their active ingredients, drug components and related brand names. The current dataset (March 1, 2007) comprises 5,604 ingredients, 11,363 brand names, 13,509 clinical drug components, 17,726 clinical drugs, 14,064 branded drugs, 13,460 branded drug component, 8,311 clinical drug forms, 11,033 branded drug forms and 140 dose forms. *RxNorm* is one of a suite of designated standards for use in U.S. Federal Government systems for the electronic exchange of clinical health information.

RxNav was first developed as an interface to the *RxNorm* database and was thus restricted to displaying relations among drug names. However, besides terminology, other drug-related information could be displayed in and integrated through *RxNav*, including pharmacologic action, drug-drug interactions, indications and contraindications, adverse reactions, etc. RxNav could also provide better integration with other drug information such as the drug labeling resource *DailyMed*[3]. We give a brief review of some of the changes planned for *RxNav* in the near future, with the objective of ultimately providing an integrated view on drug information.

Equivalent names and codes

RxNorm covers many of the drug vocabularies commonly used and organizes the different names for a given drug entity into a concept. Because of intellectual property restrictions imposed by some sources, *RxNav* only displays the normalized name created by *RxNorm* for a given entity. A new function will soon be added to *RxNav*, allowing users who have obtained the required licenses to access the name of drug entities in specific sources to find equivalences between drug names across sources. Examples of equivalent names include “Acetaminophen”, “APAP”, and “Paracetamol”, whose corresponding equivalent codes include RXCUI:227257, BRAND_CODE:2177, etc.

Clinical information from UMLS source vocabularies

While most curated clinical information about drugs is compiled in proprietary knowledge bases, some of it is publicly available through resources such as the NLM’s *Medical Subject Headings* (MeSH) and the Veterans Administration’s *National Drug File Reference Terminology* (NDF RT). *MeSH* provides information about pharmacological action and *NDF RT* about indications and pharmacokinetics. Like *RxNorm*, both *MeSH* and *NDF RT* are source vocabularies in the *Unified medical Language System* (UMLS) Metathesaurus, making it easy to integrate the information they provide.

Links from RxNav to applications

Because it already provides an interface to drug names, with services such as specific spelling correction and correspondence between equivalent names, RxNav will provide an excellent entry point to applications such as the drug labeling resource *DailyMed* and medication list applications developed as part of personalized health records (e.g., *MyMedicationList*).

Semantic Interoperability and SNOMED CT: A Case Study in Clinical Problem Lists

James R. Campbell M.D.[a],

Alejandro Lopez Osornio M.D.[b]

Fernan de Quiros[b], Daniel Luna[b], Guillermo Reynoso[c]

[a]University of Nebraska Medical Center, Omaha, NE

[b]Departamento de Información Hospitalaria, Hospital Italiano de Buenos Aires, Argentina

[c]Conceptum, Buenos Aires, Argentina

University of Nebraska Medical Center

Hospital Italiano de Buenos Aires

Abstract

Sharing clinical data between institutions requires a shared semantic model and reproducible metrics for comparing post-coordinated clinical record data. We evaluated the interoperable features of SNOMED CT by merging and comparing SNOMED problem list dictionaries between primary care sites in Nebraska and Argentina.

The two problem subsets had modest differences in semantic content, but differed substantially in frequency of post-coordinated content. 64.3% of the final merged problem vocabulary was post-coordinated. 0.9% of the merged concept set was found to have semantic duplication. Classification employing SNOMED Normal Forms was found to effectively identify semantic equivalency in 65.2% of cases studied.

The most frequent reasons for failure of the classification procedures included: post-coordination not compliant with SNOMED guidelines (28.8% of cases), conflicting guidance presented in SNOMED pre-coordinated content (3.6%), unclear definition of source clinical concepts (1.2%), and limited expressiveness of the SNOMED definitional model (1.2%).

We conclude that interoperable post-coordination employing SNOMED CT is feasible, but that better dissemination of SNOMED editorial guidelines, refinement of the concept model and training of the user community will be required for reproducible and reliable implementation.

Introduction

- Semantic interoperability requires that advanced compositional vocabularies such as SNOMED CT[1] support computation of equivalence between post-coordinated concepts authored at disparate sites
- Advancing to multi-national status with formation of a new international standards development organization[2], SNOMED CT must reliably support interoperability world-wide
- We analyzed the validity of algorithms for testing of semantic equivalence while comparing SNOMED problem lists at two institutions

Methods: Study sites

- University of Nebraska Medical Center; Omaha, NE, USA

  Clinics of the University of Nebraska Medical Center employ the GE Centricity Enterprise record which includes problem list and assessment functions with SNOMED CT as coding reference. Employing "just-in-time" post-coordination[3], UNMC has developed an extension to SNOMED CT which includes 6% post-coordinated concepts within a problem data dictionary of 9800 concepts and 14500 interface terms.

- Hospital Italiano; Buenos Aires, Argentina

  Hospital Italiano is a non-profit university hospital, associated with a large network of ambulatory care services, located in Buenos Aires, Argentina. Hospital Italiano employs a health information system developed in-house including an institution wide electronic medical record supporting all levels of care. Clinical data entry uses a local interface terminology for diagnosis and procedures. This terminology was created from 2 million terms of free text recorded by local users in legacy systems. Every concept from the terminology has been coded with SNOMED CT. Current Hospital Italiano terminology has 24,800 concepts and more than 100,000 interface terms, with approximately 70% post-coordinated content.

Methods

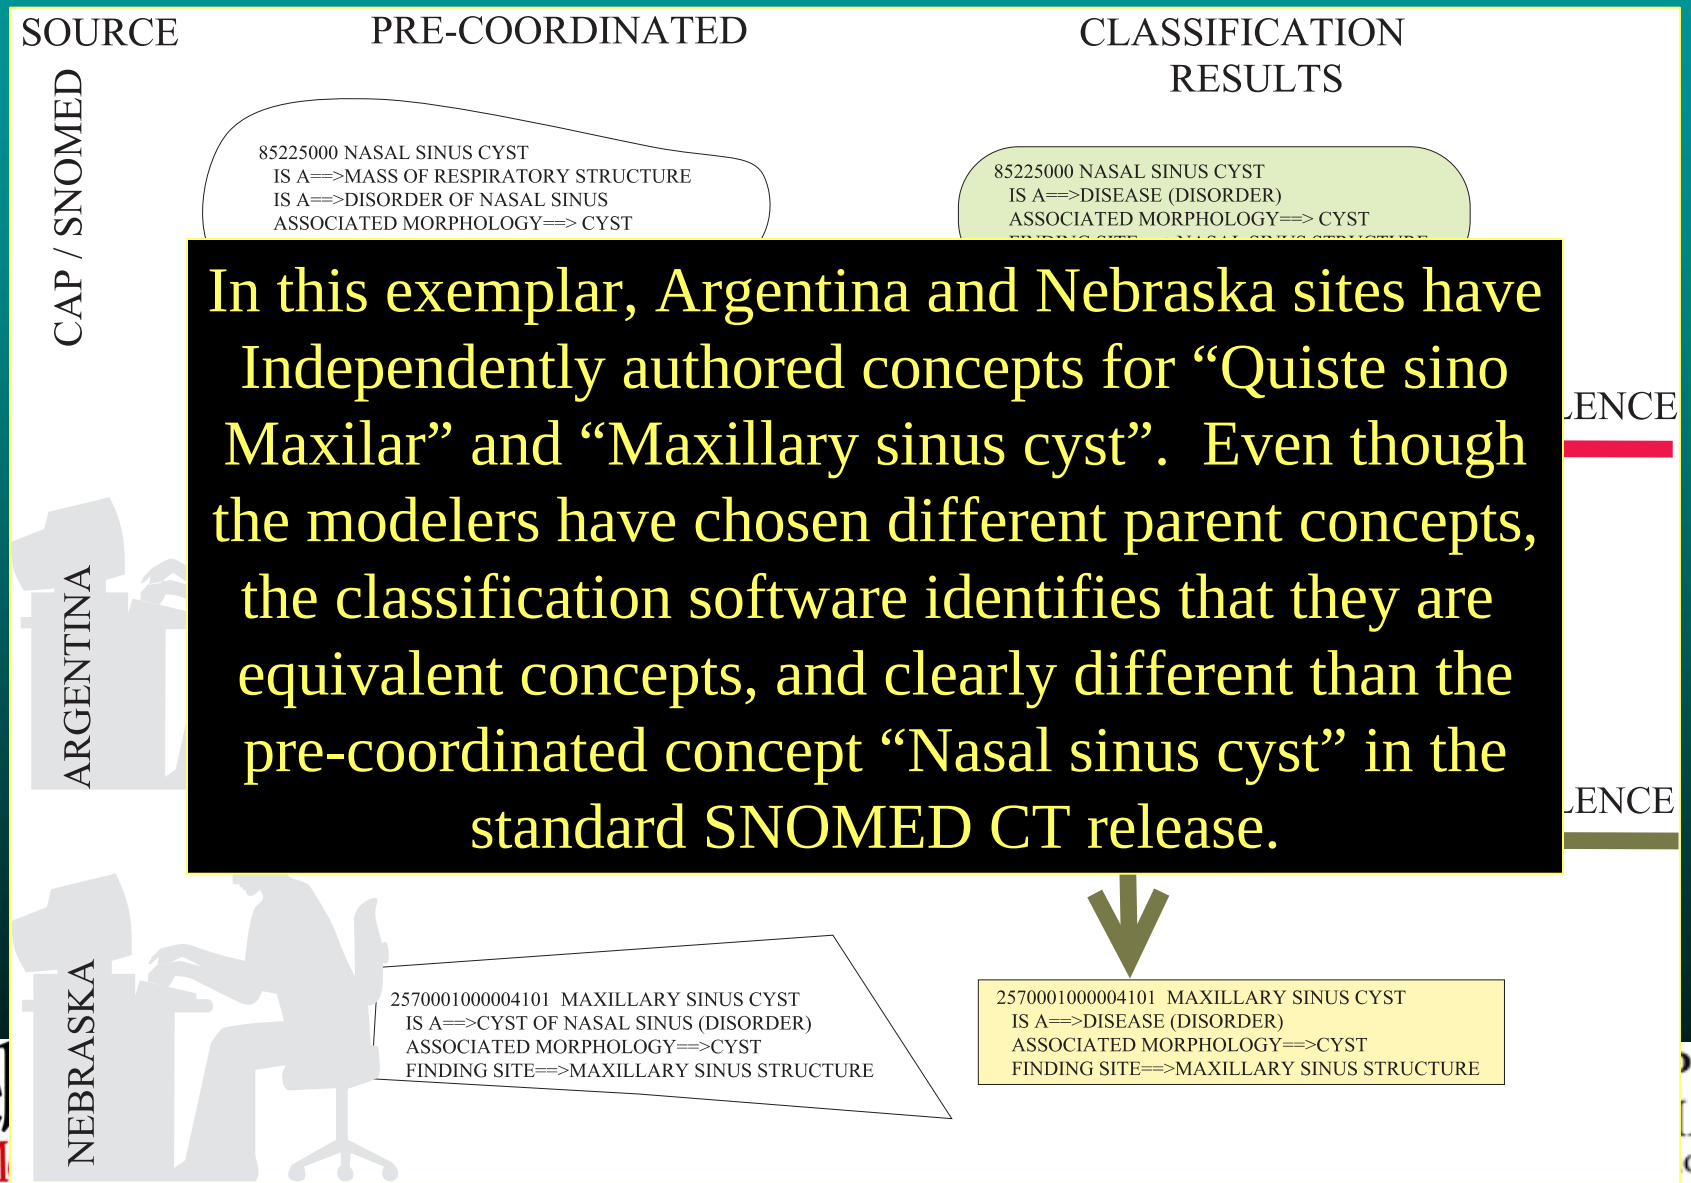
- SNOMED CT problem lists were merged and compared in order to develop a shared problem list vocabulary for primary care
- The merged concept inventory was processed with a classifier compliant with SNOMED guidance[5] in order to compute Long Normal Forms[6] for each concept

Methods

A sample of the classifier output was systematically evaluated by the authors:

1) verifying the intended meaning in the original concept term
2) verifying SNOMED editorial guidance for modeling of the meaning
3) validating the post-coordinated concept against published SNOMED editorial principles[4]
4) verifying true synonymy of content where asserted by the classifier
5) assessing for “hidden synonymy” against concepts classified as unique by intensive review of related concepts and alternative post-coordination strategies.

Classification and comparison of post-coordinated concepts



Results

	Nebraska	H Italiano	Merged
Pre-coordinated	9734 (94.3%)	7666 (23.7%)	14069 (35.7%)
Post-coordinated	585 (5.7%)	24727 (76.3%)	25312 (64.3%)
Total concepts	10319	32393	39381

Problem list subsets at the two institutions were notably different in concept inventory, frequency of post-coordination and semantics. This table summarizes the number of concepts at each institution that were pre- and post-coordinated.

Results

	Nebraska	H Italiano	Merged
Disorders	7467 (72%)	15891 (65%)	20633 (66%)
Findings	1372 (13%)	3516 (27%)	7328 (23%)
Events	30 (0.3%)	82 (0.3%)	104 (0.3%)
Procedures	1098 (10.6%)	112 (0.5%)	1201 (3.8%)
Situation w/ explicit context	339 (3.2%)	864 (3.5%)	1178 (3.7%)
All other	(0.9%)	(3.7%)	3.2%)

This table summarizes the differences in SNOMED semantic inventories between the two institutions and the merged problem list subset. Note that Nebraska employed more procedure history and Hospital Italiano more findings.

Results

Failure of post-coordination	
Vague source concept utterance	3 (1.2%)
Limited expressiveness of SNOMED model	3 (1.2%)
Conflict of SNOMED guidance	9 (3.6%)
Non-compliance with SNOMED editorial guidelines	72 (28.85)
Subtotal of classification errors	87 (34.8%)
Masked synonymy	3 (1.2%)

We sampled 250 concepts classified as unique from the merged subset and systematically evaluated the post-coordination and classification output for accuracy. Our review supported reasonable and accurate performance of semantic equivalency testing in 64.8% of cases. This table summarizes the problems we identified during detailed study of the classifier analysis of post-coordinated concepts.

Discussion / Conclusion

- Studies have demonstrated the limitations of conventional classifications and confirmed the requirements of compositional forms to deal with an ever expanding clinical knowledge base[7]
- Our research supports the utility of SNOMED Normal Forms for comparing disparate data sets, however…
- The greatest deficiency we identified in post-coordination was inconsistent behavior in the data modeling staff at the two institutions
- Furthermore, the SNOMED standards board must extend support for post-coordination by:
  - Addressing consistency within the SNOMED CT data model
  - Document and disseminate SNOMED data model standards
  - Promoting open discussion and training in SNOMED use
  - Providing clear guidance supporting reproducible and understandable post-coordination algorithms

Abstract

Sharing clinical data between institutions requires a shared semantic model and reproducible metrics for comparing post-coordinated clinical record data. We evaluated the interoperable features of SNOMED CT by merging and comparing SNOMED problem list dictionaries between primary care sites in Nebraska and Argentina. The two problem subsets had modest differences in semantics, but differed substantially in frequency of post-coordinated content. 64.3% of the final merged problem vocabulary was post-coordinated. 0.9% of the merged concept set was found to have semantic duplication. Classification employing SNOMED Normal Forms was found to effectively identify semantic equivalency in 65.2% of cases studied. The most frequent reasons for failure of the classification procedures included: post-coordination not compliant with SNOMED guidelines (28.8% of cases), conflicting guidance presented in SNOMED pre-coordinated content (3.6%), unclear definition of source clinical concepts (1.2%), and limited expressiveness of the SNOMED definitional model (1.2%). We conclude that interoperable post-coordination employing SNOMED CT is feasible, but that better dissemination of SNOMED editorial guidelines, refinement of the concept model and training of the user community will be required for reproducible and reliable implementation.

Keywords:

controlled terminology, Systematized Nomenclature of Medicine, semantic interoperability

Introduction

Semantic interoperability denotes the ability of two different clinical information systems to seamlessly share clinic record content and recognize meaning within and between those records. Semantic interoperability requires standardized coding of conceptual content as well as understanding of the information model employed by the clinical systems. Interoperability requires that the system be able to recognize equivalence between post-coordinated concepts developed at different clinical sites by different authors.

SNOMED CT is an advanced terminology supporting post-coordination. It is demonstrably the most comprehensive and useful clinical reference terminology available to vendors today. Under the governance of a new international standards organization, it is poised to support interoperability of clinical systems within and between those nations where it is deployed.

While organizing and characterizing the semantic features of a shared SNOMED CT problem list for primary care, we analyzed for equivalence in clinical concepts authored by separate clinicians working on two continents. From systematic study of classifier data, we identified similarities and differences in our practices, and discovered issues for the interoperable deployment and use of SNOMED CT.

Methods

Study sites

Clinics of the University of Nebraska Medical Center employ the GE Centricity Enterprise record which includes problem list and assessment functions with SNOMED CT as coding reference. Employing "just-in-time" post-coordination, UNMC has developed an extension to SNOMED CT which includes 6% post-coordinated concepts within a problem data dictionary of 9800 concepts and 14500 interface terms.

The Hospital Italiano of Buenos Aires is a non-profit university hospital, associated with a large network of ambulatory care services, located in Buenos Aires, Argentina. Hospital Italiano employs a health information system developed in-house including an institution wide electronic medical record supporting all levels of care. Clinical data entry uses a local interface terminology for diagnosis and procedures. Every concept from the terminology has been coded with SNOMED CT. Currently Hospital Italiano terminology has 24,800 concepts and more than 100,000 interface terms, with approximately 70% post-coordinated content.

In order to collaboratively develop a SNOMED CT subset to support problem lists for primary care, UNMC and Hospital Italiano merged and compared their SNOMED data dictionaries, evaluating for similarities of content. Frequency of use statistics for concept codes were further compared in order to identify useful SNOMED concepts for inclusion in a standardized problem subset. This merged problem subset comprised the source content used for this study.

SNOMED post-coordination and classifier software

Post-coordination refers to the definition (or modeling) of a concept that is required for clinical recording but which is not found in the standard SNOMED CT release. Post-coordination requires the concept to be compared to the SNOMED CT definitional model. Relationships and attribute values are chosen to encode the required meaning, and the new post-coordinated concept is employed in the vendor SNOMED extension.

Due to the richness of the SNOMED model, two or more alternative post-coordinated expressions are often possible. In order to support equivalence testing between these alternatives,

SNOMED CT provides technical guidance for the development of classifier software which will convert SNOMED expressions to Normal (Canonic) forms for comparison. Comparing the Normal Forms of two user concepts allows for a computable determination whether the two are synonymous or unique. Classification software systematically computes normal forms for all concepts within a set and determines the relationship of concepts to each other within the taxonomy while identifying synonymous content.

Problem list classification

We compared the separate SNOMED CT subsets representing problem list coding at the two institutions, first characterizing the shared pre-coordinated content and then analyzing post-coordination. Classifier software developed at UNMC was employed to compute Normal Forms for all concepts in the merged set. We identified synonymous concepts by comparing classifier results and assessed the validity of post-coordination of concept samples from both sites. We searched for masked synonymy employing exhaustive editorial search within the merged problem set.

Results

Problem list subsets at the two institutions were notably different in concept inventory and frequency of post-coordination. Only minor differences in local problem list recording habits were reflected in the semantics of the SNOMED CT use at the two institutions, reflecting more frequent recording of procedure history at the Nebraska site. Clinical disorders, findings and events were the majority of concepts in use, while "past medical history" and "family history" concepts, occurred regularly at both institutions.

The Normal Form was computed for 31,382 concepts in the merged subset. 293 concepts were identified as duplicating concept meaning with other subset members including 9/578 (1.6%) of Nebraska post-coordination, 281/16807 (1.7%) of Hospital Italiano post-coordination, and 3 cases in which a Nebraska concept was identical in meaning with a concept from Hospital Italiano.

Table 1 summarizes the issues we identified during detailed study of the classifier analysis of post-coordinated concepts.

Table 1 – Analysis of post-coordination / classification errors

Failure of post-coordination	
Vague source concept utterance	3(1.2%)
Limited expressiveness SNOMED model	3(1.2%)
Conflict of SNOMED guidance	9(3.6%)
Non-compliance with editorial guidelines	72(28.8%)
Total classification errors	87(34.8%)
Masked synonymy	3(1.2%)

Discussion

Clinical reference terminologies employing features of ontologies create new opportunities for interoperability of clinical systems, but they also lead to a new set of challenges. Experience at the two sites presented in this paper confirms that the organizational and information science approach of the enterprise can lead to rather different needs for support and maintenance of post-coordination.

Assuring that post-coordinated data sets interoperate requires attention to many details. It is especially challenging at this time when the technology of clinical systems such as SNOMED CT are evolving. While our research supports the utility of SNOMED Normal Forms for comparing disparate data sets, reliable and consistent results require that information system managers have well trained and consistent data modeling staff. This was the greatest single deficiency identified in our analysis and accounted for the largest variation from expected results. The SNOMED standards board must extend support to the enterprise employing post-coordination by addressing consistency within the SNOMED CT data model. But even more important for post-coordinated data management is dissemination and documentation of the SNOMED data model standard, promotion of open discussion and training in SNOMED use, and provision of clear guidance supporting reproducible and understandable post-coordination algorithms.

Sustainable Health Systems: Using Metadata Registries with Nursing Terminology

LuAnn Whittenburg, Virginia K. Saba

University of Maryland

Abstract

Health data and information sharing using a metadata registry promotes cross-system and cross-organization descriptions of common units of health data and allows nurses, health administrators, and hospital systems to make significant strides towards sustaining health system information systems. Metadata registries contribute to patient safety, efficient and successful electronic health record system implementation, and lower of healthcare costs in electronic health record system implementations by avoiding multiple data translations and mapping, data duplication and messaging errors.

Keywords:

Clinical Care Classification; terminology, nursing, metadata, registry, CCC, health systems

Introduction

The online metadata registry with an organization's strategic plan allows healthcare organizations to share data in a common format with descriptions of common units of health data and demonstrate actual resources, cost, patient management and outcomes. Metadata information in the United States Health Information Knowledgebase (USHIK) contains the Clinical Care Classification System (CCC) developed by Saba and Colleagues which encompass assessments, diagnoses, interventions, actions, and the actual and expected outcomes for describing, communicating and evaluating interdisciplinary practice within the electronic documentation of nursing practice.

Materials and methods

In healthcare organizations, with disparate data elements collected for many departments in different presentation formats on various electronic system screens, the ability to provide efficient patient management information that is sustainable in a health system requires standardized data elements. Data standardization increases the cross-system and cross-organization comparison of clinical

information. In an electronic health record (EHR) and in Computerized Provider Order Entry (CPOE) systems; the selection of a common data format, e.g. metadata is the vital component.

As of October 2006, the Health Information Technology Standards Panel (HITSP) sponsored by the American National Standards Institute (ANSI) with funding from

The Office of the National Coordinator for Health Information Technology, United States Department of Health and Human Services mandated by Executive Order 13335 compliance with Health Information Technology Standards Panel standards that includes an initial Nursing Terminology: Clinical Care Classification system; a nursing terminology available in the United States Health Information Knowledgebase (USHIK) (www.ushik.org). In the United States Health Information Knowledgebase public and private organizations have access to Standard Development Organizations data elements about what nurses' chart and manage.

Results

A metadata registry harmonizes information formats even though data needs change. A controlled clinical vocabulary, e.g. the Clinical Care Classification system (CCC) is the key to measuring outcomes, improving patient safety, reducing error rates, and lowering cost. Technology puts nursing at the bedside and nursing terminology promotes evidence-based medicine and sustainable health systems.

Conclusion

A metadata registry allows an organization to review specific disease management practice guidelines by location and decreases the variations in disease screening; 2) allows the comparisons of the process of care delivery and promotes the transformation of a health information system into a unit management information system; 3) consolidates redundant health data and standardizes data elements and attributes with each organization; and 4) supports the 'Magnet' concept of the American Nurses Association for data driven organizations. The United States Health Information Knowledgebase is excellent source to use within multi-hospital systems to compare and harmonize interventions, results and outcomes. USHIK enables the browsing, comparison, synchronization and harmonization of facts about health data in a uniform query and interface environment that allows nurses to identify and manage multiple data elements in an electronic health record.

A metadata registry is a place to keep facts about characteristics of data that are necessary to clearly describe, inventory, analyze, and classify data.

A metadata registry supports data sharing with cross-system and cross-organization descriptions of common units of data.

A metadata registry promotes a common understanding of shared data by unit of data meaning, representation and identification.

Value of Lessons Learned to Nurses and Nursing Standards Development Organizations

- Standards have multiple means of versioning (e.g. major / minor numbering, re-release with corrections) and multiple versions available at any one point in time
- Workload entailed in loading different identified items varies widely due to the different levels of standardization
- A large amount of effort required in grooming the metadata to fit into the standard format as most exciting metadata does not exist in any kind of standard format
- Once in USHIK - standards data can be used many times

Value of Lessons Learned to Nurses and Nursing Standards Development Organizations

- New standards versions do not identify a delta (difference) between the versions, so a metadata difference analysis must be determined

- Many points for data errors with a tremendous quality assessment responsibilities to analyze the standard, determining the differences between versions, format the metadata, and enter the health information technology standard data elements

- Metadata analysis reveals standards may require change to correct errors:
  - Changes may be in the structure of the standard
  - Changes may have a cascading affect that may change data meanings
  - Changes must be reviewed to determine if data element still meets the needs of the Nursing Community of Interest

Relationship of Health Metadata Registries

UMLS: National Library of Medicine Unified Medical Language System (UMLS) project develops and distributes multi-purpose, electronic "Knowledge Sources" and associated lexical programs for system developers. Researchers will find the UMLS products useful in investigating knowledge representation and retrieval questions."

Used to: Research terms and phases to use in developing definitions for data element concepts or data elements.

USHIK "The United States Health Information Knowledgebase (USHIK) provides and maintains a metadata registry of health information data element definitions, values and information models that enable browsing, comparison, synchronization and harmonization within an uniform query and interface environment."

Used to: Publish data elements or designate the group of standards that meet functional requirements and that registration organizations want public and private organizations to use for the adoption of health information technology standards

Next Steps

- *Eliminate a barrier to health data interoperability by matrix comparison of nursing data elements for the Customer – Centered Electronic Health Record*

- Educate on the United States Health Information Knowledgebase (USHIK) health metadata standards

- *Maintains the USHIK document registry of all historical documents of record behind a data analysis (metadata of terms & definitions)*

The Use of UMLS to Establish a Mediation Terminology for Exchanging Patients' Allergy Profiles between two U.S. Federal Agencies' Electronic Health Records

Nhan V. Do[a], Fola Parrish[a], Omar Bouhaddou[b], Pradnya Warnekar[b], Nancy Orvis[a]

[a]*Department of Defense, Tricare Management Activity, Falls Church, Virginia, USA*
[b]*Department of Veterans Affairs, Salt Lake City, Utah, USA*

Abstract and objective

Recognizing that interoperable health information system can lower costs, reduce medical errors, and improve quality of care, the Department of Veterans Affairs (VA) and the Department of Defense (DoD) are working towards seamless sharing of real-time clinical data between the respective agency's Electronic Health Records (EHR). One strategy to achieve this goal is through the mapping of the two agencies' proprietary terminologies to standard vocabularies. However, the difficulty is that most terminologies are not fully mature to adequately cover the allergy domain. This paper describes the process of using the Unified Medical Language System (UMLS) to derive a mediation code set for exchanging patient's allergy profile. With our initial effort, 84% of allergens sent by the VA are successfully mediated, computed on, and stored in the DoD's Clinical Data Repository (CDR) and 82% of allergens sent by the DoD are successfully mediated by the VA's Health Data Repository (HDR).

Keywords:

unified medical language system, electronic health records, computerized/* terminology standards, allergy and immunology/*standards

Introduction

Having interoperable health information systems has been recognized as a necessary step toward improving the quality of health care, reducing medical errors, and controlling costs. Over the past decade the VA and the DoD have been making great efforts at sharing the health information of their mutual beneficiaries. In 2004, the VA and the DoD successfully prototyped the Clinical Health Data Repository (CHDR) application for the exchange of codified patient data. Through this application, health information can be transferred and stored at the other agency's clinical data repository as computable data which then can be used in clinical decision support applications. In 2006, the two agencies continued to improve upon this prototype to exchange medication and allergy profiles. Patient safety researchers have pointed out that giving patient medication that they are known to have an allergy against is one important and preventable cause of adverse drug events. Since no designated set of standards exist for the allergy domain at the initial start of the CHDR project, the two agencies evaluated the use of UMLS to mediate the two agencies patient's allergy lists.

Methods

The DoD extracted a set of UMLS Concept Unique Identifiers (CUIs) associated with RxNorm concepts. RxNorm alone does not provide adequate coverage of the allergy domain because it does not contain a semantic type for drug classes. However, the DoD used RxNorm concepts as the initial effort to harvest UMLS CUIs already mapped to RxNorm. Automated mapping between the DoD's allergen file and the RxNorm concepts was made through exact string and lexical variants matching. When there were one-to-many matches, terminology subject matter experts manually set a precedence flag. The VA extracted its mapping to CUIs directly from the UMLS metathesaurus. Independent experts reviewed the two mapping tables side-by-side and identified any discrepancies. The System Acceptance Testing (SAT) for CHDR was carried out at William Beaumont Army Medical Center, El Paso Texas during the period of September 11-15, 2006.

Results

The mapping tables contained respectively 7157 and 8358 allergens for the VA and the DoD. The expert review of the 1924 common concepts identified less than 3% discrepancies which were resolved. The majority of the vocabulary differences were due to the use of generics and brand names and ingredient base or salt forms. The SAT indicated that 84% of allergens that are sent from the VA to the DoD are successfully mediated, computed on, and stored in the DoD's CDR and 82% of allergens that are sent from the DoD to the VA are successfully mediated, computed on, and stored in the VA's HDR.

Conclusion

The Consolidated Health Informatics panel has now recommended a set of terminologies to cover the allergy domain: FDA UNII codes for drug ingredients; RxNorm for brand names (which have relationships to generic names), NDF-RT for drug classes. However, the FDA UNII codes are incomplete and not ready for implementation. The VA-DoD patient exchange project has demonstrated that the use of UMLS is an effective mediation standard for the drug allergy domain.

Interoperability and Security: Design and Development of a Clinical Documents Repository Digitally Signed using CDA Standard

Fernán González Bernaldo de Quirós, Adrián Gómez, Fernando Campos, Jorge Severino, Fernando Plazzotta, Daniel R. Luna

Medical Informatics Department, Hospital Italiano of Buenos Aires, Argentina

Abstract

The amount of institutions with hospital information systems has increased. Different technologies and standards available makes possible to satisfy many information exchange needs. HL7's CDA is a marked-up document standard, which specifies the structure and the semantics of a clinical document. Digital Signature is a tool that guarantees the authorship and integrity of electronic documents. The Hospital Italiano of Buenos Aires, has developed and implemented a CDA documents repository along with the creation of its own PKI infrastructure, obtaining then a trustworthy and unique registry of the medical acts, making possible the access to documents in a format that allows full legibility, also allowing process and later inclusion of this information in other systems or applications, guaranteeing its authorship and integrity.

Keywords:

medical records systems, computerized,
computer security, standards, electronic documents, digital signature

Introduction

The growth of hospital information systems, the information exchange needs and the proliferation of technologies implemented on the Internet, allowed medical documents to be shared and exchanged between organizations, hospitals and healthcare providers [1]. This made possible the development of protocols and methods to assure medical information exchange in a standard format, increasing the possibilities of achieving semantic and syntactic interoperability.

One of the main standards families in health information systems setting is Health Level Seven (HL7). CDA stands for Clinical Documents Architecture and is a markup standard, which specifies the structure and the semantics of a clinical document. The present version is 2.0, is part of version 3 of HL7 standard and describes its semantic content in the Reference Information Model (RIM) [3].

On the other hand, paper documents have traditionally guaranteed its authorship and integrity by handwritten signature. In medical settings physicians records in paper and signs at the end of the chart. Each later registry must be signed, indicating the authorship and responsibility of any modification made from the previous signature.

When it comes to digital charts, the use of simple electronic signatures, like "username and password", does not fulfill all the requirements needed to replace the hand written signature.

Digital signature is a technological tool that guarantees the authorship and integrity of digital documents, giving them the same validity of those signed in paper.

In the present work we will describe the design, development and implementation process of a digitally signed clinical documents repository, created from an electronic health record, using CDA standard and the asymmetric key infrastructure (PKI - Public Key Infrastructure).

Materials and methods

Scenario

The Italian Hospital of Buenos Aires (HIBA) is a tertiary care, teaching and research hospital with a 150 year old history. Since 1998 a full scale HIS has been gradually implemented, including ambulatory Electronic Health Record (EHR), several health informatics standards had been implemented, including HL7, CDA 2.0, ICD-9CM, DRG and ICD10 [4].

Digital Signature legislation in Argentina

In 2001, bill number 25506 of "Digital Signature" was sanctioned, it essentially recognizes the use of digital and electronic signature, and its legal validity, allowing the truthfully identification of individuals making electronic transactions. This way, when a document requires a handwritten signature, that exigency is also satisfied by a digital signature.

This bill also describes in its fifth article the figure of electronic signature as an integrated electronic data set, related in a logical way to other electronic data, used by the signatory like his means of identification, which lacks some of the legal requirements to be considered digital signature [5].

Medical information security

Our project includes as a key issue the development of the security mechanisms needed to operate and maintain a decentralized medical record system, knowing that medical information security is based on five fundamental aspects:

- **Privacy**: medical information cannot be accessed by third parties not related to the attention process.
- **No Disavowal**: references the authorship of the document, only the person who possesses the digital signature is in charge of the generated and saved data.
- **Authenticity**: it refers to the character of authentic of a document, that is to say, that is the original one.
- **Integrity**: related to the previous one, talks about the content of the medical information preventing that it original content is altered.
- **Chronology**: directly related to integrity, allows keeping registry of the date and hour of the creation of the original information, thus giving the data a temporary sequence.

CDA documents creation

The information system of our institution, registers all the medical events generated in the health care process. The clinical document generation begins with the medical encounter or "health care event", for the outpatient setting is the aggregation of all the actions made (medical problems, medical progress notes, orders entered, clinical observations, pharmacologic prescriptions, date and hour).

For in patient and emergency settings, clinical document example is the epicrisis; and, in the case of information generated by ancillary services, each procedure inquired is equivalent to a health care event, reason why it generates a document, using the information made in the report system.

Once the health care event is stored into the clinical data repository (CDR), a web service is in charge of generating a CDA document. This service recovers the medical information recorded from the CDR and creates the document (a XML file). Then the user is asked to validate the information through a confirmation process and the document is digitally signed. This signed documents and its control parameters are stored in file data system.

Digital Signature of medical documents

HIBA took the initiative to create its own PKI by developing an "in house" application that makes possible to lead all the process of creation and administration of public and private keys and digital certificates.

In order to guarantee its integrity and authenticity, a digital document must fulfil three basic characteristics:

- Having a HASH to guarantee the document's integrity.
- Been signed with private and public key system, to guarantee its authorship.
- Having a Time Stamping service, that guarantees document's temporality.

In our project, public and private keys are stored in a cryptographic USB E-Token given to providers and it's asked for its insertion at the moment of the signature. The E-Token is an electronic component with USB (Universal Serial Bus) interface.

When a XML clinical document is created, the application calculates a single HASH value and encrypts it using the private key stored in the E-token. This encrypted file maintains its original information and the digital certificate [6].

The exact moment when the primary load of information happened is one of the most important variants, since the medical document existence at a certain moment in time must be determined in a safe way. We chose to generate a process of time stamping, which stores a digitally signed time registry with the document signed by the user.

Discussion

The summary of providers work, documented in a single XML file, adding Digital and Electronic Signature, provided by the E-token, will allow the creation of a trustworthy and unique registry of the medical acts.

On the other hand, current graphical interfaces, although provide improvements in usability and information visualization, does not correspond with the traditional charts in paper. Traditionally the professionals records their observations and findings in documents and then sign them. The implementation of CDA and Digital/Electronic Signature maintains this sequence.

Conclusion

The implementation of this solution allowed users to access laboratory results, imaging reporting, referral notes, discharge letters, progress notes, diagnoses, procedures and medical prescriptions, in a fully legible format and the possibility of information processing for its later inclusion in other information systems or related health care applications.

Documents visualization was personalized using XSL style sheets being able to render styles, typographies and icons recognized and validated by the institution. A time stamping service (also digitally signed), will allow temporality to this unique registry of medical acts.

CDA standard implementation with the aggregate of digital/electronic signature in an electronic health record is a true challenge, since it entails an important technological

and organizational impact. At this moment we are carrying out a pilot test for the completion of the system and the norms and procedures created to such aim.

HOSPITAL ITALIANO de Buenos Aires

Departament of Medical Informatics

Introduction

- Medical documents can be shared and exchanged
  - →Growth of hospital information systems
  - →Information exchange needs
  - →Proliferation of Internet technologies
- Standard formats - semantic and syntactic interoperability
  - →HL7, CDA

Introduction (cont.)

- Handwritten Signature
  - →Traditionally guaranteed authorship and integrity of paper documents
  - →Is written at the end of the document to prove that what is authenticated has not been modified
  - →Medical setting works by this same modality
- Impossibility of physically signing digital documents
  - →Simple electronic signatures can't replace handwritten signature
- Digital Signature guarantees authorship and integrity of digital documents
  - →Giving them the same validity of those signed in paper
  - →Uses mathematical processes to relate the signed document with information from the signing person

Objectives

- Describe the design, development and process of implementation of a clinical electronic documents repository digitally signed, using CDA standard and the asymmetric key infrastructure (PKI - Public Key Infrastructure).

Materials and Methods – Scenario

- Hospital Italiano de Buenos Aires (HIBA)
  - →Tertiary care, teaching and research hospital with a 150 year old history
  - →Since 1998 a full scale HIS has been gradually implemented
    - Including Ambulatory Electronic Health Record (EHR)
    - Several health informatics standards had been implemented, including HL7, CDA 2.0, ICD-9CM, DRG and ICD10

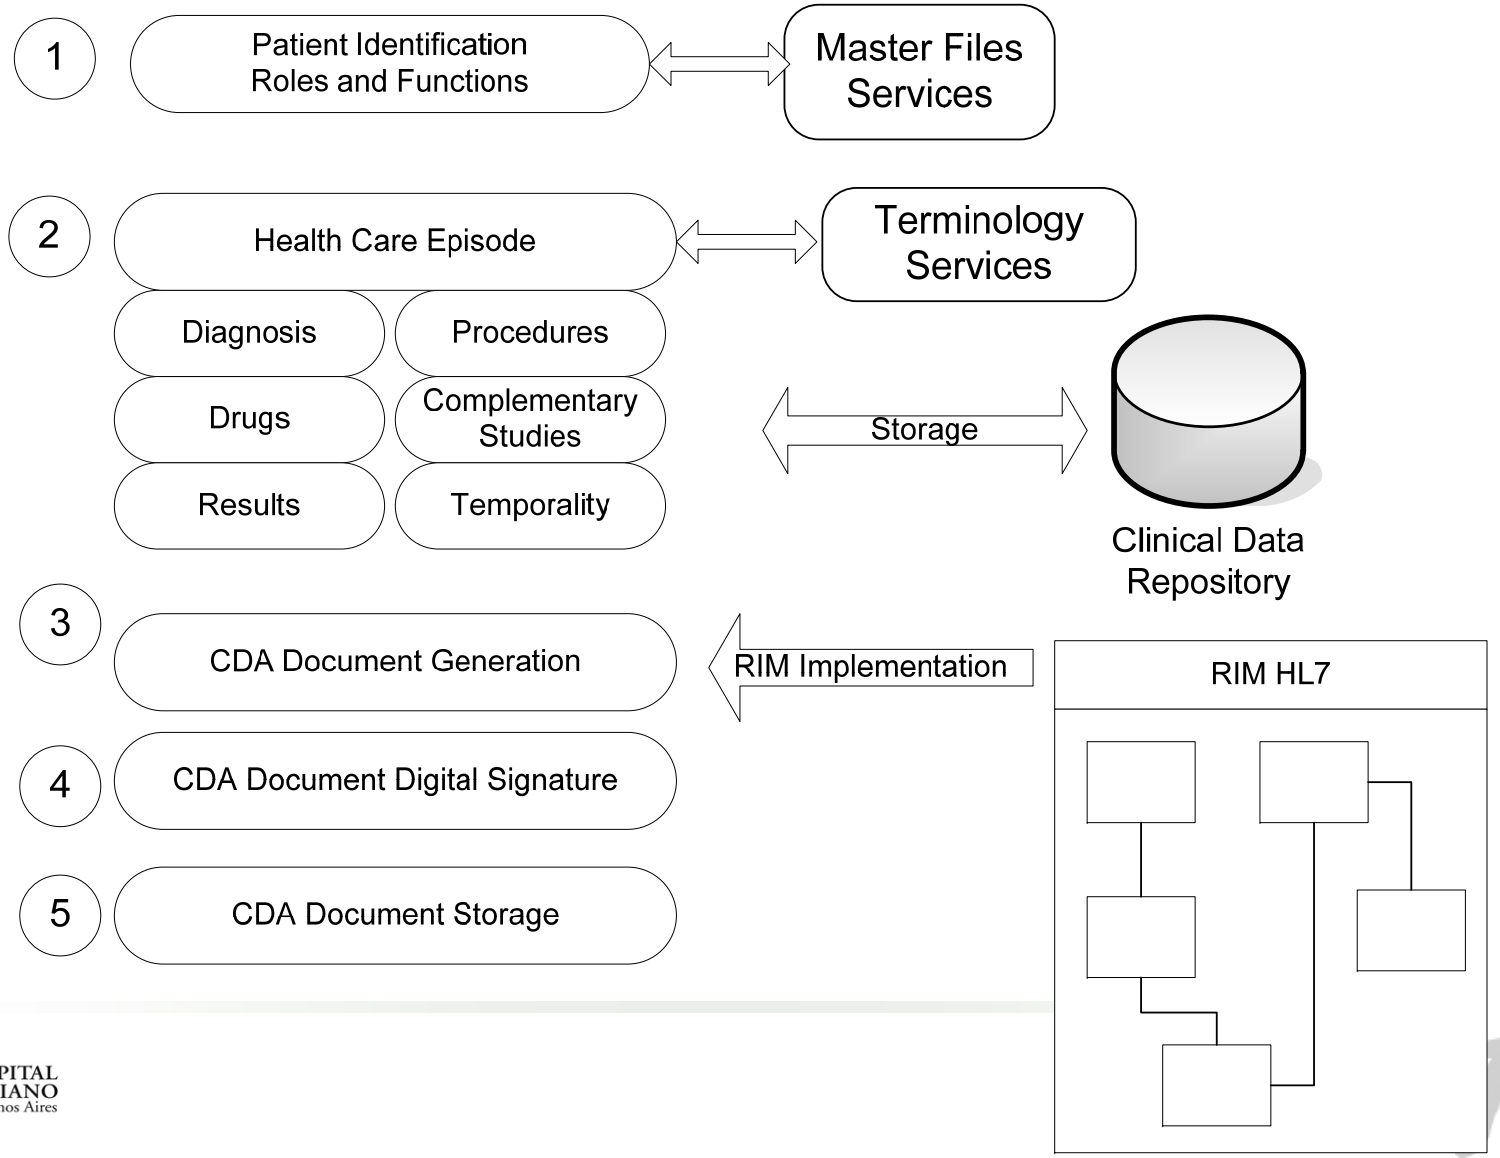
Digital Signature Legislation in Argentina

- In 2001, Bill 25506 of "Digital Signature" was sanctioned
  - →Recognizes the use of digital signature, and its legal validity
  - →Allows truthfully identification of individuals making electronic transactions
  - →When a document requires a handwritten signature, that exigency is also satisfied by a digital signature.
  - →Also describes the figure of electronic signature as an integrated electronic data set, related in a logical way to other electronic data, used by the signatory like his means of identification, which lacks some of the legal requirements to be considered digital signature

Medical Information Security

- Key issue
  - ⟶Development of security mechanisms needed to operate and maintain a decentralized medical record system
  - ⟶Based on five fundamental aspects:
    - Privacy
    - No Disavowal
    - Authenticity
    - Integrity
    - Chronology

CDA documents creation



Signature of Medical Documents

- "In house" application, with own PKI
  → Creation and administration of public and private keys and digital certificates.
- Three basic characteristics of digital documents:
  → Having a HASH to guarantee the document's integrity.
  → Been signed with private and public key system, to guarantee its authorship.
  → Having a Time Stamping service, that guarantees document's temporality.
- Public and private keys are stored in a cryptographic USB E-Token given to providers
- Each XML clinical document created, has a single HASH value and is encrypted using the private key stored in the E-token
  → This encrypted file maintains its original information and the digital certificate
- A process of time stamping stores a digitally signed time registry with the document signed by the user

Discussion

- Trustworthy and unique registry of the medical acts, allowed by:
  - →Documents in single XML files that summarizes providers work,
  - →Digital and Electronic Signature, provided by the E-token
- Current graphical interfaces
  - →Provide improvements in usability and information visualization
  - →But...
  - →Does not correspond with the traditional charts in paper.
- Traditionally the professionals records their observations and findings in documents and then sign them
  - →The implementation of CDA and Digital/Electronic Signature maintains this sequence.

Conclusion

- Users can access laboratory results, imaging reporting, referral notes, discharge letters, progress notes, diagnoses, procedures and medical prescriptions, in a fully legible format…
  - →and the possibility of information processing for its later inclusion in other information systems or related health care applications.
- Documents visualization was personalized using XSL style sheets
- A time stamping service (also digitally signed), will allow temporality to this unique registry of medical acts.
- CDA standard implementation with the aggregate of digital/electronic signature in an electronic health record is a true challenge
  - →it entails an important technological and organizational impact.

Abstract

This paper describes the Brazilian Healthcare Software Certification Process started in 2004. The Brazilian Health Informatics Society (SBIS) and the Federal Medical Council (CFM) have proposed and are conducting the certification process. This paper describes the motivation, the history, the three phases methodology adopted, and its current status. A comparison with other international initiatives of health information systems certification is also presented. To conclude the future plans are presented.

Keywords:

healthcare information systems, standards,
software certification

Introduction

The use of computerized systems in medical offices is increasing worldwide. Brazil has a long tradition of using IT in healthcare. The Brazilian National Health System - SUS adopts electronic standards for hospital and outpatient billing for more than 25 years. All information is available for consultation at the Ministry of Health homepage (www.datasus.gov.br) [1]. More recently, the National Regulatory Agency for Supplementary Health – ANS, responsible for the regulation of the private market, has published TISS, an electronic messaging standard, based on XML schemes, to send billing information to and fro healthcare providers and payers. From May 2007 on, the standard TISS becomes mandatory[2]. There is a national registry with unique identifiers for persons (so far with 116 million persons uniquely identified), healthcare providers (149 thousand) and healthcare workers (1.5 million)[3]. A national PKI (public key infrastructure) - ICP Brasil, based on open standards, gives legal validity to documents digitally signed, ever since 2002[4]. Brazil as well as Mexico is the two countries where the number of Internet hosts grows more in the world according to recent publications [5].

Motivation

Many of the hospitals and large clinics, at least in the larger cities already use health information systems, mostly for billing and patient record purposes. These organizations face the ever growing problem of storing the paper medical record. According to the Brazilian Federal Research Council it is mandatory to store the paper medical record for at least 20 years after the patient's last visit to the healthcare unit. At the same time, physicians in their medical offices are largely using electronic heath records systems. Some of these physician offices, regardless of the regulations, are paperless. As the regulations and legal validity of electronically signed documents evolved in the Country, several physicians motioned their Regional Medical Councils, looking for legal advice on whether they could become paperless. The Regional Medical Councils (there is one for each of the 26 Brazilian States) did not feel comfortable in replying and sent all those requests to the Federal Medical Council, which, in turn, decided to create a specific Technical Committee on Health Informatics and Telemedicine to, with the support of the Brazilian Health Informatics Society (SBIS) try to answer to those questions.

In 2002, due to the large number of requests from the Brazilian healthcare community, CFM and SBIS established a cooperation agreement to define and implement a software certification process that would allow, in the long run, for physicians and healthcare providers to be paperless safely and legally, according to the Brazilian regulations.

The next sections describe the methodology adopted in the certification process, the present status, lessons learned and future plans.

The Certification Methodology

Once the legal aspects of the agreement were established the technical group started to work. By 2002, there was no other international experience of software certification for healthcare, more precisely for systems that dealt with patient identified health information. The Certification Commission for Healthcare Information Technology (CCHIT) was created by the US government only in 2004 and is today a very successful example of healthcare software certification [6].

Legal background

In order to understand what we were dealing with, an extensive bibliographic review on software certification,

as well as on the Brazilian regulations for digital signatures, information security, privacy and confidentiality issues was carried out. In addition to that, the work of the ISO-TC 215 Health Informatics Committee was taken as a prime reference. As our understanding evolved, so were evolving the two basic documents we have used as references for the architecture, content, structure and function requirements of the certification process: ISO/TS 18308:2004 - Health informatics - Requirements for an electronic health record architecture [7] and the ISO/TR 20514:2005 Health informatics -- Electronic health record -Definition, scope and context [8].

The Federal Research Council published, in 2002, two specific regulations on patient records – Resolution CFM 1638/2002, and on electronic health record systems – CFM 1639/2002 [9,10]. These two resolutions together with the ISO-TC 215 documents above mentioned, and the ISO/IEC 17799:2005 Code of Practice for information security management [11] were the key documents used to define the SBIS-CFM certification process.

CFM 1638/2002 resolution defines the patient record as a document that contains text, images and signals related to the patient and that the resulting set of items is a private and confidential piece of information that can only be shared for patient care purposes. According to the Brazilian legislation, all information on the patient belongs to the patient. Physicians in their offices and health care providers in general have the obligation of keeping patient files for a period of at least 20 years (for the paper record). The 1638/2002 resolution also details the minimum content of the patient record. The recommendation is that the patient record (no matter whether electronic or on paper) has to contain the patient identification (it recommends the use of the national person identification registry), patient history, physical examination, ancillary tests and its results, therapeutics planning, diagnoses, evolution, surgical reports (if the case), and all medical orders. Summary discharges in case of hospital admissions with clear patient's recommendations in lay language. If on paper, it's mandatory that all documents be legible and signed by the attending physician. If electronic, the documents must be digitally signed according to the Brazilian PKI otherwise they must be printed and hand signed. The 1638/2002 resolution also deals with exceptions, as when the patient cannot speak, in which case it describes in detail what information has to be written on the patient file.

The 1639/2002 CFM was published a month after the 1638 in August 2002. It establishes the foundations of the SBIS/CFM certification process and describes the first set of technical recommendations for the process. These first recommendations were expanded in a full publication: The EHR systems security, content, and functionality requirements for the SBIS/CFM certification process, as described in the following sections. Among the recommendations, it says that for those who decide to use electronic health records, files must be saved forever, which means to the actual technology limit and that proper mechanisms should be granted to guarantee the compatibility of the storage devices, as technology evolves. That is also a recommendation present in the ISO/IEC 17799:2005 regulations. In addition to that, it is also recommends, and makes it mandatory for those who will have adopted the EHR, the existence of a Patient File Committee. The Head of this Committee is the one legally responsible for the patients file and for keeping its privacy and confidentiality. Should any legal problem occur, this is the person that is going to be implicated. The two resolutions made it clear to the healthcare community that it was possible to move to the paperless environment but it is necessary to improve drastically specially the small offices' *so called* "EHR" systems. Many physicians were already unable to defend themselves in malpractice suits because all they could present to the court was a paper printed from a simple system with no guarantee whatsoever that the specific piece of information was valid.

SBIS-CFM certification scope

Software certification is a rather complex task. It demands that at least two main issues are taken into account: the software product itself and its use in different organizations. For example, the same software product may be complaint with security requirements in one site, while not in others, because users share passwords, for instance. This has to do with the software utilization, rather than with the software product itself.

It was decided that the SBIS/CFM certification scope target any software product that captures, stores, manages, publishes or electronically communicates patient-identified health information, or, in other words, is an EHR. This definition is on purpose similar to the ones described in the ISO TC 215 aforementioned documents [7,8].

It was also decided that the SBIS/CFM certification is a VOLUNTEER process, meaning that only organizations that want to become paperless have to be certified. Recently the Federal Regulatory Agency for Supplementary Health, in its publication of the electronic standard for exchanging billing information, recommended that all systems implementing the communication should be compliant with at least Level 1 Security SBIS/CFM, as explained ahead.

SBIS/CFM certification phases

The SBIS/CFM certification process is composed of two basic phases: Phase 1 – Compliance Declaration; Phase 2 – Auditing and Quality Labeling. A third phase has also been envisioned in which necessarily the Ministry of

Health and ANVISA, the Brazilian Health Surveillance Agency will have to participate.

A Manual with all the Security, Content, Structure and Function Requirements for EHR was elaborated and went into public consultation in 2003, through the Internet[12]. The market reacted promptly considering the requirements too hard. The decision was then to split the process in three phases, based on the need to start with a lighter, educational phase, in which the main objective was to let the market, in special the small players, understand what the requirements were and have enough time to adapt. Brazil IT healthcare market mimics what the healthcare market is: many scattered small players attending the local market. There has always been the concern not to kill the local initiative, but rather to qualify it and make the world of standards, privacy, confidentiality and PKY for digital signature fully understandable even for the very small companies that offer "EHR" systems for the local physicians in the small communities across the country.

Since it had also and educational purpose, the Manual includes a large introduction with references to the CFM resolutions, ISO TC 215 documents, ISO 17799 Security Code of Practice and ICP-Brasil, the Brazilian PKY Infrastructure. The EHR system requirements are divided into the following sections: Security, Content, Structure and Functionality.

The Security chapter is based on the ISO/IEC 17799:2005 Code of Practice for information security management and in the privacy and confidentiality rules of the CFM Ethical Code of Practice. According to the Manual, EHR systems can be classified as Guarantee Security Level 1 or Level 2. The difference is that to be classified as Guarantee Security Level 2, the EHR system has to be compliant with all Level 1 requirements **and** provide digital signature authentication based on the ICP-Brasil.

The Content, Structure and Functionality requirements are an adaptation from the ISO-TC 215 documents. Every requirement is identified as mandatory or optional. Some are identified as "desirable", as is the case of the need to incorporate comments in any data entry or to specify the relevance level of the information. The "desirable" attribute indicates to the community that although not mandatory today, this is an attribute that will probably be mandatory in the near future.

Each requirement is uniquely identified within the Manual, has a description and a reference to the information source. All national standards for patient, healthcare provider and healthcare worker identification and description are part of the mandatory requirements of the Content Section.

Phase I – Compliance declaration

Phase I of the SBIS/CFM Certification Process is FREE and totally online by accessing SBIS's website (www.sbis.org.br). It consists of a self-proclaimed declaration from the software supplier, stating that the specific product registered at SBIS website is compliant with the Requirements Manual at the Security Level 1 or 2.

The process is simple and straightforward as depicted in Figure 1 below.

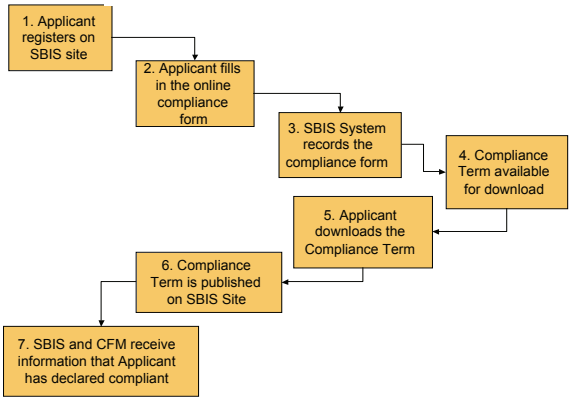

Figure 1 - SBIS-CFM Certification Process – Phase 1

The applicant is the software supplier. It may be a company, an academic institution or even a single person. The first step is the registration of the organization or person responsible for the software product. A brief description of the product is also required, such as operational system used, architecture, category (hospital, outpatient, medical office, laboratory, imaging, public health integrated system, billing). After that, the requirements are presented as a questionnaire to the applicant, to be answered on-line, as shows Figure 2 below. When finished, if all the mandatory requirements are present, the compliance declaration is published at the web site and can be downloaded by the applicant.

Figure 2 - SBIS/CFM Certification Questionnaire

Phase 1 is an educational phase for the market. Neither SBIS nor CFM takes any responsibility on what has been declared. Therefore it's not recommended to become paperless based on this compliance term.

Phase II Auditing – SBIS/CFM quality labeling

The second phase of SBIS/CFM certification process is also a volunteer one, but not without costs, since here there is the need to pay for the systems auditing.

In Phase II, all systems compliant after Phase I can proceed to Phase II and be audited by accredited organizations. The process is also simple and mostly done through the Internet as in Figure 3.

The applicant chooses the accredited certification organization, through by assessing the company's history and available auditors. Each auditor's biography is available, as well as their declaration of interest. The objective here is to have full transparency, avoiding possible conflicts of interest.

The applicant has to approve the commercial proposal for the auditing which triggers the start of the auditing process. The auditing process is objective, with the auditors (always two) having to follow very detailed script and case tests, to check the system compliance with each Manual Requirement.

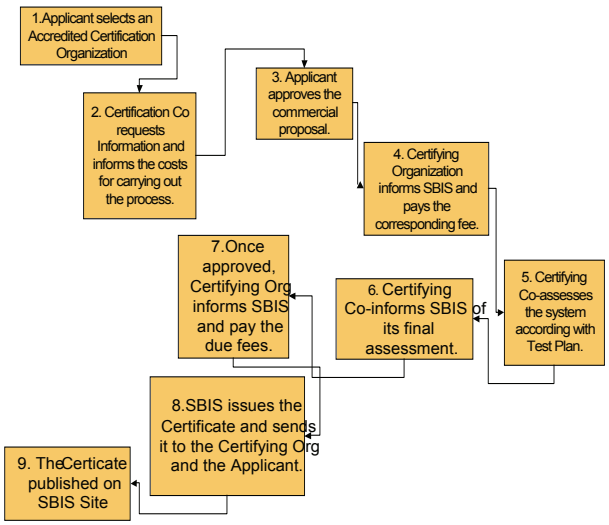

Figure 3 - SBIS-CFM Certification Process - Phase 2

Once the auditing has finished, SBIS receives the report from the accredited certification organization and, should the system be compliant, a Quality labeling is issued to the applicant and the associated certificate is published on SBIS website.

Phase III – Ministry of Health involvement

Phase III necessarily requires that the Brazilian Ministry of Health and ANVISA, the Brazilian Health Surveillance Agency, take part in the process, as those are the organisms with legal power to legislate on these matters. CFM has power over medical doctors. The Ministry of Health and ANVISA have power over all healthcare organizations. Nevertheless, Phase III deals with certification of products and their "on site" implementation. Systems that have survived Phase II are natural candidates for Phase III. Assessing how systems perform after implementation is a more complex process that relates to ISO 9000 series of certificates, and SBIS/CFM must learn from there.

Results

The SBIS/CFM Requirements Manual was first published in February 2004. Phase I of the certification process is operational since October 2004. More than 200 software developers have registered on SBIS website and have downloaded the SBIS/CFM Requirements Manual.

At the moment (December 2006), fifty one (51) software products have self-proclaimed compliance with the Manual. Products are divided in categories, according to the table bellow.

Table 1 – Categories of software compliant to SBIS/CFM requirements

Category	Number of products conformant
Public Health Systems	6
Medical office automation / EHR	17
Billing – health insurance	7
Medical Images	3
Occupational Health / Surveillance	4
Hospital Information Systems	14
Total	**51**

Present status

At the moment, the documents to initiate Phase II are ready: the Auditor Manual with all the scripts and case tests, the Code of Ethics for the auditor and the Term of Reference to accredit Certification Organizations. The training program for the auditors is scheduled for January 2007 and it is our intention to have Phase II operational by March 2007. Hopefully by MEDINFO we will have the first results of Phase II to show.

Conclusions

Certifying software is a very complicated and costly task. The Brazilian process had to start in small steps to accommodate and educate the market. Today there is a consensus that the process will qualify the software suppliers in Brazil and will allow for a secure transition to a paperless environment.

The Ministry of Health participation in this process is desirable since this would guarantee greater investment in the process. So far the work has been sponsored solely by the Brazilian Federal Council.

Biometrics for Telemedicine Operation and Management

Isao Nakajima, Yasumitsu Tomioka,Hiroshi Juzoji, Toshihiko Kitano

Nakajima Lab, Tokai University School of Medicine

Abstract

The biometric methodologies and effects on telemedicine are discussed in this paper. In developed nations, the increase of the non member of the health insurance becomes a social problem. Near future, when we had operated telemedicine (especially telehomecare) via broadband circuit, a client's biometrics become more important to confirm whether or not the client is the very person who joins to the health insurance. We feel that the optical sensor (face, iris, and retina) using the videophone system is a promising biometrics system for telehomecare. We propose the inclusion of optimized biometric methodologies and guidelines as a theme of ITU E-Health standardization and/or ISO HL7.

Keywords:

biometrics, certificate of health insurance member, standardization

Objectives

The biometric methodologies and effects on telemedicine are discussed in this paper.

We propose the inclusion of optimized biometric methodologies and guidelines as a theme of ITU's E-Health standardization.

Background

What is biometrics?

Biometrics is an individual identification technology utilizing the unique biological characteristics of humans, and is typically used to identify the owner of forms of identification such as cash cards, driver's licenses, and health insurance ID cards. The conventional technique is to compile information on individuals in the form of a database and then identify individuals using a PIN, password, and ID cards based on the stored information. This technique, however, is vulnerable to illegal acts such as forgery, theft, tapping, and identity theft.

The biometric method measures biological objects having the following three characteristics:

1. Universality (characteristics common to everyone)

2. Uniqueness (characteristics unique to each individual)

3. Permanence (characteristics that do not change over time)

Such individual characteristics--well-known examples include fingerprints, the retina, iris, voice, hand shape, palm print, and face--are stored in a database for identification.

This technique simply analyzes the biological characteristics that are expressed using images and signals, and estimates the probability of pattern matching with the data in the database. As a result, the output is only a positive recognition or negative recognition, as shown in Fig. 1; note that the matching probability is not 100%.

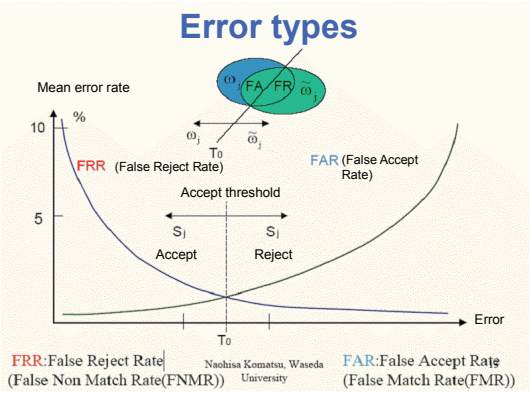

Figure 1 - Error types

Market

Increasing global concerns about terrorist activity and identity have boosted the demand for improved security. Increased media attention has raised end users' awareness of the potential of biometric technologies in security applications. Significant market opportunities are thus emerging in application areas such as physical access control, citizen identity, network security, financial services, entitlement and healthcare. For example, InfoShop-Japan reports that the world market size for access management (keyless entry) alone was USD13 million in 2002 and will reach USD70 million in 2007(Fig. 2). As shown in Fig. 3, 50% of 2004 biometric products are fingerprint sensors. Non-contact sensors are expected to increase in popularity in the near future. If they are used in the areas of telehome care and geriatric care, the market may explode in advanced countries.

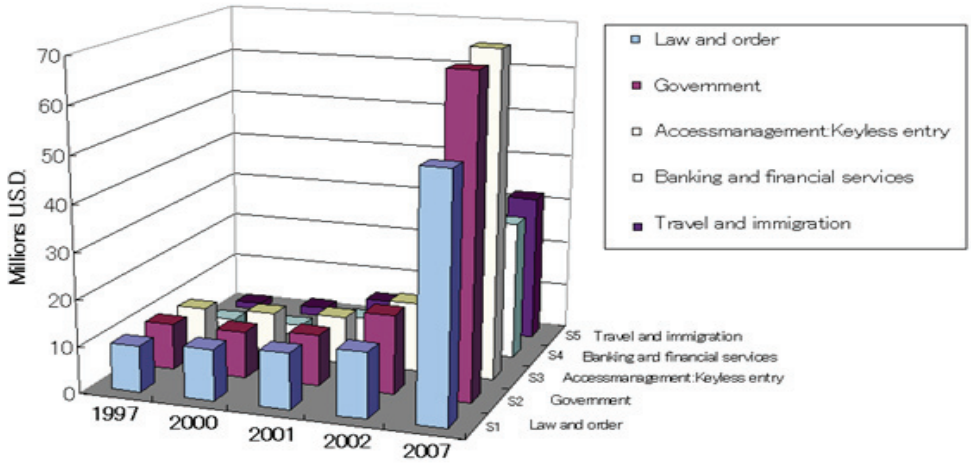

Figure 2 - The world market for Biometrics

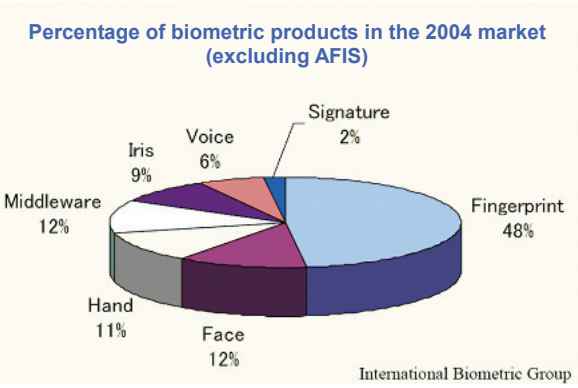

Figure 3 - Percentage of biometric products

Necessity of biometrics in telemedicine

With the increasing importance of the comprehensive management of medical information in our aging society, individual identification is essential not only for telemedicine but for information management for individual information browsing and making insurance payments. Japan is facing the problem of an increase in the number of people who do not pay health insurance fees. As the number of patients who attempt to receive medical services in an illegal manner through identification theft is expected to grow, the importance of individual identification will be enhanced.

We have identified the following needs in telemedicine for individual identification:

1. Health insurance ID certificate (or ID card in some countries)

2. Remote consulting

3. Emergency transport

4. Health check (except for diseases)

5. Return of medical fees

6. Patient chart browsing (for the patient only)

The above six applications require identification accuracy as high as that needed for the online banking system.

Proposal

We feel that the following optical sensor using the videophone system is a promising biometrics system for telehomecare.

Face

A Methodology: We learn the characteristics of each face using CCD cameras and photos in advance, prepare a database, and examine the target face based on the face patch theory (which is totally different from the neural network theory that has already been discussed extensively).

Preliminary learning: Extracts the relative positions of the eyes, nose, and eyebrows, and draws an identification curve using Adaboost Image matching: Extracts the eye, nose, and eyebrow characteristics of the target face, and matches them with data in the database

B Advantages: A videophone system using a PC-based or dedicated terminal device is used in telehome care. Thus, compared with other applications, it is easy to capture the patient's face image from the front each time with almost the same size under uniform illumination conditions that are close to ideal. Because the high-quality CCD device allows the doctor to see the symptoms of anemia, icterus, spider angioma, and nerve damage, the visual check and

face identification can be performed simultaneously. It is, however, difficult to maintain consistent identification accuracy, as the face characteristics may change over time. False identification as a result of plastic surgery on the eyes, nose, and jaw may also be possible. Thus, it is preferable to use another identification technique in addition to face identification.

Iris

A Methodology: Individuals can be identified based on the iris pattern, which is unique to each person. The iris pattern is formed within six months after birth and stabilizes within one year after birth, and does not change until death. Two devices can be used to measure the iris pattern, as follows.

1. If the videophone system is equipped with a zooming function, it can work as an iris identification device.

2. A dedicated light-reaction device can measure the speed of light reaction and examine the iris pattern simultaneously.

In the identification process, the analysis zone is selected from the iris pattern sampled using the CCD, its profile is extracted using a Gabor filter and then coded. This code is used to select the closest iris code in the database based on the Hamming distance value. The error rate is 2^{-244}, the same probability of a coin toss ending with the same result 244 times in a row.

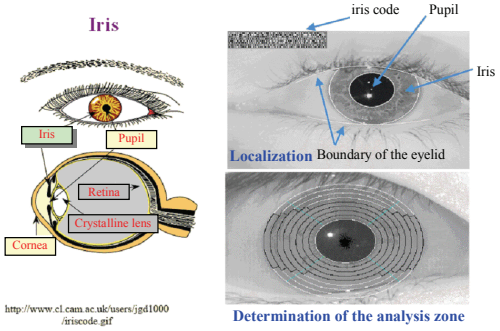

Figure 4 - Analysis of the iris

B Advantages: Non-contact, easy to use, and accurate. It would be very difficult to fake an iris, even with advanced plastic surgery and eye operation techniques. In combination with the light-reaction device, it can measure the iris reaction speed (which aids in diagnosis of problems with the brain stem and oculomotor nerve) and identify the iris pattern simultaneously.

Retina

A Principle: The vessels pattern of the retina can be used for identification. This vessels pattern remains unchanged unless the veins shrink due to diabetes or other illness. It is normally difficult to see the vein pattern without expanding the iris using chemicals (e.g., Mydrin). In recent years, however, a device has been developed that can see the vein pattern without the use of iris-opener chemicals. As dedicated equipment is necessary in both cases, it is not possible to conduct retina identification using a normal videophone system alone.

B Advantages: Non-contact and accurate, but not easy to use. The biological origin of the retina is the same as that of the brain. In fact, it is possible to estimate the condition of the blood in the brain from that in the retina, and the brain pressure from the optic papilla on the retina. Some easy-to-use devices are expected to be developed in the future. We should focus on the retina device as a promising telehomecare device.

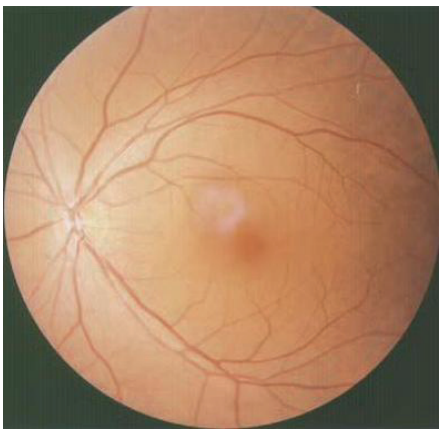

Figure 5 - The pattern of retinal blood vessels (Artery and Vein)

Prospects

Reluctance to use fingerprints

The U.S. Visit Program employed by the immigration authorities in 2004, which uses fingerprints for individual identification, has been poorly evaluated by those visiting America. This is due to the fact that this FBI technique, known as AFIS (Automated Fingerprint Identification System), has been used to identify criminals in the United States. Many people may not accept the use of such a criminal identification system for totally different medical use. Most users may prefer non-contact-type biometric techniques that do not use fingerprints. Diagnosis using the videophone system provides information on the patient's physical characteristics. Thus, it is natural to use such physical information for user identification.

Three accuracy levels

A number of biometrics companies have developed a variety of identification techniques using fingerprints, vein patterns of the palm, face, iris, and retina characteristics. These techniques are completely unrelated to each other.

Although more than one algorithm and measurement device are available, the identification result can only be one for each individual. As in the case of mathematics, there is only one correct answer. If the identification accuracy is not sufficiently high, users will be inconvenienced. Unless an identification system is shared by many users, as many sensors and devices as the number of such systems will be necessary. This is unreasonable for users. Since the 9/11 terrorist attacks, homeland security has been focused on, so it is currently difficult to establish an international standard for individual identification. However, at least objective accuracy guidelines should be considered. We feel that the following accuracy evaluation should be included in such guidelines.

1. Accuracy evaluation of the matching algorithm: Numeric degree of pattern matching between two input images

2. Accuracy evaluation of the matching device: Accuracy of hardware, including sensors

3. Accuracy evaluation of identity matching: Accuracy of identification of the correct person

Without these three accuracy evaluations, no identification technique can be objectively evaluated. Objective evaluation is the first step toward international standardization.

Efforts for standardization

The standardization of biometrics is underway in ITU-T SG-17 Telebiometrics and ISO/IEC SC37/SC17/SC27. However, there is no forum for discussing applications to telemedicine. If E-Health is standardized by ITU-T SG-16 Q-28 in 2004-2007, discussions on the standardization of biometrics for telemedicine should be kicked off as early as possible jointly with SG-17. As mentioned above, the medical needs are diverse and the telemedicine market is growing faster than expected. We feel that biometrics for telemedicine should be included in the ITU scope. If we lose this opportunity, the importance of telemedicine standardization by ITU will fall drastically. This is due to the fact that the ICT technology will involve the elderly, who often do not go out for medical care, and to the fact that the biometric market is expected to explode. If there is no international standard, the market may be driven by a de facto standard. Although de facto standards are acceptable for applications in a free market, they may cause many problems in medical applications that should be under national control. As a result of such problems, many developing countries and the weak and elderly will be left behind. Therefore, ITU is required if standardization is to be achieved in a timely manner.

Abstract

We have developed the standard electronic format based on HL7CDA-Rel.2 in the nationwide standard electronic health-document-exchange that is the indispensable infrastructure of the new national health-checkup-program (NHCP) in Japan. HL7CDA-R2 was proved to be an applicable message standard to the NHCP in Japan. The exchange has been under the test phase since F.Y.2006 and the real phase is supposed to start in the beginning of F.Y.2008. This is the first nationwide standard health-document-exchange based on HL7CDA-R2 and the estimated number of participants is between 10 million and 50 million citizens.

information standard

Introduction

In recent years, life-style related diseases such as diabetic mellitus, hypertension and hyperlipidemia are greatly increased in Japan. This situation is criticized as one of the causes of ballooning healthcare cost. For this reason, the Japanese government formed the policy which aimed at a 25% decrease of the prevalence of the life-style related diseases and the number of pre-disease state person by F.Y.2015[1].

In accordance with the above policy, the Ministry of Health, Labor and Welfare, Japan (MHLW) has decided to start the new national health-checkup-program (NHCP) which is specific for preventing metabolic syndrome from F.Y.2008 because metabolic syndrome is proved to be a key pre-stage followed by the life-style related diseases. All the health insurers that support the universal health insurance system in Japan shall be obligated to provide all the insured persons and their dependent family members aged between 40 and 74 with the routine health-checkup. They also have obligations to conduct the health consultation program which is specific for preventing metabolic syndrome in the standard method.

In NHCP, all the stakeholders (i.e. health-checkup providers, health consultation providers, insurers, and so on.) are required to exchange the health checkup and consultation data in a standard electronic format. Therefore, we developed the standard format and the guideline of its application under the special working group sponsored by the MHLW. The purpose of this project is to show problems and its solutions in applying HL7 Clinical Document Architecture, Release2 (CDAR2)[1] to the standard data format in NHCP.

Methods

In NHCP, there will be 4 major events such as health checkup, first-time consultation, mid-term evaluation and final evaluation consultation. Since the information to be exchange are different in each events, specified message formats are required for each message exchange.

In order to reduce development and management costs, we have developed a standard message model based on the HL7 CDAR2 specification [2]. The message format and XML schemas are derived from the model we have developed.

Results

Figure 1 shows the NHCP standard message model based on the HL7 CDAR2. Message schemas dedicated to each NHCP events are generated from this message model. Each message has basically one section to describe each health checkup and consultation events. Additional sections will be occurred to describe optional information, such as health insurance policy holder specified health checkup results.

The checkup results and the performance of the consultations are described in structured format conformant with

CDAR2L3 for automated data processing on the recipient side.

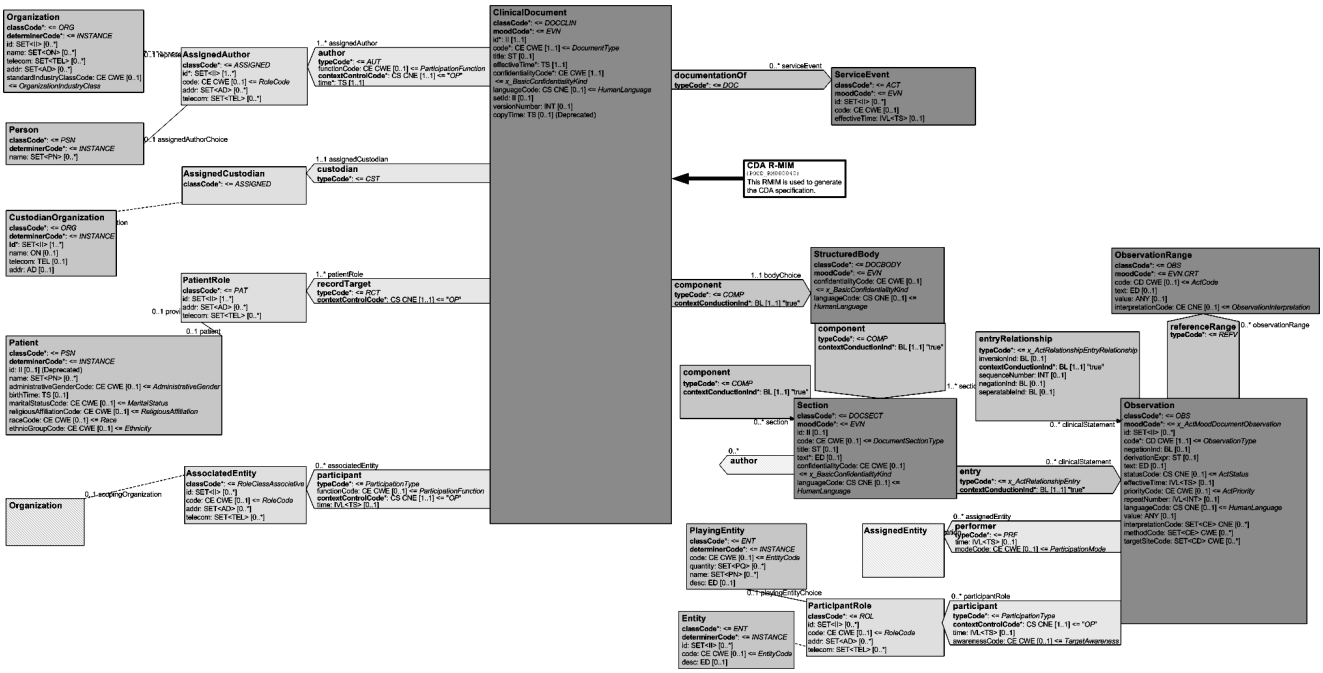

Figure 1 - The NHCP message model. This model is derived from original CDAR2 message information model

Discussion

In the NHCP, although it was found that the author, the custodian and the participants-information elements in the CDA message header have to be rewritten as the exchanging phase progresses, the HL7CDA-R2 was proved to be an applicable message standard to the NHCP.

However, since the CDA is originally an adaptable standard for the various medical documents, plural message notation exists to the identical contents. In addition to it, the NHCP requirements may be changed in the future. To guarantee the interoperability, development of a new mechanism to verify the message conformance to the standard is required.

The real phase of using the proposed standard is supposed to start in F.Y.2008. This is the first nationwide standard health-document-exchange in Japan. The estimated number of participants (i.e. the insured) is nearly 50 millions in the near future.

This message model and message format will be used for information exchange of the Health Checkup for Labors under the Occupational Health and Safety Law of Japan, and Health Checkup and Management Program for School workers under the School Health Low of Japan, as well. The authors believe that the proposed HL7CDA-based exchange program will not only contribute on the success of the NHCP in Japan but also serve as a useful reference for health document exchange in other countries.

Conclusion

In this paper, we described an outline of the new national health-checkup-program and brief structure of the NHCP message model. The exchange has been under a test phase since F.Y.2006 and the real phase is to start in the beginning of F.Y.2008. It will be the first nationwide standard health-document-exchange in Japan.

OpenECG: Promoting Interoperability Through the Consistent Implementation of the SCP-ECG Standard in Electrocardiography

Catherine Chronaki[a], Franco Chiarugi[a], Ronald Fischer[b]

[a]*Institute of Computer Science, FORTH, Heraklion, Crete*
[b]*Department of Biometrics, MHH, Hanover, Germany*

Abstract and objective

The OpenECG Network (www.openecg.net) has been created to promote interoperability in electrocardiography with tutorials, specifications, open source tools, data sets, converters, and interoperability testing. ECG vendors, members of professional organizations, researchers, and other stakeholders participate in the OpenECG network to exchange views and receive assistance in implementation. In 2006, members are more than 700 individuals from 58 countries. A specific focus area for OpenECG that concerns diagnostic quality resting electrocardiograms (ECGs) is SCP-ECG, the European standard (EN1064:2005). An online interoperability testing service assists members in consistently implementing SCP-ECG and effortlessly integrating electrocardiographs with eHealth systems. OpenECG is a case of best practice in interoperability that should be followed by medical devices and sensors for effective personalized health monitoring.

Keywords:

interoperability, standards, telemedicine, eHealth services, medical devices, electrocardiography

Methodology

Electrocardiography is the most frequently applied non-invasive examination for early detection of heart disease, a leading cause of morbidity and mortality in western countries. It is estimated that more than 100 million ECGs are recorded annually in Western Europe. The ECG allows early detection and follow-up of heart disease, but today the operation of most ECG devices is still based on proprietary protocols and file formats.

SCP-ECG is a standard communication protocol that specifies the interchange format and a messaging procedure for ECG equipment-to-computer communication and for retrieval of ECG records from the computer to the ECG equipment (if needed). Since March 2005, SCP-ECG (EN1064:2005) is the European standard for high quality diagnostic ECG exchange and if consistently implemented ensures interoperability. Nevertheless, it is rather difficult for integrators to implement SCP-ECG correctly and there are variations in implementations, which can be a barrier to interoperability. Although a number of ECG device manufacturers and integrators have implemented the SCP-ECG standard, most implementations are not fully accurate. This is due partly to misconceptions and partly to the lack of widely publicized conformance levels and IHE-like integration statements that exist for modalities in radiology.

In 2003, OpenECG established an online conformance testing service to support the OpenECG community at large in implementing interoperable eHealth systems with SCP-ECG support. A member may submit an ECG file in an alleged SCP-ECG format and receive a list of errors and warnings. If no errors are detected, the submitter may request a certificate that is granted after thorough manual review of the file.

Results

The SCP-ECG conformance testing service has been used extensively by members and in many occasions an interoperable solution was achieved with support from the help desk. In the period 2003-2006, more than 1700 ECGs were submitted for conformance testing by members in more than 20 counties worldwide. Leading is Italy with 11 members, who have submitted 37.3% of the tests. After Italy, most ECGs have been submitted by Greece (17.74%) and Hungary (11.89%). ECG devices and eHealth services have been tested, improved, and validated using online tools and support from the OpenECG helpdesk. In 2005, a web service variant of the conformance testing service was integrated to the ECG viewer that won the first prize in the OpenECG programming contest. After certain limitations of the software were identified and amended, a new version of the ECG viewer was released and is currently available at the OpenECG open source repository.

Conclusions

The OpenECG network promotes best practice in interoperability for ECGs. Innovative eHealth services capable of managing personal wellness profiles call for plug-interoperability of medical devices, which is an issue of patient safety, key to advancing quality and cultivating consumer trust in the next generation of ambient intelligent working and living environments.

Increasing the Sustainability of a Web-Based Virtual Patients System by Applying the Emerging Medbiquitous VP Standard

Nabil Zary[a], Patrik Jonsson[a], Uno GH Fors[a]

[a] *Virtual Patients Lab (VP Lab), Dept of LIME, Karolinska Institutet, 17177 Stockholm, Sweden*

Abstract

The Web-SP is a web-based Virtual Patient system developed at Karolinska Institutet with the aim to easily author, run and manage Virtual Patients (VP) for training and assessment purposes. Web-SP was successfully implemented at several universities world-wide. Our presentation will focus on the findings and experience acquired while adapting Web-SP to comply with the MedBiquitous VP XML emerging standard. An important outcome was the rethinking of the lifecycle of VP's to improve their accessibility and reusability. A new VP import/export tool was developed to support the exchange of VP learning content between universities, either as complete packages or via web services.

Keywords:

patient simulation, standards, computer assisted instruction, problem based learning

Introduction

The Web-based Simulation of Patients (Web-SP)(1, 2) project was initiated in order to facilitate the use of realistic and interactive virtual patients (VP) in medicine and healthcare education. Web-SP focuses on moving beyond the technology savvy teachers, when integrating simulation-based education into health sciences curricula, by making the creation and use of virtual patients easier. The project strives to provide a common generic platform for design/creation, management, evaluation and sharing of web-based virtual patients. Web-SP was successfully implemented at several universities world-wide. The aim of this study was to further improve the sustainability of Web-SP by remodeling the case import/export tool to comply with the Medbiquitous XML standard.(3)

Material and methods

We actively participated into the specification of the Medbiquitous Virtual Patient Schema. A remodeling of the architecture of the vp import/export tool was performed, based on the emerging XML standard published by the Medbiquitous.

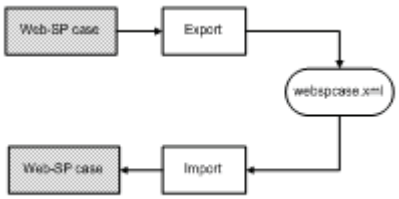

Figure 1 - shows an implementation of a proprietary Virtual Patient exchange, only allowing instances of the same system to exchange cases

Results

The Web-SP system takes advantage of the standard during export and import of a virtual patient case. Thus allowing for cross platform exchange of Virtual Patient Data.

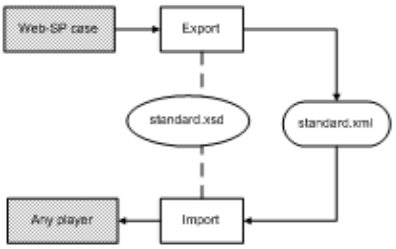

Figure 2 - shows an implementation of Virtual Patient exchange using the MedBiq standard

Acknowledgments

We wish to thank all the members and invited experts of the Medbiquitous Virtual Patient group for their valuable contribution. A special acknowledgment to Robin Eklund for his contribution to the development.

Evolutions of the Brazilian Permanent Council of Health Standards

Rigoleta Dutra Mediano Dias, Jussara Macedo Pinho Rötzsch, Maria Ângela Nogueira Scatena, Luiz Eduardo Vieira, André Feijó Barroso

National Supplementary Health Agency (NSHA), Rio de Janeiro, Brazil

Abstract

The Brazilian Permanent Council of Health Standards, COPISS in portuguese, consists of 21 stakeholders representing every part of health care system in Brazil: healthcare organizations and clinicians, patients, payers, government agencies and researchers. This council has been working on the evolution of the TISS standard, which establishes rules for data structure, terminology, communication and security policies between health plans organizations and health providers. The main evolution in TISS standard has been the design of web services to be adopted between their softwares to implement the electronic messages already defined. A reference implementation, called TISSNet, is a powerful JAVA solution for this. The COPISS results have been relevant in order to make achieve interoperability in private health care information systems.

Keywords:

medical informatics, standards

Introduction

Even though Brazil has achieved universal or near-universal cover through a national public health system, large population segments (25%), estimated as 180 million of people, are covered by private health plans. National Supplementary Health Agency, NSHA, (*"Agência Nacional de Saúde Suplementar"*) created in 2000, is responsible for regulating and assisting the private health plans organizations (HPOs), around 2000, and their integration with the health care providers (HPs).

The lack of health care data standards has led NSHA enact the federal normative resolution (RN no. 114), October 25, 2005, establishing the supplementary health information exchange standard (*"Troca de Informação em Saúde Suplementar", TISS*, in Portuguese*)*. Based on the structure of the American Health Insurance Portability and Accountability (HIPAA)[1], it establishes a set of standards for data exchange between HPOs and HPs, and also creates the Brazilian Permanent Council of Health Standards (*Comitê de Padronização de Informações em Saúde Suplementar*, COPISS, in Portuguese), which manages the implementation and evolution of TISS standard.

As a matter of fact, the COPISS has significantly contributed to achieve all stakeholders' consensus and even their recognition for the value of the interoperable data exchange. Through many debates and a collaborative methodology the stakeholders have considered the TISS standard the main project in the supplementary health market for the last years.

Methods

NSHA started the TISS standard development in 2002 as a research, sponsored by the Inter-American Development Bank (IDB). At the beginning it was a software development project based on any market health information standard. So NSHA decided to analyze some national and international standards and then developed a real national one. The software would be a reference implementation.

After disseminating the results of the research to all stakeholders through several seminars around the country, the market asked for a mandatory standard published in a resolution, which was finally enacted in October 2005. In fact, the TISS standard will be mandatory from May 2007, between HPOs and hospitals/laboratories; from November 2007 between HPOs and odontological clinics; and from November 2008 between HPOs and medical and dentist offices.

In order to improve the TISS standard, the resolution created the Brazilian Permanent Council of Health Standards, called COPISS, in Portuguese. This council has been working intensively since April 2006 and has accelerated the adoption of more standards in order to facilitate true interoperability on a national scale.

Results

Twenty-one organizations representing HPOs, HPs, federal agencies and academic and research institutions participate in COPISS. It has a coordinating committee and other four committees divided in the same way the normative resolution (RN no. 114) divides the TISS standard: data structure, terminology, communication and security.

The Data Structure Committee defines the data to be exchanged between HPOs and HPs either by paper forms

or electronic media and the terminology committee defines the semantic domains the data must adhere to.

The communication committee defines the possible transactions and protocols to be used; and the security standards define requirements to protect classified health information. The TISS communication committee is aimed at assuring interoperability between HPOs and HPs to the maximum possible extent.

It is important to mention that some significant results have been recently achieved mainly related to the communication standards. The communication committee has agreed upon a couple of rules defining a standard directory structure for batch file exchange, based on the inbox / outbox model, and a well defined set of web services in WSDL for on line transactions. NSHA has developed a reference implementation for the agreed and proposed communication standards, called TISSNet, available at the ANS web site: www.ans.gov.br, which implements each and every defined requisite. Developed entirely in JAVA 5, it can be used under Windows, Unix and MacIntosh unchanged, and is offered for free to the market, to be enhanced and improved by the players themselves. So far, it supports HTTPS, digital certification, zip compression, RIJNDAEL encryption and the JSR-181 (EJB-3.0) standard for web services, and can be wrapped into an ActiveX DLL to become a component for WINDOWS applications. Table 1 shows an example of the input / output TISS messages and web services between them.

Table 1 – TISS electronic messages and Web Services

Input Message	Web Service	Output Message
Claims/ encounter data	TISS-Claims/ encounter	Claims/encounter data response
Referrals and authorizations	TISS- Authorizations	Referrals and authorizations response
Claim status inquiry	TISS- Claim status	Claim status response
Eligibility inquiry	TISS- Eligibility	Eligibility response

Web services are a powerful tool to integrate disparate health care applications and will certainly bring many advantages to the Brazilian health care domain [2]. As can be seen, a set of web services will certainly address the functional interoperability, in other words, the ability of two or more system to exchange information. Even though it will be necessary to conform to the exact specification by calling Web Services with the names that have been specified, it may achieve a certain degree of semantic interoperability. So all information shared by systems will be understood by the receiving system. But authors consider that much has been done considering interoperability advances by COPISS. Soon NSHA intends to evaluate the use of the TISSNet software through a set of indicators and interviews and also the use of web services between the private health information systems.

Discussion

The creation of a council called COPISS has been fundamental to the evolution of health care standards in Brazil. Its members, both public and private, have been working all together in a collaborative way and have been disseminating the results for all health care organizations around the country. However, there are still relevant issues not discussed yet like vocabularies, unique drugs terminology, demographic services, reference model for data architecture, medical equipment, protocols for medical equipment and also standards for electronic prescribing and laboratory results. More studies should be done comparing the TISS standard and some international standards like ISO/ TC215, CEN/TC251 and HL7 [3], [4], [5].

Conclusion

COPISS is really a democratic forum, where standards are developed through an open-door consensus process and achieve their credibility by the participation of the stakeholders, often with contrasting or even opposing interests.

Only through this council, interoperability in health care systems will be achieved. The design of web services to change messages between HPOs and HPs is a good example. Another excellent example is the reference implementation, TISSNet, that will implement the proposed communication standards by all players since it is free and available on the web.

In such a huge market, as private health care is in Brazil, it is very important that government, HPOs and HPs work together.

Developing An Automated Mapping Algorithm for the ICNP in Japanese

Kimikazu Kashiwagi [a], Masayo Kashiwagi [b]

[1] [a] National College of Nursing, Japan
[b] Tsukuba University, Japan

Abstract

OBJECTIVES: The purpose of this study is to develop the mapping method from terms which are used in clinical settings to the Japanese Translation of the ICNP version 1. METHOD: We used n-grams for approximate matching and calculated the similarity scores between terms by the length of the n-grams and the frequency of n-grams in the ICNP. Using this method, we were able to create the lists sorted by the similarity scores. RESULTS: The proposed method seems to be useful in the mapping process.

Keywords:

ICNP, translating, terminology, International Council of Nurses

Introduction

The Japanese translation of the ICNP version 1 (International Classification for Nursing Practice) was published in July 2006. But one of the reason is that the concepts in ICNP is that some translation terms are rarely used in clinical settings.

In order to use the ICNP as a reference terminology, it is necessary for users to find the ICNP concepts from Japanese terms easily.

The simple word matching algorithm was not appropriate if the results suggest more than 20 terms.

Methods

At first, we extracted 20838 n-grams from the Japanese translation of the ICNP. To calculate the similarity scores between a query string and terms in the ICNP, we used following equation.

$$\sum_{n \in Q} \frac{Length(n)}{Freq(n)} \quad (1)$$

where
Q are the N-grams made by a query string

Length(n) is the length of the N-gram

Freq(n) is the number of documents containing the N-gram

To evaluate the method, the Japan Nursing Practice Standard Master (JNPSM) that includes the names of nursing activities and is built by the Medical Information Center Development Center (MEDIS-DC);

There was not full agreement in the mapping between the experts. We used 48 sets of the mapping as a gold standard.

Conclusion

The proposed method seems to be useful in the mapping process.

Nursing Minimum Data Set: A Literature Review

Reis Elisa [a], Marin Heimar [b]

[a] *Nursing of Interdisciplinary Care*
[b] *Federal University of São Paulo, Johns Hopkins School of Nursing, The Iowa University College of Nursing, IMIA NI SIG Secretary*

Abstract

Essential information for nurses may be obtained from information technology systems, for this reason it is fundamental the adoption of standard language which translates the essence of nursing. The Nursing Minimum Data Set and Nursing Management Minimum Data are relevant in description, register and retrieval of these data. A literature review on the use of these data sets for research on the subject, the trends and nurses' practice was accomplished. Method: Selected articles from the index of Medical Literature and Analysis and Retrieval System on Line (1993 - 2005), from the integrated library archives of Regional Medicine Library, in English and Portuguese. Final considerations: The findings permitted the identification of the total number of publications which show the necessity of dissemination and discussion of the subject among the Brazilian nurses; description of current health trends, the elderly and chronic disease patients care; nursing home care evaluate trends, justifying costs, comparing and evaluating cares. The increasing interest on the use of these data sets can be explained by the necessity of consistent and available information at the shortest length of time possible.

Keywords:

nursing minimum data set management,

nursing informatics, nursing, terminology, medical records systems

Introduction

Nowadays information has become a more significant power much than any other one. This power is frequently measured by the mastery and use of information provided by new technologies. Everyday, new technology resources are developed to enable new forms of relationship in the work, either for facilitating or creating new opportunities.

Several benefits from the use of information technologies have been incorporated by health professionals through development of more efficient medical equipment which can be interlinked, enabling professionals to access the necessary information for decision making. On the other hand, scientific and technological advance also brought more data and information.

The information volume generated by health institutions is enormous which demand the use of information technology to sustain process and management of necessary information for caring with the quality level that is demanded and deserved by the clients.

This reality brings many challenges to health professionals, mainly for nursing, which is responsible for continuous care of clients/patients. In this context it is expected from nursing professionals an adaptation to the new roles which answer the social and institutional demands, with knowledge, quality and competitiveness to attend clients who are more conscious and demanding about their rights, in a supplier/costumer relationship. Therefore, it is understood that an efficient use of information is critical for a contemporary health assistance of high quality by the professionals who are directly involved with the clients/patient care.

The use of information technology in health care has evolved from a situation where the computer was used in the accomplishment of single and isolated tasks to the level of integration of information, whose objective is to integrate diverse points of information and their use on the services.

At the beginning the use of information technologies was directed to the accomplishment of management activities with the development of financial and managerial systems. However, there is an increasing interest in development of information systems towards the registering of nursing clinical care.

The introduction of computer systems in the care environment enabled an approximation with the client.[1] Through these systems, the nurse can access more consistent and uniform information about procedures, responses to performed cares, and how clients perceive the received care.

A nursing information system focused on client must be specific to the complexities of nursing care and it needs to project the activities, interventions and outcomes for the client, which represents a great challenge since the nursing care outcomes do not occur isolated, but into a multi-disciplinary context.

In order to develop a nursing system the responses to the needs above mentioned it is fundamental the adoption of a

standardized language which can translate the essence of nursing as a profession. Therefore, several attempts have been seek out by nurses throughout the world to develop a standard list for the classification and documentation of nursing practice.

In 1984, the North American Nurses Association (ANA) started adopting a series of definitions in order to build an agreement about the necessity of defining a Nursing Minimum Data Set (NMDS) so that it would be possible the aggregation of data in a large scale. Since then, many efforts have been realized and they produced a vast knowledge throughout the years.Therefore, many nursing terminologies were developed to support the operation of nursing diagnosis, interventions and outcomes of nursing practice.

In 1988, based on the concept of Uniform Health Data Set (UMHDS) Werley and Lang built a Nursing Minimum Data Set which can be defined as set of uniform elements and information with definitions and categories related to nursing specific dimensions, with the location of necessary information to a variety of users in the health care system.[2] This data set has the following purposes: (1) describing the nursing care for the clients and their relatives in a variety of situations, (2) establishing comparisons on nursing data, (3) showing or projecting trends according to nursing care and distribution of nursing resources to clients according to health problems or Nursing Diagnosis, (4) stimulating the research in nursing through the use of detailed data present in a Nursing Information System and in other Health Care Information Systems and (5) supplying data about nursing care that can influence heath policies and decisions.

The Nursing Minimum Data Set defined by Werley[2] includes three major data categories: (a) the nursing care, (b) patients or clients demographics, (c) about the service.

In the data category abou*t nursing care* it is included: nursing diagnosis, nursing interventions, nursing results and intensity of nursing care.

The data category *patients or clients demographics* is composed by: personal identification, date of birth, sex, race and ethnics, and residence.

And, in the data category *about the service* we find: unique number of facility and service, patient's or client's health register number, nurses register number, admission episode or date, discharge or discharge date, patient's or client's location, and identification of paying source or responsible for payment.

In 1989, Huber and Delaney (.ref..) initiated, based on the work developed by Werley and Lang, the development of a data structure. The development project of the conceptual structure was based on Donabedian's[3] ideas related to structure, process and results as components for quality; from Iowa's[4] nursing management model and the nursing minimum data set by Werley and Lang[1], since the last identifies the service and demographics data as well as three important elements about nursing care: diagnosis, interventions and outcomes.

Tthe nursing management minimum data set is composed of 17 elements, grouped in three great categories: environment, nursing resources and financial resources.[5]

The use of these data sets may bring many benefits to Nursing: (1) Obtaining comparable essential data about nursing care essence and local, regional, national, and international resources. (2) Pointing out in the patient record the provided nursing care. (3) Identifying trends related to patient's or client's problems and the provided nursing care. (4) Providing Parameters to improve nursing services costs. (5) Data for quality improvement. (6) Additional stimulus for the development and refining of health information systems and electronic healthrecord. (7) Comparative research about nursing care, including research on nursing diagnosis, interventions, outcomes, and intensity. (8) Contributions to promote nursing as a discipline.[6]

Understanding the relevanceof nursingdata sets to support nurses in describing, registering and retrieving data about their activities, either assisting or managerial,; this study was developed by a review of publications which approach the use of nursing minimum data sets to better understand the subject and trends in research and practice developed by nurses.

Objectives

Identifying in national and international periodicals from 1993 to 2005, those referring to Nursing Minimum Data Set (NMDS) and the Nursing Minimum Managerial Data Set (NMMDS) and characterize the production related to some characteristics as language, origin of articles, most common periodicals, authors' performance location and the main themes approached.

Material and methods

The criteria established for the selection of periodicals were: articles that approached the subject Nursing Minimum Data Set, articles into MEDLINE (Medical Literature Analysis and Retrieval System on Line) within 1993 and 2005, articles located in the integrated library archives in theBIREME - the(Latin American and Caribbean Sciences of Health Information Center), in the English language.

The key words used for the bibliographic search in MEDLINE were: "nursing", "minimum", "data", "set", "management". The first results of this search were the

obtainment of 160 articles and the studied sample had 130 articles. The articles which were not in English or could not be found in the archive were refused.

The variables chosen for analysis of articles were: publication language, articles origins, most common journals, authors' performance location and main themes approached.

A quantitative analysis was performed in order to characterize the sample according to the chosen variables through the use of a data basein MicrosotfAccess ®. The categorization was accomplished after reading the article and filling up a script for data collecting.

Results and discussion

From the 160 articles found in MEDLINE, 155 (97%) were written in English, 3 (2%) in Dutch, 1 (1%) in French and 1(1%) in Norwegian. From the 155 articles written in English it was possible to retrieve 130 (81%) articles which constituted the sample for this study. Therefore, the analysis was accomplished using the sample of 130 articles which correspond to the described criteria.

Distributing the sample according to country of , wepublication found that they were from seven countries as it shows on table 1. The greatest number of publications are in the United States of America totalizing 101 (78%) of articles, followed by England 15 (12%), Canada 5 (4%), Holland 4 (3%), Italy and Finland with 2 (2%) articles each and Australia 1 (1%). This survey showed that within the 13 years analyzed, the United States of America was the country that produced articles more constantly.

Table 1 - Distribution of sample according to publishing country

Country of Publication	N	%
The United States	101	78%
England	15	12%
Canada	5	4%
Holland	4	3%
Italy	2	2%
Finland	2	2%
Australia	1	1%
Total	130	100%

In table 2 it can be verified the distribution of articles according to the publication year. The year 2003 was the one which showed more publications 23 (18%), followed by 2004 with 22 (17%), 1997 with 14 (11%), 2002 with 13 (10%) published articles.

It was verified an increase in thescientific production in a more constant way from the year 2002.

Table 2 - Distribution of sample according to the publication publishing year

Publishing Year	N	%
1993	3	2%
1994	8	6%
1995	8	6%
1996	3	2%
1997	14	11%
1998	6	5%
1999	10	8%
2000	11	8%
2001	8	6%
2002	13	10%
2003	23	18%
2004	22	17%
2005	1	1%
Total	130	100%

Regarding to the publishing means it was found that the sample was distributed among 67 journals which were grouped by publication area: 66% (86) of the articles were divided in three areas: 29% (38) were published in journals specialized on geriatrics, 24% (31) in journals on nursing and 13% (17) in medical journals.

This distribution may show a trend in health assistance, since the elder population has been increasing in the last decades.

Table 3 - Distribution of sample according to thematic area of journal

Journal Thematic area	N	%
Specialized on Geriatrics Journal	38	29%
Nursing Journal	31	24%
Medical Journal	17	13%
Health Journal	9	7%
Congresses Proceedings	8	6%
Quality Journal	7	5%
Neurology Journal	7	5%
Informatics Journal	4	3%
AIDS Journal	2	2%
Others	7	5%
Total	130	100%

The distribution of articles concerning to the thematic category presented on table 4 show that most of them focus on describing 'Trends related to patient's or client's problems 38% (49), followed by 'Parameters for cost improvement' 16% (21), 'Obtainment of comparable data' 15%, Data for quality improvement 12%.

Therefore, it is possible to verify that a nursing minimum data set is useful for improving nursing services, since anticipating patient's/client's needs, improving costs, comparing data and verifying quality improvement opportunities, the possibility of offering and controlling care is more concrete.

Table 4 - Distribution of sample according to thematic categories

Thematic category	N	%
Trends related to patient's or client's problems	49	38%
Parameters for cost improvement	21	16%
Obtainment of comparable data	19	15%
Data for quality improvement	15	12%
Comparative research on nursing care	11	8%
Development of Health Information Systems	10	8%
Contributions promoting nursing as a discipline .	5	4%
Total	130	100%

The distribution of articles regarding author's affiliation-shows that 68% (88) worked in Universities, 19% (25) in Health Associations or Institutions, 2% in hospitals and 11% (14) of the articles did not mention author's affiliation. From this survey it is evident the importance of educational institutes on the knowledge production. The Universities are located in the U.S.A., United Kingdom, Japan, Korea, Italy, Belgium, Taiwan, Iceland and Germany. The health associations and institutions are also concerned with knowledge production; however, much investment is still needed. It is necessary to convinceprofessionals to become integrated to these academic institutes on the accomplishment and mainly the use of research results to design and redirect . The concern is increasingly frequent for through the aforesaid, it will be possible to plan and evaluate the offered services, however, there are still much to be done.

Final considerations

This work has originated from the interest in studying the standards for the documentation of nurse care in order to incentive the development of computerized nursing systems that may register and retrieve nursing data, generating information that show the nursing contribution for health care. In other words information that supports nurses in different locations and type of nursing performance.

The search for publications about the subject was a way of identifying the nursing minimum data set related studies, verifying the benefits achieved from this use.
The findings allowed the identification of important facts as the totality of English language publications and international journals, displaying the necessity of spreading and discussing the theme among Brazilian nurses, making the language barrier less evident.

It was also possible to identify that the articles describe the current health trends and care has extrapolated the hospital, the assistance of elders and patients with chronic diseases. A variety of articles was found related to nursing home care, which use the nursing minimum data set to evaluate the nursing care trends necessary, justifying costs, comparing and evaluating these cares.

It was evidenced the growing interest by nurses on the use of those minimum data sets which may be explained by the need of consistent and available information at the shortest time length possible to guarantee high quality and optimized use of human and material resources.

Current Approaches to Secure Health Information Systems are Not Sustainable: an Analysis

Vicky Liu, William Caelli, Lauren May, Peter Croll, Matt Henricksen

Information Security Institute, Queensland University of Technology, Australia

Abstract

This paper proposes a viable IT-based solution for ensuring the privacy and security of sensitive information in contemporary Health Information Systems (HIS).

Keywords:

trusted systems, information assurance, privacy, MAC, HIS

Introduction

In today's society Information, Computer and Telecommunications technologies (ICT) are increasingly entrenched as information infrastructures for the majority of essential services in leading countries such as Australia, the UK and the USA. ICTs are being designed and deployed to process, transmit and store health information in various e-health systems globally. These systems play a significant role in the potential improvement of quality and productivity in the health sector.

In order to manage healthcare stakeholders' expectations of these systems, governments have initiated e-health blueprints which provide guidelines to the developers of HIS. These guidelines take into account the interests of all stakeholders in the health sector.

This paper is particularly interested in the implementation of HIS from an information security aspect: the protection of personal privacy and security of electronic patient records. Current approaches to information security in HIS are, in the opinion of the authors, not sustainable. This paper proposes a viable ICT solution which can reliably provide appropriate levels of secure access control for the protection of sensitive health data in HIS.

Access control in ICT

Access control is one of the fundamental security mechanisms used to protect computer resources; in particular in multi-user and resource-sharing computer environments such as contemporary HIS. The lack of adequate access control management in such systems has been demonstrated on numerous occasions in recent history: the privacy invasion scandal at Australia's Centrelink [1], the lack of adequate safeguards in the UK NHS patient records system [2], and the significant IT security weaknesses identified in the USA HHS information system [3]. These types of breaches have the potential for inflicting, and do inflict, major harm on consumers and providers alike. The issue of providing suitable access control in such systems is not an insurmountable one. This paper proposes a viable solution to this issue.

The two traditional types of access control modes are Discretionary Access Control and Mandatory Access Control:

The **Discretionary Access Control (DAC)** mechanism allows the owner of information to grant access permissions to other users or programs at his/her discretion without the system administrator's knowledge. Such a policy does not provide the actual 'owner' of the system fully centralised access control over the organisational resources. DAC mechanisms are fundamentally inadequate for strong system security because the owner of the system does not have access control over the objects (files) on the system.

The **Mandatory Access Control (MAC)** mechanism provides the ability to limit access to only legitimate users. Ferraiolo et al [4] underscore that MAC is necessary when the provision of a truly secure system is required. Access permission to information is determined by the user's security clearance compared to the security level of information determined by the system. This is also known as a multi-level security (MLS) policy, which was first introduced by Bell and LaPadula (BLP) [5] .

Role-Based Access Control (RBAC) is complementary to both DAC and MAC techniques. RBAC enables easier management by ensuring finer granularity in the access system.

The majority of current information systems which manage access control are DAC-based allowing for wide implementation of commodity software and hardware. Examples are Microsoft Corporation's Windows systems, open-source systems such as Linux and the original Unix system. These are general-purpose systems intended for use in as many applications as possible. In the healthcare sector, HIS MAC-based systems are more appropriate to, and capable of, satisfying the specific requirements of privacy and security of information.

In technical computing terms an application program resides atop a number of sub-systems, one of which is the

operating system (OS) which effectively controls what the hardware does. The security of an application program is restricted by the strength of the security that the OS allows. DAC and MAC mechanisms are enabled at the OS level as well as higher levels including data network management and the database management systems for the application.

Our approach

ICT is now sufficiently advanced that a MAC-based electronic healthcare management system is feasible. Our research to date has indicated that current OS structures need to be updated for HIS needs. The Health Informatics Access Control (HIAC) model is our approach to overcoming many of the privacy and security issues which have plagued previous attempts at electronic health management systems. The HIAC is based on the MAC type of OS which primarily satisfies the requirement for confidentiality of records (this is a major impediment in current and previous systems). The HIS is then developed atop the trusted OS.

For general applications, currently available products that support the MAC principles of trusted OS include "Red Hat Enterprise Linux (RHEL) Version 5, "Fedora Core 6", and "Sun Microsystems Solaris 10 with Trusted Extensions Software". The HIAC model exploits the privacy- and security-enhancement features of such trusted OS in the healthcare environment. The end result is a dedicated trusted HIS which satisfies all privacy and security requirements.

To determine the practical viability of a HIAC model for HIS a demonstrator, based on the Security Enhanced Linux (SELinux) OS with MAC and RBAC approach, was built [6] The HIAC model is necessarily MAC-based accompanied by RBAC properties for flexibility and a refined level of granularity. This degree of simultaneous control and flexibility is not achievable with DAC, RBAC or MAC individually.

The MAC-based system can provide the ability to limit access to only legitimate authorised users. The HIAC profiling mechanism allows for the system administrator to configure the organisational access policies defined and determined by the CEO/CIO and the data custodian. With MAC the access privileges of all users are equally bound by the policy, not set by the discretion of the file/program owners as with DAC. The internal adversary or disgruntled employee will not be able to access health information inappropriately or even through feeding information to an external adversary.

The MAC mechanism can protect the system from malicious or flawed applications which can potentially damage or destroy the system and its information. This can prevent an external adversary penetrating the system by exploiting Trojan Horse attacks, viruses, malware, social engineering or other illicit means to gain total access control or to tamper with audit systems. The HIAC model includes the principle of least privilege and also enforces domain separation through the use of the protected zones known as 'sandboxes' within Redhat's SELinux. These help prevent applications interfering with each other such that an unauthorised user cannot gain overall control of the system as with DAC.

HIAC incorporates RBAC which complements contemporary MAC systems by ensuring more flexibility over the more traditional MAC standalone systems. With RBAC Doctor X and Nurse Y are appointed into a role-type, for example Doctors and Nurses respectively. Access permissions are associated with these roles. In practice this approach gives more flexibility than in the traditional MAC where accesses are granted to individual persons.

In general HIAC provides for maximum flexibility within a strongly secure environment. This means achieving a balance between security needs and flexibility of implementation, which is primarily determined from a privacy risk assessment. For example HIAC provides the flexibility of having an emergency override function by switching to the emergency policy in emergency circumstances. Full auditing of the system deters potential abuses of this flexibility.

Conclusion

Current moves toward Web-based identity and authentication structures present major challenges where such structures are not based on highly trusted OS. The majority of OS in use today are DAC-based in which there are no inherent privacy and security features. All applications and supporting software which necessarily reside atop these untrusted operating systems are also untrusted and therefore vulnerable from a privacy and security viewpoint.

This paper contends that it is both timely and desirable to move electronic HIS towards privacy- and security-aware applications that reside atop trusted computing-based OS. Such systems have the real-world potential to satisfy all stakeholder requirements including modern information structures, organizational policies, legislative and regulatory requirements for both healthcare providers and healthcare consumers (privacy and security), and flexible operational demands in HIS.

This paper emphasises the need for well-directed research into the application of inherent privacy- and security-enhanced operating systems to provide viable, real-world trusted HIS. The authors propose an HIAC model which has the potential to fulfil these requirements.

Current Approaches to Secure Health Information Systems are Not Sustainable: an Analysis

Vicky Liu, William Caelli, Lauren May, Peter Croll, Matt Henricksen

**Institute of Security Information (ISI),
Queensland University of Technology, Brisbane, Australia**

Research Question

Are the current approaches to secure health information systems viable and sustainable?

Are there any cases related to health information privacy violations or weaknesses?

Privacy Invasion at Australia's Centrelink [1]

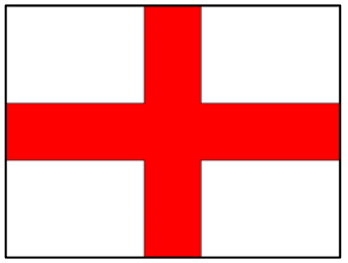
- Centrelink deploys spyware software to detect inappropriate access to client records
  - **790** cases of inappropriate access to client records since 2004
    - 19 staff were fired, 92 resigned,
    - More than 300 staff faced salary deductions or fines,
    - 46 were reprimanded, and
    - the remainder were demoted or warned.

Access control management issue

Inadequate Security Measures at UK's NHS System [2]

- 50 million patient records may be made accessible by 250,000 NHS staff
- To access patient records is on a "need-to-know" basis.
- Does not allow patients to selectively protect particular parts of their health information

Access control management issue



Security Weaknesses at HHS Information Systems [3]

- Significant security weaknesses, e.g.
  - network management, user rights and file permissions, and the auditing and monitoring of security related events
- The potential to expose clients' sensitive information to serious privacy invasions

Access control management issue

HHS : Health and Human Services

Access Controls

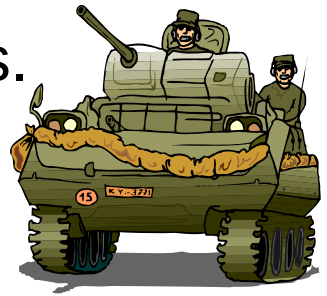
- A set of rules that specify which users can access what resources with which types of access restrictions
- **Applications**
  - Operating systems,
  - Network control systems, and
  - Database management systems
- **Access Models**
  - Mandatory Access Control (MAC)
  - Discretionary Access Control (DAC)
  - Role-based Access control (RBAC)

Discretionary Access Control (DAC)

- Most mainstream operating systems are based on DAC
- DAC enforces security by ownership
- DAC allows the owner of information to grant access permissions to other users/programs at his/her discretion, for example, in Unix/Linux
  - chmod 777 spy
- It is vulnerable to “Trojan horse” attacks

Mandatory Access Control (MAC)

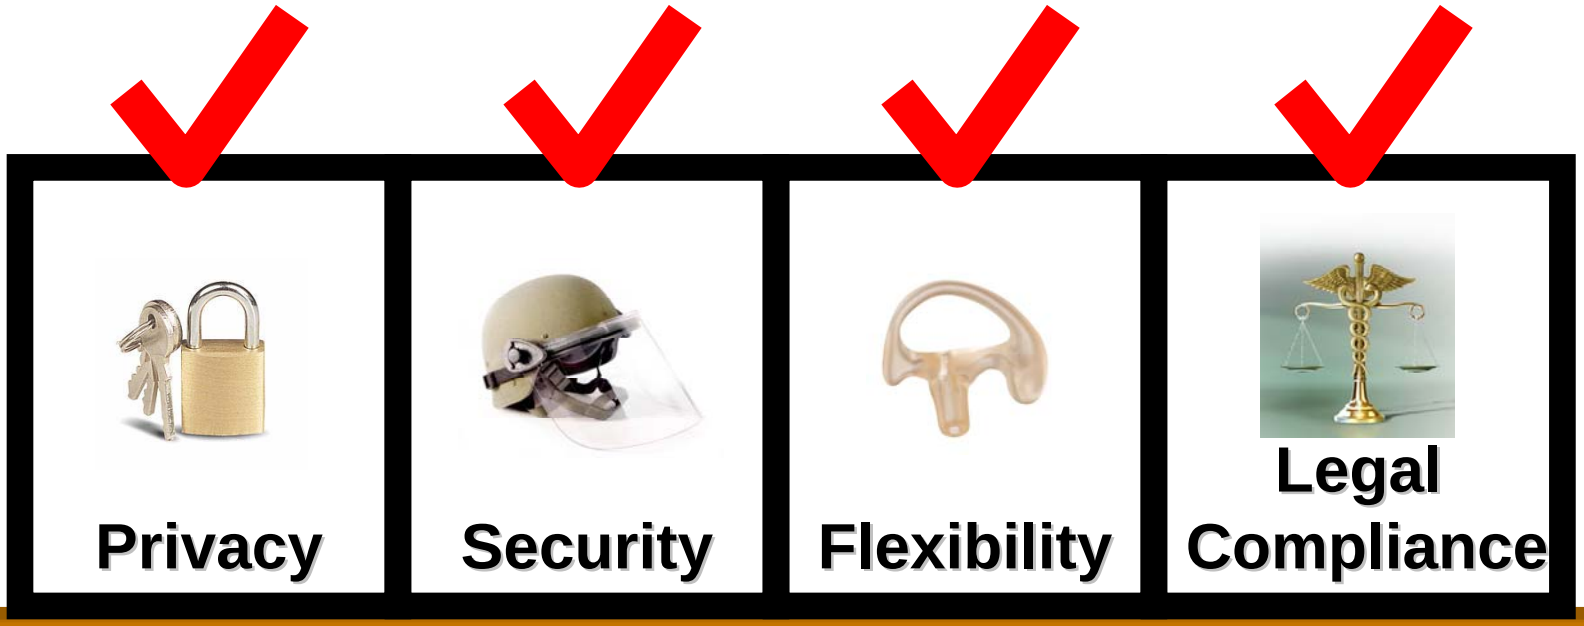
- MAC can be use to prevent some types of Trojan horse attacks. 
- The traditional MAC was originally designed largely for a military environment based on the MLS hierarchical structure.
- MAC focuses on data confidentiality
- MAC can provide the ability to limit access to only legitimate users 
- In MAC-based system, it is more difficult for an external adversary to tamper with audit systems.



Role-based Access control (RBAC)

- To simplify the management of authorisation
- Policy-independent and policy neutral i.e. not enforcing any particular protection policy
- RBAC does not efficiently support access policies in the way of general consent qualified by explicit denials

Health Informatics Access Control (HIAC)



HIAC {MAC, RBAC}

Health Informatics Access Control (HIAC)

- The HIAC system is necessarily MAC-based, incorporating RBAC properties.
- The HIAC profiling mechanism allows for health professionals to specify their requirements to a refined level of granularity.
- This degree of simultaneous control and flexibility is not achievable with either DAC or MAC individually.
- In a HIS environment, the flexibility feature is required to allow for emergency override.

Snomed CT Survey: An Assessment of Implementation in EMR/EHR Applications

Kathy Giannangelo[1] and Susan Fenton[2]

[1]American Health Information Management Association, Chicago, IL, USA
[2]Foundation of Research and Education, Chicago, IL USA

Abstract

A much-needed start to facilitating the linkage between vendor willingness to adopt SNOMED CT and actually implementing it in electronic medical record (EMR)/electronic health record (EHR) systems is to gain knowledge about the current use of SNOMED CT in applications. A descriptive study on the status of adoption and implementation of SNOMED CT in EMR/EHR systems by health information technology (HIT) vendors was conducted in late 2006. This study consisted of a Web-based survey of 25 questions. Results revealed that 42 or 58.3% had obtained a SNOMED CT license. The most common reason given for not making plans to obtain a license was no market demand. In addition, only 14 or 19.4% of the respondents had SNOMED CT currently operational. Twenty, or 27.7%, of the respondents indicated SNOMED incorporation into applications is currently being developed, is planned for 2007, or is planned for 2008 or beyond. All told, less than half, 47.2%, of the respondents have incorporated or plan to incorporate SNOMED.

Keywords:

SNOMED CT, computerized patient records, terminology, standards

Introduction

The new millennium ushered in the unprecedented national consensus that the widespread use of technology for the electronic health record (EHR) will lead to reduced medical errors, higher quality care, and improved efficiency in the healthcare industry.[1] To accomplish this it will be necessary to move beyond the administrative data currently accepted as the standard for clinical data in many health services research projects.

The National Committee on Vital and Health Statistics (NCVHS) study identified SNOMED CT as one of the core set of Patient Medical Record Information terminology standards.[2] SNOMED CT was also adopted as a Consolidated Health Informatics (CHI) standard for the following domains: lab result contents, non-laboratory interventions/procedures, anatomy, diagnosis/problem lists, and nursing.[3] In May of 2006 SNOMED CT was identified as one of the preferred terminologies in the American Society for Testing and Materials (ASTM) Continuity of Care Record.[4]

Also in 2006, the Healthcare Information Technology Standards Panel (HITSP) recommended SNOMED CT in their Interoperability Specifications.[5] Then in January, Secretary Mike Leavitt, Department of Health and Human Services, accepted the standards recommended by HITSP for the Electronic Health Records, Biosurveillance, and Consumer Empowerment use cases.[6] One of the terminology standards named was SNOMED CT.

Four years ago SNOMED CT became available to U.S. users at no cost through the National Library of Medicine's Unified Medical Language System®. However, the enablers or impediments regarding implementation of SNOMED CT into EHR systems are relatively unknown. A NLM representative, upon questioning during the July 2005 NCVHS Subcommittee on Standards and Security, recognized the need to find out what the barriers are to EHR vendors adopting SNOMED CT.[7]

With the U.S. government acknowledging the need to gain a better understanding of vendor concerns regarding integration of SNOMED CT into their clinical information systems, identifying the barriers to SNOMED CT adoption is critical. Learning what prompts vendors to include SNOMED CT in EHR systems could help draw up strategies to accelerate use and encourage implementation.

Methods

The Foundation of Research and Education of the American Health Information Management Association (AHIMA) conducted a descriptive study. This study was designed to determine the status of adoption and implementation of SNOMED CT in EMR/EHR systems by health information technology (HIT) vendors and discover the available applications for SNOMED CT in EHR systems. An additional objective included learning what prompts vendors to include SNOMED CT in EHR systems.

A list of HIT EHR vendors was created from the following sources:

- HIMSS EHR Vendor's Association

- EHRs certified by CCHIT
- Winners of TEPR awards for the past five years
- AC Group's 2006 EHR/PMS survey
- EHR/EMR category of the Healthcare Informatics 2006 Resources Guide
- EMR category of the Health Management Technology Online Resource Guide
- 2006 13th annual Healthcare Informatics 100
- Exhibitors at the 2006 HIMSS Exhibition
- AHIMA vendor director
- Commercial sites

A survey consisting of twenty-five questions was developed. Face validity was performed by AHIMA and FORE staff in order to ensure the items addressed the important aspects of determining SNOMED CT implementation in EMR/EHR systems. A group of nursing informaticians conducted content validity.

Results

The survey was e-mailed to 408 HIT vendors. Out of 408 HIT vendors who received the survey, 72 were returned with a response rate of 18%. Forty-two or 58.3% had obtained a SNOMED CT license. Thirty or 41.7% stated they have no current plans to obtain a SNOMED CT license. The most common reason given for not making plans to obtain a license was no market demand.

To address the survey's objective of identifying the prevalence of SNOMED CT integration in EHR products, recipients were asked about their plans for implementation of SNOMED CT in their product. Implementation was defined in the question to mean SNOMED CT is a part of or used in the EMR/EHR application. As shown in figure 1, only 19.4% of the respondents had SNOMED CT currently operational. Twenty, or 27.7%, of the respondents indicated SNOMED CT incorporation into applications is currently being developed, is planned for 2007, or is planned for 2008 or beyond. All told, less than half, 47.2%, of the respondents have incorporated or plan to incorporate SNOMED CT.

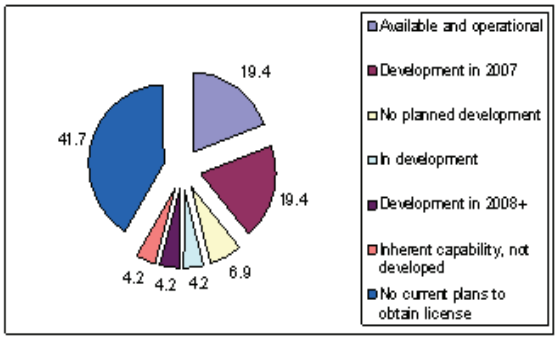

Figure 1 - Prevalence of SNOMED CT Integration

Discussion and Conclusion

Obtaining a complete a representation of HIT vendors is made difficult by the enormous volatility in the field. An additional complicating factor is finding the knowledgeable person within the company to receive the e-mail. Both of these factors may have accounted for not receiving a response to the request for survey completion.

In order for SNOMED CT to be successfully adopted and implemented, vendors need a business reason (mandate or end-user demand) to deploy it. Ultimately, adoption and implementation of SNOMED CT depends upon its ability to address very practical needs. Without incentives or drivers finding less than half of the respondents to this survey having incorporated or planning to incorporate SNOMED CT in EMR/EHR applications is not surprising. The most common reason for not making plans to obtain a SNOMED CT license was no market demand. Ways in which this demand could be created is through the inclusion of terminology for certification of electronic health records and use case requirements.

Vision ONE Voice Future

AHIMA American Health Information Management Association®

Introduction

- Electronic health record (EHR)
  - Component – the source or clinical information systems (CISs) that capture data to directly support patient care and the EHR infrastructure
    - CISs use a number of applications often focused on clinical function to enable the collection, storage, and processing of **discrete or structured** data for various purposes
      - Terminologies supply the **discrete or structured** data
        - » SNOMED CT is a reference terminology which can be used to encode discrete clinical information

Objectives

- Identify the universe of HIT vendors working with SNOMED
- Determine the prevalence of SNOMED CT integration in EHR products
- Learn what prompts vendors to include SNOMED CT in EHR systems
- Identify the available and potential future applications for SNOMED CT in EHR systems

Methodology

- Descriptive study
  - Study sample
    - Health Information Technology (HIT) vendors
  - Study tool
    - Web-based survey

Methodology: Study Sample

- Sources for HIT EHR vendors
  - HIMSS EHR Vendor's Association

Computer-Assisted Coding Software Standard Recommendations from a Workshop

Susan H. Fenton, Sandy Fuller, Kathy Giannangelo, Rita Scichilone, Mary Stanfill, Sue Bowman, Allison Viola

American Health Information Management Association, Chicago, Illinois, United States of America

Abstract

Standards for computer-assisted coding (CAC) software development are important while CAC is used for administrative purposes and are crucial when CAC is utilized in clinical care applications and clinical decision support. A workshop of CAC vendors and other stakeholders convened in September 2006 to begin a dialogue about these standards. The stated intention of the program was and is to promote a future state where automated tools are used to capture discrete coded data that can be mutually understood and shared for multiple uses within the healthcare industry. Following presentations on current CAC research the attendees divided into 5 workgroups: Software Management and Use, Audit Mechanisms, Metrics and Evaluation, Certification and Test Suite. The participants were asked to discuss issues and develop recommendations. The synthesis of the workgroup discussions revealed a series of next steps requiring input from a wide variety of stakeholders. They are presented here for discussion with interested parties.

Keywords:

software validation, information management

Introduction

Purpose of the conference

This conference was organized by the Foundation of Research and Education (FORE) of the American Health Information Management Association (AHIMA) to prepare for the future of coding and classification. The goals included: 1) raising the awareness of the need for computer-assisted coding (CAC) software standards, 2) delineating the scope of the challenge, 3) gathering input from a variety of stakeholders, 4) recommending a framework for CAC software standards, and 5) determining the necessary and desired next steps.

Methods

Conference content

The first day of the conference consisted of technical papers solicited via a call for participation. The titles are the papers presented are as follows:

1. Assessing Coder Change Rates as an Evaluation Metric by *Michael Nossal, MA; Philip Resnik, PhD; and Jean Stoner, CPC, RCC -CodeRyte, Inc.*
2. Computer-Assisted Auditing For High Volume Medical Coding by *Daniel T. Heinze, Peter Feller, Jerry McCorkle, Mark Morsch - A-Life Medical, Inc.*
3. Using Intrinsic and Extrinsic Metrics to Evaluate Accuracy And Facilitation In Computer Assisted Coding by Philip Resnik, PhD, Michael Niv, Michael Nossal, Gregory Schnitzer, RN, CCS, CCS-P, CPC, CPC-H, RCC, Jean Stoner, CPC, RCC; Andrew Kapit, and Richard Toren - CodeRyte, Inc.
4. Software Engineering of NLP-Based Computer Assisted Coding Applications by *Mark Morsch; Carol Stoyla; and Ronald Sheffer, Jr .- A-Life Medical, Inc.*
5. Computer Assisted Coding For Inpatients - A Case Study by *Cheryl Servais, MPH, RHIA - Precyse Solutions, LLC.*
6. How Does the System Know It's Right? Automated Confidence Assessment for Compliant Coding by *Yuankai Jiang, PhD; Michael Nossal, MA; and Philip Resnik, PhD, - CodeRyte, Inc.*
7. Computer Assisted Coding Software Improves Documentation, Coding, Compliance and Revenue by *Sean Benson, - ProVation Medical.*
8. Automated Coding and Fraud Prevention by *Jennifer Garvin, Ph.D. - Medical Informatics Postdoctoral Fellow, Center for Health Equity Research and Promotion; and Valerie Watzlaf, Ph.D., RHIA, FAHIMA - University of Pittsburgh.*

The second day consisted of 5 workgroup breakouts:

1. Software Management and Use – including implementation issues. CAC must interface with other systems to provider adequate Return on Investment for its use. Quality checks on CAC data will be required for the foreseeable future.
2. Audit Mechanisms – also called Quality Assurance. These checks are integral to all healthcare data, not just data coded with a computer. Sample size and acceptable accuracy rate issues remain to be resolved for all coding.

3. Metrics and Evaluation – how to determine the accuracy of CAC software. There are multiple levels of evaluation requiring different types of metrics. This group believed it to be vital to have a reference or "gold" standard for evaluation purposes.
4. Certification – possibly needed to promote user acceptance. Different possible certifi-cation models were discussed and a list of desirable certification criteria constructed. This group felt it was too early in the standard development process to discuss certification.
5. Test Suite – a standard source for testing functionality and accuracy. The group felt that development of a test suite would not only require a high level of government involvement and cooperation, but would also be very expensive. Overall, while this might be a desirable objective, the group felt the industry needed to understand the issue more thoroughly before beginning on a project like this.

A more detailed summary of the breakout group results can be found in the proceedings.

The final morning featured a reactor panel whose purpose was to present different perspectives on the issue of CAC software standards.

The entire proceedings can be found at http://www.ahima.org/perspectives/conference_papers.asp.

Results

Next steps for beginning the CAC software standards development process emerged over the course of the conference. Short term next steps included:

1. establishing a public forum for continued dialogue and development,
2. benchmarking current U.S. coding processes in order to better understand the impact of CAC,
3. begin an education process with all stakeholders,
4. reconvene in 2007 (in Philadelphia, PA on October 5, 2007), and
5. develop a consensus on a standard U.S. coding process as a precursor to a best practice and metrics.

Long-term steps were also discussed including:

1. fully defining a coding gold standard for accuracy – dependent upon consensus and benchmark results,
2. determining what combination of testing, certification and conformance are the best, correct choices to achieve standardization,
3. educating current and future coding professionals to ensure they can effectively use CAC software, and
4. continued pursuit of the "right" code – assigned with 100% certainty.

Conclusions

CAC is an emerging technology having an effect on all purposes for which coded data is used. AHIMA/FORE will continue to sponsor the development of consensus standards as the technology matures. We welcome opportunities for discussion with all interested parties.

INTRODUCTION

- Goals:
  1. Raising awareness of the need for CAC software standards
  2. Delineating the scope of the challenge
  3. Gathering input from a variety of stakeholders
  4. Recommending a framework for CAC software standards
  5. Determining the necessary and desired next steps

FORE Foundation of Research and Education of AHIMA

AHIMA American Health Information Management Association®

METHODS – FIRST DAY

- Presentation of solicited technical papers in the following areas:
  - Evaluation methods and metrics
  - Software development
  - Implementation testing
  - Regulatory Issues

FORE Foundation of Research and Education of AHIMA

AHIMA American Health Information Management Association®

METHODS – SECOND DAY

- Working group breakouts
  - Software Management and Use – including implementation issues
  - Audit Mechanisms – AKA Quality Assurance, this is integral to all healthcare data
  - Metrics and Evaluation – determining the accuracy of CAC software

FORE Foundation of Research and Education of AHIMA

AHIMA American Health Information Management Association®

METHODS – SECOND DAY

- Working group breakouts (con't)
  - Certification – possibly needed to promote user acceptance
  - Test Suite – standard source for testing functionality and accuracy. Very complex and expensive undertaking.

FORE Foundation of Research and Education of AHIMA

AHIMA American Health Information Management Association®

SHORT-TERM NEXT STEPS

1. Establish a public forum for continued dialogue and development
2. Benchmark current U.S. coding processes to better understand the impact of CAC
3. Begin an education process with all stakeholders

FORE
Foundation of Research and Education of AHIMA

AHIMA
American Health Information Management Association®

SHORT-TERM NEXT STEPS

4. Reconvene in 2007 (now scheduled for October 5-6, 2007 in Philadelphia, PA)
5. Develop a consensus on a standard U.S. coding process as a precursor to a best practice and metrics

FORE Foundation of Research and Education of AHIMA

AHIMA American Health Information Management Association®

LONG-TERM NEXT STEPS

1. Fully defining a coding gold standard for accuracy
2. Determining what combination of testing, certification and conformance are best for standardization
3. Educating current and future coding professionals to effectively use CAC
4. Continued pursuit of the “right” code – assigned with 100% accuracy

What Health Influences Are Caused By EMR Working? - In Case of Japanese Nursing Situation

Yukie Majima [a], Yasuko Maekawa[a]

[a] *School of Nursing, Osaka Prefecture University, Osaka, Japan*

Abstract

The purpose of this study was to determine how nurses used visual display terminals (VDT) and whether the use of VDTs had any influence on their health. In our study, the use of the EMR and the health influences of introduction of the EMR were surveyed using a questionnaire in a general hospital. The results indicated that VDT works were conducted in nurse stations rather than at the bedside. Only about 10% of nurses did exercises to prevent neck, shoulder and back pain before starting work. Since more than half of the nurses remained standing while inputting, extra guidelines should be developed for this aspect as the MHLW guidelines currently only deal with seated operations. Health influences after introduction of the EMR, more than half the subjects complained of worsened symptoms including eye strain, stiff shoulders and neck, and general fatigue, all of which are signs of VDT syndrome.

Keyword:

nurses, VDT works, electronic medical record system(EMR), health influences

Introduction

Currently in Japan, the use of EMR and digital ordering systems in hospitals is increasing. Since medical service is one of the seven main fields of the e-Japan priority policy program, it is assumed that digitalization will be promoted in medical facilities. Accordingly, appropriate workplace health measures should be taken in response to changes in the working environment of nursing personnel.

Methods

1) Study period: March 8 to 29, 2005. 2) Subjects: Nursing care personnel (378 individuals) working at a private general hospital (477 beds) in Japan which had introduced an EMR around a year previously. 3) Method and contents of study: Self-reported questionnaire study. A questionnaire was delivered to the subjects and was recovered on completion under ethical cares. It consisted of questions regarding the VDT working situation of EMR((1)posture, (2)place, (3)adjust materials around PC, (4)input device, (5) time per one use of EMR, (6)brightness around PC on each shift, (7)setting-up exercise before working) and the health influences (eye strain, low vision, dried eyes, stiff neck and shoulders , numbness of fingers, back pain, fatigue, headache, stress, gloomy) after using the EMR.

Results

323 questionnaires delivered were recovered (85.4% recovery). 193 subjects (59.8%) were in their 20s, 80 (24.8%) were in their 30s, 27 (8.4%) were in their 40s and 19 (5.9%) were in their 50s. Four subjects (1.2%) did not reveal their age. The average number of years working at the hospital was 5.67.

1) The VDT working situation of EMR

VDT works were conducted in nurse stations rather than at the bedside. Since more than half of the nurses remained standing while inputting records.

2) The health influences after introduction of the EMR

Only about 10% of nurses did exercises to prevent neck, shoulder and back pain before starting work. More than half the subjects complained of worsened symptoms including eye strain, stiff shoulders and neck, and fatigue, all of which are signs of VDT syndrome (Figure 1).

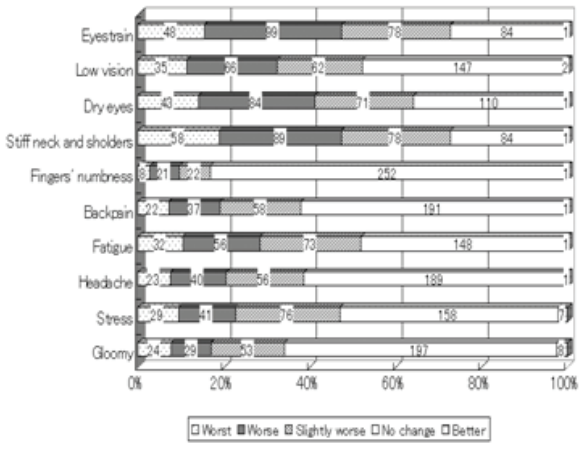

Figure 1 - Subjective signs of health influences after using EMR

Conclusion

Nurses' VDT working situations are different form those of office workers etc. Workplace health measures for VDT operations by nurses should be urgently revised based on the results of this study.

M. D. Anderson Cancer Center: Gaining Capacity by Improved Patient Throughput

512 Beds

$409 million in research funding in FY06

16,000 Employees

1367 Faculty

4366 Trainees

FY06 Clinical Activity	5-year Growth
21,221 Admissions	14%
155,551 Patient Days	15%
27,340 New Patients Served	28%

8.8 million square feet

Capacity Issues at M. D. Anderson

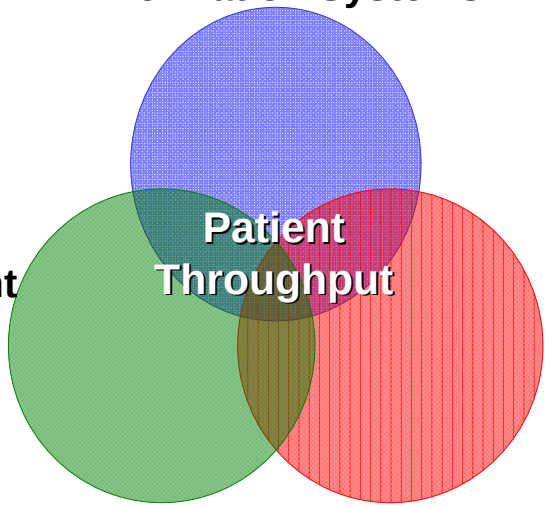
- In 2005, census overwhelms capacity and patients wait for beds in following areas:
  - Emergency Center
  - Operating Room/Post-Anesthesia Care Unit (PACU)
  - Admissions
- Limited space available to create or build additional beds
- Construction projects very expensive to plan and undertake
- Demand for oncology services will continue to increase as population ages

Goal of Project BED
Bringing Efficient Discharge

By focusing on short- and long-term solutions related to the discharge process, teams in Clinical Operations will make hospital beds available more quickly and gain capacity by improving patient throughput.

Administrative Team*
Admissions, Housekeeping
Patient Transportation
Information Systems

Teams:
- **Measured discharge process steps**
- **Targeted specific steps to improve**
- **Eliminated process flow obstacles**

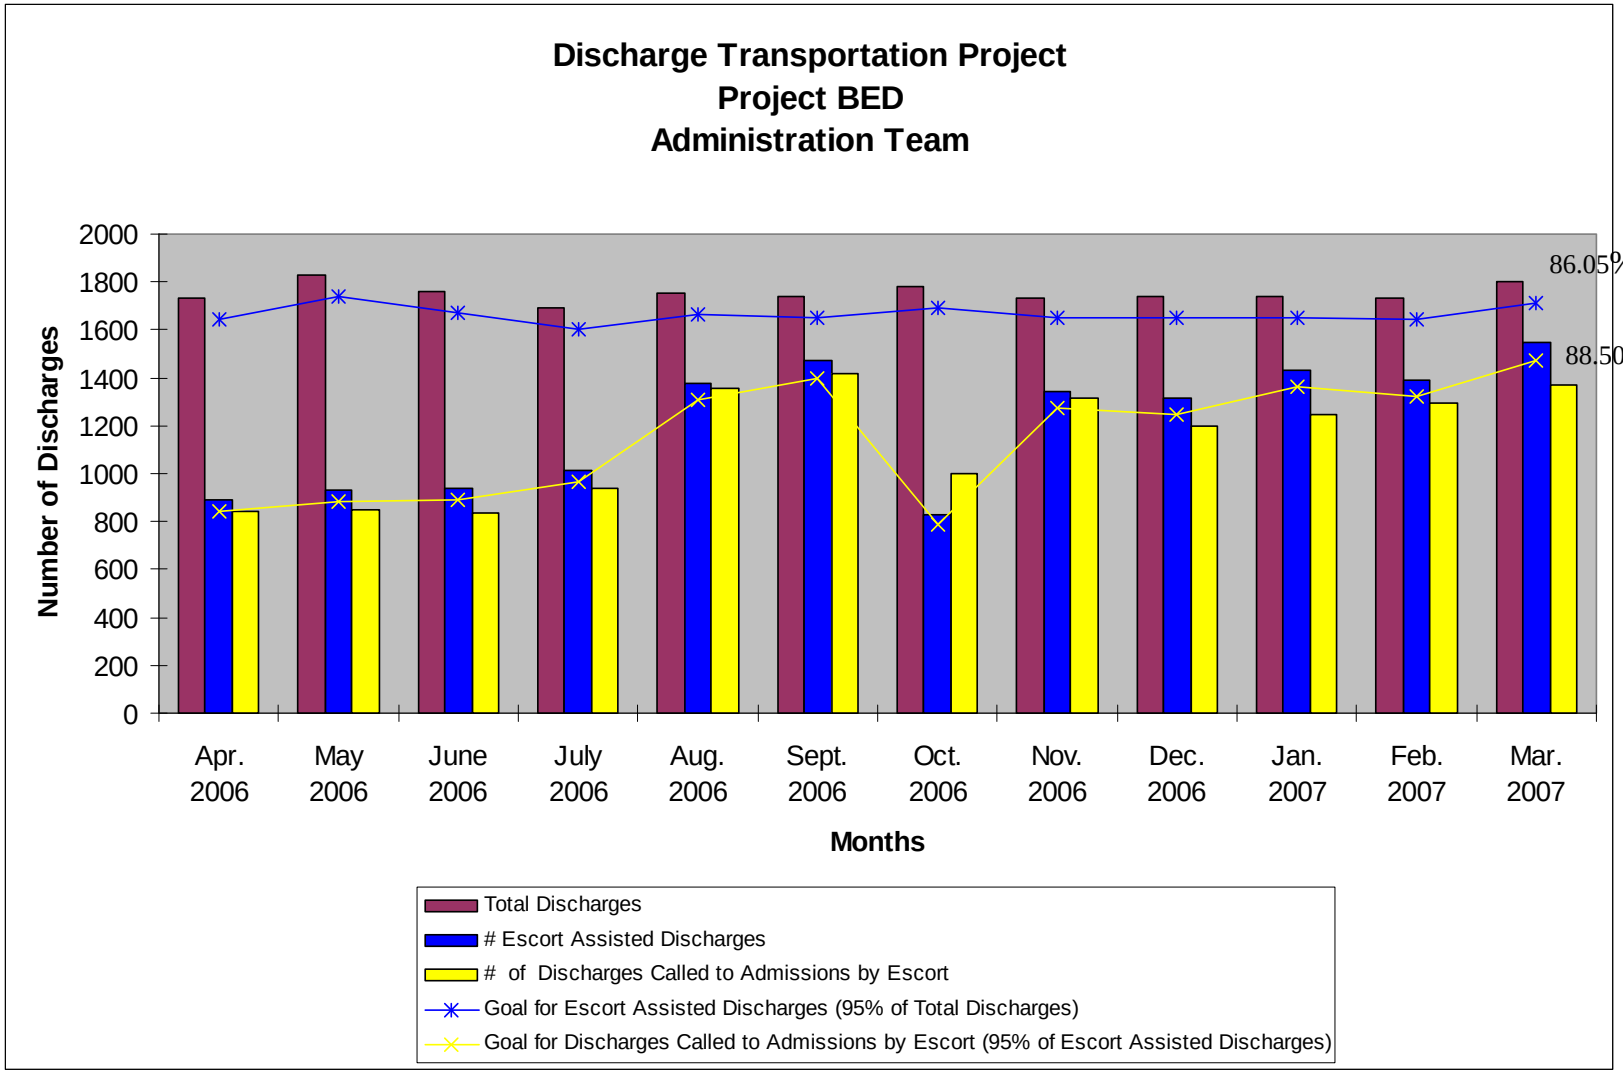


Clinical Team
Nursing
Case Management
Pharmacy

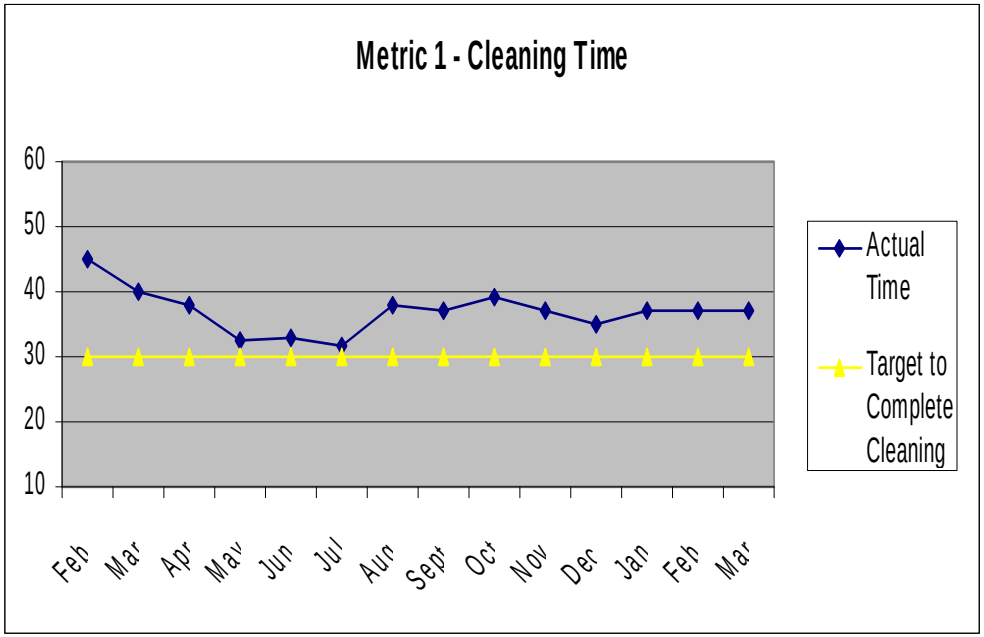
Medical Team
Medical Staff
Leadership

*This presentation focuses on the efforts of the administrative team, while recognizing the efforts of all involved.

Escort-Assisted Discharges



Housekeeping Room Turnaround Times 06 - 07



Goal for blue line

March 2007
Highest Cleaning Time 44 min
Lowest Cleaning Time 23 min
Mean Cleaning Time 37 min

EFFORT	OUTCOME
Design the process to meet institutional bed initiative goals	Alignment to institutional goals
Involve the customer in defining process	Customer satisfaction
Received historical data from customer	Alignment
Change work schedule to match customers needs	Alignment
Write new Work Instructions (WI)	Constancy and consistency
Added mechanical and electrical checks to WI	Constancy and consistency
Involve infection control in WI review / approval	Alignment to institutional goals

Discharge Nurse Role Created
Ongoing Projects

- Discharge Assessment
  - Establish expected discharge date based on historical length of stay (LOS)
  - Assess patients for resources and services needed after discharge
  - Standardized checklist
- Identify learner(s) and apprise unit staff of those to engage
- Medication Reconciliation – review maintenance meds and anticipate
- Application of Acute Care Criteria
- Hand-off Communication – provide summary to next provider
- Discharge Preparation Checklist
- Transition Home Measures – apply acute care criteria daily

Improved Throughput Adds Incremental Capacity

"Effective" Beds Gained from Length of Stay (LOS) Reduction[1]

LOS Reduction \ Hospital Size	 200 beds	 300 beds	 400 beds	 500 beds	 600 beds
0.25 day	8	12	16	20	25
0.50 day	16	25	33	41	49
0.75 day	25	37	49	61	74
1.00 day	33	49	65	82	98
1.25 days	41	61	82	102	123
1.50 days	49	74	98	123	147

At M. D. Anderson, for the month of October 2006, a half-day reduction in LOS would translate into $4.5 million.[2]

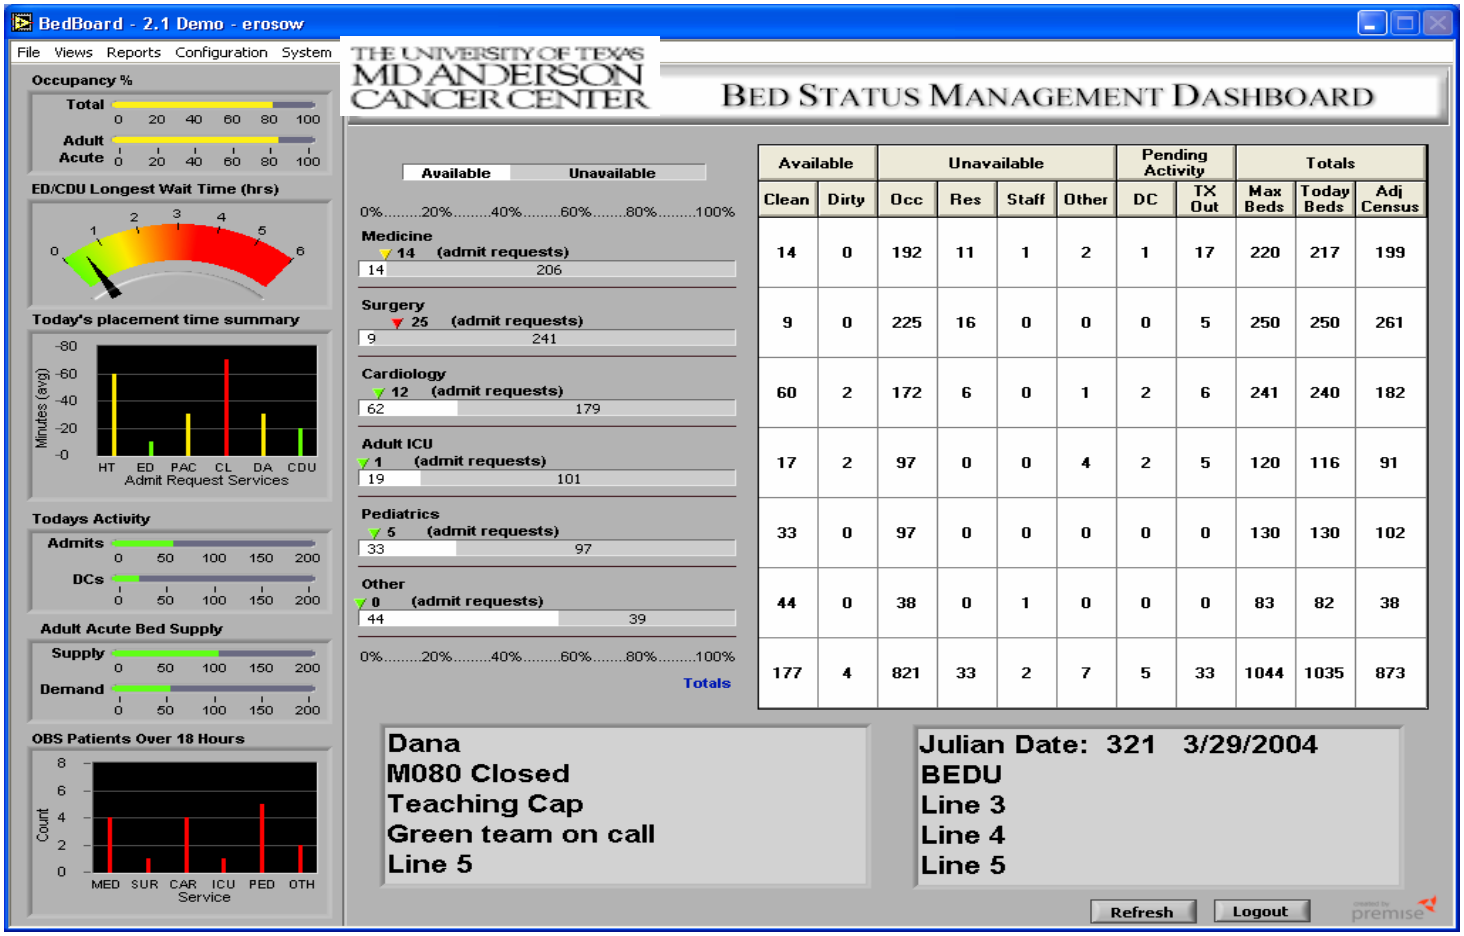
For the average 500-bed hospital, reducing LOS by a half day is the equivalent of adding 41 new beds to the facility.

[1]Assumes initial LOS of 5.2 days, 85 percent occupancy; savings based on simple LOS reduction. Source: Health Care Advisory Board, 2006.
[2]M. D. Anderson Cancer Center Institute for Performance Excellence, 2006.

Electronic Bed Management Project Timeline

Phase	Go Live	Impact
Phase I – Transportation **Transport Dashboard**	4/30/07	All users call to request patient escort, and dispatchers use Transport Dashboard to enter job requests and dispatch escorts.
Phase II – Transportation and Housekeeping **Transport Dashboard & BedXpress**	6/13/07	All users input requests for transport jobs; bed turnover notifications automated. All inpatient units use BedXpress for room turnover. Housekeeping receives dirty bed pager notifications and views bed status.
Phase III – Electronic Bed Management **Bed Management Dashboard**	8/22/07	Nursing and Admissions will use for patient placement and pending discharges. Electronically tracked patient room status will provide automatic notification to Housekeeping, Transportation, Admissions and Nursing. Bed status information will be immediately accessible to leadership.

Electronic Bed Management
Bed Status Dashboard



Select Project BED Metrics

Effort	Goal/Benchmark	Actual Performance	Status
Short-Term: Patient Transportation would provide **escort-assisted discharges** to transport all discharged patients from rooms	95% of discharges would be escort-assisted	86% achieved in March 2007	Increased from initial measure of 52%, efforts continuing
Short-Term: Housekeeping developed room turnaround teams to standardize process, clean and make minor room repairs	30 minute cleaning time, 10 minute travel time, quality score 90%	37 minute cleaning time, 3-5 minute travel time, quality above 90%	Continuous improvement in cleaning time, exceeding goals on other measures
Short-Term: Evaluation and selection of **Electronic Bed Management System**	Selection of a electronic solutions partner	Criteria reviewed and vendor selected	Institution currently in go-live status, will be fully implemented in August of 2007
Long-Term: Reduce institutional **length of stay (LOS)**	Sustained reduction in LOS	Preliminary reduction in LOS at clinical division level	Anticipate institutional LOS reduction with full implementation of long-term strategy, including electronic bed management

M. D. Anderson Cancer Center: Gaining Capacity by Improved Patient Throughput

Gerard J. Colman[a], Frank R. Tortorella[b], Renee T. Konstanzer[a]

[a]*Clinical Operations, The University of Texas M. D. Anderson Cancer Center, United States*
[b]*Clinical Support Services, The University of Texas M. D. Anderson Cancer Center, United States*

Abstract

As demand for services increases, healthcare organizations must be able to efficiently diagnose and treat more patients utilizing fewer resources. By focusing on the inpatient discharge process, M. D. Anderson Cancer Center developed short- and long-term solutions: formation of housekeeping room turnover teams, creation of a patient-escorted discharge process, assignment of discharge nurses and selection of an electronic bed management system. The first three solutions as listed resolved the immediate issue of patient boarding time in the Emergency Center, Admissions and the Operating Rooms; in combination, all solutions show promise in achieving a longer-term reduction in length of stay (LOS) and a capacity gain.

Keywords:

capacity, patient throughput, patient discharge, bed management

Methods

Increasing demand requires faster patient throughput, optimally allowing for more admissions with the same scarce staff; this faster throughput provides the hospital with additional "free" beds [1]. Beginning in 2004, M. D. Anderson Cancer Center faced a critical bed shortage as patients boarded for several hours in the Emergency Center, Operating Rooms, and Admissions while beds became available. As bed space and staff were limited, the institution focused on developing innovative short- and long-term solutions to meet demand.

In 2005, Clinical Operations initiated Project BED (**B**ringing **E**fficient **D**ischarge) to improve patient throughput. The Administrative, Clinical, and Faculty teams identified and measured each step in the current discharge process, targeted specific steps to improve, and eliminated process flow obstacles.

Results

In September 2005, patient escorts began to transport all discharged patients from their rooms to reduce turnover time. Patients waiting on external transportation were relocated to a central holding area. In the initial eleven months of operation, escort-assisted discharges increased from 52 percent to 85 percent of discharges.

In December 2005, Housekeeping standardized its processes and established room turnaround teams on nine inpatient units in order to quickly inspect, clean and make minor repairs to each room. Since February 2006, cleaning time was reduced by five minutes to 40 minutes per room; the goal is 30 minutes per room. Quality scores hover between the 90% target and 100%, and response time is three to five minutes, exceeding the original goal of 10 minutes.

Nurses were realigned to ensure efficient, timely, and appropriate discharge of patients. Currently, 70 nurses have been trained in discharge nurse functions - coaching bedside nurses, rounding with clinical teams, and coordinating 23-hour observation. The program goal is to reduce LOS by 0.5 days. In a 500-bed hospital, a reduction in LOS by 0.5 days translates into 41 additional beds [1]. For M. D. Anderson in October 2006, this 0.5 reduction equates to over $4.5 million in net revenue [2].

Team members evaluated and recommended purchase of an electronic bed management system to enhance productivity of and interconnectivity between Admissions, Nursing, Housekeeping and Patient Transportation. Functional requirements included an electronic bed board, electronic notification system, assignment of work, and reporting capability. Currently, M. D. Anderson is in the go-live stage and anticipates data analysis within the next quarter.

Other solutions included ordering discharge medications and writing discharge orders the day prior to discharge to reduce patient wait time. Generally, the shift toward outpatient and minimally invasive surgery has also positively influenced M. D. Anderson's ability to provide capacity.

Conclusion

Project BED efforts have added capacity and decompressed patient boarding. While some results are preliminary, these efforts show promise in longer-term reduction in LOS.

Telehealth Trends in Pacific Islands and Solutions for the Sustainable Operation

Isao Nakajima, Muhammad Athar Sadiq, Koredianto Usman
Yasumitsu Tomioka, Hiroshi Juzoji

Nakajima Laboratory Tokai University School of Medicine, Japan

Abstract

We are reporting our recent study and investigation concerning about telehealth activities in pacific islands and provide some support to keep self-sustainable operation. In pacific, three major telehealth operations are performed. However, all of them are facing strong obstructs sense for the following reason, 1) problem of running cost 2) lack of the social structure for the human resource development 3) limitation of the data speed. Based on this investigation, we are providing solutions (Universal service policy, ITU training course, and ETS-VIII satellite) in order to keep self-sustainable operation in Pacific Islands.

Keywords:

universal service fund, human resource development, isolated islands, ETS-VIII satellite

Purpose

We are reporting our recent study and investigation concerning about telehealth activities in pacific islands and provide some support to keep self-sustainable operation.

Investigation

Health professionals in various Pacific Island countries, particularly those working in rural and remote areas, have less opportunity than their peers in developed and even some developing countries to keep abreast with both technical and technological advancements in medicine and healthcare.

POLHN (Pacific Open Learning Health Network)

For their continuing education and professional development, distance education using a variety of media is an option that has been supported via funding from the Japanese Government.

In general, POLHN is a successful initiative based on actual web-based operation via internet with package media, like CD-ROM, the evaluation report, and the meeting discussions. The pilot open learning courses are well received by health professionals and the learning centers in each country, equipped with information, communication, technology (ICT) for open learning and health educational resources, are being used by countries for their health professional training and continuing education, including ICT skills trainings. There was a strong interest among the participating countries to contribute to the long-term sustainability of the POLHN and a desire for greater ownership by the countries, of the open learning centers. There was also consensus that it would be important to integrate POLHN as a component of national human resources for health programmes of the ministries of health, and that the network's coverage should be expanded to include other countries and to make it a Pacific regional learning network. There are two phase projects in the POLHN.

Phase One: the establishment of computer laboratories as resource centers for the health professionals (HPs) in ten countries in the Pacific (Cook Islands, Fiji, Kiribati, Marshals, Federated States of Micronesia, Palau, Samoa, Solomons, Tonga and Vanuatu) has been completed. Computer laboratory equipped with computers, servers, networked printers, data projectors, web cams and Internet connectivity. Various learning and reference materials are also available in the resource centers including the blue trunk library kit.

Phase Two: using the computer laboratories as resource centers for the continuing education of professional health workers of the Pacific started in later 2003.

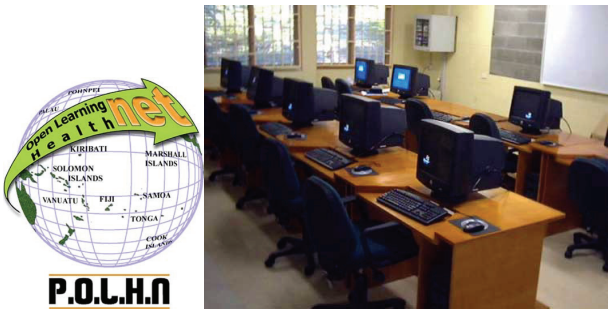

Figure 1 - PLOHN operation room in Solomon

Pacific Basin Telehealth Initiative

The U.S.-affiliated Pacific Islands jurisdictions represent over 2,200 small volcanic and coral islands stretching across 4,500,000 square miles, with about 400,000 inhabitants living on a landmass smaller than the state of Rhode Island. Due to their geography and isolation, coupled with limited finances, poorly developed infrastructures and lack of skilled staff, these islands provide an ideal environment for developing and implementing telehealth applications.

In 1999, the Health Resources and Services Administration (HRSA) launched a multi-year Pacific Basin health initiative to bring telemedicine to the region. This initiative came out of recommendations from two events the previous year: a HRSA-sponsored summit meeting in Rockville, Maryland with the health ministers from the six U.S.-affiliated Pacific Basin jurisdictions and the publication of the Institute of Medicine's report "Pacific Partnerships for Health: Charting a New Course." Both the report and participants at the summit identified telehealth (i.e., telemedicine and distance education) as a key strategy for improving primary care delivery, enhancing prevention activities and supporting the training of health personnel. This telehealthnet work has been funded by the OAT(Office for the Advancement Telehealth) of the U.S. Government.

PPHSN (Pacific Public Health Surveillance Network)

“Training in applied epidemiology and public health surveillance” is one of the five strategies of Pacific Public Health Surveillance Network (PPHSN). It aims to develop a regional pool of experts in public health surveillance and responsefor the Pacific Islands. The PPHSN was created in 1996 under the joint auspices of SPC (South Pacific) and WHO. The Goal is to improve public health surveillance and response in the Pacific Islands in a sustainable way. In 1996, the idea of a modular training programme with field-based components, involving universities, health development agencies and professional associations came up. This programme should be accredited by a training institution. From 1998 to 2001, SPC made a first move in that direction and ran two different series of subregional training sessions in surveillance, outbreak investigation and the use of Epi Info 6 software for surveillance activities. The overall objective of these training sessions was to build a critical mass of health professionals who share a common set of tools and methods for public health surveillance. SPC can also provide attachment and hands-on field training opportunities for trainees in public health practice. A memorandum of understanding was signed between SPC and FSM in 1999. The article suggests the areas of future FSM/SPC collaboration in public health surveillance: the accreditation of SPC courses by FSM; the addition of a microbiology component; the identification of opportunities for field training; and the evaluation and harmonisation of the training programme(s).

Considerations and our solutions

Based on these investigation, we understand that all of them are facing strong obstructs for the following reason, 1) problem of running cost 2) lack of the social structure for the human resource development 3) limitation of the data speed. So we are willing to provide solutions (an idea of Universal Service Policy, ITU telemedicine expert training course, and ETS-VIII satellite with free of charge) in order to keep self-sustainable operation in Pacific Islands.

Universal Service Fund

In order to reduce running cost of the operation, and to assist continuous self sustainable operation of tele-health in developing nations, especially remote island and isolated area, we have to consider a universal service fund.

The Universal Service Principles in the United State[3] are:

(1) Quality and rates.--Quality services should be available at just, reasonable, and affordable rates.

(2) Access to advanced services.--Access to advanced telecommunications, broadband and information services (Internet) should be provided in all regions of the territory.

(3) Access in rural and high cost areas.--Consumers in all regions of the territory, including low-income consumers and those in rural, insular, and high cost areas, should have access to telecommunications and information services, including interexchange services, broadband and advanced telecommunications and information services, that are reasonably comparable to those services provided in urban areas and that are available at rates that are reasonably comparable to rates charged for similar services in urban areas.

(4) Equitable and nondiscriminatory contributions.--All providers of telecommunications services should make an equitable and nondiscriminatory contribution to the preservation and advancement of universal service.

(5) Specific and predictable support mechanisms.--There should be specific, predictable and sufficient public mechanisms to preserve and advance universal service.

(6) Access to advanced telecommunications services for schools, healthcare and libraries.--Elementary and secondary schools and classrooms, health care providers, and libraries should have access to advanced telecommunications services.

(7) Additional principles.--Such other principles as the Joint Board and the Commission determine are necessary and appropriate for the protection of the public interest, convenience, and necessity.

Universal telecom service is implemented by the Universal Service Administrative Company. While contributions to the Universal Service Fund are required by telephone, wireless and VOIP service providers, these carriers generally recover this cost by passing on a surcharge to retail customers as a billing line item -- often labeled as USF charge. A surcharge of approximately 10% of interstate usage currently appears on telephone, wireless and VoIP bills. The Universal Service Administrative Company cur-

rently administers four distinct programs as authorized in the federal telecommunications Act of 1996.

Rural health care division of the Universal Service Administrative Company (USAC) is responsible for ensuring for health care providers in rural areas to obtain the benefits of the internet and current communications technology as provided for by the United States Congress and the Federal Communication Commission (FCC) through universal service support. The FCC established program funded 56 million U.S.D. in 2003(Fig.2), 400 million U.S.D. in 2004 to rural health care providers so that they don7t need to pay move than their urban counterparts for the communication services.

In addition to USF, another organization support telehealth in the U.S., it is the the OAT(Office for the Advancement of Telehealth) under the umbrella of the U.S. Department of Health and Human Services. This organization is promoting the use of helehealth technology for health care delivery, education, and health information services, and providing the funds more than $34.9 million U.S.D.

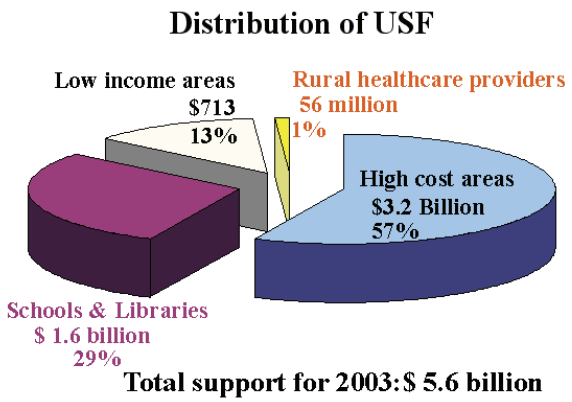

Figure 2 - Distribution of the Universal Service Fund in the US in 2003

Human resource development

The objectives of our cooperation related Pacific Island through ITU, APT, NICT, Sasakawa Fund, and other private sectors in developed nations is to bring research teams in health care field, governments sectors in island, and other stakeholders in the region to discuss the different applications of telecommunication and information technology in the health care sector. Based on our investigations, we intend to invite some researchers from Pacific Islands to provide an opportunity to study more advanced telehealth at the ITU Telemedicine Expert Training Course in the Shonan Campus, Hiratsuka Japan from 2006 to 2009.

To familiarize themselves with the specifications and implementation details of telehealth;

To assist in the management of the transition process from IPv4 to healthcare specialist to end user(client); and

To share information on the development and deployment of telehealth to other countries and regions.

WINDS satellite for broadband network

WINDS is currently under joint development by JAXA and the National Institute of Information and Communications Technology, as part of the e-Japan Priority Policy Program of the Japanese government's IT strategy headquarters. WINDS will be launched by an H-IIA Launch Vehicle in the fiscal year 2007 to establish the world's most advanced information and telecommunications network (the broadband transponder of Ka-band). It is expected that this information and telecommunications network's speed and capacity will be much higher than anything achieved previously. The WINDS satellite communication system aims for a maximum speed of 155Mbps (receiving) / 6Mbps (transmitting) for households with 45-centimetre aperture antennas (the same size as existing Communications Satellite antennas), and ultra-high speed 1.2 Gbps communication for offices with five-meter antennas. In addition to establishing a domestic ultra high speed Internet network, the project also aims to construct ultra high speed international Internet access, especially with Asian Pacific countries and regions that are more closely related to Japan. We believed that the WINDS can support the infrastructure of the tele-halth network in pacific.

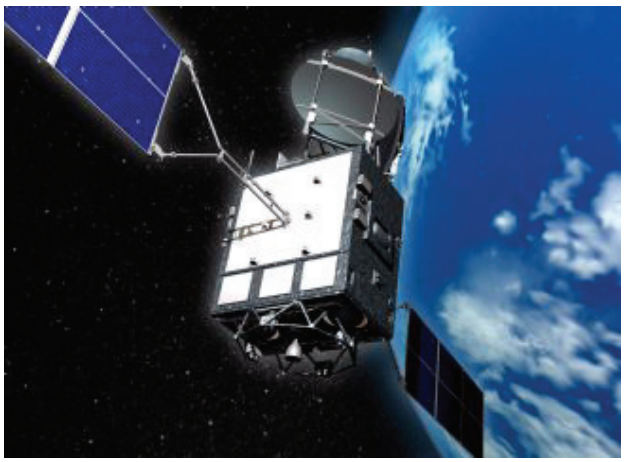

Figure 3 - Ka-band broad band circuit for the Pacific with WINDS satellite

Acknowledgments

This study was supported by the APT-HRD, NICT and PIDO (a self-funded initiative of the Sasakawa Pacific Islands Nation Fund)

Regional Health Information Networks: Towards Sustainable Health Systems Globally

Tip Ghosh[a]

[a]*Department of Healthcare Administration & Policy, University of Nevada-Las Vegas*

Abstract

There has been tremendous growth in regional health information organizations (RHIOs) in the US. There has been emergence of similar networks in the UK, Australia, Singapore, Greece, and New Zealand.

Keywords:

community health networks; regional health planning; information networks; collaboration

Background

Globalization has had an impact in accelerating the development of regionalism in the delivery of health services throughout the globe. There has been tremendous growth in regional health information organizations (RHIOs) in the US. There has been emergence of similar networks in the UK, Australia, Singapore, Greece, and New Zealand.

The value of networks arises principally from the enrichment and extension of the social frameworks that motivate human behavior by creating social capital. Such features of social capital in networks are knowledge sharing and trust, that facilitate coordination and cooperation for mutual benefit. Mutual knowledge can be characterized as shared experiences or close mutual understanding of the respective contexts of individuals. This allows network participants to identify shared problems and communicate solutions and individual experiences in a meaningful way.

Trust is necessary to pass on tacit knowledge from one network member to another. Accepting the contributions and suggestions of other network members require trust in each individual's expertise. Sharing one's expertise with other network members requires trust that shared knowledge will be used appropriately. Trust in networks is built through repeated rounds of interaction that allows network members to make judgments about the trustworthiness of others.

There are a number of examples throughout the globe where regional health information networks are emerging. In Australia in New South Wales, the Greater Metropolitan Transition Taskforce has programs networking sixteen specialty services, enabling the coordination of activities over a population of at least 5 million (Braithwaite, 2004). These networks enable different types of clinicians to work with management and community representatives over many administrative boundaries. The taskforce has demonstrated the ability of institutions to learn from each other in comparing practices, benchmarking performance, developing innovations and testing alternative systems. (Southon, 2005). Such a structure has worked in conjunction with regional bodies, maintaining and developing standards for integrated health services with the local Boards responsible for local coordination of the different services, and for addressing local issues.

There has been development of a regional health information network in Greece in the island of Crete. (Constantinides & Barrett, 2006). A Greek initiative urged all healthcare regions in Greece to develop regional networks. This regional network received the European eHealth award for technologically advanced design.

In the US, the Indianapolis Network for Patient Care links major hospitals, physicians, and public health sharing information such as lab results, medications and immunizations. (McDonald, 2005). The Utah Health Information Network (UHIN) grew out of a coalition of health insurers, hospitals to create value for all participants and is comprised of providers who pay an annual fee.

Methods

We utilized a brief information gatheirng of the emergence of regional healthh networks throughout the globe. Then we conducted a series of key informant interviews with key health care decisionmakers in the US and UK. These individuals were selected based on knowledge of regional networks. Multiple interview formats were used with the key informants.

Conclusion

Sustainable health systems involve shaping and adapting health information networks to a given regional context. This means cultivating regional learning processes and embedding collaborative and knowledge sharing that persist over time. Establish such networks create opportunities for sharing of experience, knowledge, technologies between the various nodes of the network. Embediing these change processes over time requires

understanding, engaging with the specific dynamics around sensemaking and knowledge sharing.

Is Sustainable Health a Paradigm Based in Reality?

Graham Wright and Janette Bennett

Centre for Health Informatics Research and Development (CHIRAD), United Kingdom

Abstract

This paper considers the factors affecting the technical drive and political intent to bring about transformational changes in health care investment and delivery, from sickness to health

Keywords:

transformational change, economics,

Introduction

It is doubtful that anyone could foresee the transformational changes in delivery that technology has brought about in industries such as banking and international travel. That it has happened is evident so why hasn't the same transformational, customer oriented change happened in the health industry?

This article puts forward a view that paradigm changes in delivery requires more than technology and political imperatives and that social and cultural acceptance are also essential.

Technology has a history of both acceptance and rejection, not just because of cultural fit, or social acceptance, but due to leadership, entrepreneurialism and plain luck. For example VHS v Betamax. Beta max was perceived as the better technology and more economic to produce. The VHS format's defeat of the Betamax format is now identified with the verbal phrase "to Betamax", wherein a proprietary technology format is overwhelmed in the market by a format allowing multiple, competing, licensed manufacturers [1].

Technology is on occasion very rapidly embraced. The young, and young at heart, have instigated a new way of purchasing and listening to music, and brought about the resurgence of an old one. UK records are sold on line and downloaded straight to an MP3 player [2]. This has transformed the industry and supply chain – pop groups, including the Arctic Monkeys [3], are using the internet and MySpace

Sustainable transformation

How much technology is being used at the coalface? In England some 99.9% of GP's use clinical information systems on a daily basis to undertake tasks which are routine and common in general practice, for example recording observations and clinical notes, through to writing prescriptions.

However the use of technology to change behavior in a fundamental way is not evident. There are some GP practices who provide a telephone service for registered patients, some use email. However work by Malec & Wright [4] indicate that these services are more prevalent in US, mainly due to differences in the economic/ financial reward model where primary care physicians do not act as gatekeepers.

So what is it that is it about health that is intended to be transformed? We know that the population is ageing, globally and within specific countries. Some countries face more acute problems of healthcare crises as a result, in terms of supply of healthcare facilities and affordability of healthcare. Healthcare levels of expenditure in the USA according to Gingrich [5]

"Healthcare consumes 26% of all federal spending and growing, dwarfing every other priority."

But will transformational change happen because; policy makers and consumers want it, or because technology is driving it, or are other factors key to success?

So how does this impact on the shift in health care focus, from cure to prevention?

Politically in countries from England to Australia, most government agencies and health care providers are already recognising the need for capital investment in health information technology infrastructure to reduce expenditure and improve the quality of patient outcomes. Some, such as England, are using consumerism under the banner of patient choice to challenge the acceptability of waiting times, poor conditions and service. Future health service priorities will intend to bring about improving access and increasing the knowledge base, while infrastructure such as buildings and other resources will continue to be downsized per head of population. Information technology and 'Labour-saving" technology will consolidate and expand key services with Governments driving the need optimise return on ICT investment

The political drive is largely led by economic imperatives. There is a growing staff shortage internationally, and in most first world countries there are less children being born, and therefore less future tax payers and healthcare workers coming through. Outsourcing is becoming more

usual in healthcare; letters in the UK, Los Angeles or Brisbane typed up by staff in India, even basic x-ray reporting has been outsourced by some countries [6].

Social

The earlier major causes of death and disease, from trauma and infection, are being tamed in the first world, through planned interventions. But chronic disease is now the problem at both individual and national economic levels [7]. Historically chronic disease has been treated rather than prevented (asthma, diabetes) with professions and specialisms such as podiatry and opthalmics evolving on this basis. Everybody gets inoculation for smallpox etc, but for diabetes and HIV there is currently no immunisation possible and the causal factors and impact of the disease itself are heavily influenced by lifestyle choice at an individual level. Chronic disease management (CDM) will requires personalisation but the technological support for CDM at the moment is generic. Given that each age group and societal strata readiness to accept or adopt change may differ there is a need for different methodologies to be adopted.

Is this where healthcare can learn from banking? Are health and lifestyle coaches the way to meet individual need and manage whole population problems? Will generic tools allow clinicians time for more personalised treatment? Can you move to preventative care if no technical infrastructure in place?

With the next 5 –10 years seeing integrated systems across healthcare boundaries and electronic health record and point-of-care support. Mobile clinical support will include fully integrated medication management systems. Computing will be ubiquitous and incorporate decision support and communications with knowledge management capabilities and comprehensive, searchable knowledge bases at the point-of-care. But who will pay for these cross boundary solutions, and who will reap the benefit? Which organisations will be so altruistic, or is entrepreneurialism to be the luck factor?

Integrated technologies, such as internet enabled digital video phones, will increasingly find their way into use in health care and teleHealth could be used successfully to improve healthcare delivery, delivering in circumstances where it was previously difficult or impossible, and in a way that is cost-effective. This will enable entrepreneurial delivery of services whether from an acute care hospital or primary care will be dependent on the technology available, and on social and geographical constraints.

Technology has developed so quickly that legalisation and policy development are lagging behind and in some areas projects are being implemented before trials have finished. Smart homes which can detect what is used, who is in the house, and provide dietary advice informed by sensors in the toilet already exist. Will the location of our new homes in the future be based on genomic data, because the individual has a genetic marker for osteo-arthritis or malignant melanoma?

Conclusion

It is not always possible to foresee social change – Bob Geldorf and Liveaid brought about subsequent celebrity use of their own status to influence and the impact of entrepreneurialism is often just as much an accident as planned, for example – friends reunited

People and technological infrastructure are needed in combination to make transformational pilots successful on a scaleable way in healthcare but at a way that is meaningful and desirable to the individual, whether they be involved in the delivery, or the recipient of healthcare services. Systems need to target lifestyle if chronic disease is to be avoided, and better managed but do people want health portals or do they really want health chat rooms or is this likely to be heavily influenced by their age and experience in IT use?

The health professions may not look anything like they do now in ten years time. In England a new role has already emerged that may result in a new professional group –the Emergency Care Practitioner. The drive to keep people out of institutions and in the community will grow and result in multi-disciplinary teams working across traditional structures, or continue to create new roles and new professions? What will happen to the old ones?

Is sustainable health a paradigm based in reality?

Prof Graham Wright and Janette Bennett

Centre for Health Informatics Research and Development (CHIRAD), United Kingdom

Introduction

- Could the transformational changes in delivery that technology has brought about in industries such as banking and international travel be forseen?

  This presentation puts forward a view that paradigm changes in delivering healthcare requires more than technology and political imperatives and that Social and cultural acceptance are also essential.

- Technology has a history of both acceptance and rejection, not just because of cultural fit, or social acceptance, but leadership, entrepreneurialism and plain luck. For example VHS v Betamax. Beta max was perceived as the better technology and more economic to produce but the entrepreneurs who created film libraries chose VHS. They led a new market which found a stronger demand than technological robustness; a social appetite for a new service and cultural acceptance of libraries.

- Technology is on occasion very rapidly embraced. UK records are sold on line and downloaded straight to an MP3 player [1]. transforming the industry and supply chain

Why hasn’t health made same strides?

- Is it because it isn’t possible to anticipate the extent of change? In banking concerns about closures and accessibility have long been surpassed by a plethora of contact and accessibility mechanisms.
- Governor Olson, Before the First Annual Convention of the Ohio Bankers League said that “In the process, we also spawned a new generation of more sophisticated and rigorous risk-management practices. “ [2]
- Is the eHealth story one of bad luck despite good technology or just that we are only on the first page? Arguably no health service anywhere in the world has yet managed to bring teleHealth into the mainstream of service delivery.
- Picture Archiving and Communication Systems (PACS) [3] has been heralded as bringing significant patient benefit, but fundamentally it too is a replacement technology for film, although some institutions still print film for orthopaedic consultants. An attraction for purchasers is that the cost benefits that occur in introducing PACS largely do so within an organisation [4].

What healthcare transformation is needed?

- Globally the population is ageing, with specific countries facing acute problems of healthcare crises as a result - according to Gingrich [5]

  "Healthcare consumes 26% of all federal spending and growing, dwarfing every other priority."

- UK demand for change in delivering patient, community based preventative care rather than high spend on hospital based curative measures.

- Will transformational change happen because; policy makers and consumers want it, or because technology is driving it, or are other factors key to success?

The people factor

- Political drive and technology capability are inevitably generic in approach, however there exists differing experiences and expectations of technology within age groups.

- Using a simple PEST (political, economic, social, technical), framework we consider why health has not undergone a transformation in service delivery by looking at 3 age groupings, albeit no group is homogenous.

Current mid-teens to 20-somethings

Technical

- Early adopters of technology.
- Always in communication with their peers
- Most, not least, have a mobile phone
- Some with asthma receive high risk SMS warnings
- Some update their health record, upload physiological data, receive health care education, access to health providers directly
- Convergent technologies allow multi media through single devices
- Communication Technology standards increase interoperability possibilities, breadth of coverage and security

Political

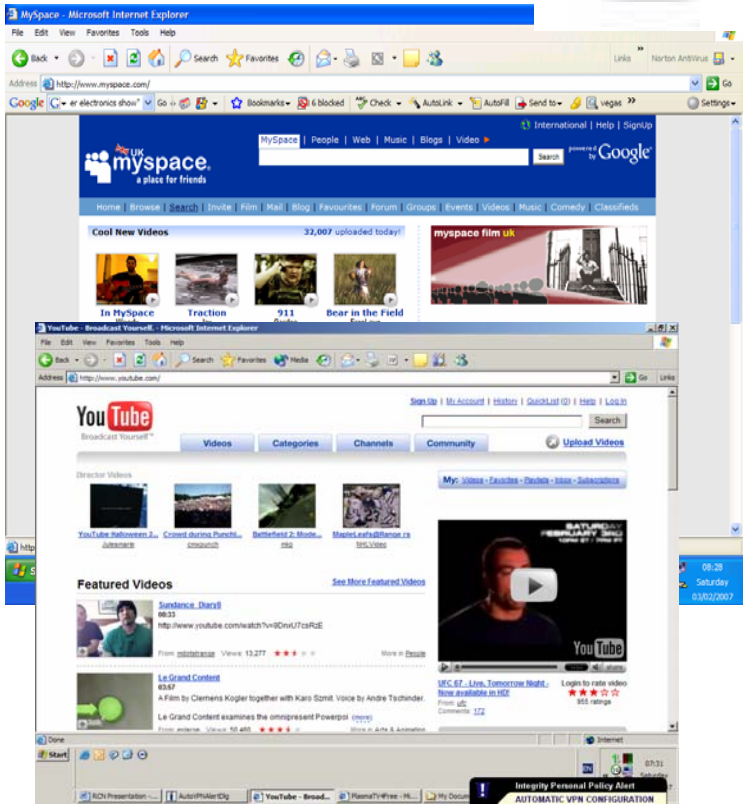
- Concerned about the environment, but less interested in actually getting out in it.
- Not exposed to the competing interests of curative v preventative care

Economic

- Likely to have to work longer, with a fragmented career path
- Stay at home longer than their parents did, and buy homes later
- Expect service, for things to happen when they want it to in a way and time that they want. They are not used to queueing

Social

- Their communication is fragmented, abbreviated language, one line of text with long gaps between and use computers for communication far more than for data processing .
- interact any time, any place anywhere, allowing more collaborative working too.
- seamlessly alternating between channel-hopping and 150% focus.
- intolerant of having less access to knowledge and real-time mentoring
- lifestyle and health choices are heavily influenced by friends and family



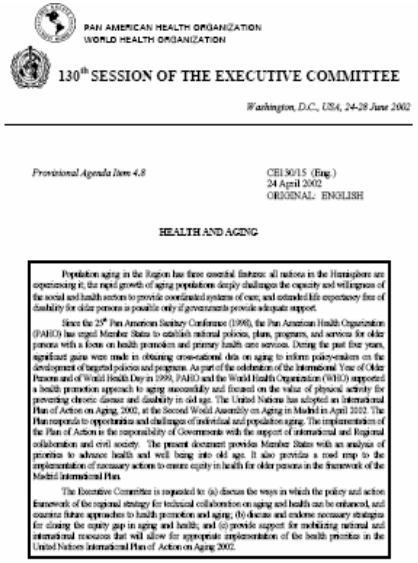
What of that of the 75+

Technical

- A generation of letter writers, but also the first users of the telephone and television but less dexterous fingers cannot readily send text, and aged eyesight finds small font size even on keyboards difficult
- They use sensors in the home to identify changes in their routine, with alarms to instigate a response

Political

- The Age discrimination act is too late for them, many are already to old to work or already out of the workplace
- They have seen some Acts, such as Sunday shopping introduce significant social change (only in some countries)



PAN AMERICAN HEALTH ORGANIZATION
WORLD HEALTH ORGANIZATION

130th SESSION OF THE EXECUTIVE COMMITTEE

Washington, D.C., USA, 24-28 June 2002

Provisional Agenda Item 4.8

CE130/15 (Eng.)
24 April 2002
ORIGINAL: ENGLISH

HEALTH AND AGING

Economic

- The demographic changes will result in less people working (including nurses), and paying taxation to support those who are retired
- Pensions have not kept up with cost of living expenditure, causing many to suffer financial hardship.

Social

- Communication is a whole conversation, a social time or phone call in a place and often appointed time
- Longer life expectancy
- Lifestyle will be dependent on their income, social network and relationship with their families
- Healthcare choices influenced by their community pharmacist, GP
- They are used to, and continue to, wait for their turn

Providers for all 25 - 65

Technical

- Technology is used to make life easier and to maintain status quo overall rather than changing what they do
- Growing use of on line shopping and internet banking
- Communication technology overload – email
- Those working in health have concerns of technology output overload of telehealth – who is going to look at the output of telemonitoring, home sensors?

Political

- Terrorism has impacted on travel both in where they go, and the experience of travel itself
- These are the active policy makers, organisational and government managers, clinicians, technicians with vested interests at national, local and familial level

Economic

- Busy looking after younger and older generations leaves them time poor and economically strained

Social

- For those in health there is insecurity as to what the workforce will look like, and is what they became a professional for?
- Will they need new skills that are more technical and what are their expectations of social interaction with the patient and at work?
- They expect queues and waiting times which are somehow seen as fair
- Heath visitors and midwives came to the house but you go to a surgery to see a doctor
- shopping as a social event, and growth of coffee shops

how does this impact on the shift from cure to prevention?

- Consumerism challenging acceptability of waiting times, poor conditions and service.
- Improving citizen access and increasing the knowledge base
- Healthcare buildings will downsize per head of population.
- ICT and ‘Labour-saving” technology will consolidate and expand key services with Governments optimising return on investment
- Traditional notions of organisational boundaries will need to give way to a concept of ‘health care without walls’.
- Economic imperatives; staff shortage internationally, less children being born, less future tax payers and healthcare workers. s
- Importing expertise v recruitment from overseas

Chronic Disease

Previous causes of death and disease, are tamed through planned interventions. But chronic disease is now the problem at both individual and national economic levels. with causal factors and impact of the disease heavily influenced by lifestyle choices. Chronic disease requires personalisation not generic IT support. Given that each age group and societal strata readiness to accept or adopt change may differ there is a need for different methodologies to be adopted.

Technology

- Computing will be ubiquitous and incorporate decision support and communications with knowledge management available at the point-of-care. But who will pay for these cross boundary solutions, and who will reap the benefit? Which organisations will be altruistic, or is entrepreneurialism to be the luck factor?
- Integrated technologies will increasingly find their way into use in health care enabling entrepreneurial delivery of services.
- Technology is developing so quickly that legalisation and policy development are lagging behind.
- Traditional notions of organisational boundaries will need to give way to a concept of 'health care without walls'.

Enabled applications

Conclusion

- It is not always possible to foresee social change
- People and technological infrastructure are needed in combination to make transformational pilots successful on a scaleable way in healthcare but at a way that is meaningful and desirable to the individual. Systems need to target lifestyle if chronic disease is to be avoided, The health professions may not look anything like they do now in ten years time.
- The social expectations of those manning the organisations at the moment has yet to be adressed - Several teleHealth projects have used nurses within specialised call centres but do nurses want to work this way
- Perhaps it's just too soon to know what patients really need
- "Experience suggests that if the investment requires integration of information and processes across these systems and business units in order to be cost-effective, then re-organising processes, changing responsibilities, re-training large numbers of staff, and finding additional funding can be an incredibly complex undertaking."

Model Driven Realization of Business Processes in Care Paths Based on a Service-Oriented Architecture in a Hospital Infrastructure

Espen Møller, RN, MSc Student[abc]

[a] *IT- department, Ullevål University Hospital, Norway*
[b] *Department of Informatics, University of Oslo, Norway*
[c] *The Foundation for Scientific and Industrial Research at The Norwegian Institute of Technology, Norway*

Abstract

This presentation will share work from my ongoing master thesis.

At Ullevål University Hospital there is a major challenge in integrating different IT systems in core processes, i.e. patient treatment.

The challenge is a two-way street. It is hard to embed these systems in the treatment processes (care paths) giving optimal value for patients, clinicians and the hospital. Treatment processes are not straightforward and the systems need to be flexible to align the processes.

At the same time complexity is emerging as a result of the way the systems are integrated. New technologies come and go, increasing heterogeneity and lowering flexibility in the way these systems interacts.

The focus in the master thesis is on realizing flexible computer-support in business processes by using concepts from OMG's MDA framework and investigating the use of BPMN and BPEL in this context. The use of reference ontologies are also investigated.

Keywords:

Integration, Model Driven Architecture, Service-Oriented Architecture, Modeling Language, BPEL, BPMN, Ontology, Logistics, Interoperability, Sustainable Development.

Introduction

In my master thesis I will investigate the framework of Model Driven Architecture (MDA) and Service-oriented Architecture (SOA) with the intention to realize flexible system integration aligned with core processes.

The main objective is to find a suitable modeling language(s) to map business processes to IT-infrastructure. Business processes, e.g. treatment processes and care paths, will be captured and used as input to a computational independent model in MDA.

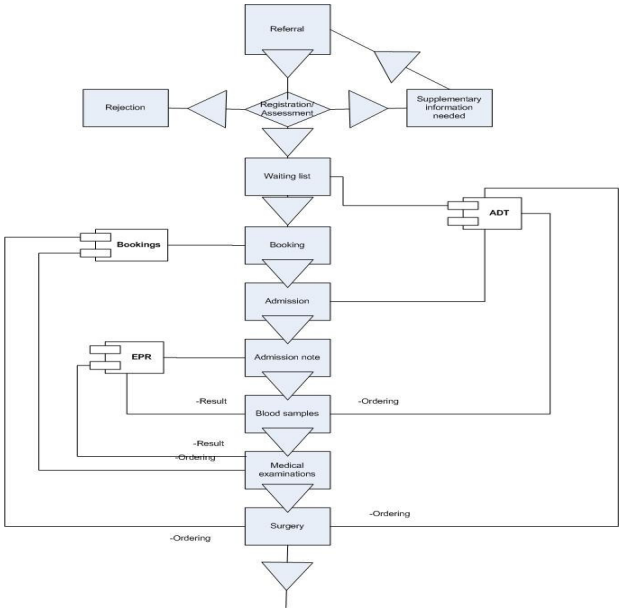

Figure 1- A subset of the treatment process

Methods

The capturing of business processes will be done by conducting structured interviews at a hospital department and modeled informally by the use of simple flow charts. Methods used to capture this and the results are not evaluated.

The captured business processes are modeled in BPMN. Further, models for realizing service chaining and service oriented architecture are made. A platform specific model conforming to BPEL metamodel is made in an attempt to realize service chaining using a specific technology.

Mappings between models are made experimentally revealing the abstraction levels that are needed.

An ontology is also made conceptually and mapped to the MDA stack.

Discussion

In the discussion, the BPMN-BPEL-chain, reference ontologies and the MDA framework is evaluated, raising the following questions:

- What is lost in abstraction to the different technologies?
- Are the technologies suited for integration of health information systems?
- Do the technologies fit into the MDA framework?
- Where do reference ontologies fit in the MDA framework and how should it be realized in a hospital setting?
- How should a reference ontology for semantic mappings of clinical and organizational data in EDI standards, like EDIFACT and HL7, be realized and what are the profits to expect?
- Identifying pitfalls in realization of the conceptual frameworks?

Results and Conclusion

The master thesis is due August 2008.

Model Driven Realization of Business Processes in Care Paths Based on a Service-Oriented Architecture in a Hospital Infrastructure

Espen Møller, RN, MSc Student - [abc]

[a] *IT- department, Ullevål University Hospital, Norway*

[b] *Department of Informatics, University of Oslo, Norway*

[c] *The Foundation for Scientific and Industrial Research at The Norwegian Institute of Technology, Norway*

Introduction

- The IT-portfolio at Ullevål University Hospital is growing larger and more complex:
  - making it harder to reconciliate systems to business processes.
- Integration of systems are typically done ad-hoc and is lacking structured semantic mappings from business domain to corresponding technical artefacts:
  - Making system integration expensive, rigid and error-prone.
- Manual maintenance of documentation:
  - Not to be trusted – changes demand reverse engineering.
- Need to compose services (service chaining) to composite processes, e.g. patient logistics

Objective

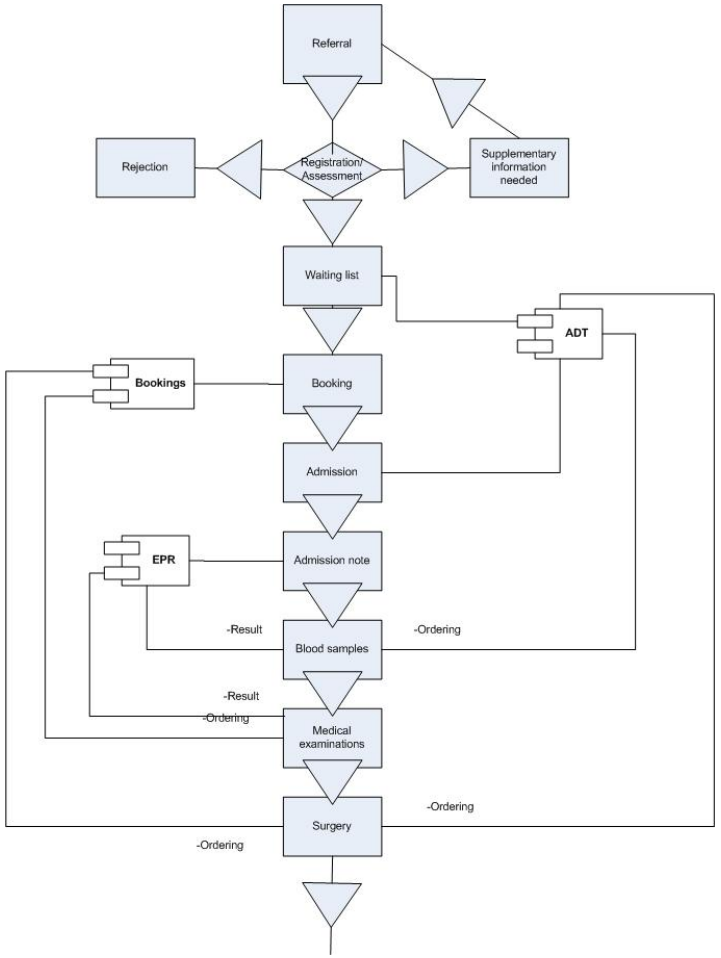
- Improve reconciliation of business processes and IT-portfolio at Ullevål University Hospital by applying MDA /MDD principles.
- Assessment of BPMN and BPEL as technolgies to map business processes (Computational Indepent Model - CIM) to IT-infrastructure (Platform Independent Model /Platform Specific Model – PIM/PSM).
- Assessement of reference ontologies as tools for improving semantic mappings in system integration and in interoperability with external partners.

Methods

- Capture business processes by structured interviews and informal modeling. The methods used and results will not be evaluated or discussed.
- Realizing models for business processes in a BPMN-tool
- Realizing models for service chaining by the use of BPEL metamodel. Map and transform BPMN to BPEL either directly or through a PIM model to constrain implementation to SOA paradigm and further to a PSM model of BPEL.
- Realizing a reference ontology conceptually in a hostpital setting.
- Map MDA CIM and PIM layers to reference ontologies

Methods: Capturing Business Processes

- Structured interviews
- Informal modeling, e.g. simple flow charts
- The accuracy of the captures is not important
- The captures are input to BPMN-models



CIM/PIM Modelling (BPMN /SOA)

- Realizing BPMN models.
- Investigate the need to map BPMN-models to a SOA model in order to achieve a Service Oriented Architecture.

PSM Modelling (BPEL)

- Make a BPEL model that conforms to BPEL metamodel and map it to the CIM model (directly or indirectly)
- Do we need a BPEL model? Is a direct transformation of CIM/PIM model to BPEL the way to do it in real life?

Evaluation of Reference Ontology (RDF and OWL)

- Evaluation of Reference Ontology in the MDA / hospital context
- Evaluation of existing technologies, RDF and OWL, in order to create a reference ontology for integration of health information systems.

Research questions

- Evaluating the BPMN-BPEL-chain:
  - What is lost in transformation from BPMN to BPEL?
  - Is the technologies suited for integration of health information systems?
  - Where does referance ontology fit in the MDA framework and how should it be realized?
  - What are the profits to expect using a reference ontology in semantic mappings of clinical and organizational data in, e.g. EDIFACT and HL7

Research questions: Integration of Health Information Systems

- Does an MDA /MDD approach with BPMN and BPEL:
  - Make integration cheaper,simpler, faster and less error- prone?
  - constitute a platform for configuration and control of the IT-portfolio – making it easier to tailor service chaining and user interfaces for specific needs?
- Pitfalls and criticism?
- Considerations in the health Information systems domain

Discussion and Conclusion

- The master thesis is due August 2008…

Social Construction of the Patient Through Problems of Safety, Uninsurance, and Unequal Treatment, a Discourse Analysis of IOM Executive Summaries

Lisa J. Trigg

School of Nursing; Biomedical & Health Informatics, School of Medicine University of Washington Seattle, WA

Abstract

This is a second preliminary report from a larger research project. The purpose of the larger research project is to study how the Institute of Medicine discourse promoting the health information technology may reproduce existing social inequality in healthcare. Subject position is a concept from critical theory which is used to study social justice through such approaches as discourse analysis. Social constructionist and critical discourse analysis combined with corpus linguistics methods has been used in methods testing to study the subject positions constructed for receivers of health care across the executive summaries of three different Institute of Medicine reports. Preliminary data analysis revealed differences in the way receivers of health care are constructed in the three texts selected for this study.

Keywords:

corpus linguistics, critical theory, discourse analysis, health information technology, social constructionism, inequality, social justice

Introduction

The 2003 American Medical Informatics Association Spring Congress outlined a social justice agenda for health informatics by calling for the development of health information technologies (HIT) that bridge the digital divide and support improved health care outcomes for both vulnerable and underserved populations. The white paper reporting on this Congress outlined barriers for HIT development for vulnerable and underserved populations and offered policy, funding, research, and education and training recommendations to overcome these barriers.(Chang et al., 2004)."

This is the second report from a study of how the Institute of Medicine (IOM) discourse promoting the deployment of health information technology and the development of the proposed National Health Information Infrastructure (NHII) may reproduce social inequality in health care. This research is in progress using critical discourse analysis of two Institute of Medicine report series: the Quality Chasm, and the Insuring Health series, as well as the standalone report on the unequal treatment of racialized populations, Unequal Treatment (Institute of Medicine & Board on Health Care Services, 2005; Institute of Medicine & Committee on the Consequences of Uninsurance, 2004; Smedley, Stith, Nelson, Institute of Medicine, & Committee on Understanding and Eliminating Racial and Ethnic Disparities in Health Care, 2003). The overarching goal of this research is to examine these texts for their contribution to the social justice agenda outlined by the 2003 AMIA Spring Congress using a study of the construction of subject positions in the textual data.

Methods

Data. A detailed description of the data selection for this research was outlined in the first preliminary report (Trigg, 2006). Briefly, each of the reports was published by the IOM between 2000 and 2005. To Err is Human of the Quality Chasm series was selected for its strong recommendations for HIT in the interest of improving health care safety and quality (Institute of Medicine et al., 2005) Coverage Matters, from the Insuring Health series (Institute of Medicine et al., 2004) and the standalone report Unequal Treatment (Smedley et al., 2003) were selected because they outline specific social justice problems in United States health care—those associated with uninsurance and the unequal treatment of racialized populations (racialized populations are persons grouped together solely based on the construct of 'race'). The executive summaries were selected for the preliminary data analysis in order to limit the scope of the project for methods testing.

Data Management & Processing. All texts were purchased from the National Academies Press (National Academy of Sciences, 2006) in both paper book and digital .PDF formats to facilitate comparison of surface features of all texts and random checking of agreement between the text versions. Data was cleaned using ConvertDoc™ (Softinterface, 2006) in preparation for analysis using corpus linguistics computer analysis tools. Oxford WordSmith™ Tools 4.0 (Scott & Oxford University Press, 2006) was used initially to create KWIC concordances for the three separate executive summaries for the truncated keyword patient*. Subsequent keyword concordances for the words person* and consumer* were created based on analysis of the results of the initial patient* concordances.

Results

In this section only, Coverage Matters = CM, To Err is Human = TEH, and Unequal Treatment = UT. Table 1 shows the results of the KWIC searches and includes number of tokens in executive summary.

The most notable result of the keyword in context concordancing was the small number of times that the word patient* is used in CM, compared with the number of times it is used in the other two texts.

Table 1 - Word Frequencies

KWIC	CM	TEH	UT
Patient*	2	81	129
Person*	27	2	3
Consumer*	3	7	1
Total word tokens	4764	5139	7729

*Table 1 - This table shows the number of times each truncated keyword appears in each text according to the KWIC concordance. Each line represents a set of concordances. The words person, patient, and consumer are all used to refer to receivers of health care in these executive summaries. Each carries a somewhat different connotation. * = truncation*

The sentence from CM quoted in the last paragraph actually distinguishes between "uninsured persons" and "patients with coverage," reporting that uninsured persons often pay more for medical care than patients with coverage. This distinction is curious and contradictory, given that if "uninsured persons" are "paying more than others for medical care," they must at some time have also been "patients."

Discussion

Exploration of definitions of these words yields interesting distinctions of meaning and therefore social action through language. One of the top current definitions for "person" in the Oxford English Dictionary Online™ (Simpson, 2006) (OED) is "an individual human being." A top OED definition for the word "patient" is "a person receiving or registered to receive medical care." Earlier and currently archaic OED definitions for the word "patient" are "a sufferer" and "a person who suffers from injury or disease." OED defines a "consumer" as "he who or that which consumes, wastes, squanders or destroys." OED definitions of "consume" include "to make away with, use up destructively," "to destroy," "to decompose," and "to spend, especially wastefully, to waste, to squander." American Heritage™ provides another definition for "consumer" as "someone who purchases a good for personal use" (Trefil, Kett, & Hirsch, 2006). Each variation suggests different requirements of an information system.

Given the limited corpora used in this study, little can be made of this distinction. However if this distinction between uninsured persons and patients pervades the Insuring Health texts, and enters the policy level requirements specification for the NHII, the needs of receivers of health care who are uninsured may not be adequately represented in a NHII which is designed for "patient safety."

Conclusion

The combination of critical and social constructionist discourse analysis with corpus linguistics methods has proven to be adequate for investigating textual data for discursive signs of the social action of language in creating subject positions in the selected IOM report executive summaries. It should prove useful in the larger study, which will use a much larger corpus, and make a closer interrogation of the textual data. The automation of corpus linguistics methods doesn't replace human interpretation in discourse analysis, but provides systematic ways to find language use patterns of interest to this research.

Social Construction of the Patient through Problems of Safety, Uninsurance, and Unequal Treatment, a Discourse Analysis of IOM Executive Summaries

Lisa J. Trigg, Ph.C., MN, ARNP
School of Nursing
BHI, School of Medicine
University of Washington
West Seattle Psychiatric Hospital
Seattle, WA - USA

Abstract Larger Research

- Question: Does the Institute of Medicine discourse promoting HIT/National Health Information Infrastructure reproduce existing social inequality in healthcare?
- Methodology:
  - Analyze social action of language in selected Instititute of Medicine reports using
    - Social constructionist and critical discourse analysis
    - Computer Assisted Corpus Linguistics methods
- Corpus/Data:
  - IOM reports: Quality Chasm, Consequences Uninsurance, Unequal Treatment

Abstract
Methods Testing Studies

- # 1: broad strokes; textually oriented discourse analysis
- # 2: social constructionist & critical discourse analysis; study of subject positions for receivers of health care
- Corpus linguistics used for both
- Same texts used

Background

- ↑Promotion of HIT/NHII in US to improve patient safety & quality through Quality Chasm reports
- Proposal of NHII, now called NHIN
- AMIA 2003 Spring Congress white paper--social justice agenda for HIT
- Unequal treatment of racialized populations
- Uninsurance problem

Rise in Interest in Discourse

- Fairclough (2001):
  - "...a 'knowledge-based economy'....entails a discourse-based economy:

knowledge is produced, circulates, and is consumed as discourses...which are operationalized as new ways of acting and interacting."

(Fairclough, 2001. CDA as a Method in Social Scientific Research, in Wodak & Meyers, Methods of CDA, p 127.)

Existing Social Inequality in Health Care

- **Interlocking nature of oppression (Collins, 1986)**
  - **Intersection of multiple structures of oppression**
- **Social circumstances & health care outcomes mutually constitutive:**
  - **Social position affects health care outcomes**
  - **Health status also affects social position (Blane, 1999)**
- **No universal health care in US, resulting in "uninsurance" problem**

(Collins, 1986. Learning from the outsider within. *Social Problems, Vol 33, No 6: Blane, D. 1999. The Life Course, the Social Gradient, and Health. In M.G.Marmot & R. G. Wilkinson (Eds.), Social Determinants of Health (pp. 64-80). New York: Oxford University Press.)*

Methods: Data

- For methods testing studies:
  - Executive Summaries, abbreviated for Table 1:
    - TEH = Err is Human, (2000)
    - CM = Coverage Matters, (2002)
    - UT = Unequal Treatment, (2003)

Methods: Processes

- IOM reports purchased in digital & book format
- ConvertDoc^{tm}: .pdf converted to .rtf
- KWIC searches:
  - First search patient*
  - Then person* and consumer* based on results of first search

Results

Table 1. Word Frequencies			
KWIC	**CM**	**TEH**	**UT**
Patient*	2	81	129
Person*	27	2	3
Consumer*	3	7	1
Total word tokens	4764	5139	7729

Discussion

- OED (Online 2006):
  - Patient = person receiving or registered to receive care; sufferer (archaic); person who suffers from injury or disease
  - Person = an individual human being
  - Consumer = he who or that which consumes, wastes, squanders or destroys; to make away with, to use up destructively, to squander

Discussion

- Three separate subject positions for a ‘receiver of health care’
- Each has different connotation
- Each connotation may reflect differently in a requirements specification
- Subject positions may conflict

Conclusion

- Social constructionist & critical discourse analysis combined with corpus linguistics are sufficient study subject position in even in small corpora
- Further research should facilitate planning to prevent the reproduction of social injustice in the NHII/NHIN

INDICATOR: A Comprehensive Cyberenvironment For Infectious Disease Surveillance, Modeling, and Response

Ian S. Brooks[a], Wendy Edwards[a]

[a] *National Center for Supercomputing Applications, University of Illinois at Urbana-Champaign, USA*

Abstract

Infectious diseases continue to be a major factor in public health and emerging diseases threaten to cause a pandemic. To combat these threats it is necessary to detect outbreaks and determine the most efficient response as quickly as possible. Information technology can give health professionals the tools they need to do this, but these tools must be integrated, effective, scalable, and user friendly. NCSA is currently developing INDICATOR, an infectious disease informatics cyberenvironment, to address this need.

INDICATOR will accept data from a wide variety of sources, including hospitals, public health departments, veterinary—medicine clinics, and remote sensor networks. It will use established spatial and temporal analysis algorithms, e.g. SatScan, to combine these data sources and identify outbreaks. INDICATOR will also support epidemiological modeling with programs, e.g. EpiSims, to help develop preparedness plans and determine the most effective remediation strategies for controlling an existing outbreak. In addition it will provide collaborative, visualization, social networking, and workflow management tools. Once in production INDICATOR will provide a major new resource to the surveillance, modeling, and response communities.

Keywords:

infectious disease informatics, cyberenvironments, public health, surveillance, modeling, response

Introduction

An effective response to an outbreak of an infectious disease, whether routine or rare, naturally occurring or deliberately caused, requires the coordinated effort of healthcare providers and public health officials. To be able to respond effectively, these groups need to have rapid access to information about the outbreak including its location, size, and spread. They also need to have access to models that correlate this information with potential remediation strategies and determine how likely each strategy is to successfully contain the outbreak.

There are currently a number of software solutions available to assist in the detection of an outbreak, including the US Center for Disease Control's (CDC) National Electronic Disease Surveillance System (NEDSS) [1], Early Aberration Reporting System (EARS) [2], Laboratory Response Network (LRN) [3], BioWatch [4], and BioSense [5]; John's Hopkins' Essence [6], the Open Source Realtime Outbreak and Disease Surveillance (RODS) from Pittsburgh [7], Health Canada's Global Public Health Information Network (GPHIN) [8], and the SatScan algorithm from Harvard [9]. There are also a number of formalized surveillance systems relying on communication between physicians such as the International Society for Travel Medicine and CDC GeoSentinel group [10] and the CDC Emerging Infections Network (EIN) [11]. Most of these systems, however, work with a single type of surveillance data, such as syndromic data, mandatory reporting data, or laboratory data and focus almost exclusively on human surveillance.

There are far fewer options for planning the response to an outbreak. Developing these plans is not a simple exercise and requires conducting significant numbers of simulations based on complex modeling studies such as those being carried out by the U.S. National Institutes of Health (NIH) MIDAS (Models of Infectious Disease Agent Study) team using tools such as EpiSims [12], and EpiCast [13]. These modeling studies require the handling and processing of very large, diverse datasets and multiple complex models in a heterogeneous large scale computing environment. Ready access to high performance computers, and datasets that include biological, population, behavioral, and geographic databases requiring a significant information technology infrastructure are also necessities.

Coordinating the computing and IT resources for surveillance and modeling and integrating them into an effective system for decision makers and responders is challenging. Adding the time critical nature of a response to an outbreak, the dynamic nature of the models (where parameters need to be modified in real time), and the need to

share the results quickly and visually makes for a frontier problem that must be addressed quickly. We are working to develop a cyberenvironment to address this need.

Cyberenvironments

Today's scientists spend too much of their time moving data from place to place and format to format—time that could be better spent generating new knowledge. In the infectious disease and bioterrorism community this leads to planners working with obsolete data and modelers lacking access to real time infectious disease information from sentinel systems. What is needed is the next generation of tools to make the research process more efficient—tools that truly integrate data, models, and communities.

Cyberenvironments are this next generation. They are an integrated set of tools and services tailored to a specific discipline community that allow these communities to realize the full potential of the national cyberinfrastructure in their research, development, and teaching activities. They provide an interface to local and shared instruments and sensor networks, data stores, computational capabilities, and analysis and visualization services within a secure framework enabling management of complex projects, automation of processes, and collaboration with colleagues both near and far.

The National Center for Supercomputing Applications (NCSA) is currently working with a number of scientific and engineering communities including earthquake preparedness, atmospheric sciences, and environmental sciences to produced cyberenvironments MAEviz [14], LEAD [15], and ECID [16] respectively. These environments are aimed at revolutionizing scientific practice at the scale of communities, enabling deep collaboration within disciplines and the linking of research with application of that research. Having accurate outbreak detection algorithms and good models of the spread of infectious disease agents is of limited use if the information cannot be shared quickly and easily with all members of the wider preparedness and response community.

In these projects and others in which NCSA is involved, strong support from domain researchers, and their desire to tackle very challenging problems, is driving the development and deployment of technologies. In many of these projects there have already been clear scientific successes enabled by the new capabilities, leading to requests for additional infrastructure. Cyberenvironments involve more than the simple application of new technologies to current science and engineering practice; they enable new ways of organizing, performing, and applying research that will ultimately be shaped by the evolution of community processes.

INDICATOR

The authors together with partners from NCSA's cyberenvironments and technologies division, and external collaborators from the surveillance, modeling, and public health communities are applying the concept of cyberenvironments to infectious disease informatics to produce INDICATOR, Figure 1.

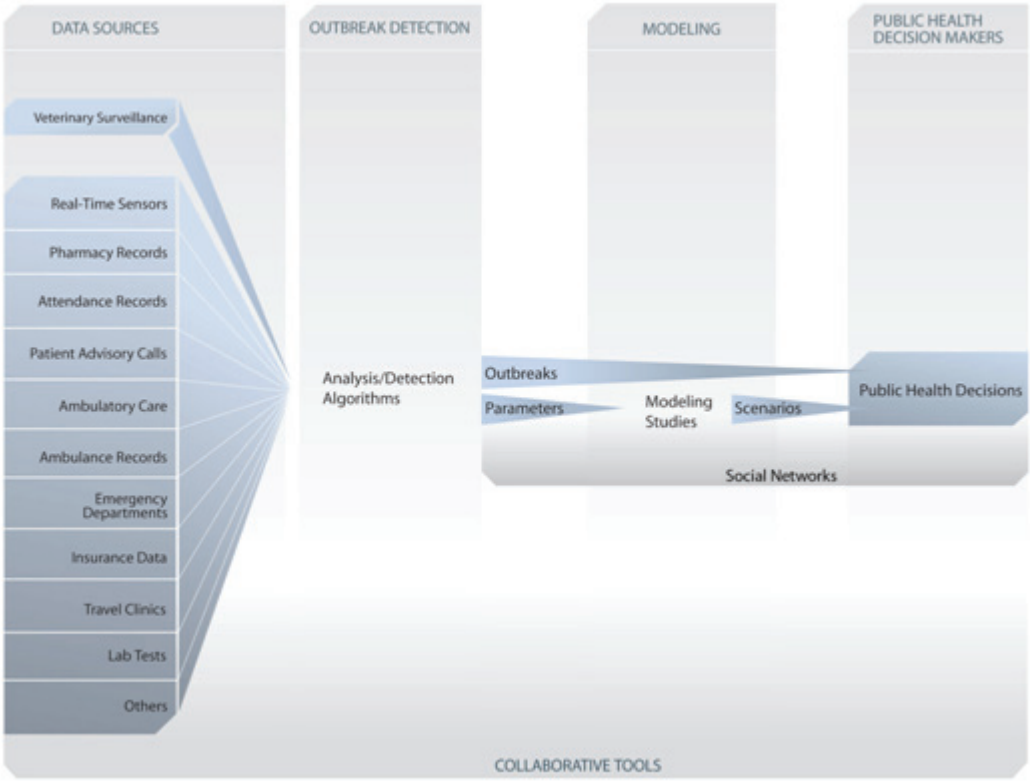

Figure 1 - Conceptual inforation flow for INDICATOR

Figure 1- Conceptual information flow for INDICATO is designed with a focus on the information needed by public health officials to make informed decisions on how best to respond to an outbreak. In most routine outbreak situations, such as the annual influenza season, it will be sufficient to detect the outbreak quickly and present the information to public health authorities in a format that they can quickly interpret. In more serious outbreaks, however, it will be essential to use parameters estimated from the outbreak detection, such as mortality and reproduction number to enable accurate modeling studies to be performed.

Effective surveillance requires the integration of multiple types of surveillance data, including syndromic, laboratory, real-time sensor networks, mandatory reporting, and veterinary data. The inclusion of veterinary data is of particular significance given the ability of wildlife monitoring to provide an early warning on the emergency of zoonotic diseases such as avian influenza and West Nile virus. Combining all of these data sources to provide a coherent picture of the health of a population is an ongoing research problem but one that INDICATOR can help algorithm developers such as Kulldorff (SatScan) address more easily. Recognizing that the data needed to identify an outbreak and model it for public health is the same data needed to advance research in surveillance INDICATOR will also provide the workflow tools needed for efficient management of algorithm testing and ensemble calculations. This will enable large numbers of computer experiments to be submitted to remote compute resources, such as NCSA supercomputers, automatically.

INDICATOR has the potential to facilitate collaboration among multiple organizations using heterogeneous technology. Users may include researchers and practitioners from many different fields, including medicine, public health, environmental science, geography, and veterinary medicine. This offers the opportunities for innovative cross-disciplinary research, but it also poses significant challenges.

Implementation

INDICATOR uses the concept of "workflow" to describe processes at multiple levels. This allows us to describe the technologies and processes in a way that can be analyzed, shared, and reused. Workflow encompasses the high-level graphical user interfaces that domain scientists use, the

low-level job execution, and the data storage and movement. Linking between views requires semantic descriptions, provenance tracking, scalable execution engines, and interfaces for managing workflows.

The workflow for an infectious disease cyberenvironment will involve heterogeneous data, including proprietary formats, processed data, and metadata. Additionally, there will be a need to support different levels of data sharing. Participants will be allowed to identify the part of their own workflows they choose to share, e.g. raw data, results, or abstract descriptions of protocols. INDICATOR will also support provenance tracking to maintain information about the origin of data.

To address these issues, we plan to develop a secure collaborative cyberenvironment and metadata/data repository, leveraging existing components created by NCSA's MAE-Viz team. Users can automatically email, upload their data, or provide an HL7 feed and INDICATOR will parse and process it as necessary. Metadata, including provenance information, will be generated and stored in the repository along with the original data. Spatial and temporal analysis software, e.g. SATSCAN [9] and WSARE [17], will be available as services.

The cyberenvironment will allow users to browse available data sets and metadata, control how their own data is shared, and select data sets and services to run. The resulting data is also stored in the repository and INDICATOR will support visual analysis, e.g., GIS maps and graphs. Users will be able to anonymize their data with FLAIM [18], a tool originally developed by NCASSR to anonymize computer security logs.

To support workflow management, we will be leveraging ECID, Environmental Cyber Infrastructure Demonstration Project, also developed at NCSA. ECID introduces the concept of "meta-workflow" which provides users with the following capabilities [16]

1. Browsing registries of data, tools, and computational resources
2. Creating meta-workflows for batch processing
3. Reuse and repurposing of meta-workflows
4. Executing meta-workflows locally or remotely
5. Incorporating heterogeneous tools and transparently linking them

For example, a user looking at emergency room chief complaint data might suspect a zoonoses-related outbreak, and want to look at veterinary data to see whether there have been unusual patterns with animal illness. The user would either browse the data or perform a metadata-based search. They could then create a new workflow using multiple services, execute it, and view the results. These results would then be stored, and the user could decide whether to share his results.

We also plan to leverage social network analysis to help users discover relevant data and services. ECID is currently exploring this technology as it develops a "dashboard" that provides a dynamic overview of the activities within the current environment [19]. This would also be useful for INDICATOR. For example, someone investigating an outbreak in one county would be able to discover recent results of a similar analysis of a neighboring county.

The LEAD (Linked Environments for Atmospheric Discovery) cyberenvironment allows the user to dynamically control real-time streaming feeds from weather sensors [15]. INDICATOR plans to leverage this technology for its remote sensing data. Weather and environmental data are often linked to infectious disease outbreaks, but the sheer volume of information has often been a problem for researchers analyzing remote sensor data. Allowing the user to dynamically choose real-time feeds would provide a solution to this problem.

Preliminary work has focused on detection of outbreaks from chief complaint data obtained from calls to a local patient advisory nurse. Having evaluated many of the available syndromic surveillance systems and algorithms SatScan and WSARE were selected for initial implementation as services based on their portability and functionality. The evolving nature of a cyberenvironment means that others may be added without disruption to the existing services and in fact INDICATOR provides an ideal platform for comparison of different algorithms.

Conclusions

Cyberenvironments have been employed successfully in multiple scientific and technical domains. These include the earthquake preparedness domain that uses data feeds to detect an earthquake, computational modeling to predict structural damage, and high end visualization to present results to emergency response authorities. The knowledge and experience gained with other cyberenvironments will be applied to the infectious disease domain to develop INDICATOR which will have analogous capabilities to use data feeds to detect an outbreak, computational modeling to predict disease spread, and high end visualization to present results to emergency response authorities. Over the next year we expect to implement workflows for SatScan and EpiSims, implement a cybercollaboratory for EIN, and move our chief complaint surveillance component into production.

Acknowledgments

The authors would like to thank Martin Kulldorff and Ken Kleinman of Harvard Medical School for their help with surveillance

algorithms and identifying their workflow needs; Steven Eubank and Madhav Marathe of Virginia Tech University for help understanding EPISims and the needs of the modeling community; David Freedman of GeoSentinel for help in understanding international surveillance issues; Phil Polgreen from EIN for helping us design the collaboratory features of INDICATOR; Lynne Reagan, Cora Musial, Lynne Barnes, Judy Kaureauf, and Napolean Knight for insights into the needs of the public health and emergency response communities; and Jim Myers, Jay Alameda, Adam Slagell, Mark Marikos, and Lorri Coey of NCSA for providing us with their technical experience on this project.

Future Market Expectation for Korean u-Health by Analyzing Demand Forecast and Adoption Factors

Kyoung-Yong Jee[a], Moon-Koo Kim[a], Jong-Hyun Park[a]

[a] *IT Technology Strategy Research Division, Electronics and Telecommunication Research Institute(ETRI), Korea*

Abstract

With progress in ICT and health care and medical technology providing capability, the introduction of u-Health has been propelled by an increasing demand from both service providers and users. The benefits expected from u-Health are enormous. In addition to the tremendous contribution to the welfare of health care users, it is projected to entail huge economic effects, bolstering the growth of the health care industry as a whole, as well as the ICT industries. In this paper, we, predict demand for both the services and related equipment based on the results of a consumer survey, identify factors affecting the diffusion of this new service system, and, finally, suggest market development strategies for it.

Keywords:

u-Health, ICT, adoption, forecast, market

I. Introduction

The advent of ubiquitous networking promises to bring about dramatic changes at all levels of our life. Ubiquitous networking, by interlinking computers, consumer electronics, automobiles, home appliances, medical equipment, transportation systems, animals and plants through an overlapping of electronic spaces and physical spaces, is expected to provide an environment that enhances our lives through improved convenience, efficiency and safety in all areas. This paper is concerned with strategies to accelerate the diffusion of u-Health services in Korea. In the rest of this paper, we examine the concept and characteristics of u-Health, forecast demand for both services and equipment, and identify factors influencing the adoption and diffusion of these services, using the results of a consumer survey, and finally, based on this analysis, propose development strategies for the u-Health market.

II. Concept and characteristics of u-Health

u-Health, the short form of "ubiquitous health," refers to a health care system making use of ICT to provide preventive care, consultation, treatment, and follow-up care to patients from anywhere and at any time. While e-Health is an electronic information sharing system between patients, the general public, health care institutions and solution providers, u-Health goes one step further to integrate the physical spaces of health care users and providers with electronic spaces, operating cutting-edge medical technologies.

To explain the emergence of u-Health, one must invoke, first of all, progress in ICT and medical technology, and then the desire and willingness on the part of health care institutions to adopt the new service concept and increased health care demand. The extended business areas covered by telecom operators and software solution providers and support from government authorities have been contributing factors as well.

III. Demand forecast and factors influencing on adoption of u-Health

To estimate demand for the u-Health market and identify factors influencing the diffusion of related services, ETRI's Network Economic Research Team conducted a survey between September and October 2005, on a sample population of 800 adults in their 30s and 40s. The market research was preceded by a FGI (Focus Group Interview) on target group [1], from which generic needs relating to u-Health among health care users were determined. The FGI results were further used as a basis for designing a structured survey questionnaire. A leading Korean research firm was contracted to conduct the survey, in the form of one-on-one, face-to-face interviews. Information cards were used to help survey respondents' understanding of the service [2].

1. Adoption intention of u-Health

Consumers appeared to be all in all favorably disposed toward u-Health. 71.8% of respondents perceive u-Health as an exciting service formula, followed by 63.6% finding it interesting, 58.2% preferring it to standard health care services and 55.8% considering it indispensable.

The overall intention to adopt u-Health services appeared to be rather high, amounting to 56.9% of respondents. The intention of adoption was higher among women than men, among respondents residing in metropolitan cities or other small and medium-size cities than those based in Seoul and among stay-at-home wives than people in other occupational categories.

2. Factors influencing on adoption of u-Health

Consumers perceive the level of investment of resources and capabilities on behalf of medical institutions and government policy as more important factors in the achievement of a u-Health environment than a ubiquitously-networked health care infrastructure.

The biggest obstacle to the creation of a u-Health environment was the poor level of informatization in medical facilities (23.0%), followed by insufficient public information efforts concerning u-Health services (20.4%), lack of knowledge (21.0%) and inadequate ICT infrastructure in health care institutions (14.8%).

3. Demand forecast of u-Health

The survey found that the global intention to adopt u-Health in consumers in their 30s and 40s stands at about 46.9%. The intention to adopt health care institution-provided services was measured at 40.9%, and the intention to adopt subscription-based services, 9.1%.

The size of the u-Health market in number of users aged 30 to 49 is estimated at 7,026,000, which breaks down to 6,128,000 for health care institution-provided services and 1,352,000 for subscription-based services.

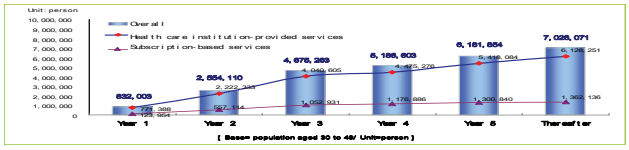

Figure 1- Forecasted number of u-Health users

Total sales in u-Health services and related equipment are projected to amount to an approximate KRW 1,075.6 billion (1,036 million dollars)[1], which breaks down to KRW 562.4 billion (494 million dollars) for health care institution-provided services and KRW 513.2 billion (542 million dollars) for subscription-based services.[2] The high estimation for sales generated by subscription-based services, used by a much smaller projected number of users, is a result of taking into account the high willing-to-pay price indicated by potential users of this type of service, and costs of equipment and devices.

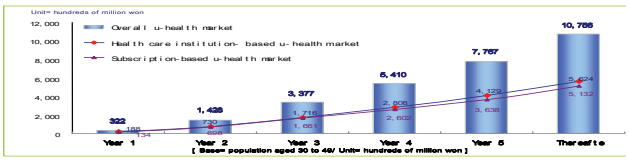

Figure 2- Projected sales in u-Health services and equipment

IV. Conclusion

In this paper, we explored the background to the emergence of u-Health, and examined its concept and characteristics. Based on a consumer survey, we predicted future demand for u-Health, and identified factors accelerating the creation of a u-Health environment and factors hindering it. Finally, we presented success factors and issues for market development efforts in u-Health. The following is implications for participants of the u-Health market.

First, the survey used in this study was limited to a population segment aged 30 to 49. Therefore, if one includes other age groups and takes into consideration forward and backward linkages, both the size of the u-Health market and its economic effect are likely to be substantially greater.

Second, the in-depth analysis revealed that interest in u-Health services was significantly higher among people who were less interested in health than the average, or not all interested, than among the rest. This means that u-Health will be able to generate new demand and create new markets.

Third, introducing necessary revisions to related health care laws and regulations is an urgent task.

Finally, the national government and local authorities must work to actively promote u-Health.

Challenges to the Regional Comprehensive Electronic Health Record (rcEHR) - the Experiments in Koriyama -

Yoichi Ogushi(a), Yasuo Haruki(a), Hisao Hara(b)

a *Department of Medical Informatics, School of Medicine, Tokai University, Japan*
b *Koriyama Medical and Nursing-care Hospital, Japan*

Abstract

This paper reports on our efforts and the further challenges that we are having in our experiments in Koriyama. We have been developing electronic medical charts and health examination databases for medical and healthcare facilities, as well as eHealth cards and computer network systems on a regional basis. By integrating all of these functions, we have developed the Regional Comprehensive Electronic Health Record (rcEHR) in Koriyama. This paper explains the solutions to common problems generated in EHR development on a regional level, and upcoming challenges.

Introduction

In Japan, the sharing of health checkup results and medication information on a regional basis began as the eHealth Card system around 1995. The Japanese government has experimented with numerous business models using the electronization of health insurance cards as its ultimate goal. However, there are just a few regions where the operations are still currently available. In regard to regional healthcare via computer networks, even though the government initially poured a sizable budget into the development of the system, an issue remains regarding its sustainability because of lack of personnel and economical reasons due to the elimination of the subsidy.

Without relying on the national budget, we have developed such systems as electronic medical charts, electronic health cards, regional medical computer networks, and a database of health checkup results. In these systems, operability, economical efficiency and interoperability have all been taken into consideration. The systems have been used for the past 20 years, and are well-established in many regions. This paper reports on the sustainable systems we have developed by integrating these operations in Koriyama in Fukushima Prefecture.

Methods (1/2)

We are providing patients with their medical records and health data via electronic media used in digital cameras or cellular phones. We have named these systems My eChart and My eHealth Card respectively.
For medical and healthcare service providers, computer systems are needed to improve the efficiency of each operation at their facilities. Thus, we have developed electronic medical charts for medical facilities, an information system to record health checkup results and issue notifications for health examination clinics. Additionally, we have also developed a health checkup results database and an information system to support health guidance for the facilities. Moreover, from these systems, My eCharts and My eHealth Cards can be downloaded onto personal electronic media systems

Methods (2/2)

In regard to sharing health information between regionally-based medical and healthcare service providers, there are many restrictions in terms of time and amount of data when using patients' portable media systems. Since Internet communication is more convenient, we provide regional medical information sharing systems via highly encrypted networks.

In June 2006, we began using the electronic medical charts and My eCharts at Koriyama Medical and Nursing-care Hospital. Figure 1 shows an example of the medical imaging displayed on My eCharts. In September, we began using My eHealth Cards for workers that contain the data for physical examinations, physical fitness tests and nutritional assessments at the Health Promotion Foundation of Koriyama. We also began My eHealth Cards to provide elderly people with their general health checkup data at the Public Health Center in Koriyama. Figure 2 shows an example of the time-line graphs of the health checkup results in My eHealth cards. In April 2007, we started regional medical network to share patients' data.

Figure 1, 2

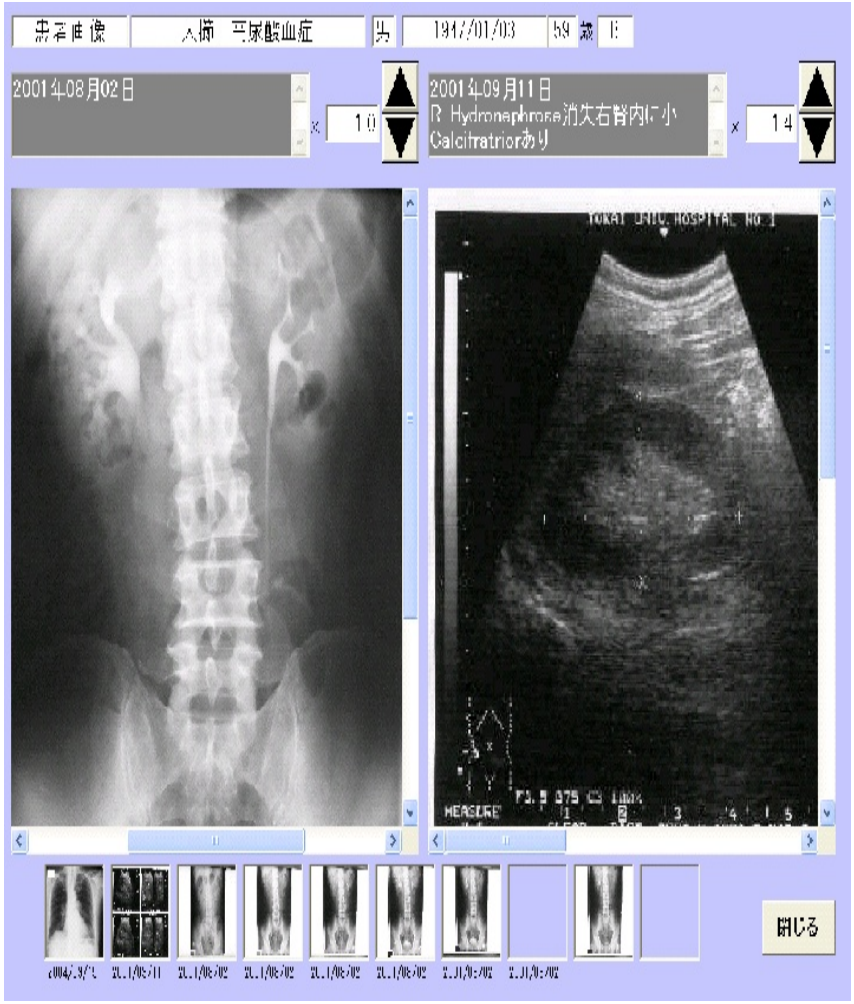

Figure 1- An example display of My eChart medical imaging

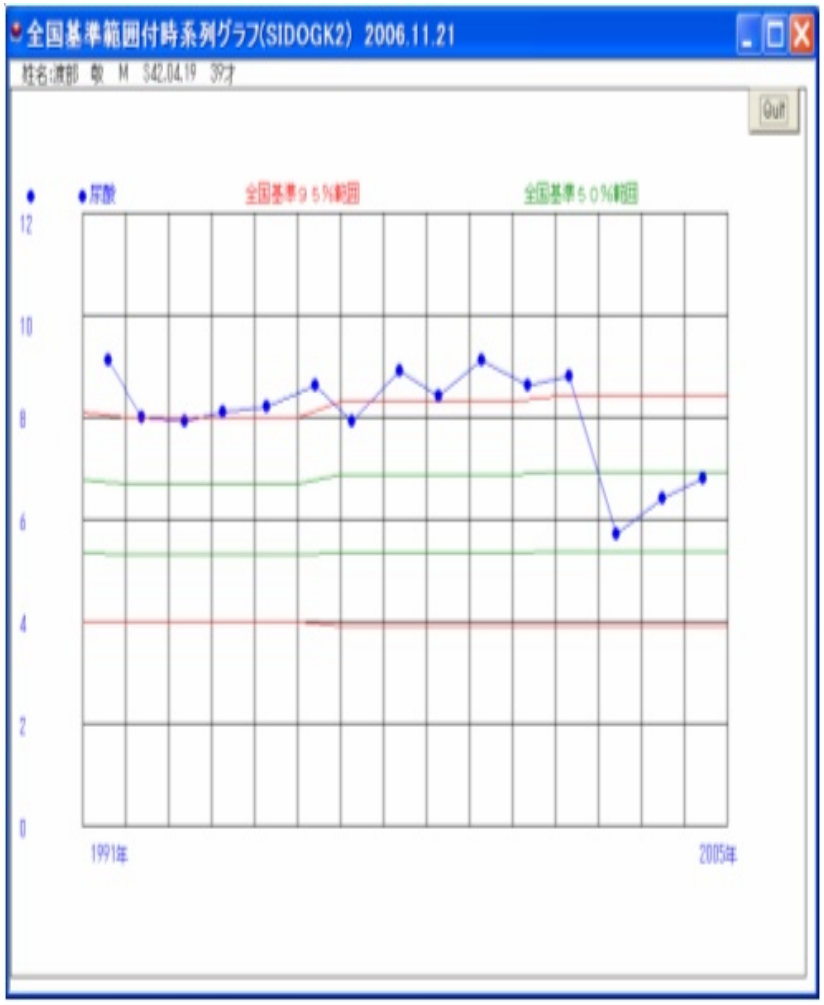

Figure 2- An example of My eHealth Card time-line graphs

Results (1/3)

1. **Operability**
   We applied the touch-screen system to our electronic medical charts. The terms, phrases and illustrations used by each doctor are programmed into the system as a table beforehand, and this reference table will be displayed on the entry screen so that the doctor can enter data with the touch-screen. For My eCharts and My eHealth Cards, the patients will see the same screen that the doctors or health nurses do. These systems enable the patients to refer to their personal health information at home or at work without going through any special training on its operations.

Results (2/3)

2. Easiness to provide My eChart or My eHealth Card

By just clicking the data-providing button on the guidance screen for the patients, personal data will be downloaded automatically onto their My eChart or My eHealth Card. The access program, the execution environment such as DLL or OCX files, and the operation manual in the HTML format are also transferred all at once. This process takes only a few seconds and hardly affects day-to-day operations.

3. Security

The regional medical networks can be accessed only by the registered medical or healthcare specialists. An encrypted password is issued for each user as personal authentication in accessing the networks. SSL is used for communication to prevent interception. Since the data is encrypted and registered in the database in real time, it cannot be decoded through unauthenticated access(Figure 3).

Figure 3

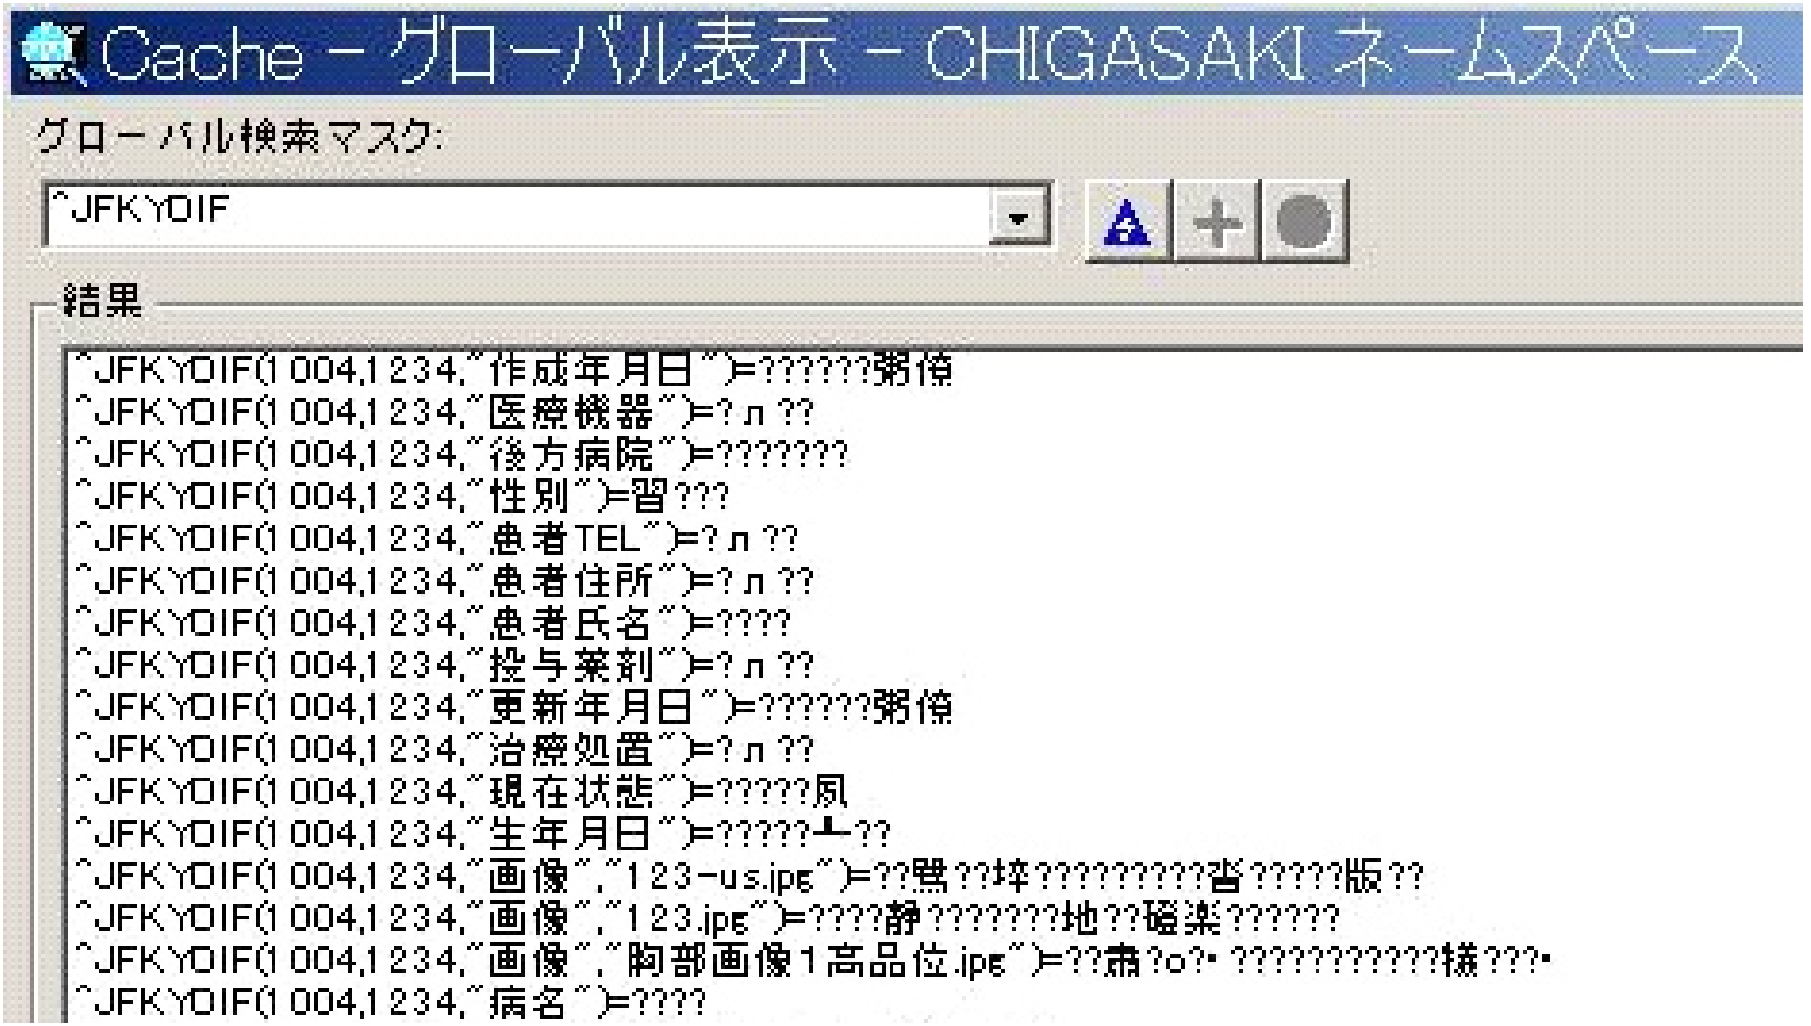

Figure 3- The database encrypted in real time

Results (3/3)

4. **Coexistence of applications among facilities**
   Coding schemes, examination methods and reference intervals, screen designs, and development environments often vary from facility to facility or from region to region. We are providing health data to the patients' media systems along with the programs and the execution environment. On the patients’ media systems, we create folders for each facility, put their data, programs, tables and execution environment in them, and use each folder for one object. By using this method, even the systems developed by other manufacturers or vendors will be able to co-exist in a single patient’s' media system.

Discussion

The interoperations are considered to be the key element, and the standardization of communication protocols and coding schemes is in progress. Moreover, it is not easy to integrate information systems that have been developed and operated by each facility and organization. But, especially with the rapid increase of medical accidents and expenses, EHR is in such a high demand as measures against them that there is no time to wait for standardizations.We are aiming to create interoperations by implementing applications as objects although this is still on a regional basis. The sustainability of the systems is not proportional to the amount of money invested. Sustainable systems are the ones that have gradually been developed and have had functions added to them based on the needs and practical uses in the region. The foundation to support the sustainability of EHR systems can be seen in the prerequisite of the systems. It is believed that the interoperation of the EHR systems will lead to medical safety and the reduction of medical costs through the reduction of duplicate checkups, the prevention of dangerous drug interactions, support for doctors' treatment policies, effective healthcare guidance, and self health care. Having experienced further challenges in Koriyama, we are planning to assess these outcomes quantitatively and clarify the overall effects including extension of healthy lifetime.

Evaluating Designs Against Users' Requirements in Latin America: An Experience of Human-Centred Methods, Techniques and Tools on a Low Budget

Analía Baum[a], Alejandro Mauro[a], Damián Borbolla[a], Daniel Luna[a], Fernán González Bernaldo de Quirós[a]

[a] *Department of Medical Informatics, Hospital Italiano de Buenos Aires, Argentina*

Abstract and objective

Informatics designs centered on the human being are multidisciplinary activities which demand a knowledge of the human factors related to human-computer interaction, the ergonomics of the work and of different evaluation techniques. The Medical Informatics Department of the Italian Hospital of Buenos Aires has gradually implemented a full-scale HIS since 199 and is also responsible for periodically evaluating user interfaces. Using qualitative techniques, diverse problems in the problem management interfaces were found and led to multiple modifications in this section of the HER. Using The Questionnaire for User Interaction Satisfaction we evaluate the new interface. The results show that the doctors found the new Problem Administrator easy to use, and there was high overall user satisfaction.

Keywords:

user-computer interface; consumer satisfaction; questionnaires; medical records systems

Introduction

ISO 13407, the standard for human-centred design (HCD) processes for interactive systems, describes human-centred development as "An approach to interactive system development that focuses specifically on making systems usable. It is a multi-disciplinary activity, which incorporates human factors and ergonomics knowledge and techniques. Applying ergonomics to the design of systems involves taking account of human capabilities, skills, limitations and needs."[1]

The Italian Hospital of Buenos Aires is a tertiary care, teaching and research hospital with a 150 year-old history. Since 1998 a full-scale HIS has gradually been implemented. This includes an ambulatory Electronic Health Record (EHR), is a problem-oriented record, Web based, that generalist physicians use in their routine practice to take care of patients[2].

Since 2002, the hospital has had physicians in a residency program in medical informatics. During our daily work, we perceive problems with the utilization of the EHR. Then we make proposals for the improvement of the problem management system. We began with this part of the system because all interaction with the EHR implies the creation of a new problem or the modification of an existing one.

Background

One of the purposes of the HCD process is to establish and maintain a focus on stakeholder and user issues in each part of the organization which deals with system markets, concepts, development and support. To achieve this first stage we conducted a previous study using qualitative techniques based on ethnography[3]. This evaluation allowed us to clarify how information is communicated and used, as well as to identify the causes and consequences of inadequate information flows and to meet users' needs, their tasks, expectations and problems with the information resource.

In the second place we set up a multi-disciplinary team (medical informatics, nurses, sociologist) and developed a plan specifying how to solve the problems seen and to improve the overall system development process[4]. We are now at stage known as "Evaluate designs against requirements". The purpose of this process is to collect feedback from end users on the developing design.

This study was undertaken to measure user interaction satisfaction with the redesigned EHR in routine clinical practice in order to begin to understand which aspects of the system meet the users' requirements and which do not.

Materials and methods

To accomplish the HCD, we focus on Usability testing, in particular on one method; the Questionnaire for User Interaction Satisfaction (QUIS). In addition to the use of the QUIS, one investigator observed and listened to the clinicians during the evaluation of the interface, to answer questions, to document user comments made during data entry and to observe any difficulties met. Five general practitioners participated in the first study[3].

Setting

This study was carried out in a clinician's office. We used mock patient data to ensure that all items of the problem list administration module were included.

Instrument

Version 7.0 of the paper format of the QUIS was used for the study. The QUIS uses Likert scales and a hierarchical approach in which overall usability is divided into 12 sections of 4 to 6 questions each. We used sections from 1 to 8 because sections 9 to 12 were not applicable to the interface[5].

Data analysis

Data from the returned questionnaires were double entered on an Excel spreadsheet. SPSS 11.00 was used for quantitative data analysis.

Results

A total of five general practitioners agree to participate, one woman and four men, ranging in age from 30 to 44, with a mean age of 38.8. Users spend at least 10 hours per day with the EHR for more than 3 years. All were familiar with computer hardware, word processor, database software, e-mail and the Internet. Table 1 shows the mean user response to each section of the QUIS.

Table 1 - Mean user response for each section

Object	Mean	St. Dev.
Overall user reactions	7.5	0.7
Screen Design and layout	7.5	0.8
Terminology and System information	7.6	0.6
Learning	7.2	1.4
System capabilities	7.1	0.8
Online Help	8.2	0.5

Discussion

In this evaluation study, the problem list administration module scored high in all areas. The score for overall user reactions is consistent with the score of the rest of the sections.

The highest score was in "Screen design and layout" and in "Terminology" and the lowest in the areas of "Learning" and "System capabilities". These findings were not too surprising because most of the clinicians' requirements in the first study were met by a terminology server after they had made some suggestions on user interface, that were taken into account when rebuilding the problem list administration module. In addition, based on extensive user feedback, screen designs and quality of terminology had improved significantly.

Interface satisfaction studies have been conducted successfully because we meet users needs on the EHR redesign.

Conclusion

People and organizations used to think that usability testing is very costly and complex and that it should be reserved for the big project with a huge budget and a lavish time schedule. Not true. The best results come from testing no more than five users and running as many small tests as you can afford. This study allowed us to evaluate redesign in the context of users' requirements and to empower users and motivate them.

Future directions

To undertake evaluation studies on the effect or impact of information resources on users, to find out whether these changes increase productivity, enhance the quality of work, and improve health and safety.

Evaluating designs against users' requirements in Latin America: an experience of human-centered methods, techniques and tools on a low budget

Analía J. Baum, Alejandro M. Mauro, Damián Borbolla, Daniel R. Luna, Fernán González Bernaldo de Quirós

Department of Medical Informatics, Hospital Italiano de Buenos Aires, Argentina

HOSPITAL ITALIANO de Buenos Aires

Department of Medical Informatics

Introduction

- ISO 13407 describes human-centered development (HCD) as “An approach to interactive system development that focuses specifically on making systems usable. It is a multi-disciplinary activity, which incorporates human factors and ergonomics knowledge and techniques. Applying ergonomics to the design of systems involves taking account of human capabilities, skills, limitations and needs.”

Introduction (cont.)

- Since 1998 the Hospital Italiano de Buenos Aires (HIBA), a tertiary care, teaching and research hospital, has gradually been implemented a full-scale Health Information System

- Since 2002, the hospital has had physicians in a residency program in medical informatics. During our daily work, we perceive problems with the utilization of the problem management system.

- We began with this part of the system because all interaction with the Electronic Health Record implies the creation of a new problem or the modification of an existing one.

Introduction (cont.)

- The first stage of HCD process is to establish and maintain a focus on stakeholder and user issues.
- To achieve this first stage we conducted a previous study using qualitative techniques based on ethnography.
- This evaluation allowed us to clarify how information is communicated and used, as well as to identify the causes and consequences of inadequate information flows and to meet users' needs, their tasks, expectations and problems with the information resource.
- In the second place we set up a multi-disciplinary team and developed a plan specifying how to solve the problems seen and to improve the overall system development process.
- We are now at stage known as "Evaluate designs against requirements". The purpose of this process is to collect feedback from end users on the developing design.

Objective

- This study was undertaken to measure user interaction satisfaction with the redesigned EHR in routine clinical practice in order to begin to understand which aspects of the system meet the users' requirements and which do not.

Materials and Methods

- We focus on Usability testing, version 7.0 of the paper format of the QUIS was used for the study.
- We used sections from 1 to 8 because sections 9 to 12 were not applicable to the interface[5].
- In addition to the use of the QUIS, one investigator observed and listened to the clinicians during the evaluation of the interface
- The study was carried out in a clinician's office. We used mock patient data to ensure that all items of the problem list administration module were included.

Results

- Five general practitioners agreed to participate, one female and four males, ranging in age from 30 to 44, with a mean age of 38.8.
- Users spend at least 10 hours per day with the EHR for more than 3 years.
- All were familiar with computer hardware, word processor, database software, e-mail and the Internet.

Results (cont.)

Object	Mean	St. Dev.
Overall user reactions	7.5	0.7
Screen Design and layout	7.5	0.8
Terminology and System information	7.6	0.6
Learning	7.2	1.4
System capabilities	7.1	0.8
Online Help	8.2	0.5

Mean user response to each section of the QUIS.

Discussion

- In this evaluation study, the problem list administration module scored high in all areas.
- The highest score was in “Screen design and layout” and in “Terminology” and the lowest in the areas of “Learning” and “System capabilities”.
- Interface satisfaction studies have been conducted successfully because we meet users needs on the EHR redesign.

Discussion

- These findings were not too surprising because most of the clinicians' requirements in the first study were met by a terminology server after they had made some suggestions on user interface, that were taken into account when rebuilding the problem list administration module.

- Based on extensive user feedback, screen designs and quality of terminology had improved significantly.

Conclusion

- People and organizations used to think that usability testing is very costly and complex and that it should be reserved for the big project with a huge budget and a lavish time schedule. Not true.

- The best results come from testing no more than five users and running as many small tests as you can afford.

- This study allowed us to evaluate redesign in the context of users' requirements and to empower users and motivate them.

[b] *Watson School of Engineering, Binghamton University, New York, United States*

Abstract

Although internet technology and management information systems are frequently used in health promotion activities and health assessment in individual worksite, school, or clinic settings, their use in community settings for program monitoring and evaluation is much less common. The purpose of this paper is to examine the process and technology used in two internet-based applications (PROMS and PMDES) intended for monitoring, data collection, and evaluation of a large scale health promotion programs in New York State. Using the fundamental concepts of program evaluation, we developed a comprehensive Web-based application that used MS Windows Server, MS SQL Server, .NET framework, and Crystal Reports. The end product enables users across New York State to collect and report standardized data, retrieve information, and generate a variety of reports. Program managers in the state capital Albany can monitor individual projects' progress on a regular basis and generate statewide or project specific reports. This initiative has already proven to be user friendly, cost effective, fast, and accurate.

Keywords:

program evaluation, health promotion, internet

Introduction

According to the Centers for Disease Control, program evaluation involves useful, ethical, feasible, and accurate procedures that help improve and account for public health actions [1]. Furthermore, through successful evaluation procedures, health program managers can make decisions on: the best use of time and resources, determining if the program is achieving its stated goals, demonstrating the effectiveness of a program to funders and other stakeholder groups [2]. In the last few decades, program evaluation has gained prominent position as a key component of public health research. Social programs have become increasingly complex with multiple intervention sites, multiple intervention levels, and multiple audiences [2, 3]. In response, program evaluation theory, intervention designs, and methods have improved to reflect these changes. Government Performance and Results Act (GPRA) has also contributed to the proliferation of community health program evaluation efforts with its requirement that agencies set performance targets and track their progress against these benchmarks. It is, however, surprising that despite all the importance that computer and internet technology play in the 21st century, examples of internet based data collection tools and monitoring systems are only occasionally mentioned in the evaluation of community health programs [4].

At its best, the use of technology by large scale community health programs for data collection consists of electronic compilation of data on individual PCs, either in a template in Excel, Access, or in another data base program. Each project site then transfers their data to a central administration office through e-mail.

This process is not only inefficient and time consuming, but also generates less than reliable and consistent data. Individual projects that submit the data ordinarily do not have access to the data submitted by other projects or have the ability to retrieve and edit their own data. Any modifications or updates to the system would require dissemination of new software and training.

In contract with the New York State Department of Health, we developed two internet-based applications (PROMS and PMDES) that streamlined program monitoring, data collection, and report generation activities in sites across New York State.

STEPS to a Healthier New York Program

Steps to a Healthier US is an initiative from the U.S. Department of Health and Human Services (HHS) to implement chronic disease prevention efforts with the goal of helping Americans live longer, better, and healthier lives. Through this 5-year program, states, cities, and native tribes receive funds to implement chronic disease prevention efforts. The focus areas are diabetes, overweight, obesity, and asthma and address three related risk factors—physical inactivity, poor nutrition, and tobacco use [5]. In New York State 13 projects in four counties received funding. Program administrators are required by the U.S. Federal Government to monitor, evaluate, and report on the progress of projects.

NYS Healthy Heart Program

In 2004, New York State Department of Health released "Cardiovascular Health in New York State: A Plan for 2004 — 2010." "This plan has 19 objectives to promote healthier behaviors, further enhance the quality of care and reduce known disease risks. It promotes interventions in four sectors: communities, schools, worksites, and health care settings. Funds are provided to local communities to conduct physical activity and nutrition interventions in schools, worksites and the community, and to ensure people receive appropriate health care for risk factors for cardiovascular disease" [6]. Currently, 27 sites in four counties administer projects. Program administrators are required by New York State to monitor, evaluate, and report on the progress of projects.

Methods

The need for a new system of data collection for evaluation purposes for both projects was clear. The existing paper and a flat, Access data base driven systems and reporting tools were not efficient, effective, or useful. Project managers were frustrated with the rigidity of the system and the lengthy narratives they had to provide; the administrators at the central office were unhappy about the quality of the data. They were spending inordinate amounts of time integrating data from many sites into a single data base and then extracting data for their reports. Satisfied that an internet-based system could fill an important void, the state level administrators provided the funding to the team at Binghamton University to develop the new system.

The technical team consisted of two software engineers and one system administrator. The project lead was a faculty member in the Decker School of Nursing.

To ensure that the monitoring and data collection system could capture the breadth and depth of local intervention projects, all stakeholders provided feedback on content through program managers at the central office. Hardware and software decisions were made on the basis of recommendations from the computing services of Binghamton University and the expertise of the technical team, resulting in SQL server running on Microsoft Windows Server.

For both systems, the initial prototype went through a number of transformations over a two year period. As the program managers and local project managers realized the possibilities with the systems, many components and additional functionalities were added.

System specifications

The system consists of server and client sides. The first layer of the server side is the operating system. We used Microsoft Windows Server. We deployed a back-up Windows Server that has all functionalities of the main server. In case the server ever goes down, the back-up would immediately take the role of the main server. The second layer is the data base. For the data base we used Microsoft SQL Server and designed a relational data base which contains many tables and view. For example, the PMDES consists of 63 tables, 24 views and over 200 fields. The use of SQL Server provided us additional features such as an easy back-up process, replication, and export of data into other applications such as PDF, Access and Excel.

The third layer of the server side is the application layer. This layer consists of .net framework and Crystal Reports. The .net framework includes web forms, xml, ADO.NET, and ASP.NET. ASP.Net provides the commands to show various text, labels, pictures, checkboxes, radio buttons, tables, and graphics in web forms. Behind all these components, we used C Sharp (C #) to connect all applications and to maintain system functionality.

For the report functions of the system, we used C Sharp and xml to extract data. The data was then passed to Crystal Reports for the end user reports. Finally, the clients access the system through the internet. A graphic representation of the technical specifications of the system is in Figure 1.

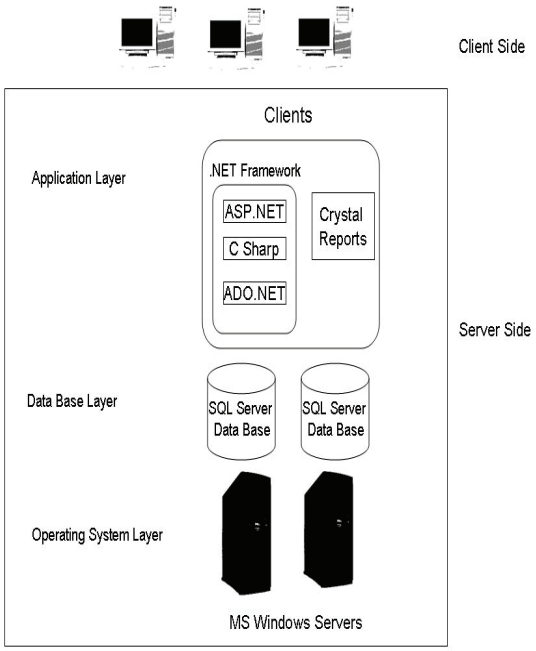

Figure 1 – Technical specifications of the system

Results

User interface

Prior to the full launch of the system, a manual was prepared and on-site training sessions were conducted with clients. The manual was also included on the web page.

Users log-on to the secure web site with their pre-assigned user id's and passwords. All screens following the log-on process are customized for the specific user and project. Since there are different types of roles among the clients, the system is able to recognize the user and his/her role and provide the functions that are appropriate for the specific user.

The decision tree for the user interface is in Figure 2. The users can insert new data into the system or update previously entered data. Alternatively, they can view previously entered data or generate reports for their particular projects.

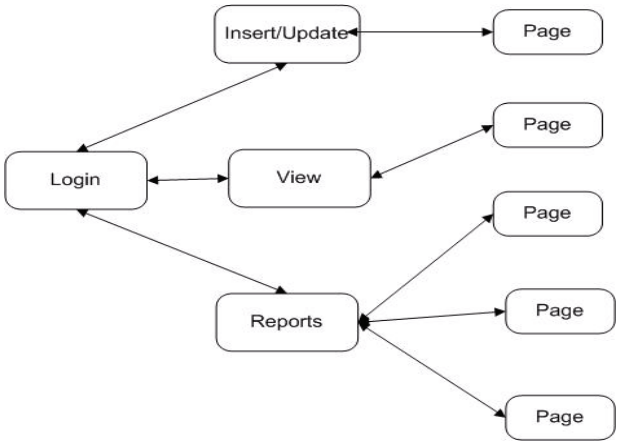

Figure 2 – User interface decision tree

An example of one of the initial screens for PMDES is presented in Figure 3.

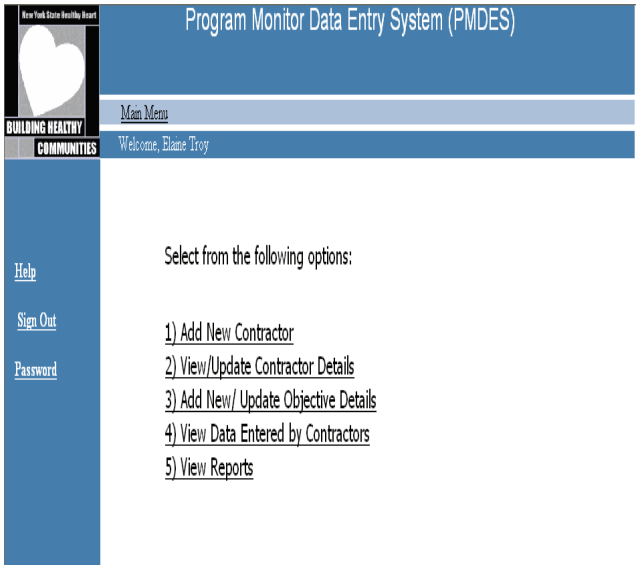

Figure 3 – An initial screen from PMDES

The complexity of the interventions is evident in the number of web forms created for the users. PMDES has over 100 web forms and PROMS has 175 web forms. The following figure (Figure 4) is as sample screen shot from PMDES.

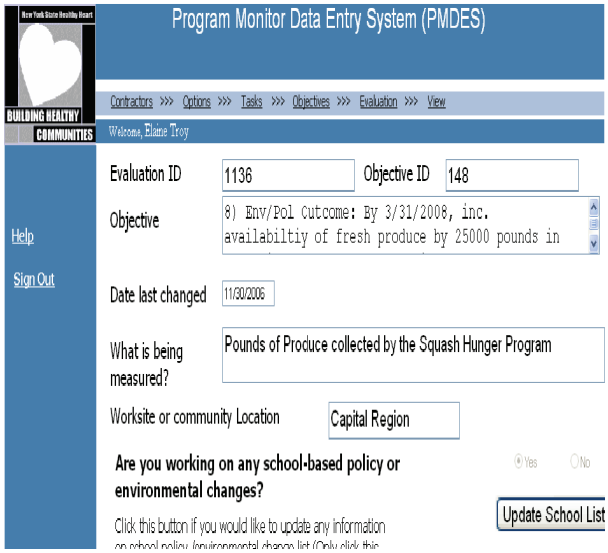

Figure 4 – A sample screen from PMDES

Reports

We used Crystal Reports for the report functionality of the system. PMDES has 20 and PROMS has 30 reports. Different access privileges to the system allow different types and number of reports for various client groups. For example, program managers in STEPS using PROMS can generate statewide or individual project reports, while the

project managers in counties can only generate reports for their own projects. In some reports, data from other counties is presented in an aggregate for comparison purposes. Despite the ease of use for the clients, report generation is a complicated procedure that involves extracting data from the SQL Server feeding it into xml and then into Crystal Reports. The following figure is a graphic representation of this process.

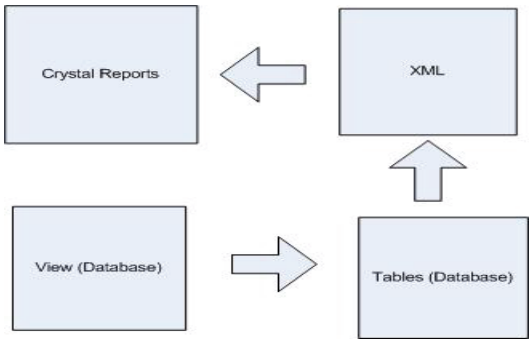

Figure 5 – Report Generation Process

Crystal Reports provides both text and graphics based reports that are presented with a user friendly interface. Through the web interface, clients can select from a variety of parameters to generate highly customized reports. We again use C Sharp in the background for all essential processes. Any report can be printed or exported into a number of file formats including PFD or Word. Figure 6 is an example of a report generated by the PMDES system.

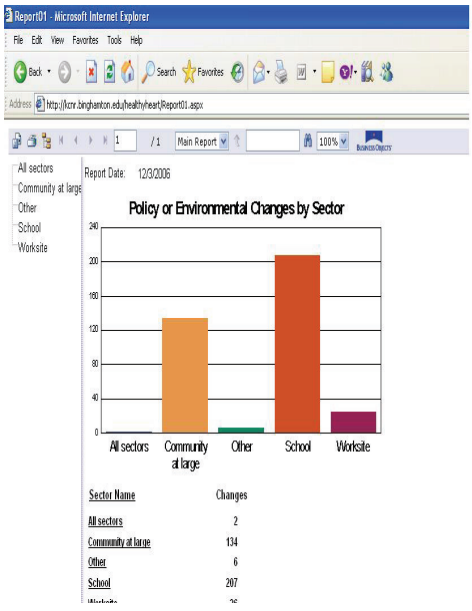

Figure 6 – An example of a report

Conclusion

The applications we developed enable users across New York State to collect and report standardized data, retrieve information, and generate a variety of reports. Program managers in the state capital Albany can monitor individual projects' progress on a regular basis and generate statewide or project specific reports. This initiative has already proven to be user friendly, cost effective, fast, and accurate and met the key requirements of program and project managers with minimum technical assistance. Regardless of the location of individual projects, with internet access, PROMS and PMDES are designed to handle many more clients and potentially go national.

Large scale community health programs that have multiple sites may wish to consider collaborating with nearby academic institutions that can offer the required technical expertise, hardware, and application development.

Some of the lessons we learned through the development of the systems are listed below:

- No system is able to meet all data collection, program monitoring and evaluation requirements for complex community health programs.
- It is not easy to find employees who have the technical expertise to develop a quality system.
- Modifications and additions to the system after initial development should be avoided. Written agreements with funders specifying each field, web form, and reports are highly recommended.
- It is a mistake to assume that anybody can operate a computer and access the internet. We realized during our training sessions that a number of our clients required additional technical support.

HISA Ltd Australia

A Knowledge Portal for the Illawarra Community Mental Health Rehabilitation Services Community of Practice

Leone J Dunn

School of Economics and Information Systems, Faculty of Commerce, University of Wollongong, NSW Australia

1.Introduction

"Every person with mental health problems and their carers should have access to services that promote hope, help find meaning in life and support the individual in taking responsibility for their own recovery, enabling a collaborative working towards their goals, for the best possible quality of life" [1].

Rehabilitation is the component of the mental health service that focuses on these areas of a person's life[1] .

To guide service development and recovery, five goals have been identified in the Illawarra Mental Health Rehabilitation Services Strategic Plan. These are:

1. Provide recovery focused rehabilitation services and promote a recovery orientation throughout the mental health service;
2. Deliver best practice quality rehabilitation services
3. Ensure rehabilitation services are accessible and coordinated across the Area Health Service
4. Develop and maintain effective partnerships with key service providers and community organizations
5. Ensure rehabilitation services are effective and achieving positive outcome

This paper describes a new and ongoing research project in collaboration with the Illawarra Area Community Mental Health Rehabilitation Services, referred to in this paper as the Mental Health Rehabilitation Services (MHRS), based at Fern Hill in Wollongong NSW[1]. The aim of the project is o develop a knowledge portal and service oriented architecture for community mental health rehabilitation services. It is hoped that once the portal becomes operational, it will enable all members involved in mental health rehabilitation – clients, professionals, carers, advocates, educators, etc. to evolve into a more effective community of practice by providing a collaborative infrastructure for knowledge sharing. It is anticipated that the portal will enhance cross-domain integration and strengthen and support multidisciplinary teamwork in relation to mental health issues. The project is funded by the Faculty of Commerce Social Innovation Networks Program at the University of Wollongong.

2.Communities of Practice

A Community of Practice (CoP) is a voluntary network of people who share information, build on existing knowledge, develop expertise and solve problems for a common purpose, driven by the interest of the community involved. The CoP portal for MHRS is intended for clients and carers, as well as health care professionals involved in the delivery of rehabilitation services, so that they can share their knowledge and expertise to help close evidence practice gaps and improve services. The benefits of Communities of Practice have been researched by Fontaine and Millen [2] and are sumarized in Table 1 below.

Type of Benefit	Impact of Community *It has improved or increased the following*	% Agree
Individual Benefits *What does participating in the community do for individuals?*	Skills and Know How	65%
	Personal Productivity	58%
	Job Satisfaction	52%
	Personal Reputation	50%
	Sense of Belonging	46%
Community Benefits *How does collective participation benefit others?*	Knowledge Sharing, Expertise and Resources	81%
	Collaboration	73%
	Consensus and Problem Solving	57%
	Community Reputation and Legitimacy	56%
	Trust Between Members	50%
Organization Benefits *How does participating in a community increase organizational efficiency, better serve customers and partners, and provide insights for the future of the firm?*	Operational Efficiency	57%
	Cost Savings	51%
	Level of Service or Sales	46%
	Speed of Service or Product	42%
	Employee Retention	24%

Table 1 - Individual, Community and Organizational benefits of CoPs [2].

The concept of a community of practice comes from the work of Wenger and Snyder [3] who define it as "a group of people informally bound together by shared expertise and passion for a joint enterprise," or similarly, as a collection of individuals bound by informal relationships that share similar work roles and a common context. Examples

of communities of practice are found in many organizations and have been called by different names at various times, such as "learning communities" "family groups" , "thematic groups" , and "knowledge networks", but they remain similar in general intent [3].

2.1The evolution model of CoPs

According to Gongla and Rizzuto [3], the creation of a Community of Practice can be summarized in five distinct stages, according to an evolution model, as illustrated in Figure 1 below.

Table 1 Community evolution model definition

	Potential	Building	Engaged	Active	Adaptive
Definition	A community is forming.	The community defines itself and formalizes its operating principles.	The community executes and improves its processes.	The community understands and demonstrates benefits from knowledge management and the collective work of the community.	The community and its supporting organization(s) are using knowledge for competitive advantage.

Figure 1 - The CoP Evolution Model

These are the characteristics that distinguish COPs at each stage of their development. The Evolution model recognizes formative and growth stages of development but unlike Wenger's model, it is not a lifecycle model. Communities may stay at certain stages and not evolve to another level; communities may move "backward and forward" between the stages; communities may have some characteristics of one stage while they are still primarily at another stage; communities may "rest" for extended periods at one stage and suddenly evolve quickly to another stage. At each stage CoPs have defining characteristics and functions [3], as shown in Figure 2 below.

Table 2 Fundamental functions for the stages of evolution

	Potential Stage	Building Stage	Engaged Stage	Active Stage	Adaptive Stage
Fundamental Functions	Connection	Memory and context creation	Access and learning	Collaboration	Innovation and generation

Figure 2. Functions of each stage of the evolution model

2.2 The Influence of people process and technology on COP evolution

According to Fontaine and Millen[2], there are four types of resources required to enable effective CoPs. These are *People* – to fill certain community roles and manage the community's activities; *Activities*- to bring the community together in meetings and events; *Technology* – to facilitate the flow of knowledge and information between activities; and *Content* – to manage and share the explicit knowledge that the community creates. The next section will focus on the generic technology – the service-oriented knowledge portal.

3.Service Oriented knowledge portals

This research is proposing that the mental health rehabilitation service delivery be implemented as an ecology of e-business services providing services for all members of the MHRS community and enabling collaboration with global partners as well. What is presently manual (with desktop support) will become Internet based as a service. The services will be implemented as web services.

3.1Service Oriented Architectures

A Service Oriented Architecture views every application or resource as a service implementing a specific, identifiable set of (business) functions that are identified during business process analysis. The services may be fine- or coarse-grained depending upon the business processes. Services are defined by interfaces that allow them to be published, discovered and invoked. An enterprise can choose to publish its services externally to business partners or internally within the organization. A service can also be composed from other services. Services communicate with each other by exchanging structured information—messages or documents (sometimes called business objects). A Service Oriented Architecture views every application or resource as a service implementing a specific, identifiable set of (business) functions. Thus Service Oriented Architectures are a convenient way to achieve application integration by allowing new and existing applications to be quickly combined into new contexts. Existing applications are "adapted" to service declarations. The interaction of services can be direct, or can be mediated through an intelligent infrastructure, called an Enterprise Service Bus (ESB)[4].

3.2Web Services Architecture

A web services architecture (WSA) is a service oriented architecture that has implemented its services as Web Services, as is the case with the proposed research. The advantage of the web service oriented architecture is that it is based on global internet standards and protocols for all business application. This makes the application truly integrated across organizations. Web Services utilize the WS – I standard services.

3.3 Portals

Portals are commonly used to provide people with access to information and applications in a condensed form. Typically, portals display personalized information from various sources in a single page, thus allowing the user to efficiently access this information instead of visiting vari-

ous Web sites one after the other [5]. Depending on customizable user settings, various portlets usually rectangular areas that display information are included in the web page. Portals and portal development tools allow for integration of web services as data sources. An example of this integration can be illustrated by a news feed scenario. A news portlet that allows the user to configure the news categories to track and then gets the news for these categories live from a Web service whenever it is displayed. In this case, the portlet code runs locally on the portal and uses the Web service to access information. The rendering of the content is done by the portlet itself (see Figure 4 below)[5].

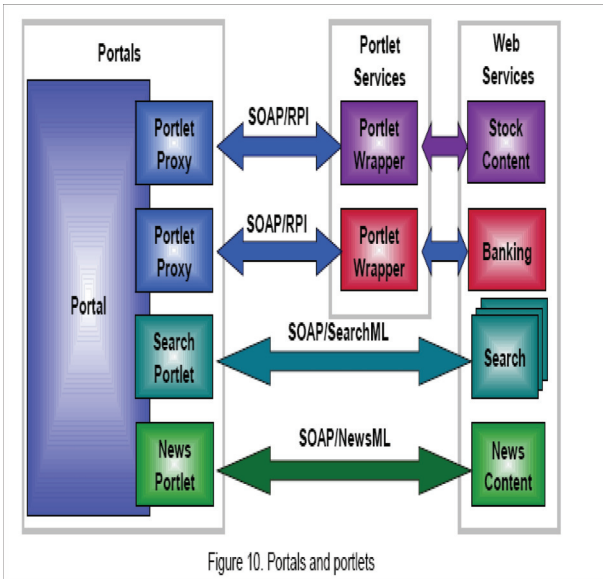

Figure 10. Portals and portlets

A portal should support the following desirable functions and features:

- Allowing different information- and service-providing departments to set up and update their own information and services tailored specifically for different user groups according to the common user profiles (such as grades, departments associated, etc.) and the specific needs of these user groups at specific times.
- Presenting automatically the information and services that a user would need according to his profile at the appropriate time.
- Allowing a user to select the information and services that are his interests and to customize their presentation.
- Setting up information and services from users' perspective rather than from the angle of convenience of the services providers.
- Supporting the "Single-sign-on" feature so that a single sign-on step would enable the user to gain access to the different information resource and services that are supported by different application systems provided by different departments and/or communities.

The Service Oriented Portal Architecture proposed for MHRS is illustrated below in Figure 4.

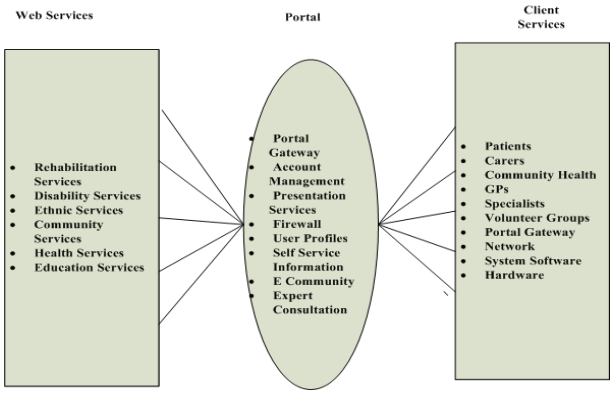

Figure 4 - MHRS Service Oriented Portal Architecture

4.The MHRS project progress

The MHRS project is in its initial stages of evolution – the *Potential* Stage. Several initial concept prototypes were developed last semester by students at the UoW in the Information Systems Project class. These prototypes were based on initial ideas by the author and staff members at Fern Hill rehabilitation centre. At the end of semester projects were presented to a larger audience at Fern Hill and permission was given to go ahead with the project.

Referring further to the evolutionary model, the enablers for moving forward are discussed below.

People: The project must now identify all stakeholders in the core community group, that is potential individual and group members

Activities: Location of potential community members.

Facilitate bringing members together. Establish roles of members of core group.

Perform stakeholder analysis and establish the requirements of the of individuals and groups in the CoP.

Technology: Technology at this stage will be electronic messaging, email, lists, teleconferencing, online forums and directories, and electronic document management.

Content: Information

5. Summary

This paper has described the initial stages of the MHRS project, which began in July 2006 and the proposed next 6 months of the project. The benefits to Mental Health Rehabilitation will be enormous from the carer, client, health

professional, and consultant perspective. It will provide an 'application aware development framework' for all mental health services. At present many basic point of care health services are implemented in individual applications and cooperation between different applications is difficult. By providing an infrastructure such as the service oriented portal architecture, a common standardized service can be provided. The portal architecture will also support the mapping of services to different clients based on their profiles delivered to their mobile devices. The model will also support location based service applications. The potential for location based community support is another component of this project and is described elsewhere [6].

Abstract

We were selected to work with "Development of e-Learning Program to help enhance human resource ability based on needs," which is a government supported program of fiscal year 2005 to address modern education needs (Modern GP). The program has therefore been underway since 2005. The objectives of the program are to use e-Learning to further improve education and teaching practices qualitatively for nursing education, to supply high-level nursing practice capabilities, and provide a new environment in which students can study independently in an efficient manner. The main targets to achieve the program goals are: i) to produce e-Learning training materials that include examples of nursing to use for the study of nursing practice and support students' acquisition of problem-solving abilities during nursing operations; and ii) to construct an environment to support ubiquitous on-demand studies in which students can study for themselves easily, at any time, and anywhere on campus or on the actual practice site using this e-Learning methodology. This paper presents a report of an actual lecture class conducted in 2006 using such training materials.

Keywords:

education of nursing, nursing practice ability, e-Learning, ubiquitous on-demand study, human resource improvement

Introduction

As medical treatment levels are becoming more advanced and patients' requirements become increasingly diverse, what is requested now by every organization that is taking part of nursing education is the need to better cultivate human resources to work in nursing positions so that they can gain proper proficiency in nursing practice, which means the ability to assess a patient's situation correctly, then understand and provide the most appropriate nursing care to that patient. To respond to that social need for human resources, we believe that it is necessary to improve the education and instruction of nursing more qualitatively, and to provide students with a new environment in which they can study efficiently.

Among all educational activities, the most effective way for students to acquire actual nursing capabilities is to have the learner join on-site practice training, which is a required part of the nursing education curriculum. Through on-site practice, students can learn comprehensively by communicating directly to patients or those who require nursing care. However, such practicing facilities are spread out in various locations. For that reason, the situation available on site is not necessarily as good a study environment as that available on campus. The campus might provide facilities such as libraries, Internet capability, and IT equipment. By making e-Learning available at every on-site practice location, we believe that we can not only improve the study environment situation, but also help to raise the quality level of the study itself.

Under these circumstances, the School of Nursing at the Osaka Prefecture University was selected to work with "Development of e-Learning Program to help enhance human resource ability based on needs," which is a government-supported program of fiscal year 2005 to address modern educational needs (Modern GP). The actual title is "e-Learning to help acquire nursing practice ability –Construction of a ubiquitous on-demand study supporting environment–." The program began activities last year as the "CanGo" project. "CanGo" stands for "Communication", "Art", "Nursing", "Good practice", "Osaka prefecture university".

This paper reports the actual classes taught in 2006 using materials that were developed specifically for this project based on project activities undertaken in 2005, and of the results obtained from on-site training support we gave to students.

CanGo project summary

The CanGo project objective is to fill the gaps that are readily noticeable from one study method to another, to improve the efficiency and usefulness of every study activity on-campus or off-campus, and to improve students' attitudes toward study more aggressively. This objective must be achieved so that students can acquire the ability to solve study-related problems that might often occur in lectures, or during practice sessions made on-campus or on-

site, all of which are conducted in the regular curriculum of nursing education.

To introduce an e-Learning program in education curricula of our school starting in 2008, we are making a three-year project plan (Figure 1) and establishing a new organization in our department (Figure 2) to accomplish that plan.

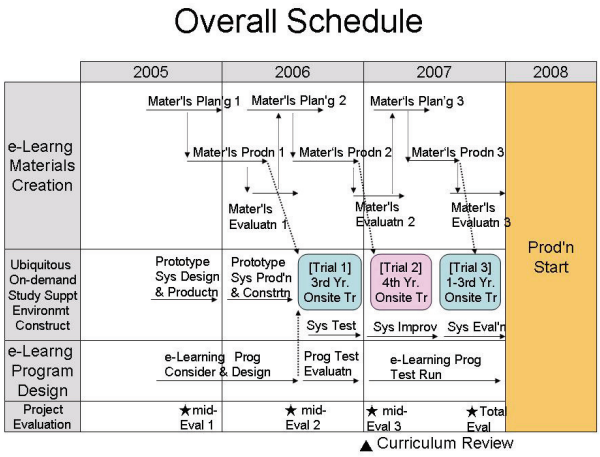

Figure 1 - Overall schedule of the CanGo project

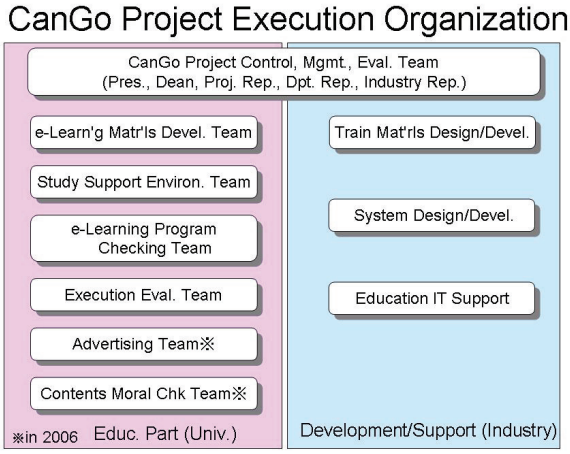

Figure 2 - CanGo project organization

The backbones of our activities are: i) to produce e-Learning materials for the study of nursing practice and examples for use by students to acquire problem-solving ability; and ii) to construct a ubiquitous on-demand study-supporting environment in which students can study independently through e-Learning at any time, anywhere, and without any difficulty whatsoever. Through these four-year studying opportunities on and off campus, we are hoping to help students acquire capabilities to solve all kinds of nursing problems efficiently and aggressively so that, eventually, we can produce in our society good human resources with full proficiency in advanced nursing practice capabilities.

Specifically, the following three unique environments are available to support students' study.

Utilizing USB memory that stores the recorded study history, anyone can easily download examples of nursing from the nursing training materials server machine. Each student is allowed to compile a digital nursing dictionary by downloading the necessary sub-training materials before the on-site practice starts. We believe that any student can study independently while compiling such a "personal digital nursing dictionary." During that study process, a learner would be able not only to review and summarize the contents of past study, but also to proceed with meta-recognition that would point to further study or related activities, and what knowledge and nursing technology must be acquired before the on-site practice starts. Finally, to support self-study, a bi-directional study support environment would be prepared in which a student can receive guidance from the instructor through e-mail that might be available using a cell phone or other media equipment.

Figure 3 depicts the overall structure of the CanGo project. Table 1 shows its targets and accomplishments of 2005.

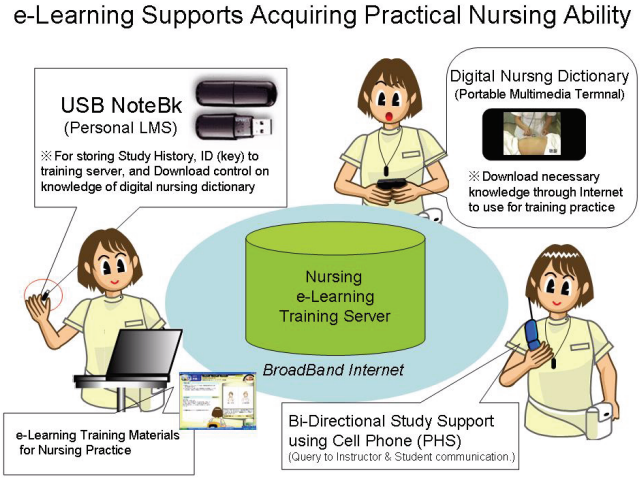

Figure 3 - Overall structure of CanGo project

Table 1- CanGo project targets and its accomplishments in 2005

[Targets] 1) Develop 100 examples of nursing by re-structuring the existing nursing examples documents, and construct a training-material database 2) Construct a ubiquitous on-demand study support environment that is openly available to students [Accomplishments of 2005] 1) Development of 57 examples in four specialized nursing areas, and a total of 641 references for the digital nursing dictionary 2) Supplying equipment for study support environment 22 portable multimedia terminals 14 laptop PCs to support lecture classes 1 wireless attachment for a projector

e-Learning Materials For Nursing Examples

We produced nursing training materials with examples for each specialized nursing area based on prototype training frames for e-Learning of nursing, developed by Majima et.al. [1]–[5] and Seta et. al.[6]–[7] to improve nursing students' problem-solving abilities.

Training frames (Figure 4) consist of two study modes. In study mode 1, a series of nursing processes can be studied through "Understanding patients' examples", "Problem studies on nursing", and "Evaluation of analyzed results". Study mode 2 is available for each example of a patient, in which the student can self-study, when necessary, through the contents of basic and required knowledge of specialized nursing practices, nursing techniques, and national-examination-related materials. Training materials were produced using multimedia techniques incorporating sound effects, animation, and illustrations. Contents that are organizing the training materials can be reorganized and reused for other digital sub-training materials, allowing the creation or addition of any new training materials without difficulty. Moreover, after downloading, they can be used to create a new digital nursing dictionary (Figure 5).

Results

Practice and example in nursing education

During the first half of 2006, we hosted a series of lectures using training materials developed in 2005, and used portable multimedia terminals for on-site practice. Following are the ideas and opinions given to us after that on how to improve practices, as well as other useful advice.

Lectures using training materials with nursing examples

Instructors who joined in the creation of training materials actually used them in their classes. We asked them to report about how they used the training materials in their classes in addition to the responses they received from their students. To have them conduct such training in their classes, the study-support environment development team of the project organization (Figure 2) supplied the training

materials, computers and assemblies, and other materials to instructors who requested them. The execution evaluation team helped create questionnaires for students and the reporting formats to be used by the instructors.

The actual lectures were intended mainly for third-year nursing department students (about 120–140) studying for work in five different nursing fields.

Following are some examples of how training materials were used: i) Starting with the introduction of the patient starring in the training materials of examples on nursing (giving self-introduction narration by the patient), the patient subsequently presented scenes in which nursing problems are described; then the students were separated into work groups and each was expected to make a nursing care plan, and to present it before others, which were finally evaluated by the instructor with appropriate comments provided. ii) Introduction of some nursing examples and scenes of nursing care problems were posed. iii) Providing the students with some nursing care problems beforehand to use them in later work to be done by every group. Therefore, different approaches seem to have been taken by each instructor. Figure 6 shows photographs of the classes conducted using each approach.

Figure 6 - Class photographs

Some opinions from the students are as follows: "It was easy to grasp the images of the examples," "It was easy to read the patient's emotions shown in the examples," "It was realistic, so it was easy to understand," "It was realistic and practical," "It was good from a visual perspective with the image pictures provided," "It was easy to know the necessary information," "It was good to hear the information given by voice," and "I was able to understand the priority of the nursing care problems." Additionally some students pointed out not only about how to collect information, but also about the methodology of how nursing-care assistants should recognize situations to move forward to create opportunities to educate patients.

The following are opinions and impressions elicited from instructors based on their reports.

(1) Impacts on using the training materials

i) It was recognized that understanding every nursing example by image is important to learn processes of nursing care (i.e. processes of solving nursing problems).

ii) Students seem to have a special interest in the contents of the images and the training materials given.

iii) The nursing example training materials were useful to communicate reality to the students even if they were something to be expected for use in learning beforehand.

(2) Information equipment operations by students

Students soon became accustomed to using the training materials in general: no chaos occurred.

(3) Information equipment operations by instructors

i) The fact that it takes time for PC manipulation causes students to wait for a long time, resulting in stopping the smooth lecture flow and losing students' concentration.

ii) That idle time, when it happened to be created during the equipment manipulation, seemed to cause the students to engage in private conversations.

(4) Class environment support

i) I appreciate all the equipment setup done by teachers of the study support environment team.

ii) Being supplied with PCs, CD-ROMs and such equipment was very helpful and appreciated. However, it must be very hard to do it alone, all by myself.

iii) All the instructors should become accustomed to using equipment before using the training materials.

(5) Others

i) I think not only the students, but also I, as an instructor, had a good time in the class.

ii) It takes time to prepare for printing materials and to set up PCs. Therefore, it would be nice if a group work could be done all through a computer network.

On-site practice support by portable multimedia terminals

We prepared portable multimedia terminals (PSP, Play Station Portable; Sony Corp.) loaded with training material contents prepared for the associated nursing practice areas, and lent them each to students who agreed to monitor them. Subsequently, we requested that they use them during the entire practice period. We requested them to give us opinions regarding the operability of the training mate-

rials and other information when they had to return the terminal. Following are some of the comments.

(1) Portable multimedia terminal

i) It was good to be able to find and view the necessary document without taking much time.

ii) Because it is basically a game machine, its operability is good.

iii) It was easy to use the training materials in this way.

iv) The images in the training materials are useful, as if we were playing a game.

v) It is easy to carry because it is small and light.

vi) The screen was easier to see than I thought.

vii) The battery power duration time is too short.

viii) It would be nice if there were a search function available everywhere in the training materials.

(2) Training materials' contents

i) They were helpful in the practice class. It would have been nice if they had been available before.

ii) What we wanted to see out of the training materials was restricted for our practice class.

iii) It was very convenient to be able to see technically related pictures close at hand. It was helpful to understand things using images.

iv) We can see it anytime anywhere. Therefore, it is helpful when we study at home after the nursing technique practice is over.

After having had the training materials and the contents we produced used in the actual classes, we found that the students' evaluations were good partially because it is something new to them. Nevertheless, their comments and opinions accurately reflected their experience, and helped us to determine the issues clearly and work continuously to correct and improve them in future versions of the system. Some instructors were not very happy with manipulation of information equipment, which underscores the importance of support them during use in actual classes. Through the process of having the training materials used in actual classes, we can continue to search for the most appropriate training materials. In so doing, we can review previous teaching methods and adapt and reconstruct them, if necessary. Additionally, using such training materials in actual classes, we can review the class proceedings and teaching methods the classes with the materials combined. Above all, the fact that the instructors felt that teaching a class was fun should create a positive impact on future educational activities resulting in leading to develop of our faculty.

Summary

This report described our introduction of e-Learning in the School of Nursing at the Osaka Prefecture University (as the CanGo project), and reported comments and opinions given when we had the nursing practice example materials and sub-material contents we produced during 2005 used for the actual classes of the first half of 2006. In addition, we reported those comments and opinions given from the experiences we had when supporting the actual on-site practices.

Future studies will further introduce e-Learning techniques based on the plan, along with regular and constructive review. We would be happy if the knowledge and experience we received were referenced and used anywhere else.

Acknowledgments

This project was conducted through the aid of the Modern Education Needs Supporting Program of the year 2005 offered from the Ministry of Education, Culture, Sports, Science and Technology.

e-Learning Training Materials

Nursing Practice Examples (Nursing Process) of "Basic Nursing Knowledge", "Basic Nursing Techniques" and "National Examinations" are studied through e-Learning.

Practice and Evaluation(2006)

- We hosted a series of lectures using these training materials, and used portable multimedia terminals for on-site practice.

Lectures using training materials

Portable Multimedia Terminal (Digital Nursing Dictionary)

Lectures using nursing examples materials

- Method:
  - Instructors who joined in the creation of training materials actually used them in their classes.
  - We asked them to report about how they used the training materials in their classes in addition to the responses they received from their students.
  - The actual lectures were intended mainly for third-year nursing department students (about 120–140) studying for work in five different nursing fields.
- Some opinions and comments from the students
  - It was easy to grasp the images of the examples.
  - It was easy to read the patient's emotions shown in the examples.
  - It was realistic, so it was easy to understand.
  - It was realistic and practical.
  - It was good from a visual perspective with the image pictures provided.
  - It was easy to know the necessary information.
  - It was good to hear the information given by voice.
  - I was able to understand the priority of the nursing care problems.
  - Some students pointed out not only about how to collect information, but also about the methodology of how nursing-care assistants should recognize situations to move forward to create opportunities to educate patients.

On-site practice support

- Methods:
  - We prepared portable multimedia terminals loaded with training material contents prepared for the associated nursing practice areas, and lent them each to students who agreed to monitor them.
  - Subsequently, we requested that they use them during the entire practice period.
  - We requested them to give us opinions regarding the operability of the training materials and other information when they had to return the terminal.
- Some opinions and comments from the students
  - It was good to be able to find and view the necessary document without taking much time.
  - Because it is basically a game machine, its operability is good.
  - It was easy to use the training materials in this way.
  - The images in the training materials are useful, as if we were playing a game.
  - It was easy to carry because it is small and light.
  - They were helpful in the practice class.
  - It would have been nice if they had been available before.
  - It was very convenient to be able to see technically related pictures close at hand.
  - It was helpful to understand things using images.

Conclusion

- We introduced our CanGo project, and reported students' comments and opinions given when we had the nursing practice example materials and sub-materials contents used for the actual classes.
- We reported those comments and opinions given from the experiences we had when supporting the actual on-site practices.
- Future studies will further introduce e-Learning techniques based on the plan, along with regular and constructive review.

Translation, Implementation and Evaluation of a Medical Informatics Distance Learning Course for Latin America

Paula Otero[a], William Hersh[b], Daniel Luna[a], Alejandro López Osornio[a], Fernán González Bernaldo de Quirós[a]

[a] *Departament of Medical Informatics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*
[b] *Department of Medical Informatics & Clinical Epidemiology, Oregon Health & Science University, Portland, OR, USA*

Abstract

There is a growing need and interest worldwide for healthcare professionals trained in medical informatics. Distance learning technologies are increasingly used to deliver such education, but mainly limited to the English language. We describe the implementation of a medical informatics course delivered in Spanish for a Latin American audience. The course was based on the 10x10 program of the American Medical Informatics Association and Oregon Health & Science University and translated and adapted to the Latin American setting. The course consisted of ten one-week units. A total of 152 individuals enrolled in the course, 93% of whom completed it. Most of the students were healthcare professionals and the largest proportion was from Argentina. Student satisfaction with all aspects of the course was high. The initial experience obtained in training healthcare professionals in medical informatics in Latin America in their own language demonstrated that it can be used across the region, and this could represent a model for disseminating knowledge of medical informatics across other languages and cultures.

Keywords:

medical informatics/education, distance learning/ methodology, teaching

Introduction

There is a growing need to train individuals in medical Informatics (MI), the field concerned with the capture, management and use of information in health and biomedicine [1, 2].

International programs using distance learning to deliver MI education have been developed in the United States, New Zealand and Europe. In Latin America, an international program has been developed in Brazil but is delivered by means of in-person training sessions and is not on-line. Latin America is a wide and diverse region, making the delivery of in-person training programs a difficult task. Distance learning programs provided by Internet tools, may be a possible strategy to deliver MI education.

In 2005, the American Medical Informatics Association (AMIA) and the Department of Medical Informatics & Clinical Epidemiology of Oregon Health & Science University (OHSU) launched the 10x10 Program [3].

In order to develop a training program in MI that was more locally focused and delivered in the Spanish language, the MI task force of the Hospital Italiano at Buenos Aires (HIBA) entered into an agreement with OHSU to translate and adapt the OHSU 10x10 course to the Latin American region. This paper reports the experience of adapting, translating, implementing, and evaluating our effort.

Materials and methods

The goal of the course was similar to the English version in giving participants the tools for the development of solutions to specific healthcare problems using informatics principles. Moreover, at the end of the course, the participants would develop the necessary skills to implement healthcare information projects in their own workplace.

The course adhered to roughly the same outline as the English version from OHSU, covering the following main topic areas: Overview of the discipline; Biomedical Informatics; Electronic Health Records; Decision Support and Health Care Quality; MI Standards: Privacy, Confidentiality and Security; Information Retrieval and Digital Libraries; Multimedia and Telemedicine; Organization and management issues in biomedical informatics; Biomedical Informatics Subspecialties; and Information Systems in Public Health.

The teaching modalities used for the course included lectures, threaded discussion boards, recommended readings, and self-assessment.

Two surveys were administered to determine the students` opinions regarding aspects of the course: one related to the format – voice-over-Power Point vs. reading material – and the other assessed their perceptions of other aspects of the course.

Results

The course was launched in March 2006 with 152 registered students. A total of 142 (93%) of them completed the course. The overwhelming majority of students were physicians (104/152).

Most students were from Argentina (128/152), although others came from a number of different Latin American countries and Spain.

The "lecture" portions of the classes were available in two different formats. The first provided reading material on the screen and for printing, while the second consisted of voice-over-Power Point presentations.

The students needed an Internet connection to enter the virtual campus to access the course. The content was designed so that even dial-up connection could be used. The material was published in HTML or PDF, with the audio-visual material was delivered via Flash format.. Students were asked about the quality of the content using a Likert scale (1 worst to 10 best). The reading material obtained an average score of 8.5, whereas the voice-over-Power Point format obtained an average of 7.6. The combination of both formats obtained an average of 8.6

At the end of the course, students were asked about the course characteristics, the interaction with the teachers, the modality of e-learning and the main features of the course using a Likert scale (1 worst to 5 best). The whole course was scored with 4.2, the score regarding the e-learning part of the course was 4,3 and when the student were asked if they would recommend this course to their colleagues the score was 4.3.

Students were also asked how they planned to use the knowledge obtained from the course. About 42% answered that the course was preliminary training for an electronic health record implementation, 17,5% said the course taught them how to use the electronic health record, and 7% answered that the course trained them on how to assume a new role such as Chief of Medical Informatics in their institution

Discussion

MI training has been developed mainly in the USA [4] and Europe [5]. Most of these programs are taught in-person only, and the number of Spanish language courses available is limited. Most of the material related to MI training – text books, bibliography, etc. – is published in English, which provides a barrier to Spanish-speaking students. Furthermore, most of these courses do not take into account specific regional needs (e.g., American courses devote time to topics of less detailed interest in Latin America, such as the Health Insurance Portability and Accountability Act, HIPAA).

We therefore not only had to translate the course, but also add information and examples describing healthcare that was applicable to the region. We also had to create a handbook in Spanish language to explain the course materials that contained 750 pages and was rated highly by students.

When selecting the topics for the Spanish version of the course, we decided to exclude certain units, as "Evidence-based Medicine" or "MI Professional Development in the USA". We added some other topics that were relevant to our educational needs, such as "Use of Controlled Vocabulary and Terminology Services", "Digital Signature", and "Law on Privacy, Confidentiality.". We also added additional material on "Picture Archive and Communication Systems" (PACS) in radiology and "Biological Signal Processing in MI." We also broadened coverage of the impact of MI on public health, focusing on epidemiological surveillance, immunization records, and geographic information systems.

We have demonstrated that MI education can be provided in Latin America via distance learning. This kind of training was received positively by students. Future efforts will focus on improving the course and offering to a wider audience, particularly as MI applications become more prevalent in the region.

OREGON HEALTH & SCIENCE UNIVERSITY

Results

- Launched in March 2006

- 152 registered students.
  - →93% completed the course.
  - →68% physicians.
  - →84% from Argentina.

Results

- Students' evaluation of the course (Likert scale 1-5)

Question	Score
1. Did the course content meet the program's description?	4,5
2. The course gave me practical and useful information for my daily work	4,1
3. Was the course correctly balanced? Was it interesting?	3,9
4. Did the teacher have adequate knowledge regarding the topics?	4,7
5. Was the teacher organized when presenting the contents?	4,6
6. Did the teacher answer the questions promptly?	4,6
7. Was the length of the course correct?	3,8
8. Were the course materials effectively presented? Was the surfing process easy?	4,4
9. Did the course fulfill my expectations?	4,2
10. Would I recommend this course to my colleges?	4,3
11. Which is my score regarding the e-learning part of the course?	4,3
12. Which score would I give to the whole course?	4,2

Results

- Students were also asked how they planned to use the knowledge obtained from the course.
  - ⟶42% preliminary training for an electronic health record implementation
  - ⟶17,5% how to use the electronic health record
  - ⟶7% how to assume a new role such as Chief of Medical Informatics in their institution

Discussion

- MI education can be provided in Latin America via distance learning.
- Training was received positively by students.
- Future efforts will focus on improving the course and offering to a wider audience, particularly as MI applications become more prevalent in the region.
- Model for translation and dissemination of MI education to audiences in other regions of the world who speak other languages.

Health Informatics in the Philippines

Alvin B. Marcelo

National Telehealth Center, National Institutes of Health, University of the Philippines Manila

Abstract

The progress of biomedical informatics in the Philippines has been fraught with many highs and lows. Called 'health informatics' locally, the field has been in informal and formal development for the past ten years since the first professionals commenced investing time and energy to pursue the field as a distinct discipline. Although local efforts have been hampered with infrastructure issues, there have been many activities that have provided strategic foundation for the implementation of future activities. Foremost among these is the Master of Science in Health Infromatics offered by the University of the Philippines Manila. The program offers a unique approach to learning health informatics by putting emphasis on community-based and community-managed health information systems that are appropriate for resource constrained environments. It is also unique for its heavy adoption of the principles of primary health care (as manifested by the Declaration of Alma Ata) in its curriculum design and implementation.

Keywords:

Philippines, education, informatics, health

Introduction

As a science, biomedical informatics had been loosely practiced in the Philippines as early as the nineteen eighties. Residents in tertiary care facilities who had access to IBM compatible machines were already using word processors to store patient information. In other areas, anecdotal evidence of database management systems was used for storing patient information. Epidemiologists from the Department of Health who took the Field Epidemiology Training Program (DOH-FETP) used Epi-Info[1] extensively in their practice. In fact a professional association, the Philippine Association for Medical Informatics (PAMI) led by Dr. Benjamin Marte was formed with membership mostly composed of Department of Health staff. The PAMI was able to represent the country in initial meetings of the Asia Pacific Association for Medical Informatics and was the de facto representative for the country in APAMI for the years 1994 to 1995.

It was however during the late nineties when a more structured approach to 'medical informatics' (as it was called then) appeared. This was through the establishment of the Medical Informatics Unit in the University of the Philippines Manila. Preceding the MIU however were several important events. First there was the incorporation of a non-governmental organization called the Philippine Medical Informatics Society, Inc composed mostly of academicians from the University of the Philippines Manila (UPM). Then the PMIS initiated many of the scientific activities related to the field such as the First Symposium on Medical Informatics and Seminars on Telepathology (Dr. Paul Fontelo, Armed Forces Institute of Pathology), Medical Records Management (Dr. Michael Yang, OACIS), and Integrating Technology into Medical Education (Dr. Emmanuel Besa, Medical College of Pennsylvania). However, although these activities served to keep the interest and awareness in medical informatics, they were too far in between to actually to push the science forward in the country.

Academics

By 1998, faculty members from the UP College of Medicine began taking formal courses in medical informatics in different institutions around the world; in particular, at the University of Washington, the National Library of Medicine in Bethesda, Maryland, and University of Warwick in Coventry, England. These faculty members served as the core group of what will be the Medical Informatics Unit at UP Manila.

Research

Upon return, the faculty core group started working on health information systems projects and applied many of the principles they learned from their training. Most of these researches were conducted at the Medical Informatics Unit of the UP College of Medicine while others at the World Health Organization and the Department of Health. With the experience from these projects, faculty members were able to refine their techniques and protocols to address the growing informatics needs of the country. One such project was the Community Health Information Tracking System [2], a Linux, Apache, MySQL, PHP-based system released under the general public license (GPL). CHITS was named finalist at the Stockholm Challenge

1 Epi-Info. http://www.cdc.gov/epiinfo/

2006 and one of top three e-government projects in the Philippines by the Asia Pacific Economic Cooperation Digital Opportunity Center. Several other projects with the United States Agency for International Development and International Development Research of Canada provided the experience for the faculty and staff of the MIU to handle increasingly complex projects in medical informatics.

By 2003, the faculty members realized the need to generate new blood and to formulate a structured learning program for medical informatics. A proposal for a Master of Science in health informatics was crafted together with the College of Arts and Sciences (who had a program in bioinformatics). This combined program, now called Master of Science in Health Informatics (MSHI) was finally approved in 2004 and implemented in academic year 2005-2006.

Service

A key component of the MSHI was service as well as research. As designed, students of the MSHI are expected to implement the principles and concepts of health information systems development within an existing environment relevant to their practice. As seen with the first batch of students, most of these projects are for databases for their professional organizations or specialty affiliations.

Context

A unique spin in medical informatics in the Philippines is the bias of pioneering faculty on community health informatics. This is due to the fact that most of the initial efforts began at the UP College of Medicine where a community-oriented curriculum serves as the central recurring theme in all institutional activities. This community-orientation permeates the design and delivery of the MSHI, and in the program students are asked to immerse themselves and to integrate with local health facilities to understand the issues in health information management at the grassroots level. This is very different from the approach of first world counties who expose their students to complex, sophisticated, and resource-intensive health facilities, many of them at the secondary or tertiary level. In fact, the MSHI program is unique in that it revolves around patient level data within a public health system infrastructure forming the staging are for the development of public health informatics in the future.

A clear manifestation of this philosophy is the staunch advocacy of the UPM for the use and promotion of free and open source software (FOSS). In fact, the National Telehealth Center (an institutional product of the MIU) has been named as UNDP Regional Center of Excellence for Free and Open Source Software and node of the International Open Source Network[3] for ASEAN+3.

Issues

Despite the many developments in health informatics in the Philippines, the nation still suffers from several issues that impede progress. Foremost is the lack of health human resource interested in the field. Most of the initial enthusiasts were clinician specialists who were engaged in health informatics more as a novelty rather than as a profession. When the pull of economic and professional constraints are felt, priorities shift towards clinical responsibilities to the detriment of the health informatics discipline.

A second problem is the network infrastructure (which also involves IT human resource). While connectivity is an important component of a health information systems, the availability of affordable IT human resource and their retention in the age of globalization remains an issue.

Third, the benefits of information technology have not yet dawned to many decision-makers in the health sector. The huge capital outlay for a health information system remains a stumbling block to the integration of IT in health operations.

Opportunities

An exciting development in the country is the rapidly maturing wireless cellular network with value-added services. The Philippines is the texting capital of the world and is home to 300 million messages a day. It is also a large laboratory for SMS based applications that range from games to banking. Definitely, with a wide penetration nearing fifty percent[4], SMS is a protocol waiting for a health informatics application.

A joint cooperation of the Department of Health, Department of Science and Technology, the University of the Philippines Manila, and the Philippine Health Insurance Corporation to formulate standard secure health messaging across health facilities is opening up a lot of business opportunities both for health informatics practitioners and for IT vendors as well. Called the Philippine National Health Information Infrastructure (PNHII), it will form the

3 International Open Source Network. http://new.iosn.net

4 Lucas D. Cell phone penetration rate seen to peak at 50%. http://news.inq7.net/infotech/index.php?index=1&story_id=78818

framework for the automation of many health transactions and may eventually pave the way for the justification of IT investments in health.

The BuddyWorks Telehealth project of the National Telehealth Center, an e-government project, is nearing completion and offers the possibility of managing electronic patient records needs of the government health bureaucracy. BuddyWorks is based on open source and is flexible enough to plug into any system that will be chosen by DOH. It can also serve as the reference implementation of the Philippine National health Information Infrastructure.

Next Steps

At center stage in health informatics in the Philippines is the Master of Science in Health Informatics program. Designed to produce the leaders who will push for the needed organizational and technological changes in the health sector, the MSHI program aims to participate actively in the efforts of the PNHII and of BuddyWorks. The cellular infrastructure will play a major role in the delivery of health messages because of its wide coverage in the country.

The Philippines will continue to focus its informatics to the real needs of the Filipino people, especially those who are marginalized and underserved.

Live Interactive Surgical Tele-Workshop on Rhinoplasty - A Tele-CME case study

Nabeel.M.K.

Academy of Medical Sciences, Pariyaram, Kerala INDIA

Abstract

This paper is based on a Live Interactive Tele-Surgical Workshop on Rhinoplasty conducted by the departments of ENT & Plastic Surgery in association with the Malabar branch of the Association of Otorhinolaryngologists of India. The Centre for Tele-Health & Medical Informatics co-ordinated the CME. IP based VSAT telemedicine connectivity provided by the Indian Space research Organisation (ISRO) is confined to a small telemedicine room with limited capacity. We have extended the facility with minimal cost to two more lecture halls of different capacities and Operation Theatres.

As a part of the workshop, a Rhinoplasty was done by the mentor from an operation theatre which was viewed and interacted upon by CME participants situated one at the lecture hall of our own institution (less than half a kilometre apart) and secondly and most importantly from the Tele-medicine conference hall at the Thiruvananthapuram Medical Colege. (More than 500 kilometre apart.) All three centres viz. Operation theatre, lecture hall and the remote centre could interact with the other two centres. Such a programme was conducted for the first time in the Kerala State Tele-Medicne network. Using the technology available then, only one remote centre could be catered. But attempts to multicast such programmes to many centres is nearing completion and even that would be possible ina month.

The various challenges, the problems faced by our team and our attempts to solve will also be described in this paper and it is hoped that it will give some lessons for all those who are planning to utilise the technology in Universities and teaching centres in low resource settings..

Why Teach Computer Security to Medical Students?

Ana M. Ferreira [ac], Ricardo Cruz-Correia [ab], Altamiro Costa-Pereira [ab]

[a] *CINTESIS - Center for Research in Health Information Systems and Technologies, Faculty of Medicine of Porto*
[b] *Biostatistics and Medical Informatics Department, Faculty of Medicine, University of Porto*
[c] *Department of Informatics, Faculty of Medicine, University of Porto*

Abstract

The introduction of Electronic Medical Records (EMR) within the healthcare practice can be beneficial in order to integrate and centralize heterogeneous patient information. However, there are still some problems that hinder the successful use of EMR. The concern for patient privacy is one of them. The aim of this paper is to present the results of a study that assesses attitudes of 1st year medical students towards computer security and the EMR. An anonym questionnaire was given to the students at the beginning and at the end of the academic year of 2003/ 2004 for them to comment on several security related scenarios. 238 questionnaires were answered at the beginning of the year whilst 222 were answered at the end of the year. The students feel, at the end of the year, that they understand better what computer security is and how to protect patient privacy information. This shows that teaching computer security to medical students, the future users of EMR, can greatly influence the success of EMR integration and therefore improve and fasten healthcare treatment.

Keywords:

computer security; education, medical, undergraduate

Introduction

The introduction of Electronic Medical Records (EMR) within the healthcare practice allows for the integration of heterogeneous information that are usually scattered over different locations [1] [2]. However, there are some barriers that impede its successful integration in most healthcare practices [3] [4].

One specific barrier relates with the privacy and security of patient information [5]. The use of new information systems within healthcare stresses the need for young doctors to comprehend them from their conception so that they can be used in a beneficial way and support their future daily work. As such, all the feedback provided during their training into the medical profession is essential for the enhancement of those systems [6], moreover in terms of computer security.

The Biostatistics and Medical Informatics Department of Porto Faculty of Medicine teaches Ethics and Medical Informatics to 1st year medical students [7]. The later subject includes theoretical and practical lectures about Electronic Medical Records (EMR) and computer security.

This study aims to assess the opinions, attitudes and awareness of 1st year medical students towards computer security issues relating to EMR, and how these can affect the successful integration of EMR within the healthcare practice.

Methods

An anonym questionnaire was given to the students both at the beginning and again at the end of the academic year of 2003/2004. It was applied two times so that we could compare their attitudes before and after they had attended the Ethics and Medical Informatics' subjects.

The questionnaires introduced 3 scenarios for the students to comment. The first scenario described a breach of patient privacy to an EMR by one of their colleagues. There were two questions relating with this scenario:

- Q1.A – Is the described scenario a security breach?
- Q1.B – What would you do if you found out about this breach?
- The second scenario included additional information to the first scenario. It explained that the colleague in question had shared his password with a friend and that friend was the one to access patient private information, without him knowing it. The question related with this scenario was:
- Q2 – Would you change your attitude if you found out this new piece of information?
- The third scenario introduced the issue of more sensitive information (e.g. HIV, Cancer results or even VIP related) and how this information must be protected. The question presented within the questionnaire was the following:
- Q3 – Do you think this kind of information requires stronger security measures than other types of information?

The answers to these questions were inserted into SPSS® and analysed separately.

Results

A total of 460 questionnaires were filled by the students. 52% (238) were answered before the lectures started whilst 48% (222) after the lectures finished. Table 1 shows the results obtained from the applied questionnaires.

Table 1 – Results obtained from the questionnaires

		Before the lectures % (n)	**After the lectures % (n)**
Answered questionnaires		*(238)*	*(222)*
Q1.A	*Valid answers*	*98 (232)*	*98 (217)*
	Yes	100 (232)	100 (217)
Q1.B	*Valid answers*	*61 (144)*	*60 (132)*
	Reason with	54 (77)	44 (58)
	Inform	40 (58)	50 (66)
	Others	6 (9)	6 (8)
Q2	*Valid answers*	*62 (148)*	*62 (138)*
	No	74 (109)	83 (115)
	Yes	26 (39)	17 (23)
Q3	*Valid answers*	*43 (103)*	*91 (204)*
	No	44 (91)	38 (77)
	Yes	55 (112)	62 (127)

For Q3, the main reason given by the students that felt no extra security measures were needed to access more sensitive information is that all security measures must be effective for all cases, independently of the patient or healthcare performed. The majority of the students that thought extra security measures were necessary agreed that this would provide for the protection of certain social groups from discrimination.

Conclusion

According to this study's results, after Medical Informatics and Ethics' lectures, students feel more conscientious to report privacy breaches to responsible parties (Q1.B). They understand better what computer security is and how to behave in order to protect confidentiality of electronic information. They consider indirect disclosure of sensitive information, such as with another person's password, a serious fault (Q2). Further, at the end of the year, students become more aware for the need of different protection levels of security depending on how sensitive information can be (Q3).

We believe that the introduction of Medical Informatics and Ethics early in the degree of the Medical course has an influence in the awareness and attitudes of first year medical students towards computer security and EMR. This can greatly influence the success of EMR integration whilst improving and fastening healthcare treatment.

Ethics and Health Informatics: Professional Imperative

Laurinda B. Harman[1], Virginia L. Mullen[2]

Abstract

The complexities of protecting patient privacy increase ethical challenges for medical/health informatics professionals. These issues surface as a result of the uses of information (coding, quality review, research, public health); the electronic health record (security, software development, e-health); sensitive information (genetics, adoption, behavioral health); and professional relationships with others, including as managers and when working with vendor and as entrepreneurs and advocates. The importance of ethical principles, professional values and the use of a code of ethics are essential. The American Health Information Management Code of Ethics is used as a reference, noting that many other health care codes can be used as resources. Specific cases and a decision-making matrix is presented that will facilitate ethical decisions in the context of work.

Keywords:

privacy, ethics, medical/health informatics, electronic health record

Introduction

The health information system contains many sacred stories that must be protected, even as information is shared with legitimate stakeholders across the continuum of care and services. The ethical obligation to protect this information is at the center of decisions made on behalf of patients, the healthcare team, peers, colleagues, the public, or the many other stakeholders who seek access to patient and consumer information [1]. Core health information issues include what information should be collected; how the information should be handled, who should have access to the information, and under what conditions the information should be disclosed. Health informatics professional values must guide ethical decision-making. Ethical obligations are central to the professional's responsibility, regardless of the employment site or the method of collection, storage, and dissemination. Sensitive information (genetic, adoption, drug, alcohol, sexual, and behavioral information) requires special attention to prevent misuse. Given the corporate/business relationships in the health care community, entrepreneurial roles require expertise in the protection of the information in the world of business and interactions with consumers [2].

Ethics provides a language and a framework for formally discussing ethical issues, taking into account the values and obligations of others. Ethical discussion offers an opportunity to resolve conflicts when competing values are at stake. Ethical decision making requires people to explore choices beyond the perspective of simple right or wrong (moral) options. According to Glover, ethics refers to the formal process of intentionally and critically analyzing the basis for your moral judgments for clarity and consistency [3]. When making health information decisions, informatics professionals must go beyond the personal right or wrong moral perspective and evaluate the many values and perspectives of others who are engaged in the decision to be made [4].

Ethical responsibilities of the informatics professional

In general, the HIM professional's primary responsibilities include those related to designing and implementing a system to ensure the completeness, accuracy, and timeliness of health information. In support of these responsibilities, the HIM professional is accountable for complying with laws, rules, regulations, standards, and policies from many sources, including the government, accreditation and licensure organizations, and the healthcare facility. Some of the health informatics professional's core ethical responsibilities include the following [5]:

Protecting patient privacy and confidential information [6] ; making appropriate decisions regarding the selection and use of clinical diagnostic and procedural codes [7] ; developing policies and procedures that ensure coding accuracy that supports clinical care and research and meets the requirements for reimbursement, while avoiding fraud and abuse violation [8]; reporting quality review outcomes honestly and accurately, even when the results might create conflict for an individual or an institution [9] ; ensuring that research and decision support systems are reliable[10]; releasing accurate information for public health purposes for patients with communicable diseases, such as AIDS or venereal disease, and assisting with the complexities of information management in the context of bioterrorism and the threat or reality of global diseases, such as smallpox or avian flu [11] ; supporting managed care systems by providing accurate, reliable information about patients/consumers, clinicians, healthcare organiza-

1 Temple University, Department of Health Information Management, Pennsylvania
2 Centura Health, Service Quality Measurement, Colorado

tions, and patterns of care, with special care devoted to issues related to access to information [12]; facilitating the exchange of information for patients, families, and providers of care, especially for those affected by chronic and terminal illness, that ensure patient autonomy and beneficence [13] [14]; ensuring that the EHR meets the standards of privacy and security according to HIPAA and other federal and state laws [15] the standards of information security [16] and software development [17] ; ensuring that clinical data repositories, data marts, data warehouses, and EHRs meet the standards of the best practices of health information and database management [18]; participating in the development of integrated delivery systems so that patients can move across the continuum of care and the right information can be provided to the right people at the right time [19] ; working in the context of e-health technologies that allow consumers, patients, and caregivers to search for health information and advice, create and maintain personal health records, and conduct virtual consultations with their care providers [20] ; ensuring that health information technology systems, including EHRs, electronic prescribing, bedside bar coding, computerized physician order entry CPOE), and clinical decision support systems reduce errors and improve quality [21] ; managing the protection of sensitive information, including genetic information [22]; drug, alcohol, sexual, and behavioral information [23]; and adoption information [24]; developing moral awareness and nurturing an ethical environment in the context of managing a health information system [25]; serving as advocate for patients, the healthcare team, and others who have interests in the health information system [26] [27] ; working with vendors in the development of business relationships that ensure ethical processes when selecting and communicating with vendors, managing vendor relationships, and dealing with the contract negotiation process [28] .

Discussion

It is important to clarify the differences between values, morality and ethics. A value is a principle, standard or quality considered worthwhile or desirable. Morality is based on values and represents your personal moral choice, i.e., this is "right" and that is "wrong." Ethics is a formal process of intentionally and critically analyzing a problem, taking into account all the facts, professional obligations and ethical principles and values of those involved in the decision, such as, patients, HIM professionals, employees, health care providers, administrators or society-at-large. The goal is to resolve conflicts among competing stakeholders.

Professional responsibilities often require an individual to move beyond personal values. For example, an individual might demonstrate behaviors that are based on the values of honesty, providing service to others, or demonstrating loyalty. In addition to these, professional values might require promoting confidentiality, facilitating interdisciplinary collaboration, and refusing to participate or conceal unethical practices. Professional values could require a more comprehensive set of values than what an individual needs to be an ethical agent in their personal lives. Professional values define the nature of all interactions in all settings and circumstances in which informatics professionals operate.

Health informatics values important to the patient/consumer include providing service; protecting medical, social, and financial information; promoting confidentiality; and preserving and securing health information. Values important to the healthcare team include promoting the quality and advancement of healthcare demonstrating expertise and skills; and promoting interdisciplinary cooperation and collaboration. Professional values important to the employer include protecting committee deliberations and complying with laws, regulations, and policies. Professional values important to the public include advocating change, refusing to participate or conceal unethical practices, and reporting violations of practice standards to proper authorities. Professional values important to individual and professional associations include obligations to be honest; bringing honor to self, peers and profession; committing to continuing education and lifelong learning; performing Association duties honorably; strengthening professional membership; representing the profession to the public; and promoting and participating in research [29]. These various professional values will require a complex process of balancing the many conflicts that can result from competing interests and obligations of those who seek access to health information and require an understanding of ethical decision-making. Values are not universally shared, so ethics gives us a framework for formally discussing the issues, taking into account the values and obligations of others. Ethical decision-making provides a framework for resolving conflicts when competing values are at stake.

Professional code of ethics and decision-making matrix

A code of ethics sets forth values and ethical principles, and offers ethical guidelines to which professionals aspire and by which their actions can be judged. A code is important in helping guide the decision-making process and can be referenced by individuals, agencies, organizations, and bodies (such as licensing and regulatory boards, insurance providers, courts of law, agency boards of directors, government agencies, and other professional groups) [30].

Glover [31] has proposed a seven-step process to guide ethical decision making. When faced with an ethical issue, the informatics professional should ask and answer all of

the following questions. The questions represent the steps in the decision-making process.

1.What is the ethical question?

2.What facts do you know, and what do you need to find out?

3.Who are the different stakeholders, what values are at stake, and what are the different obligations and interests of each of the stakeholders?

4.What options for action do you have?

5.What decision should you make, and what core HIM values are at stake?

6.What justifies the choice, and what are the value-based reasons to support the decision? What choice or choices cannot be justified?

7.What prevention options can be put into place so that this issue will not come up again?

Summary

Bioethical decisions involving the use of health information require action, and such actions always require courage. The healthcare team, the patients, and the others who are served need to know that the informatics professional has the expertise and the courage to make appropriate ethical decisions. Technical expertise must be combined with an understanding of ethical principles and the application of a professional code of ethics.

Implementing IT Knowledge to a PostGraduate Health Care and Nurse Studying Program

Tatjana Welzer[a], Peter Kokol[a] , Ana Habjani[b], Marjan Družovec[a] , Marko Hölbl[a]

[a] *University of Maribor, Faculty of Electrical Engineering and Computer Science, Smetanova 17, SI-2000 Maribor, Slovenia,*
[b] *University of Maribor, Faculty of Health Science,*

Abstract

Nowadays every visit to the doctor requests the cooperation between the nurse and IT technology. But are nurses really sufficiently equipped with knowledge about their working environment, as far as IT technology is concerned? Without doubt, more knowledge about the possibilities, benefits, possible mistakes and their consequences related to IT technology is needed for being used adequately in the health services. In the paper we will present the postgraduate program which aims at moving those possible obstacles and targets also at decreasing the lack of knowledge in this field of knowledge. We will present the study program in general and, additionally, will focus on specific IT areas like databases. The paper will also discuss the experiences and assessments which are acquired during the last years by the students in the database lecture. The mentioned lecture constitutes a part of the IT modules in the postgraduate health care and nursing program.

Keywords:

IT, postgraduate program, databases, information systems, education models, health informatics, nurse informatics, assessment

Introduction

Providing better health care for all is closely related to fast and secure information processing including data gathering, decision making, data mining and information generation, either in the health care centers, pharmacies, hospitals or any other health care institution. To meet all this requirements, it is demanded that appropriately trained staff is involved in activities where IT is a part of everyday work and life. To cope with this situation, nurses have to be trained in a proper way [7], [14].

Taking into consideration the needed knowledge from IT, we believed that the proper way to equip the responsible persons with sufficient knowledge is a regular undergraduate or post graduate education, which enables nurses to play an active role in the lecture phase as well as later in daily work with and for IT. To reach these goals, we developed a postgraduate nursing curriculum in the frame of the EU Phare Tempus project called NICE - Nursing Informatics and Computer Aided Education [1], [7] in which, as already the name itself reveals, informatics and IT are pointed out.

In the paper we will give a brief overview on the NICE curriculum. Furthermore, we will concentrate on some details in the Database lecture which is part of one of the modules of the study program. Additionally, we will present our experiences which we acquired during the last years since teaching the mentioned lecture. Experiences are very important for a further upgrading of the lecture and for up-to-date lectures materials available on webpages. Since the numbers of regularly enrolled students is approximately 15 per year, we are not able to work on summative assessment [12], but we need to find a less formal but, nevertheless, correct form for dealing with formative assessment or evaluation. The paper will be concluded by teaching results and final remarks, given in the Conclusion.

NICE curriculum

What is the concept behind “nursing informatics”? Simply speaking, we can define “nursing informatics” as the usage of information technology (IT) to support and make easier activities carried out by nurses. Some other definitions [2], [3] view nursing informatics as a discipline applying computer science to nursing processes or a combination of nursing science, informatics (information science) and computer science to manage and process nursing data, information and knowledge to support the delivery of health care.

Taking into account these definitions, we have decided that the nursing informatics curriculum needs to provide the students of the program with the following knowledge: basics of computer technology, medical informatics, nursing informatics, computer-aided patient care, computer networks and information retrieval as well as computer-assisted learning tools.

At the end of the nineties of the last decade, the NICE project was established with the aim to develop and introduce new short cycle degree courses from nursing

informatics at the university colleges. The project partners came from Austria, France, Greece, Italy and Slovenia [1]. The team who developed the curriculum consisted of members of various professions like nurses, engineers, computer scientists, medical doctors and administrators, who have very different views, opinions and beliefs on nursing informatics in general and in particular on the content of the nursing informatics curriculum [4]. The postgraduate program in Slovenia was the first one of his kind which integrated IT lectures to the curriculum for educating people of the health care and nursing domain. One of the top priority goals by establishing the program was, besides integrating informatics and computer science knowledge to the program, the integration of experts from the mentioned fields for giving lectures for nurses and health care domain staff.

After discussing various approaches that had been used in education [5], [6] as well as talking about other system approaches [6], we agreed on the common definition about teaching nursing informatics and IT as follows[1]: Teaching nursing informatics is a process in which students obtain knowledge from basics of informatics and computer science, informatics in health care (medical informatics), informatics in care and nursery (nursing informatics) computer communications and security (internet), medical instrumentation and simulation supported by computers with the aim to support nursing care processes as well as making nursing work more visible and enjoyable and, last but not least, to provide and enable better health care for all. On this foundation, taking into account also the before mentioned knowledge, the postgraduate nursing and health care informatics curriculum was developed and approved to by Slovenian authorities. Until our satisfaction with the curriculum was met, hard work was necessary and common decisions were done for each module and each single lecture.

The program is, like all other study programs for postgraduate students at our university, offered as a part time study. Most of the students are part time students (regular matriculation is also possible, but only exceptional required from students), mostly working as nurses or keeping other similar positions, having already a background knowledge from the nursing area duties or closely related to it. Some of the students have a technical background in computer science and informatics and are working in health care institutions, pharmacies, hospitals and similar institutions. Having started the program in 2001 which was attended then by one student, the number of students in the meantime has reached 10-12 students starting every year. The postgraduate program can be finished within 1,5 year (3 semesters). While two of the semesters are dedicated to attending classes and lectures, the students will spent the last semester on preparing their thesis and research. Within two semesters, the students have to pass 18 exams. Additionally to the lectures and to the gathering of practical experience, the students individually need to organize themselves when it comes to arranging time which is required for exercises, seminar work and the preparation for exams.

The offered lectures of the program are divided into three modules: Nursing informatics, informatics in health care and search for information in computer networks. In the following we will focus on the first module and give insight to the single lectures: “Information systems”, “Telematics in health care”, “Databases”, “Intelligent Systems”, “Ethics” and “Security of computerized data.” Already the titles of the lectures reveal the multidisciplinary content of the curriculum. Knowledge from the nursing program is combined with knowledge from the informatics and computer science program and is added by electrical engineering cognition. The teachers of the individual lectures have high competence in their subject as they have achieved their expertise in this specific field of knowledge. Lectures like “Information Systems”, “Databases”, “Intelligent systems” and “Ethics and security for computerized data” are given either only by a lecturer from informatics and computer science or by lecturers from two or three areas who will then cooperate in the same lecture.

For each single lecture also teaching materials were produced, concretely books were written [9] and PowerPoint presentations were prepared. Books were published in the NICE series, covering all lectures and providing basic knowledge which is required to finish the obligations of the program. Books have been a part of the NICE project as well. Additionally, PowerPoint presentations and other electronic materials and tools [13] are as response to the achieved feedback from lectures of the last years available for students via webpages [7], [14] and [15].

Database lecture: the content

This lecture covers five sections that include methodologies and techniques for database development. The lecture details are as follows:

- *Introduction:* This part briefly introduces the importance of the database and gives basic definitions and information on the architecture
- *Database design:* Database design is the most important part when developing a database. The work is divided into three parts: conceptual, logical and physical database design. The focus is on the conceptual model as a basic work for further design and development. The Entity-Relationship model is presented as a basic technique for conceptual database design.
- *Relational database:* This part discusses the logical level of the database design with properties and trans-

formation rules from the E-R model to the relational database.

- *Databases in the future:* Special areas such as medicine, health, pharmacies and some others develop special models for special needs, quite often upgraded also with the knowledge and knowledge based systems. Students will get the encyclopedical knowledge from the knowledge based systems as well as enterprise and domain models.
- *Summary:* Instructors guide students to have a look at database from their own field of profession. The enterprise is defined by each student for his/her seminar work and database design is done on a conceptual level. Results are presented and discussed with other students, the instructors and the lecturer. Final conclusions are done after having gained practical experience.

Experiences

After getting a brief overview on the nursing and health care postgraduate program and after having presented the "Database lecture", we would like to present some experiences acquired during the last years. Most of the experience we share is gathered in the informal discussion with the students after the exam of the "Database lecture" (formative assessment/evaluation). More formal assessment (summative assessment/evaluation) is not possible because the group of the participating students tend to be very small (between 5 and 12 students). Furthermore, as assessment is much more difficult when new teaching methods and experiments are just being introduced.

In general, the process of educational assessment can be approached as being the process of gathering, describing or quantifying information about learning performance. The person or lecture being evaluated can range from the performance of students and instructors to that of lectures materials, courses and or the whole study program. Educational assessment/evaluation can be done either during or after lectures and with different purposes. Generally speaking, assessment can be defined as the systematic process used to obtain information about student achievements [12] in order that that information can be used to:

- Give feedback to students.
- Make educational decisions about students.
- Make decisions about the lecture or the program and the effectiveness of the lecturer.

Students usually attend the Database lecture after having finished the Information system lecture, where they are equipped with basic knowledge about what is an information system, what are its processes and activities as well as being told the basic importance about data and database for each information system and/or application.

Among the books in the NICE-series a book for the Databases lecture is available and we, additionally, have a PowerPoint presentation about the most important parts as well. The main goal is that students understand what is a database, its importance, as well as how to develop it. They are also informed how to implement it and access data, but we do not provide any special training on this part because mostly the students will be not actively involved in the implementation or writing SQL queries, for example. But in cases where they will in the future come across developing and using a database, **we expect that queries will be very basic one.** For those involved exceptionally more practically to data access, another chapter in one of the NICE series book is available [10].

One of the goals of the lecture is to prepare students to be actively involved to the development of the database, while they will have probably the role of a domain (nursing, health care) expert consultant. Therefore they have to acquire knowledge and exercise how to do this. Thus every student has to select his or her own domain to develop a database conceptual model (abstract presentation of the database).

How do the students normally react when being asked to develop such a model? Up to then, they are mostly not familiar with the topic (except most of students with non nursing background or undergraduate study) and they are motivated to "reject" the lecture and/or to pass it as fast as possible, neglecting the importance of the topic.

After the first "shock" ("we are not able to do this"), the students slowly start making themselves familiar with the importance of collecting data and developing databases for nursing or health care processes. Usually, after having developed the conceptual model, they make themselves familiar with the importance of the whole system that they have selected or with at least a part of it. This incident is maybe surprising because they have already been close to the selected domain or working there partially already for a long time. Questions about its importance tend to arise, they ask themselves what is important, which data is need or if something is maybe missing. From the quality point of view (quality of the conceptual model), they have been in the past time very successful in their profession. One goal to be reached during the teaching process is raising awareness for the fact that the students own a very important knowledge which contributes to the success of a database. Our students also become aware that they can be an important member of the team working on developing databases on their own domains (nursing, health care). Students with a background from informatics and computer science acquire for their future work very important domain knowledge.

In the formative assessment the students tells us their own stories, quite close to that just described above. For our

students it is an unusual situation to be asked to be active in selecting and deciding on the content of their seminar paper (they select the domain as well as the possible application for which the database should developed). Transferring the gathered knowledge of the study program then later to their workplace in reality, they find out to be happy to play an active role.

In the summative evaluation, a secondary emphasis was put to assess students' achievement at the end of the lecture. The assessment data which has been collected can also be used to provide feedback about lecture materials, approach, **exacting of the whole lecture** and, last but not least, gives information on the adequacy of the lecture in the presented program.

Conclusion

The main idea of this paper was to clarify the importance of IT in the nursing and health care educational programs. Actually, IT is nowadays a part of every day life, when it comes to activities ranging from shopping up to working place surroundings and when consulting a doctor. Whenever things take an unpleasant, unintended direction, we are unsatisfied and complain either to the shop assistant or vendor or both or to our webmaster, IT engineer and, last but not least, put forward our complaints to the nurse or even to the doctor. Quite often we blame persons who are not responsible for the failure because actually the fault is related to the system which is either not good or not working correctly. But, without doubt, there is sometimes also a lack of knowledge by people using these IT systems and this deficit we would like to avoid and thus we have developed and implemented the just mentioned post graduate program.

We have decided to introduce the knowledge of IT to the educational program, independent from the fact that for our students this so far has been a new, mostly unknown domain. The NICE curriculum provides the postgraduate students with the opportunity to compensate the before mentioned lack of knowledge. By using lectures from the field of computer science and informatics we motivate our students to take over an active role in real projects in their daily work environment including developing new IT products for the mentioned domains. Depending on the environment, those products are still rare, and, after all, nurses hardly ever have an active role or do have a lot of influence in IT domains, but we are optimistic that this could chance. In the future, nurses with the required IT knowledge will not only be experts when in comes to acting as an consultant, but they will also be able to make their own proposals, suggestions and solutions concerning the conceptual level, while the implementation of it will remain the domain of IT and computer science experts and engineers.

Slovenia

Introduction

- NICE curriculum
  - EU Thempus project
- Nursing informatics in NICE
  - Obtained Knowledge
  - Part time study
  - Three modules
  - Teaching materials
- IT lectures and Experiences
  - Databases
- Conclusion
- References and contact details

NICE Curriculum

- EU Thempus project
  - Develop and introduce new short cycle degree courses from nursing informatics at the university colleges.
  - Project partners from Slovenia, Austria, France, Greece and Italy.
- Nursing informatics definition for needs of NICE

Nursing informatics in NICE

- **Obtained knowledge**
  - Basics of computer technology,
  - Medical/Nursing informatics,
  - Computer-aided patient care,
  - Computer networks,
  - Information retrieval,
  - Computer-assisted learning tools,
  - E-learning.

Nursing informatics in NICE

- Part time study
  - 1,5 year or 3 semesters:
  - 2 teaching semesters (18 exams)
  - 1 semester to prepare the thesis
- Three modules
  - Nursing informatics,
  - Informatics in health care and
  - Search for information in computer networks
- Theacing materials
  - Books
  - PowerPoint presentations

IT Lectures

- Databases
  - Lecture structure
    - Lectures
    - Practice – developing databse
  - Student obtain basic knowledge about:
    - information system, processes, activities and importance of data and database
  - Student must develop a database from their domain

IT Lectures

- Database Lecture: The content
  - Introduction
  - Database Design
    - Conceptual
    - Logical
    - Physical
  - Relational database
  - Database in the future
  - Summary

IT Lectures

- **Database Lecture: The content**
  - Conceptual database design
    - Entity-Relationship model
      - Basic technique – it importance
      - Elements (Entity, Relation, Atribute)
      - Advices for development
      - Exampels
      - Literature
      - Others

Experiences

- **Assessment**
  - Systematic process about students achievements
    - Feedback to students
    - Educational decisions
    - Decisions about lecture, program, lecturer
- **Databases**
  - Formative assessment
    - Informal discussion with students
  - Summative assessment
    - Collecting data for longer period – valid data according to the number of matriculated student

Experiences

- Results
  - First: students are motivated to reject the lecture
    - “We are not abel to do this!”
  - Later: interest because of the known domain
    - “What can I do better?”
    - “What is important for nurses?”
  - Raising awareness
    - “We are/should be member of a development team”
  - Playing active role

Conclusion

- **Knowledge of IT is inportant**
  - Part of every day life all over
- **NICE curriculun is successful**
  - Since 2001 regular matriculation
  - Small groups
- **Experiences**
  - Students previous (working) experiences
  - Teachers experiences
  - Students (new) IT experiences
    - Formative assessment
    - Sumative assessment (up to four generations)

Live Interactive Surgical Tele-Workshop on Rhinoplasty - A Tele-CME case study

Nabeel.M.K.

Academy of Medical Sciences, Pariyaram, Kerala INDIA

Abstract

This paper is based on a Live Interactive Tele-Surgical Workshop on Rhinoplasty conducted by the departments of ENT & Plastic Surgery in association with the Malabar branch of the Association of Otorhinolaryngologists of India. The Centre for Tele-Health & Medical Informatics co-ordinated the CME. IP based VSAT telemedicine connectivity provided by the Indian Space research Organisation (ISRO) is confined to a small telemedicine room with limited capacity. We have extended the facility with minimal cost to two more lecture halls of different capacities and Operation Theatres.

As a part of the workshop, a Rhinoplasty was done by the mentor from an operation theatre which was viewed and interacted upon by CME participants situated one at the lecture hall of our own institution (less than half a kilometre apart) and secondly and most importantly from the Tele-medicine conference hall at the Thiruvananthapuram Medical Colege. (More than 500 kilometre apart.) All three centres viz. Operation theatre, lecture hall and the remote centre could interact with the other two centres. Such a programme was conducted for the first time in the Kerala State Tele-Medicne network. Using the technology available then, only one remote centre could be catered. But attempts to multicast such programmes to many centres is nearing completion and even that would be possible in a month.

The various challenges, the problems faced by our team and our attempts to solve will also be described in this paper and it is hoped that it will give some lessons for all those who are planning to utilise the technology in Universities and teaching centres in low resource settings..

Patterns of Practice of Telemedicine at a Quaternary Super-speciality Referral Hospital in a Developing Country

Dr S Satpathy [a], Dr RK Pathni [b], Dr PC Chaubey [c], S Kailash [d]

[a] *Additional Professor, Department of Hospital Administration, AIIMS, New Delhi, India*
[b] *Resident, Department of Hospital Administration, AIIMS, New Delhi, India*
[c] *Professor& Head, Department of Hospital Administration, AIIMS, New Delhi, India*
[d] *Systems Analyst, Computer Facility, AIIMS, New Delhi, India*

Abstract

All India Institute of Medical Sciences (AIIMS) is the apex super-specialty, quaternary referral hospital of India. Telemedicine facilities have been available at AIIMS since 1999. A study was undertaken at the Institute from October 2005 to September 2006 to assess the patterns of practice of Telemedicine and identify the difficulties faced by the doctors. Results of the study conducted across 23 surgical and non-surgical disciplines are presented..

Keywords:

telemedicine, telemedicine utilization, tele-consultation, developing country, super-speciality hospital

Introduction

India has the second largest population in the world (1.1 billion) and providing medical care to all its citizens is a Herculean effort. The task isn't made any easier by the fact that this population is spread over the world's seventh largest land mass stretching 3214 km (North to South) and 2933km (East to West) over all kinds of terrain - from Himalayan mountain ranges to remote islands and from deserts to tropical forests. In the above scenario Telemedicine would appear to be the panacea for all ills that plague the Indian healthcare system.

All India Institute of Medical Sciences (AIIMS) is the apex super-specialty quaternary referral hospital of India. It was established in 1956 with the mandate to develop the highest standards in the trinity of medical education, research and patient care. A pilot Telemedicine project started by the Ministry of Communication & Information Technology in 1999 has developed into a full-fledged Telemedicine Facility.

The present descriptive study was undertaken at the Institute from November 2005 to October 2006 to assess the usage pattern of the Telemedicine and identify the difficulties faced by the doctors. The study demonstrated the need for distant consultation currently being fulfilled by the doctors by using conventional methods rather than Telemedicine. Most of the use of Telemedicine at AIIMS was found to be in the form of "second opinion" type Doctor-to-Doctor consultations – conforming to the role of the Institute as an apex super-speciality quaternary referral center. The problems in usage of Telemedicine relating to technical, connectivity and administrative issues as well as personal concerns of the doctors were also studied.

Materials and methods

A record-based retrospective study of last 3 years (1 July 2003 to 30 June 2006) was carried out at the Telemedicine Facility to determine the utilization pattern of the Telemedicine services at AIIMS. A non-randomized purposive sample of representative surgical and non-surgical disciplines was selected for further study on the basis of maximum frequency of usage of Telemedicine Facility during the last three years. The study was descriptive in nature, study design was cross-sectional and reference period concurrent.

A semi-structured self-administered survey was planned for the next phase. A pilot study was conducted (n=6) and the questionnaire was modified based on the inputs received. The questionnaire survey was conducted over three months (August to October 2006) amongst the doctors (Faculty members) from the disciplines selected from the above retrospective study with the following objectives:

1. To study the present pattern of providing distant medical advice from AIIMS to other doctors and patients.
2. To assess the usage pattern of Telemedicine at AIIMS
3. To identify the problems faced by the doctors in using the Telemedicine Facility.

In order to increase the sample size the study population was expanded to include Faculty members from all other surgical and medical disciplines which had utilized Telemedicine Facility during the last 3 years. To reduce bias, at

least 2 Faculty members were randomly selected from the department-wise list of designated Faculty.

The data was analyzed using Stata (ver 9.1) statistical software package which is a complete, integrated statistical package for data analysis, data management, and graphics. The findings were further analyzed to see if there was any difference in usage pattern depending on whether the respondent was from a surgical or non-surgical discipline. Fishers exact test was used as the test of significance.

Results

Total 61 questionnaires were distributed to the faculty at AIIMS of which 58 (95.08%) were completed and returned. Non-response rate was reduced to about 5% by repeated visits after stipulated collection date. 45 (77.6%) of the respondents were male and 13 (22.4%) were female. The respondents were aged between 31 – 60 years (Mean age = 44.37 years).

The respondents were from 23 clinical specialities (Table 1 - Specialities covered in the study1). 35 (60.3%) of the respondents were from non-surgical disciplines and 23 (39.7%) were from surgical disciplines.

Patterns of consultation

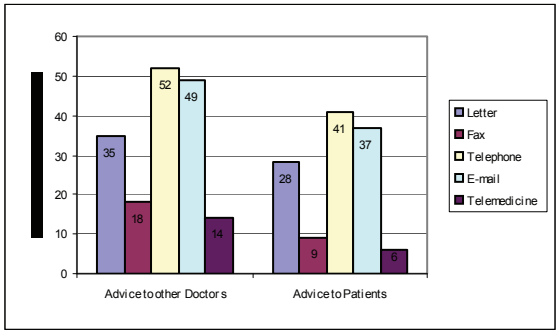

Figure 1- Methods of providing medical advice

Almost all the respondents were using conventional methods viz. letter, fax, telephone or e-mail to provide medical advice to doctors / patients in other places (Table1). Only 3 (5.17%) doctors said they did not use any of these methods, to provide advice to doctors / patients in other places.

Use of Telemedicine at AIIMS

The Telemedicine Facility had conducted a total of 481 tele-consultations in the three-year period (from 1 July 2003 to 30 June 2006). This included Telemedicine sessions with various hospitals and medical colleges within India and abroad (including UK, France, USA and Canada).

The frequency of use of Telemedicine facilities was found to be low. About one-third (32.8%) of the respondents had never used Telemedicine and 30 (51.7%) had used it less than once a month. Only 2 (3.4%) respondents had used Telemedicine every week. An overwhelming majority of the doctors i.e. 34 (87.18%) had used Telemedicine for tele-consultation and the rest 5(12.82%) had used Telemedicine only for tele-conferencing.

Table 1 - Specialities covered in the study

Non-surgical disciplines	**Surgical disciplines**
Cardiology	ENT
Dermatology	General Surgery
Endocrinology	Gastro-intestinal Surgery
Gastroenterology	Gynaecology & Obstetrics
Haematology	Neurosurgery
Medicine	Ophthalmology
Nephrology	Orthopaedics
Neurology	Paediatric Surgery
Medical Oncology	Oncosurgery
Paediatrics	Surgery
Physical Medicine & Rehabilitation	Urology
Psychiatry	
Rheumatology	

There was no significant difference in frequency of use between male / female doctors. Doctors from surgical disciplines were found to be more likely to have used Telemedicine than those from non-surgical disciplines though the difference was not statistically significant *(Table 2 –Usage of Telemedicine: Surgical vs Non-surgical 2).*

Doctors in higher age groups *(Table 3 – Relationship between usage of Telemedicine and age3)* and those with more than 10 years of experience (Table 4 - Relationship between usage of Telemedicine and experienceTable 4) were more likely to have used Telemedicine. A linear trend was noticed in the relationship between the age groups and usage of Telemedicine but the trend was not statistically significant (p=0.054). The correlation with number of years of experience was found to be statistically highly significant (p=0.019).

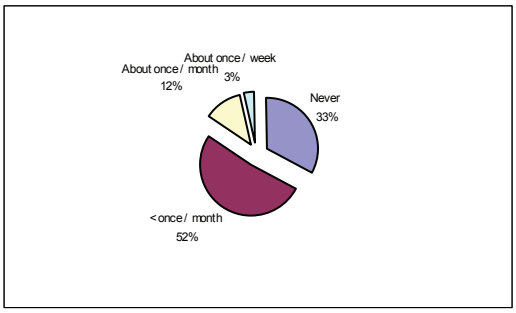

Figure 2 - Frequency of use of Telemedicine

Table 2 –Usage of Telemedicine: Surgical vs Non-surgical

Discipline	Used TM		Total
	N	Y	
Non-surgical	14	21 (60%)	35
Surgical	5	18 (78.26%)	23
Total	19	39	58

Table 3 – Relationship between usage of Telemedicine and age

Age	Used TM		Total
	No	Yes	
31-40 yrs	10	12 (54.55%)	22
41-50 yrs	7	15 (68.18%)	22
51-60 yrs	2	12 (85.71%)	14
Total	19	39	58

Table 4 - Relationship between usage of Telemedicine and experience

Experience	Used TM		Total
	No	Yes	
<= 10 yrs	8	5 (38.46%)	13
> 10 yrs	11	34 (75.56%)	45
Total	19	39	58

Patterns of telemedicine use

A cross-sectional analysis of the consultation pattern was done by asking the respondents about their last Telemedicine session. Only in 17 (43.59%) cases the patient was present during the Telemedicine session. Interaction between the specialist (at AIIMS) and the remote patient was there in only 12 (30.77%) cases. The patient was examined by proxy i.e. the remote doctor was asked to do specific physical examination, during the session in only 9 (23.08%) cases. Patient's clinical history was taken in 21 (53.85%) cases and laboratory investigations and radiological investigations were reviewed in 26 (66.67%) and 22 (56.41%) cases, respectively. Live ultrasonographic examination was done in just one case (2.56%) and special equipment like electronic stethoscope, digital ECG machine, etc. were used in only 2 (5.13%) cases.

This clearly shows that Telemedicine at AIIMS was used mainly for providing "second-opinion" type doctor-to-doctor consultations. Use of Telemedicine for direct patient evaluation was very limited.

Data transfer

Over half of the Telemedicine sessions involved online transfer of data. Only 3(7.69%) respondents had used the offline mode. 1/3rd of the respondents had used both modes – online as well as offline – and that was the preferred mode for receiving data.

Satisfaction with technical quality

Respondents had a high level of satisfaction with the technical quality with nearly 3/4th of the respondents rating it as 3 and above on a Likert scale (5=Excellent, Mean score 2.923).

Problems faced in utilization of telemedicine facilities

The various problems faced by the respondents in utilizing the Telemedicine facilities were grouped as follows (Figure 3)

1. Technical problems
2. Connectivity problems
3. Administrative problems
4. Personal concerns

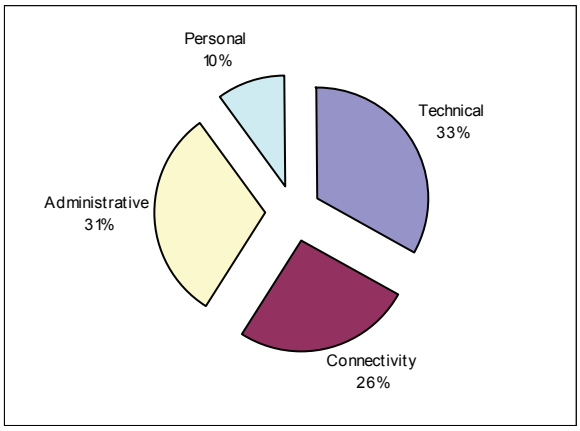

Figure 4 Problems faced in using telemedicine

More than half the respondents felt that improvements in the technological aspects (Technical and connectivity related problems) would improve their usage of Telemedi-

cine *(Figure 4 Problems faced in using telemedicine4)*. Poor quality of video was the commonest technical problem faced by more than half of the doctors. Nearly half the respondents had suffered frequent disconnections during Telemedicine sessions. More than half (61.54%) of the doctors reported difficulty in sparing time for Telemedicine because of busy work schedule. Again, more than half the doctors (56.41%) had apprehensions about limitations of Telemedicine in conducting physical examination of the remote patient and more than one-third (38.46%) were concerned about the reliability of investigations in the peripheral hospitals. The details of the various problems faced by the doctors are listed at *Table 5-Problems faced by users of Telemedicine Facility5*

Table 5-Problems faced by users of Telemedicine Facility

Technical problems	
Poor Video quality	22 (56.4%)
Audio-video mismatch	19 (48.7%)
Poor audio quality	13 (33.3%)
Poor Image quality (X-rays, photos, etc)	13 (33.3%)
Connectivity problems	
Frequent disconnection during the session	19 (48.7%)
Difficulty in getting connection	15 (38.5%)
Inadequate bandwidth	11 (28.2%)
Administrative problems	
Overcrowded work schedule	24(61.54%)
No agency to coordinate	16(41.03%)
Inconvenient timings	12(30.77%)
Distance of Telemedicine Centre from own Dept.	7 (17.95%)
Personal concerns	
Difficulty in performing physical examination of the remote patient	22(56.41%)
Medico-legal issues	16(41.03%)
Unreliable investigation reports from peripheral hospitals	15(38.46%)
Data security & confidentiality	10(25.64%)

Discussion

All India Institute of Medical Sciences (AIIMS) was established in the year 1956 as an autonomous body with the triple mandate– to develop the highest standards in medical education, research and patient care. AIIMS has lived-up to its role as the apex super-specialty, quaternary care hospital of India.

Table 6 - AIIMS : Important annual statistics (2004 - 05)

1	Teaching Departments and Centres	50
2	Faculty members	510
3	Total number of hospital beds	2012
4	Total annual OPD attendance	2,394,270
5	Total annual A & E attendance	179,574
6	Total annual admissions	212,612
7	Total annual surgeries performed	118,234

Telemedicine at AIIMS

There are two telemedicine projects in AIIMS. The first was a pilot project by the Ministry of Communications & Information Technology in 1999. This was followed by point-to-point satellite connectivity provided by Indian Space Research Organization (ISRO). These have been expanded step-by-step to now include 81 districts all over the country. The connection is through ISDN lines or through satellite communication. 6 ISDN lines have been provided each with 128 kbps bandwidth. The lines can be used singly or can be cascaded together to have an effective bandwidth of upto 768 kbps. Satellite communication is provided by ISRO through INSAT 3A satellite.

Being the apex medical institution of the country, AIIMS has a very important role to play in terms of providing super-specialist medical advice to the rest of the medical community in India. The present study shows that 95% of the doctors at AIIMS frequently provide medical advice to doctors and patients at distant places. Telephone and e-mail are the most popular methods, although some still use letters. This is proof of the immense need for means to provide super-specialist medical advice to doctors in distant places where no such facilities are available. It also establishes the fact that the doctors are comfortable with the concept of providing remote medical advice to distant places and do not have any significant concerns while using conventional methods. Thus "*the practice of medicine at a distance*", i.e. telemedicine in a broader sense, appears to be widely prevalent at AIIMS albeit using conventional forms of communication. It may safely be surmised that adoption of Telemedicine in its high-tech avatar is just a matter of getting used to the technology.

In a literature survey of teleconsultations Laatinen, et al (2002), reviewed 128 articles identified through Medline, and found that 79% of the teleconsultations were between doctors and only 8.5% were between doctors and patients[1][1]. In the present study where it was found that most of the teleconsultations were "second opinion" type doctor-to-doctor consultations and interaction between doctor and patient took place in less than 1/3rd cases.

1 Laatinen P.T., Forsstrom J.J., Loula P. Teleconsultations : who uses them and how? Journal of Telemedicine and Telecare. 2002: 8 (16) : 319-324(6).

AIIMS has had state-of the-art equipment at its Telemedicine Centre since 7 years but the present study found its use to be rather low. The usage was low in comparison with even other Indian Telemedicine projects. AIIMS had only 481 Teleconsultations in a span of 3 years whereas Christian Medical college, Vellore, in South India reported over 100 consultations in a period of 4 months[2][2] and Amrita Institute of Medical Sciences (AIMS), Kochi, again in South India, reported 874 tele-consultations in a period of 2 ½ years (Sep 2002 – Feb 2005)[3][3]. A study at the same Institute in 2004 had noted that the majority of physicians felt that better quality of patient care could be provided only in person [4] . The low usage at AIIMS could be due to lack of awareness of the potential of the technology and apprehensions about its limitations.

Most users had complaints about the technical quality and connectivity problems (Table 5-Problems faced by users of Telemedicine Facility5 & Figure 4 Problems faced in using telemedicine4). These issues will have to be addressed before more users embrace Telemedicine as a way of practice.

Significantly, it was found that doctors in higher age groups and those with more than 10 years of experience were more likely to have used Telemedicine. This difference was contrary to expectation as the younger generations are thought to be more tech-savvy and more inclined to use newer technologies. The reasons for this may be that the younger doctors are busier with routine clinical work whereas the senior doctors have more spare time and more opportunities to work outside their own department. Another reason could be that the senior doctors, because of their well-established reputation were more likely to be consulted for a "second opinion" than their younger colleagues. The good news here is that the resistance to change and adoption of new technology in any organization usually comes from the "*old block*". At AIIMS the "old block" has already been conquered and it is a matter of time before the use of Telemedicine becomes routine practice.

Some important issues in implementation of Telemedicine in the country are – availability, accessibility, acceptability and affordability and reliability[5][5]. Acceptability of Telemedicine to the clinicians can be improved by increasing their awareness about the technology and educating them about its utility.

A large number of respondents felt the need for a coordinator – a role that can be fulfilled by a Hospital Administrator.

Conclusion

This is the first study of patterns of practice of Telemedicine at this apex quaternary super-specialist referral hospital. Almost all clinicians at AIIMS were found to be using conventional methods (telephone, e-mail, letter,, fax) to provide distant medical advice. But the level of usage of Telemedicine was low even by Indian standards. Use was mostly for "second opinion" type consultations between doctors, which matches the mandate of the Institute and is also similar to international patterns of usage. Most of the problems faced by the users related to technological issues (technical and connectivity issues).

India, with its wide inequity in distribution of healthcare resources, can benefit immensely from the immense potential of this technology to take super-specialist care to the masses. But a sustainable model of Telemedicine is possible only if can we address the gaps in technology and, at the same time, improve acceptability of the technology amongst the clinicians.

Acknowledgements

We are grateful to the staff at the Telemedicine Facility for all the help rendered in conducting this study.

Abstract

The follow-up of patients with liver transplant is a complex task for any multidisciplinary team. Such complexity grows when patients live far away from the healthcare center area where this procedure was performed. In order to provide a greater quality of care for our patients, our primary objectives are the creation of an academic community network to improve the interaction between our transplant team and the remote care provider, and the creation of a clinical data repository using telemedicine. We developed a web based system, used by follow-up physicians to improve the quality of care and the follow-up of transplanted patients.

Keywords:

telemedicine, liver transplantation, follow-up

Introduction

The Hospital Italiano of Buenos Aires is internationally recognized among health care organizations as a care giving leader, and a referring educational and research center in Latin America.

625 liver transplants have been performed, transforming this hospital into a national and international center of reference.

It's a well known fact that the follow-up care of the patients with liver transplant by a multidisciplinary team is a daily complex task to deal with. This complexity increases considerably if the patient does not live in the city where the procedure was performed [1, 2].

This project aims to improve the quality of the care of our patients, through the interaction between our transplant team and follow-up professionals in charge, allowing referring doctors, during the monitoring, to access medical data of their patients. There is clear evidence of the effectiveness of telemedicine in improving the health of patients, giving support to their referring physicians, mainly when the geographic distances matter [3].

Materials and methods

By the end of 1999 the Hospital Italiano of Buenos Aires started the development of a Health Information System (HIS), and its most emblematic product is its Electronic Health Record "Itálica" [4, 5], which allowed the centralization of all the health care information of our patients. It's on our HIS where we set the basis to implement this liver transplanted patient follow-up system.

In addition, the Hospital has a very well trained multidisciplinary team that provides comprehensive care to each patient, from the evaluation visit through the transplant procedure and postoperative period. In this follow-up instance is where required learned skills are difficult to transmit to a third-party team.

Finally, we have a network of teams, each one conformed by physicians located outside the area of Buenos Aires, which refer us the patients. These associated providers continue monitoring the evolution when the patients return to their home places.

We have decided to develop a web based system, supported by the data modeling established in our HIS, to allow the referring physicians, in different cities, to access all the health care information of their patients, as well as to update it.

Liver transplant program processes

Including a patient into our liver transplantation follow-up system is not a complex task. The system has a representation of the stages which a liver transplanted patient must pass through. It consists of five stages: (1) Patient Enrolling, (2) Aptitude Evaluation, (3) Pre-Transplant Waiting List, (4) Transplant, (5) Post-Transplant Follow-up List.

Local data registry system

The system was designed to represent all the stages in the liver program; in addition it incorporates one more instance that allows the referring doctor's office to record what happens in the follow-up visit.

Enrollment of patients refers to the capture of certain administrative data (for example the allocation of the med-

ical team that will continue with the monitoring) and medical data (diagnosis pre-evaluation, etc.). The data is required by the Liver Program, supported by our Hospital Master Patient Index [6], based on CORBAmed [7, 8].

All data is loaded by physicians of our institution, registered in our HIS, and then, associated with other patient's medical data in the Electronic Health Record (EHR).

Remote visualization and data registry system

Once data is generated, referring doctors may visualize this information along with the rest of the patient's EHR data, from their offices via Internet. They access the system through a connection established on a VPN (Virtual Private Network) [9].

The remote data entry module is used by the referring physicians, and allows them to record any medical events during the period between Hospital Visits. They may also load results of complementary studies, either by typing or by digitalization of all the information that the patient can require.

For this last issue we had to develop an archive storage system (text documents, images, videos, etc.) that includes a viewer of JPEG images and DICOM files, which allows us to reproduce a CT scan or MRI console in practically any PC used as Workstation.

Technological requirements

We have developed our system under the security standards established by Windows XP SP2, and we considered necessary, for an optimal performance, a Pentium IV with a 512 Mb RAM. The minimum connection requirement is at least 256 Kbps of broadband connection.

Results and discussion

Today we have connected two distant monitoring medical teams of our patients, one within the province of Buenos Aires (República Argentina) and other one in Montevideo (República Oriental del Uruguay). The team at Montevideo is monitoring 78 Uruguayan patients transplanted in our Hospital. At the closure of the present work, we have 410 enrolled patients in the Transplant Program.

We have reviewed some experiences using telemedicine to follow-up and to assist patients [10], but we have not found references in the literature about the use of these applications for the remote monitoring of patients with liver transplant. We hoped that the implementation of this type of solutions can settle an improvement in the quality of the care of our patients, bringing assistance to distant doctors thanks to new TIC's.

On the other hand, we are in an experimental stage, running the program in a pilot level and still we know that we depend on the interaction and commitment of the distant medical team, nevertheless we clearly believe that this tool will contribute much to fulfill one of our main institutional objectives: the continuous search for the best quality of patient care.

There is no way to believe that the system will replace contact between the referring doctors and our local transplant team, but is a complement for the daily transdisciplinary work.

We expect to generate an academic and clinical community, which allows care givers access the patients' medical records with this remote data entry module. Today we have been using it in the follow-up of patients with liver transplant; but we think that it might be able to support any kind of patients. We state for sure that it could be the beginning of the remote consultation to the EHR of our patients.

A Business Model of Taiwan's RFID Network Platform in Healthcare Industry

Frank Kuo [1], Jerome C. Chou[2], Li Liu[3], Yeali S. Sun[1]

1 Department of Information Management, National Taiwan University
2 Department of Business Administration, Hwa-Hsia Institute of Technology
3 Department of Medical Informatics, Taipei Medical University

Healthcare is life-critical. Any medical mistakes may cause irremediable regret. Patient safety is the most important issue in healthcare industry. The bottleneck of Hospital Information Systems (HIS) is the inability of tracking and identifying the patient's information like name, dispose content, operational time, and location. Radio Frequency Identification (RFID) technology can provide some supports to solve the problems to make better decision by HIS.

There are some RFID pilot projects in healthcare which have verified that it can enhance care quality, decrease medical errors, and increase both efficiency and effectiveness in healthcare resource. A "RFID Network Platform" is necessary for spontaneous and innovative applications to proliferate, and the business model is important to the platform provider for stimulating and channeling innovations to drive the network effect in healthcare industry.

This research proposes a business model for Taiwan's RFID network platform in healthcare industry. Based on the platform business model, we examined RFID applications in drug control, blood bag control, emergency medical service, and long-term care service.

Radio Frequency Identification (RFID), network effect, platform strategy, business model, National Healthcare Information Infrastructure (NHII)

Introduction

Healthcare is life-critical. Any medical mistakes may cause irremediable regret. Patient safety is the most important issue in healthcare industry. World Healthcare Organization (WHO) and other organizations all pay much attention about reducing medical errors and creating a medical environment for patient safety. The famous organization in healthcare, Institute of Medicine (IOM), proposed that many medical errors occur because of human carelessness. The bottleneck of Hospital Information Systems (HIS) is the inability of tracking and identifying the patient's information like name, dispose content, operational time, and location. Under such situation, it is difficult to make better decision from HIS.

Radio Frequency Identification (RFID) technology can provide objects identities, tracking and tracing. Some pilot projects have verified that it can enhance care quality, decrease medical errors, and increase both efficiency and effectiveness in healthcare resource deployment if RFID technology is applied.

In terms of economic value, there are many potential fields to implement RFID technology such as in biotechnology labs, pharmaceutical manufactories, medical appliance transportations, hospitals, and in extended healthcare service providers. Some of the applications may soon become killer applications if the government policy or some other factors trigger a mass-scale implementation.

An RFID network platform is necessary for spontaneous and innovative applications to proliferate, and the business model is important to the platform provider for stimulating and channeling innovations.

The level of information technology implementation in Taiwan's healthcare industry is high because hospitals need information systems compatible with the monopolistic from "National Insurance System" to apply medical expense. The research in the field of healthcare information management in Taiwan is also advanced because of the popularized internet infrastructure and universal users adopt rate.

Taiwan government has been paying considerable attention to RFID related industries, especially in healthcare industry. There are some government-funded pilot projects seeking to deploy RFID technology in hospitals. However, RFID implementation demands intensive and extensive data exchanges not only between levels but also across different organizations. This calls for a technologically robust and commercially sustainable platform.

This research proposes a business model for Taiwan's RFID network platform in healthcare industry. The result of research has been adopted by the Department of Health (DOH) and Ministry of Economic Affairs (MOEA) in Taiwan as guidance for future government-funded projects.

Conclusion

This research proposes a business model for Taiwan's RFID network platform in healthcare industry. We design

system architecture and the whole infrastructure for healthcare which reference from EPC Network in MIT. Based on the platform business model, we examined RFID applications in drug control, blood bag control, emergency medical service, and long-term care service.

There are some RFID pilot projects in healthcare which have verified that it can enhance care quality, decrease medical errors, and increase both efficiency and effectiveness in healthcare resource. An "RFID Network Platform" is necessary for spontaneous and innovative applications to proliferate, and the business model is important to the platform provider for stimulating and channeling innovations to drive the network effect in healthcare industry.

"RFID Network Platform" stands on a critical position in healthcare value chain. It's an important research issue for us to plan a suitable platform for healthcare to solve many existing problems in healthcare industry. And it will create many new business opportunity in the evolution about integrating RFID technology in healthcare.

The research is an exploratory study to investigate the planning and the developing strategy of "RFID Network Platform". In the future research, will reference more researches and reports from the "financial transaction platform in banking", "supply chain management (SCM) platform", and research about platform developing strategy. And finally, we will try to develop a model about the information platform developing strategy in healthcare.

Abstract

Objective: The objective of this study was to describe the development of a dynamic and interoperable clinical platform prototype designed by Emergency Physicians.

Method: The investigators used collaborative innovation approach.

Results: A disease specific clinical platform that streamlined information processing and incorporated clinical pathways and quality control into workflow.

Conclusions: Collaborative innovation and problem orientated approaches are required to develop effective health informatics solutions in Emergency Medicine.

Keywords:

asthma, decision support, collaborative innovation

Introduction

Implementation of interoperable health information technology (IT) platforms and electronic decision support systems (EDSS) are important strategic goals for future health systems around the world[1,2].

Acute asthma is a common cause of presentations to Emergency departments. Current evidence suggests that asthma management in Emergency Departments (ED) is inconsistent, resulting in suboptimal compliance with evidence-based guidelines[4,5,6,7]. We report on the first interoperable and dynamic EDSS developed by Emergency Physicians for use in ED.

Methods

Conceptualisation and hypothesis generation

Key to development was identifying problems and dilemmas facing clinicians in a busy emergency department. Some of the problems identified through consensus were multiple and disparate information or data entry points, inconsistent use of clinical pathways and lack of real time quality control mechanisms.

Literature review

We performed a literature search through Medline and relevant Health Informatics publications from 1996-2006 to identify examples of EDSS for ED

Field study

A feasibility study was undertaken by Health Information Specialists to review processes of care in the current ED environment

Collaborative innovation

This concept involves the collaboration of business and consumer partners to create new products or identify new trends based on consumer needs [8]. In this project a small group of clinicians and health informatics specialists (HIS) worked together to identify clinician needs and structure workflow models (Medical Systems Development and Research Group - see www.msdrg.org).

Clinical platform development

HIS and clinicians collaborated to model clinical workflows in ED. Rapid prototype engineering was employed to continually improve on the modeling process.

Clinical platform architecture

The system aimed to comply with the National E-Health Transition Authority (NEHTA) standard guidelines for electronic decision support systems [9]. The system was also developed to adhere with HL7 principles relating to semantic and functional interoperability [10].

System evaluation

The system was evaluated in three phases: internal beta testing, simulation trials using emergency department doctor performance and clinical implementation trials.

Results

Clinical platform development

Through collaborative innovation over 12 month period, an online interface known as the Asthma Clinical Assessment Form and Electronic decision support (ACAFE) was developed.

Clinical platform features

The clinical platform incorporated multi-environment display panels focusing on ED workflows. Panels were organised using pan-out user interface design and followed the logical steps from top to bottom and left to right. ACAFE offered decision support in several dimensions. This included support for clinical diagnosis and management plan processes. The system promoted uptake of evidence based guidelines through severity grading pathways. ACAFE allowed monitoring of various clinical performance indicators such as waiting times, consultation times and discharge rates.

Basic System Architecture

Minimum server operating requirements for ACAFE system included PC with Intel Pentium III™ compatible 700MHz processor, 512MB RAM, with Windows XP Professional Service Patch 2™ operating system. The system was hosted on Internet Information Services 5.1 and accessible via hospital intranet. Further details of the system can be viewed at http://www.ostechnology.com.au/product_acafe.html

Discussion

ACAFE was the first decision support system designed to solve specific problems relating to ED information flows and adherence to clinical pathways. This problem orientated process was achieved through collaborative innovation.

The result was a dynamic interoperable clinical platform which enabled streamlining and consolidation of ED documentation and facilitated use of clinical pathways. This was coupled with real time quality control features that allowed monitoring of trends and variations in clinical practice.

Conclusion

We have demonstrated that novel solutions to information processing problems in the ED can be created using collaborative innovation and problem-orientated approach. This has important practical implications for future EDSS developments.

Asthma Clinical Assessment Form and Electronic decision support (ACAFE) project

Dr Michael Dinh MBBS FACEM

Staff Specialist Emergency Department, Co-Director Trauma Services

Royal Prince Alfred Hospital, NSW Australia

Introduction and scope

- Emergency Departments (ED)
  - High acuity
  - Rapid patient turnover
  - Information and communication critical
- Sustainable solutions to clinical pathways, multiple data entry, quality control
- EDSS and integrated clinical management systems designed for ED

Objectives

- Demonstrate collaborative innovation for development of problem orientated solutions
- Develop integrated EDSS using asthma clinical pathway as prototype
- Demonstrate performance improvements using this system

Methods

- Conceptualisation
  - Multiple data entry
  - Inconsistent uptake of clinical pathways
  - Limited quality control
- Literature review
- Collaborative innovation
  - 12 month project
  - Emergency Physicians
  - Health Information Specialists
  - Workflow modeling, data fields and clinical pathways

Methods

- System development
- System evaluation
  - Internal
  - External
- Ethics approval

ACAFE System Evaluation Outcomes	
Category	Indicator
History	Asthma precipitating factors
	Previous Intensive Care admissions
Examination	Oxygen saturations
	Ability to verbalise (words, phrases, sentences)
	Chest ausculation findings
	Peak Flows (pre and post bronchodilator PEF)
	Asthma Severity (mild, moderate, severe)
Discharge	Written asthma plan provided
	Smoking cessation advice provided
	Oral corticosteroids

ACAFE FUNCTIONALITIES

Basic Functions	Patient registration and tracking
	Triage
	Clinical assessment forms
	Management summary
	Medication chart
	Electronic order entry
	Progress notes
	Discharge summary
	Discharge documentation
Clinical Document Management	Automated discharge summary
	Automated asthma management plan
	Treatment order field and management plan linkage
Electronic Decision Support	Asthma severity grading
	Suggested treatment pathways
	Allergy alerts
	Smoking cessation and asthma management plan advice
Performance management	Waiting times, consultation times, time of clinical review
	Alerts for missing data fields
	Tracking multiple patients along clinical pathway
Quality control	Waiting times
	Admission and discharge rates
	Investigation order entry trends
Potential functions	Automated GP electronic communication

Thematic Analysis of CPOE Implementation in Inpatient Settings Using Fit and Subjective Usability in the DeLone Model

Rekha Gaikwad [a], Elizabeth Keay [b]

[a] *Research Fellow, Faculty of Computer Science, University of Auckland, New Zealand*
[b] *Health Informatics Research Associate, School of Health Information Science, University of Victoria, British Columbia, Canada*

Abstract

Computerized Order Entry Systems (CPOE) are transformational technologies: their successful implementation is a process of change within complex healthcare settings. This paper presents a practical thematic analysis of a sample of the CPOE implementation literature. By using the concepts of subjective usability and fit within the Information System (IS) success model of DeLone and McLean, we show that models can be used to both organize themes and explain the concepts themselves. The DeLone model does not address change, however, therefore we suggest a broader context for the model. This study begins to address Kaplan's concerns about gaps in implementation knowledge of user acceptance and changes in work. It also provides a practical tool for organizing themes for future research. Increasing awareness about the IS implementation context will ultimately improve the safety and effectiveness of these systems.

Keywords:

attitude to computers, Computerized Physician Order Entry System, qualitative research, thematic analysis

Introduction

The healthcare system is a complex adaptive system and successful Computerized Physician Order Entry (CPOE) implementation is a process of transformation within these complex healthcare settings [2]. Success is difficult to measure. One way of assessing success is to apply established models of system implementation success as sources of themes that lead to success or, conversely, failure. Kaplan [1] feels that reviewing implementation is important because it is often ignored, it does not often concern issues of user acceptance or changes in work and finally, it does not examine processes of actual system use during daily activities. We begin to address the gap in the literature identified by Kaplan [1] with a thematic analysis of CPOE system implementation in inpatient settings.

An "efficient technology" is referred to as the one which reinforces current ways of working and performing ongoing tasks, and a "transformational technology" as the one which changes the nature of the work, as differentiated by Sviokla [3]. Physician order entry (POE) systems are transformational technologies [3]. To transform work practices requires an awareness of collaboration in healthcare [4].

The process of implementation of CPOE in an inpatient setting is successful only when the system satisfies the human end-users of the system. Satisfaction is a perception following the implementation of the system in an organizational setting. We examine a sample of the CPOE implementation literature with the concepts of fit and subjective usability within the IS success model of DeLone and McLean (Figure 1) [5]. We hypothesize that successful CPOE implementation means that the system has good fit at the organizational level and satisfaction at the user level as defined by subjective usability. There are several advantages to placing themes in a model: first, this helps to organize themes; second, and conversely, the themes may also begin clarifying the abstract concepts of fit and subjective usability; and third, there is a practical purpose in describing our approach that others might find useful.

Concepts used in this study

Fit. Kaplan describes fit as *"there are a variety of dimensions to 'fit,' including the following: workflow, level of expertise, professional norms, values, institutional setting, communication patterns, organizational culture, technology and information needs. 'Fit,' then, is useful for understanding implementation issues surrounding a particular system, why the same system may be viewed differently by different users, and also why it may be implemented more successfully in one setting than in another. 'Fit' also links evaluation and design."* [6]. We shall apply Kaplan's dimensions to the CPOE implementation literature to categorize organizational themes.

Usability. We use Hornbæk's model of usability as it provides the ISO 9241 standard usability definition as the *"[e]xtent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction [7]."* We shall be concerned with the satisfaction element of usability. Satisfaction is also difficult to measure as there are subjective usability mea-

sures of users' perception of or attitudes towards the interface, the interaction, or the outcome; and, objective measures using standardized instruments [7]. We shall use subjective usability to categorize user satisfaction themes.

DeLone and McLean's IS success model: the link for usability and fit

The IS success model of DeLone and McLean is an established construct for evaluating information system (IS) success as a process of understanding of IS and their impacts. van der Meijden et al. have established the usefulness of this model for system evaluations [7]. They used the 1992 version of the DeLone model. IS success is multidimensional and interdependent [8]. We felt this trait would be helpful for this thematic analysis of implementation of CPOE systems into inpatient settings. We have placed fit within net benefits because this both captures the higher level organizational dimensions of Kaplan and includes the organizational impact element of the 1992 model. Information, system, and service quality are not discussed here. Figure 1 shows the model adapted to show subjective usability and fit.

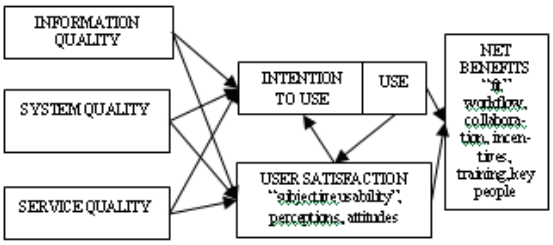

Figure 1 - Adapted from DeLone and Malone's updated D & M IS success model [5]

Methods

Literature Search

We performed a literature search using the terms "CPOE" OR "order entry" OR "e-prescribing" OR "electronic prescribing" or "electronic prescription" OR "computer prescription". This was to provide for the greatest search sensitivity. We interpreted CPOE for the purpose of this study broadly as a clinical information system [9]. The bibliographic databases PubMed. CINAHL, ISI Web of Science, and Compendex, were searched using the above search terms for the period ending November 1, 2005. Later a few articles were found incidentally. A start period was not specified. Since we found that the majority of the articles found in the other databases overlapped with those retrieved from PubMed, we used only the PubMed articles to maintain uniformity in the information and reduce redundancy of information. The bibliographies of the selected articles were not used to find additional references.

Study Criteria

The titles and abstracts of the articles were analyzed against the "inclusion" and "exclusion" criteria (Table 1) to obtain articles for the narrative review. The overall strategy was to review CPOE implementation in general within inpatient settings. A detailed reading of the included articles against the criteria allowed a further reduction in the study set to provide a final set that met the inclusion criteria.

Quality Assessment

The articles were then analyzed for their quality using assessment sheets based on the Critical Appraisal Skills Programme (CASP) appraisal tools [10] (The Quality

Assessment sheets for the selected articles can be provided on request to the authors).

Measure	Inclusion criteria	Exclusion criteria
Population	People: Physicians Inpatients Setting: Acute care	Outpatient, non-MD entry, primary care, ambulatory care, family practice, specific unit for eg. ICU, PICU, NICU
Intervention	CPOE implementation	CPOE specific manufacturers, design costing, cost/benefit, CPOE and: lab IT, radiology Information technology, health information system, decision support system, computerized information system, electronic health record, electronic medical record, guidelines, pharmacy information system, e-prescribing, specific drugs, dose calculators, barcoding
Outcomes	Human factors, usability	Changed behavior, test ordering, save time, benefit, medical error, safety, medication error, workload, nursing roles, education, training
Literature	Study type: evaluation, review, Medinfo proceedings, grey literature, expert opinion/consensus statement with evidence Language: English	Study type: editorial, opinion correspondence, commentary, interview

Table 1: Inclusion and exclusion criteria used for literature review for thematic analysis for CPOE implementation

Thematic anlysis

We undertook a simple qualitative narrative review that was concept-centric rather than an author summary [11]. This process is to identify and bring together the main, recurrent or most important issues or themes arising from a body of literature [12]. This technique was similar to the inductive approach described by Thomas [13]. This will be discussed further below. Nineteen articles met the inclusion criteria.

The quality assessment sheet had a section for themes: any comments or opinions about the CPOE implementation process were placed in this section. The sections were placed in a separate document. Re-reading of the comments and opinions permitted them to be grouped under concrete noun headings such as work, collaboration, barriers etc. Content analysis software was not used.

Results

Thematic analysis

"Fit" is a change of technology and workflow

Fit is a dynamic process [14]. Five articles describe fit as the relationship between technology and work practices or work flow [2, 4, 14, 15, 16, 17]. Fit is achieved through change or transformation of technology and work practices [14]. Some authors see only the technology as transforming work [3, 16], rather than a pure efficiency tool [3]. The organization's track record of making changes in the past influences these transformational changes as CPOE changes committee structures, member ship and accountabilities [17].

Encourage change: collaboration. This awareness can be fostered by educating all members of the healthcare team on the activities of other group members, so that each person understands what others do [16]. People work collaboratively when using clinical information systems and not recognizing this is a source of implementation failure [16]. Collaboration must also happen between administration and clinicians [18]. There must also be collaboration between problem solvers meeting regularly with users to work out procedural issues that cross boundaries [19].

Encourage change: training and support. Training and support are important tools to help staff change and accept CPOE. There must be extensive 24/7 support and a formalized training program before, during, and after implementation [18, 19, 20, 21]. Support must focus on problem solving to improve the system [19]. Problems will occur; they will be solved only if people focus upon how to make the system work better instead of being diverted by the question of whether the institution should be implementing CPOE [19]. Clinicians need to be educated about the potential long-term benefits of CPOE and remain open to the possibility of changes in their workflow [22].

Encourage change: incentives. These can include paid release-time fees to physicians to compensate them for time spent outside their clinical and administrative duties [16]. Incentive structures can also exist at the institutional level such as better access to care, better quality of care, lower cost of healthcare, lower administrative costs, improved patient management, and improved physician training incentives must be created to motivate each user

to adopt new medical technology [16]. Park et al. have attributed the high availability of CPOE systems to a combination of governmental encouragement, efforts and financial incentives and cultural characteristics in their study [23].

Encourage change: key people. Key people are identified as having universal attributes, including stability through adversity, steadfastness, initiative, and toughness [16]. These include: clinicians, top leadership, chiefs of staff, CEO, advisory groups, problem solvers [19, 21, 24, 25].

User Satisfaction is experienced as efficiency

Mekhjian et al. mention that they did not experience any significant negative results from CPOE implementation [21] though, others have experienced the opposite [22]. User satisfaction is increased when there is supportive administration and supportive heads of medical sections, direct involvement of physicians, mandatory implementation, adequate training, and sufficient hardware [25]. People who have *already changed and committed to a change* (emphasis added) focus more on issues surrounding actual implementation whereas those still contemplating the change are more concerned with the pros and cons [25].

The strongest correlates of CPOE satisfaction in the literature were efficiency characteristics such as productivity, ease of use, and speed. Van der Meijden et al. have a similar finding with a different reference set [8]: only our [4] was also discussed. The characteristics of CPOE that played a more significant role in changing the way the physicians made decisions about orders, such as reducing error and giving needed information were weaker correlates of satisfaction. In other words, although the technology itself was transformational, and patients and the hospital benefited substantively from improved quality and reduced costs, the users' satisfaction of the technology was primarily predicted by efficiency concerns [16, 21, 26]. Murff et al. suggest that the feedback of the physician's regarding satisfaction with the usage of information systems should be sought continuously and conclude that user satisfaction is a vital marker for usability of any information system [26].

Discussion

We reviewed a sample of the CPOE implementation literature that is based on inpatient settings use rather than experimental settings. The settings include the US, Holland and Korea. This points to the themes of CPOE implementation which cross boundaries. We see from the literature that fit is a key concept. Successful implementation means a good fit of technology and work practices. The literature suggests that change is necessary to achieve a good fit: some of the enablers of change are collaboration, training, support and incentives. These terms also help to define what fit is. User satisfaction also leads to fit. The users, primarily physicians in our literature, feel more efficient and are satisfied as a result.

Our thematic analysis showed that users who have changed focus on implementation and that there are enablers of change to enhance fit. The implementation process has been described as a "transformation" [2].The DeLone model does not address change. For convenience, we have placed the enablers of change within the context of organizational net benefit.

The difficulty in accommodating change into the DeLone model suggests that the DeLone model needs a broader context. Van der Meijden et al. state that the multidimensional construct of the model is appropriate for system evaluations [8]; however, change and transformation must also be captured.

Orlikowski and colleagues [27] discuss the implementation as change in a tripartite model (Figure 2): "first, the changes associated with technology implementation constitute an ongoing process rather than an event with an end point after which the organization can expect to return to a reasonably steady state; second, all the technological and organizational changes made during the ongoing process cannot, by definition, be anticipated ahead of time." They identify three types of change: *anticipated* or planned change; *emergent* or spontaneous change from local innovation; and *opportunity-based* or intentional change in response to an unexpected opportunity, event, or breakdown. The three parts of this model are interdependent.

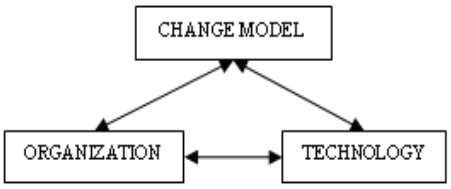

Figure 2 - Adapted from Orlikowski et al. [27; figure 3]

There is technology, or in our case, the CPOE system as described by the Delone model; the organizational context (culture, structure, roles and responsibilities); and the change model used to manage the three types of change listed above. The interaction among the three parts should be harmonious. Management can determine either a change model that is rigid with each step predefined and controlling events to fit the plan or flexible and responsive. This would require an explicit, ongoing examination and adjustment, where and when necessary, of the technology

and the organization [27]. In other words, there is constant change and feedback reacting with the system as our themes suggest.

Change and other themes could have been examined with a more rigorous method such as a general inductive approach [13]. This method uses detailed readings of raw data to derive concepts, themes, or a model through interpretations made from the raw data [13]. It is a tool used to describe the actual program effects, not just planned effects. The identification of any significant unplanned or unanticipated effects or side effects arising from program implementation can be seen as an important evaluation task [12]. The premise of evaluating effects in a structured manner would be very useful for implementation.

The outcome of an inductive analysis is the development of categories into a model or framework that summarizes the raw data and conveys key themes and processes. The category may also be linked to other categories in various relationships, such as a network, a hierarchy of categories, or a causal sequence [13]. This method is used to create models that might even show causation between satisfaction/efficiency and fit. For example, CPOE related adverse events [28] could be seen as a breakdown subjective usability and/or fit. It could also be used to examine the types of change identified by Orlikowski and colleagues [27].

Our method used an existing model, the DeLone and McLean's Information System (IS) success model to group themes, rather than creating a new model as in inductive analysis. This method is also useful to begin clarifying the concepts of subjective usability and fit themselves. This is a useful first step. Kaplan believes that because implementation is often ignored: implementation issues and barriers to system use are little different today from what has been reported over the past 50 years. This may be partly because post-implementation system evaluations often ignore issues concerning user acceptance or changes in work [1]. We find that there are limitations to the DeLone model because the change aspects identified in the literature and by Kaplan above are not easily accommodated in the model. We suggest the DeLone model addressing technology or systems be placed within a wider context of change model and organization. This would mean placing the DeLone IS success model in the "technology" construct of Orlikowski's model shown in
Figure 2.

Conclusion

We have addressed Kaplan's concern about user acceptance and changes in work by using subjective usability (user satisfaction) and fit respectively. We have used a sample of international CPOE implementation literature to find and organize some themes describing these concepts within an IS success model. Although the IS success model is useful for thematic analysis, more rigorous techniques of thematic analysis and a broader context for the IS model are needed to capture the transformational impact of implementation.

Thematic Analysis of CPOE Implementation in Inpatient Settings Using Fit and Subjective Usability in the DeLone Model

Rekha Gaikwad & Elizabeth Keay

Medinfo 2007

Acknowledgements

- Expert guidance of Dr. Michael Shepherd, Dalhousie University and Dr. Francis Lau, University of Victoria.
- Funding support from Canadian Institutes of Health Research (CIHR) Strategic Training Program (CHPSTP).

Introduction

- Healthcare system: a complex adaptive system.
- Successful Computerized Physician Order Entry (CPOE) implementation is a process of transformation within these complex healthcare settings.
- An “efficient technology” is the one which reinforces current ways of working and performing ongoing tasks and a “transformational technology” as the one which changes the nature of the work.

Objectives

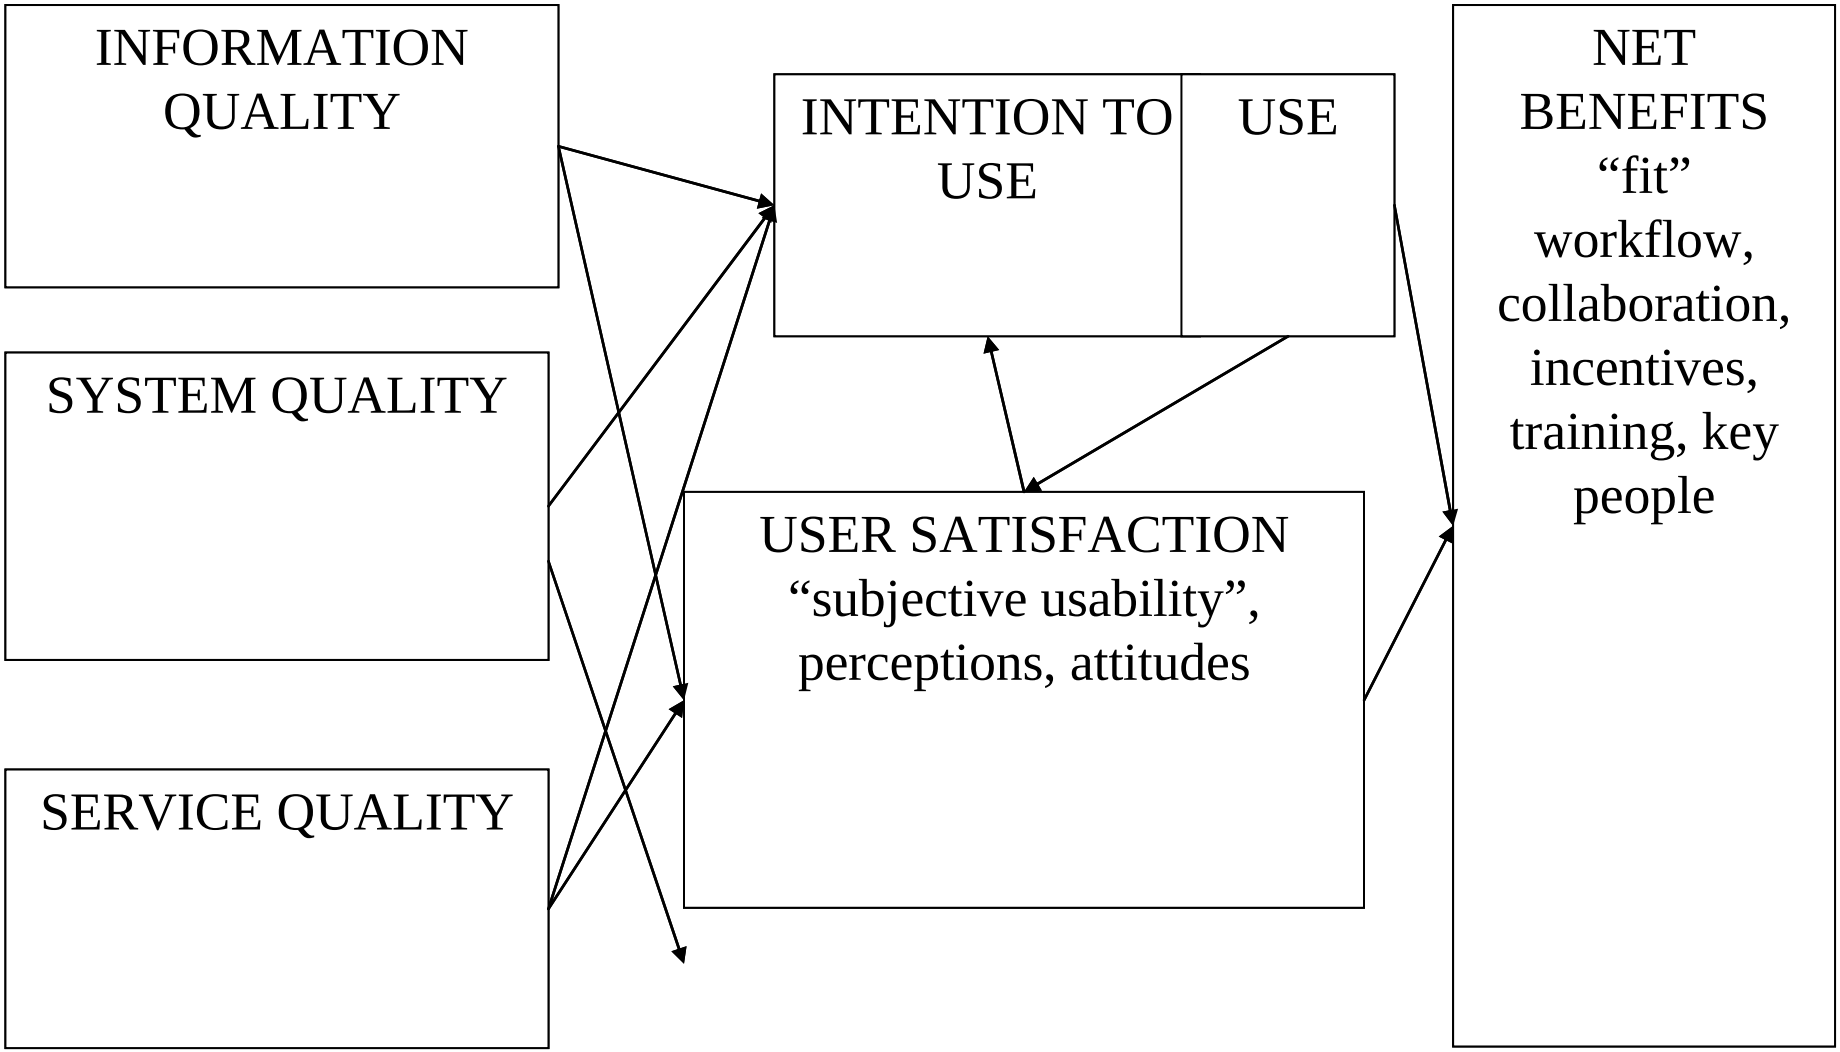
- Kaplan-reviewing implementation is important because: it is often ignored; it does not often concern issues of user acceptance or changes in work; and, it does not examine processes of actual system use during daily activities.
- We hypothesize that successful CPOE implementation means that the system has good fit at the organizational level and satisfaction at the user level as defined by subjective usability.

Concepts Used

- **Fit:** Dimensions to fit: workflow, level of expertise, professional norms, values, institutional setting, communication patterns, organizational culture, technology and information needs.
- 'Fit,' is useful for understanding implementation issues surrounding a particular system, why the same system may be viewed differently by different users, and also why it may be implemented more successfully in one setting than in another.

Concepts Used

- **Usability:** We use Hornbæk's model of usability as it provides the ISO 9241 standard usability definition as the ''[e]xtent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction. We shall be concerned with the satisfaction element of usability.
- We examine a sample (19 studies) of the CPOE implementation literature with the concepts of fit and subjective usability within the IS success model of DeLone and McLean (next slide).



INFORMATION QUALITY
SYSTEM QUALITY
SERVICE QUALITY
INTENTION TO USE
USE
USER SATISFACTION
"subjective usability", perceptions, attitudes
NET BENEFITS
"fit"
workflow, collaboration, incentives, training, key people

Results: Thematic Analysis

- **“Fit” is a change of technology and workflow**
- **Fit is a dynamic process.**
- Fit is achieved through change or transformation of technology and work practices. Some authors see only the technology as transforming work, rather than a pure efficiency tool. The organization’s track record of making changes in the past influences these transformational changes as CPOE changes committee structures, membership and accountabilities.
- **Encourage change: collaboration**
- People work collaboratively when using clinical information systems and not recognizing this is a source of implementation failure.

Results: Thematic Analysis

- **Encourage change: collaboration.**
- Awareness can be fostered by educating all members of the healthcare team on the activities of other group members, so that each person understands what others do.
- Collaboration must also happen between administration and clinicians. There must also be collaboration between problem solvers meeting regularly with users to work out procedural issues that cross boundaries.
- **Encourage change: incentives.**
- These can include paid release-time fees to physicians to compensate them for time spent outside their clinical and administrative duties. Incentive structures can also exist at the institutional level such as better access to care, better quality of care etc. Incentives must be created to motivate each user to adopt new medical technology.

Results: Thematic Analysis

- **Encourage change: training and support.**
- Training and support are important tools to help staff change and accept CPOE. There must be extensive 24/7 support and a formalized training program before, during, and after implementation.
- Problems will occur; they will be solved only if people focus upon how to make the system work better instead of whether the institution should be implementing CPOE.
- **Encourage change: key people**.
- Key people have universal attributes, including stability through adversity, steadfastness, initiative, and toughness.
- These include: clinicians, top leadership, chiefs of staff, CEO, advisory groups, problem solvers.

Results: Thematic Analysis

- **User Satisfaction is experienced as efficiency**
- People who have already changed and committed to a change focus more on issues surrounding actual implementation whereas those still contemplating the change are more concerned with the pros and cons.
- The strongest correlates of CPOE satisfaction in the literature were efficiency characteristics such as productivity, ease of use, and speed.
- In other words, although the technology itself was transformational, and patients and the hospital benefited substantively from improved quality and reduced costs, the users' satisfaction of the technology was primarily predicted by efficiency concerns.

Conclusion

- We have addressed Kaplan's concern about user acceptance and changes in work by using subjective usability (user satisfaction) and fit respectively.
- We have used a sample of international CPOE implementation literature to find and organize some themes describing these concepts within an IS success model.
- Although the IS success model is useful for thematic analysis, more rigorous techniques of thematic analysis and a broader context for the IS model are needed to capture the transformational impact of implementation.

Challenges to the Regional Comprehensive Electronic Health Record (rcEHR) - the Experiments in Koriyama

Yoichi Ogushi[a], Yasuo Haruki[a], Hisao Hara[b]

[a] *Department of Medical Informatics, School of Medicine, Tokai University, Japan*
[b] *Koriyama Medical and Nursing-care Hospital, Japan*

Abstract

This paper reports on our efforts and the further challenges that we are having in our experiments in Koriyama. We have been developing electronic medical charts and health examination databases for medical and healthcare facilities, as well as eHealth cards and computer network systems on a regional basis. By integrating all of these functions, we have developed the Regional Comprehensive Electronic Health Record (rcEHR) in Koriyama. This paper explains the solutions to common problems generated in EHR development on a regional level, and upcoming challenges.

Keywords:

personal health database, eHealth card, medical record

Introduction

In Japan, the sharing of health checkup results and medication information on a regional basis began as the eHealth Card system around 1995. The Japanese government has experimented with numerous business models using the electronization of health insurance cards as its ultimate goal. However, there are just a few regions where the operations are still currently available. In regard to regional healthcare via computer networks, even though the government initially poured a sizable budget into the development of the system, an issue remains regarding its sustainability because of lack of personnel and economical reasons due to the elimination of the subsidy.

Without relying on the national budget, we have developed such systems as electronic medical charts, electronic health cards, regional medical computer networks, and a database of health checkup results. In these systems, operability, economical efficiency and interoperability have all been taken into consideration. The systems have been used for the past 20 years, and are well-established in many regions. This paper reports on the sustainable systems we have developed by integrating these operations in Koriyama in Fukushima Prefecture.

Methods

We are providing patients with their medical records and health data via electronic media used in digital cameras or cellular phones. We have named these systems My eChart and My eHealth Card respectively.

For medical and healthcare service providers, computer systems are needed to improve the efficiency of each operation at their facilities. Thus, we have developed electronic medical charts for medical facilities, an information system to record health checkup results and issue notifications for health examination clinics. Additionally, we have also developed a health checkup results database and an information system to support health guidance for the facilities. Moreover, from these systems, My eCharts and My eHealth Cards can be downloaded onto personal electronic media systems.

In regard to sharing health information between regionally-based medical and healthcare service providers, there are many restrictions in terms of time and amount of data when using patients' portable media systems. Since Internet communication is more convenient, we provide regional medical information sharing systems via highly encrypted networks.

In June 2006, we began using the electronic medical charts and My eCharts at Koriyama Medical and Nursing-care Hospital. Figure 1 shows an example of the medical imaging displayed on My eCharts. In September, we began using My eHealth Cards for workers that contain the data for physical examinations, physical fitness tests and nutritional assessments at the Health Promotion Foundation of Koriyama. We also began My eHealth Cards to provide elderly people with their general health checkup data at the Public Health Center in Koriyama. Figure 2 shows an example of the time-line graphs of the health checkup results in My eHealth cards. In April 2007, we started regional medical network to share patients' data.

Results

1. Operability

We applied the touch-screen system to our electronic medical charts. The terms, phrases and illustrations used by

each doctor are programmed into the system as a table beforehand, and this reference table will be displayed on the entry screen so that the doctor can enter data with the touch-screen. For My eCharts and My eHealth Cards, the patients will see the same screen that the doctors or health nurses do. These systems enable the patients to refer to their personal health information at home or at work without going through any special training on its operations.

2. Easiness to provide My eChart or My eHealth Card

By just clicking the data-providing button on the guidance screen for the patients, personal data will be downloaded automatically onto their My eChart or My eHealth Card. The access program, the execution environment such as DLL or OCX files, and the operation manual in the HTML format are also transferred all at once. This process takes only a few seconds and hardly affects day-to-day operations.

3. Security

The regional medical networks can be accessed only by the registered medical or healthcare specialists. An encrypted password is issued for each user as personal authentication in accessing the networks. SSL is used for communication to prevent interception. Since the data is encrypted and registered in the database in real time, it cannot be decoded through unauthenticated access (Figure 3).

4. Coexistence of applications among facilities

Coding schemes, examination methods and reference intervals, screen designs, and development environments often vary from facility to facility or from region to region. We are providing health data to the patients' media systems along with the programs and the execution environment. On the patients' media systems, we create folders for each facility, put their data, programs, tables and execution environment in them, and use each folder for one object. By using this method, even the systems developed by other manufacturers or vendors will be able to co-exist in a single patient's' media system.

Discussion and conclusion

The interoperations are considered to be the key element, and the standardization of communication protocols and coding schemes is in progress. Moreover, it is not easy to integrate information systems that have been developed and operated by each facility and organization. But, especially with the rapid increase of medical accidents and expenses, EHR is in such a high demand as measures against them that there is no time to wait for standardizations.We are aiming to create interoperations by implementing applications as objects although this is still on a regional basis. The sustainability of the systems is not proportional to the amount of money invested. Sustainable systems are the ones that have gradually been developed and have had functions added to them based on the needs and practical uses in the region. The foundation to support the sustainability of EHR systems can be seen in the prerequisite of the systems. It is believed that the interoperation of the EHR systems will lead to medical safety and the reduction of medical costs through the reduction of duplicate checkups, the prevention of dangerous drug interactions, support for doctors' treatment policies, effective healthcare guidance, and self health care. Having experienced further challenges in Koriyama, we are planning to assess these outcomes quantitatively and clarify the overall effects including extension of healthy lifetime.

"To tell or not to tell?": Incorporating Disclosure and Privacy Requirements in Web Portal Design for Malaysian Cancer Patients

Nasriah Zakaria

Universiti Sains Malaysia, Penang MALAYSIA

Abstract

Cancer patients need to disclose their health information to their disclosure network: a group of people who patients disclose sensitive health information. The disclosure process can be done using oral as well as communication technologies like telephone and the Internet. In this paper, I propose a research agenda to ***get requirements from cancer patients and their disclosure network to build a web portal for cancer information management.*** *A web portal is conceptualized as a website set up by healthcare providers whereby patients have the ability to import necessary information (monitored and verified by healthcare providers) from their electronic medical record to disclose information to their disclosure network. Patients need to make active decision who and when to disclose as well the depth and level of information to share with others. This paper will outline the importance of the research, the methodology and expected outcomes from this research.*

Keywords:

Web Portal, disclosure, privacy, cancer information

Introduction: Health disclosure

Self-disclosure is defined as "any message about self that one communicates to another" [6]. In this paper, I will use the term self-disclosure and disclosure interchangbly. The topic has attracted scholars from diverse fields – communications, information studies, social psychology, sociology, and psychology. Northouse and Northouse (1998) presented five variables in health communication, where disclosure is one of the central variables that determine the effectiveness of communication. The authors discussed disclosure as a variable since the presence (or absence) of disclosure facilitates (or impedes) effective health communication among patients and medical teams.

Numerous studies have examined disclosure of health information. These studies looked at the content, frequency and consequences of self-disclosure in different medical situations and raised different issues of disclosure, but frequently ignored the balance between disclosure and privacy issues (Cozby, 1973; 17]. Wiener et al. (1996) explored the process of disclosure and consequences among HIV patients and their support network. It examined the caregiver-patient dyad it did not discriminate between the different roles of caregivers during the coping period, thus we are unable to conclude what specific roles are crucial for effective communication with the dyad. Another study [1] explored how family and caregivers cope with cerebral palsy, and found that support network members were dissatisfied with the information disclosure activities. That study also determined that factors such as the age of the child, the timing of diagnosis and the severity of physical disability influenced information disclosure. At the end, the study suggested "best practice" guidelines for disclosing the diagnosis of an illness to the support network. Contro et al. (2002) showed that some family members such as siblings were often not included during the information disclosure process; this in turn caused the siblings to feel "left out" of the coping process.

A few studies pointed out the lack of empirical work in understanding self-disclosure among medical teams and family in chronic illness situations [2, 5]. Families also made it clear that they wanted more information from the medical teams in order to be able to provide the appropriate support for the patient [2,9]. Other recent research on self-disclosure in healthcare examined different situations, contexts and issues as well as the nature of relationships. Topics examined include the process of disclosure (e.g. content and frequency) and its consequences [9], the dyad relationship during disclosure[14,22], practices for disclosing illness [1], disclosure of chronic illnesses [2,5] functional perspectives on health disclosure [7], privacy and disclosure [21], and the influence of illness, relationship and information-seeking on disclosure [4]. Recently, self-disclosure research in healthcare has begun to pay attention to the larger group of people involved in patient care – friends, employers, spiritual groups and self-help groups. Petronio and her colleagues (2004) explored the role of these "informal advocates" by examining the self-disclosure behavior of family and friends when they were present during a patient's visits with the physician and/or medical team.

All the empirical work mentioned above informs the question of self-disclosure in various medical situations. However, it is clear that little work has been done on the disclosure of health information using Information and Communication Technology (ICT) , specifically using web portal. Thus it is a good candidate for exploration using grounded theory, when little is known about a topic.

ICT for health disclosure

There are numerous of health websites resided in the World Wide Web today. Most of them provide health information on specific illness, treatment, drugs and rehabilitation. Websites like WEBMD (http://www.webmd.com/) and Ask Dr. Greene (http://www.drgreene.com/) are moderated by healthcare professionals and they are endorsed as one of the most reliable and trustworthy health websites. There are also many social support type websites that provide emotional support and information sharing among patients and family members. In addition, there are also new research developments for health web portal. There are many different elements that go into the web portal. For an example, a group of researcher designed and developed a diabetes web portal where patients are able to import "diabetes care plan" from their electronic medical record. Patients were able to use this information from the portal to make decisions on their own diabetes care management [8].

The focus of this research is to explore the possibility of using health web portal for health communication. The web portal has to have the ability to import medical record so that patients can use the technology to disclose information to others. The uniqueness of this research is to explore the disclosure and privacy requirements for the web portal design.

The Malaysian Government, under the Multimedia Supercorridor (MSC), has invested billions in ICT infrastructure to support Telehealth (http://www.telehealth.com.my/portals/myhealth/) projects around of the country. One of the main projects is to develop a website called Telehealth to provide credible and trustworthy health information in Malaysia context. The mission of the web portal is to enhance the quality of health among Malaysians. However, there is no cancer-specific web portal has been developed for patient communication. Thus, the outcome of this research can merge with the existing initiatives in MSC.

Methods

There are two stages for this research; the first one is to get the requirements on disclosure and privacy from patients. The technique proposed in this stage is using face to face interviews and grounded theory analysis. In the second stage, I propose to conduct software prototyping to evaluate the usability of such portal. This involves the development of desired prototype and a think aloud technique to capture user satisfaction on using the prototype.

Stage 1: Interview with patients

An interview is defined as a construction of knowledge [10] or as a "purposeful conversation, usually between two people but sometimes involving more" [13, page 93]. "Purposeful conversation" here means that interviewers have chosen a specific topic that both interviewer and interviewee can explore and discuss at length. An interview is a tool with which to elicit information from a participant, to find out his or her perceptions, meanings and construct of reality [16]; its purpose is to gather what people say about their perceptions, feelings and behaviors.; its purpose is to gather what people say about their perceptions, feelings and behaviors.

As part of my preparation, I reviewed literature pertaining to conducting interviews. From several previous research projects, I had prior experience conducting interviews with patients, family members and medical personnel in a hospital setting as well as with undergraduate students and these experiences enhanced my confidence in my ability to conduct interview-based research.

This study employed face-to-face semi-structured interviews. Interviews will be conducted wherever the subject feels comfortable. With the subject's permission, I will record the interview session using an audiotape recorder. If respondent refuse to be taped, I will take notes during the interview.

Interview protocol

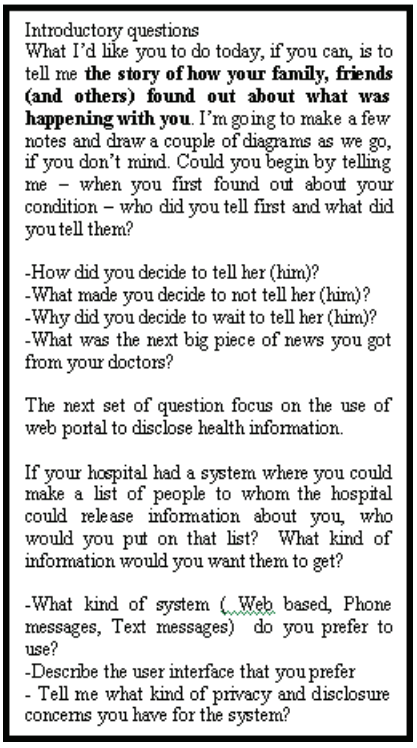
I have developed an interview protocol to start up interviews with cancer patients. I designed a protocol with a background question that asks patient's disclosure behavior when dealing with cancer. Then, I created some questions to elicit the requirements for the future web portal (Figure 1). These questions will be modified based on the feedback by the subjects.

Sampling

Research subjects comprised of medical patients in Malaysia. I will select patient with any types of cancer illness. I chose cancer illness because it is one of the leading illness in Malaysia [11]. The annual incidence of cancer was 30,000 in the year of 2000. Cancer illness has a predictable prognosis where patients have some flexibility in planning either their treatment, recovery or facing end of life situations. With this existing factual in Malaysia, it is appropriate to explore how to build a cancer specific web portal for cancer patients and their disclosure network.

Research subjects will be selected using a convenient snowball-sampling technique. The technique is convenient in the sense that respondents are recruited based on whoever who meet the criteria and was available for the interview. Using the snowball sampling technique, I will identify research volunteers based on others' recommendations [3]. Many patients who would have been reluctant to discuss their illness with a stranger were more open and willing to talk when approached by someone with whom they were comfortable. A snowball-sampling technique

takes advantage of the natural human tendency to extend trust through social relationships, since the interviewer is implicitly endorsed as trustworthy by the participant who provides the referral.



Introductory questions
What I'd like you to do today, if you can, is to tell me **the story of how your family, friends (and others) found out about what was happening with you**. I'm going to make a few notes and draw a couple of diagrams as we go, if you don't mind. Could you begin by telling me – when you first found out about your condition – who did you tell first and what did you tell them?

-How did you decide to tell her (him)?
-What made you decide to not tell her (him)?
-Why did you decide to wait to tell her (him)?
-What was the next big piece of news you got from your doctors?

The next set of question focus on the use of web portal to disclose health information.

If your hospital had a system where you could make a list of people to whom the hospital could release information about you, who would you put on that list? What kind of information would you want them to get?

-What kind of system (Web based, Phone messages, Text messages) do you prefer to use?
-Describe the user interface that you prefer
- Tell me what kind of privacy and disclosure concerns you have for the system?

Figure 1 - Interview Protocol

Data analysis

Grounded Theory is a qualitative data analysis technique that serves several purposes [20, page 24]: immersion in the real world situation to gain a deeper understanding of the research phenomena, formation of a theoretical framework that arises from the data itself, and comprehension of the process of change in real situations.

Analysis and coding will begin as soon as the first interview ends and continues until the last interview is completed and coded. Grounded theory recommends that data analysis take place in parallel with data collection [12] so that the researcher is able to make ongoing adjustments to the existing data collection process. For example, analysis of subjects' responses in the first few interviews may suggest new dimensions and directions for subsequent interviews. Ongoing data analysis in parallel with data collection also encourages the early discovery of new insights rather than waiting until the end of the entire data collection process.

Stage 2 study

In the second phase, the main research goal is to expose users to a web portal prototype and to evaluate user acceptance. The focus will be on user interface for the portal where I will explore factors that influence patient to use web portal to disclose sensitive information. Since there is no specific web portal exists yet for patient to communicate and disclose sensitive information with their disclosure network, I would like to employ a socio-engineering approach. With this approach, I will develop a software prototype and refine the design iteratively by incorporating end user needs at every stage. An adaptation of a software engineering approach called rapid software prototyping [19] will be applied to my socio-engineering nature of work.

In creating a "universal" web portal that could be used by patients all over the world, no single theory that can inform the best web portal design for disclosure activities. This is because there are many technological, human, situational and institutional factors that could influence the final product. It is a very complex design and development process to create a "one for all" system, thus a qualitative combined with rapid software prototyping approach seem to be most suitable way to proceed. In this optimization approach, researcher will try to maximize the user acceptance into system design and development. The end goal of this research is to develop an appropriate ICT innovation that could enhance social interaction among cancer patients and their disclosure network. This ICT innovation could also be incorporated in the existing telehealth system in Malaysia.

Using the rapid software prototyping approach, the main research activity is to create an artifact based on a rough approximation. The artifact will be tested and refined according to user feedback. For my research problem, I will develop the first version of the web portal using the effective web design guide. In each stage or version, I will carefully observe and document users' perception on multiple outcome variables like sense of privacy, usefulness and ease of use of the web portal. One possible way to capture users' perceptions is by using a "think aloud" technique. We can also use a technique called "aggregation" to quantify the system outcome. After each data collection, I will incorporate the users' suggestions and make necessary changes in next version of the program. I will then repeat the data collection process with end users until I find their suggestions reach saturation. I will need to observe all the outcome variables over time. The proposed duration of this prototyping process is between six to nine months. The key of this methodology is the iterative refinement process based on users' needs when they want to disclose sensitive health information over the web portal.

Expected outcomes

This research will be conducted over the duration of 24 months beginning of January 2007. It is fully funded by the Malaysia Cancer Council (MAKNA) as part of its annual cancer research award. The expected outcomes are the following:

1. a list of requirements addressing the disclosure and privacy concerns on cancer-specific web portal.
2. a web portal prototyping processes with user feedback.
3. a well developed web portal prototype.

Acknowledgement

This research work is funded by Malaysia Cancer Council (MAKNA) to facilitate the understanding of health communication through the use web portal among cancer patients and their network in Malaysia. I would also like to acknowledge Dr. Jeffrey Stanton from School of Information Studies, Syracuse University for his guidance in Information Privacy issues in health care setting.

Darwin Revisited: Lessons Learned fromA Decade-long Evolution of a State-wide RHIO

Julie J. McGowan[a,b], Cy Jordan[c], Thomas Sims[d], J. Marc Overhage[a,b,e]

[a] *School of Medicine, Indiana University, Indiana;*

[e] *Indiana Health Information Exchange, Indiana, USA*

Abstract

Regional Health Information Organizations (RHIOs) in rural areas promise improved health care for many underserved populations. However, implementation in rural areas faces many challenges. One of the most rural states in the United States is in the process of creating a second comprehensive health information network and offers an opportunity to look at success factors for implementation of rural RHIOs. Methods: Documentation was reviewed and summarized and a core group of Vermont Information Technology Leaders (VITL, Inc.) were interviewed to ascertained lessons learned in the development of Vermont's RHIO. Results: Lessons were grouped into five major categories: early planning, organization, education and marketing, technology, and financial sustainability. Conclusion: There are a number of commonalities about all RHIOs but also a number of differences predicated on location. RHIOs must remain dynamic and learn from others in order to survive.

Keywords:

community networks; computer communication networks; medical records systems, computerized

Introduction

The development of the RHIOs in rural areas could make a major impact on health care in these traditionally underserved areas. However, there are major obstacles to implementation. The capital investment required to create a health information exchange and income to operate it are more difficult to acquire in a rural environment. The low density of providers in rural areas precludes ready distribution of costs.[1]

Other factors hindering implementation of HIT in rural areas include lack of health care professionals with HIT or medical informatics training to assist in the selection of appropriate systems and foster confidence among end users and lack of wide-spread access to high-speed networking infrastructure. The Stark legislation targeting elimination of perceived kickbacks and current IRS laws have hindered rural adoption of HIT.

Vermont, arguably the most rural state in the United States, is in the process of creating its second RHIO and offers a unque testbed to identify facilitators and obstacles for RHIO development. These issues and the organizational strategies for responding to them have resulted in the formulation of a set of guiding principles or lessons learned that could assist others in the planning of small local or much larger area RHIOs. While all RHIOs are unique, they also share certain general problems and solutions. It is this set of problems and solutions, many of which are common to both iterations of Vermont's health care network, that could contribute to future RHIO development in rural areas.

Methods

To understand the issues we reviewed documents and presentations created during the development of VTMEDNET[2] and from VITL (Vermont Information Technology Leaders, Inc.), the core development group of the current statewide RHIO[3], in order to identify parallels between the two efforts.

In addition, we completed structured interviews with three of the key leaders of VITL and the Chief Information Officers (CIOs) of two of the state's twelve hospitals who had been active in the creation of VITL. All of those interviewed were part of VITL from its inception.

Results

There are major parallels between the creation of VTMEDNET and VITL and these alone offer some lessons that could be used in beginning the process for establishing a RHIO. However, the lessons learned from the interviews and documents pertaining to VITL take understanding the development process and the success factors to a new level.

Both network iterations began with a dedicated core group of visionaries who identified key stakeholders and tried to

garner buy-in from the groups or at least their representatives. Both sought to ascertain the one project that would meet the greatest need and have the greatest impact in terms of getting support from the participants. Both started small and grew in increments. Similarities continued, but the more mature RHIO concept presented some obstacles and offered some opportunities not present in the earlier network.

Data control is critical to today's health care environment. The need to feel that data is protected extends beyond protecting patient confidentiality. Regardless of the level of cooperation, some degree of competition exists among health care organizations when catchment areas overlap. This is magnified when those catchment areas cross state boundaries.

The solution to data control will vary among RHIOs. Some prefer a totally distributed and linked model; some prefer a centralized data repository. However, many chose a federated model that incorporates both accessing discrete data from hospital and health care institutions while ownership remains within the organization and storing other forms of data in a central repository.

Learning from others is critical to understanding issues, however, structuring the administration of the RHIO is virtually always local and problematic. This is some ways mimics the question of data control. With RHIOs, there are a large number of key stakeholders, all wanting some level of decision-making authority. Two lessons gleaned from the earliest beginnings of VITL were the need to have detailed Bylaws laying out the membership of the board and the process of making decisions and the need to have one or more attorneys on retainer.

Very early in the planning stages, a needs assessment of the key stakeholders should be undertaken. This serves two purposes. First, it identifies the initial pilot project that could have the greatest impact in demonstrating the value of the RHIO. Secondly, it can serve as a tool to educate those who will be actively involved in the process of creating and supporting the RHIO.

Education of key stakeholders is vital to sustainability. Healthcare providers need to understand the value of the RHIO and why they should be willing to alter their workflow and pay for its use. Patients need to be educated about how the RHIO will improve patient safety and the steps being taken to insure privacy. Legislators, payers, and private industry managers need to be educated about how the network has the potential to improve the quality of care and reduce costs. Education is a marketing tool for sustainability.

While most people implementing such systems state that the technology is not the problem, VITL found that this was not entirely true. Interoperability among hospital systems, all in various stages of implementation, would prove challenging so the vendor selected needed to provide a high level scalable and sustainable system architecture that would handle HIE.

The decision to begin with a pilot project and only two hospitals has enabled the technology issues to be resolved, thus avoiding costly missteps and mitigating some of the issues encountered over wider areas with fewer providers. Another lesson learned from others but proving invaluable was the need to understand and address workflow issues to insure that the providers at the point of care have the least disruption to their work, thus achieving greater system use.

Finally, the inability of a fledgling RHIO to address financial issues and sustainability has been one of the major contributors to RHIO failures. VITL is exploring several financial models as part of its requirement to create a Vermont Health Information Technology Plan. Most agree that the state of Vermont needs to have a major financial stake in the development and maintenance of the network and treat it as a community utility, although difficult in a rural state with limited financial resources. However, there is also a role for payers and business to play in its sustainability as they will be major beneficiaries.

Conclusion

Health information exchange fostered by the creation of RHIOs holds the promise to improve the quality of care and reduce health care costs, particularly in rural areas. However, regional health information organizations are challenging to establish. They are composed of different healthcare organizations with sometimes differing and even conflicting missions. While the goals of RHIOs are virtually all the same, the obstacles and opportunities in their creation can differ depending on their localities.

A Successful StrategyAddressing Wait Time and Matching Patient's to their Records

Sarah Kramer[a], Lorraine Fernandes[b], Susan Hyatt[c]

[a]*CancerCare Ontario, Toronto, Ontario, Canada*
[b]*Initiate Systems, California, United States*
[c]*HyattDio, Toronto, Ontario, Canada*

Abstract

Matching patients and healthcare providers has new importance as nations embrace electronic health records (EHRs) and define strategies for enhancing healthcare delivery. Silos of data are broken down in the new electronic world, striving for increased patient safety, better customer service, and more cost-effective healthcare.

Long wait lists prove the bane of customer satisfaction, government policy, and effective use of resources. Matching patients to their records across the data silos is fundamental, while maintaining the integrity, confidentiality, and security of information.

The Province of Ontario developed a strategy to reduce wait times for select procedures, addressing a chronic problem of long waits for diagnostic or surgery modalities. Ontario developed a provincial Wait Times Information System (WTIS), capturing data critical to monitoring and determining best use of resources. Now used by 1700 hundred physicians at over 60 sites, WTIS has contributed to significantly reduce wait times for cancer surgery, sight restoration, hip and knee replacement, cardiac surgery and MRI/CT – which is all now publicly reported on a regular basis.

Keywords:

EMPI – Enterprise Master Person Index,
EHR – Electronic Health Record, Canada Health Infoway,
probabilistic algorithms, wait list(s),
Cancer Care Ontario, patient matching

Introduction

Canada is blazing a trail in establishing EHRs based upon blueprints developed by Canada Health Infoway, a government funded agency that oversees and disseminates healthcare funds, and addressing the customer satisfaction issue of wait lists. The Province of Ontario is breaking additional new ground through addressing wait lists for specific treatment modalities by using an electronic master person index (EMPI) as a primary tool to create the client registries necessary for EHRs and manage a complete view of patient care.

In order to ease and validate patient data entry, ensure appropriate matching of patient information across care sites; and to track when patients are on more than one list, Ontario concurrently implemented a provincial client registry. It was also understood that implementing this core piece of infostructure at the same time as a business focused consuming system was put in place would enhance adoption and prove utility of the service in its first implementation. Neither privacy nor security of personal health information is compromised in this strategy. In fact, rigorous attention at all levels of policy development and strategy deployment has been paid to this key public issue.

Learn how the strategy was created and implemented and could be applied to numerous problems that plague the healthcare delivery system, irrespective of the country or continent.

Methods

In case study format, the presenters will explore the wait list problem, the solution set defined to address the problem, and the implementation that enabled the Province of Ontario to execute a Wait List strategy and the provincial Client Registry. Additionally, the presenters will address the Infoway blueprint for client registry and how this as served as a model for interoperability and effective use of healthcare resources.

The Province, through its Client Registry deployment, is currently managing 45M records across 100 disparate source systems and has integrated the enterprise master person index (EMPI) with the Wait Time Information System (WTIS). At full deployment, anticipated for June 2007, the WTIS will serve all of Ontario and encompass approximately 50M records and 130 source systems.[1]

Noteworthy throughout strategy development and execution is the emphasis on privacy and security of personal health information, as the WTIS developed and Implemented a Privacy Policy[2] structured around the ten fair information practice principles of the Canadian Standard

1 Ontario Cancer News. WTIS/EMPI -- Making better access to care possible. 2006; 4(5).

Association's Model Code for protection of Personal Information. [3] This emphasis was defined during planning and followed in design and implementation.

Results

From the time of contract signing for the client registry software, the implementation took nine months to fully implement the provincial EMPI, and to achieve 90 percent capture with the provincial WTIS. Multiple vendors and provincial staff worked in cohesive teams to address the core objectives and document results. Results achieved to date show a reduction of 27 percent for cataract surgery, 20 percent for knee replacement, 39 percent for angiography, and 18 percent for angioplasty. The final 10 percent for WTIS will be captured by the end of June 2007.[4]

All hospital and procedure specific data is regularly reported on the Government's website (ontariowaittimes.com) – where the 1.8M hits indicate public and media interest in results. Data generated served as a rationale and impetus for the Government to invest an additional amount of greater than $100M (Canadian Dollars) to bring problem procedures in line with wait time targets established by clinical experts

This phase will include active integration to the source systems through recognized standards consistent with the Canada Health Infoway blueprints.

Discussion

Attendees of this session will be able to:

- Gain an understanding of Canadian client registries and the registry's role in achieving an EHR
- Learn how a complex project plan with multiple vendors (under separate contract) and distinct objectives can be managed.
- Describe the necessary infrastructure for a successful wait list solution
- Recognize the process of how patient data can be successfully stored, retrieved, secured, and linked with an EMPI
- Develop strategies that address breaking down silos of data in order to enhance patient safety, customer satisfaction, and more cost effective healthcare
- Discuss the correlation between Canada's healthcare system, including Client Registry and Wait List, and those in Australia and other countries

Conclusion

Increased customer satisfaction and enhanced patient care are immediate benefits of Ontario's Wait Time Information Strategy (WTIS). Key to achieving these results in a very short timeline were a clinical business focus, strong project management, meticulous planning, service level agreements with the vendors, strong stakeholder relations, and a clear focus on defining and achieving success. Achieving this has allowed Ontario to make prudent additional investments for specific procedures since success metrics have been defined, and return on investment has already been met for the initial phases of the WTIS.

Attendees will have the opportunity to learn from the advanced efforts of a government-funded system and learn success strategies that can be applied to the global wait time problem. Timelines, key elements, success strategies and pitfalls to avoid will be discussed.

Abstract

Computer systems, often called hospital information systems (HIS), have been installed in most large Japanese hospitals. In almost all cases, HIS have a server/client type structure connected by a LAN. For voice communication among the hospital staff, a landline telephone is often used. The potential demand for the introduction of wireless communication devices for data/voice communication into hospitals is high. However, because of guidelines made to reduce problems that might be caused by electromagnetic interference (EMI) with medical electric devices, the introduction of these systems has, until recently, been shelved in almost all cases. Because it has become possible to protect against the possible occurrence of EMI, the number of hospitals introducing such wireless communication is growing. We report a case of a university hospital in which data and voice wireless communication have been safely and efficiently introduced.

Keywords:

wireless communication, cellular phone, wireless LAN, PHS, information security

Introduction

Computer systems are rapidly being installed into most large Japanese hospitals. Usually called a hospital information system (HIS), most have a server and client type structure using TCP/IP LAN. However, voice communication among hospital staff members is often still done with fixed, landline telephones. The potential demand for the introduction of wireless data/voice communication into hospitals is high because of the promise of savings these technologies bring through improvements in patient service and labor efficiency [1]. However, because of "electromagnetic interference" (EMI) with medical devices and of guidelines enacted in many countries to protect against such interference, the introduction of such systems has been shelved in almost all hospitals. In recent years, it has become possible to protect against the possible occurrence of EMI, the number of hospitals introducing wireless communications has grown. This paper describes a university hospital in which wireless communication has been safely and efficiently introduced. (hereafter termed the target hospital).

Materials and methods

Background of the target hospital

The target hospital is located in western Japan, has 616 beds, about 300 doctors, and 350 nurses. It has 12 wards, an ICU, and an NICU. Each ward has 8-10 daytime and 2-3 night nurses. The HIS of the target hospital has 44 servers and 524 client terminals.

HIS wireless data communication

Before introducing a wireless LAN, we examined the safety limits against EMI of some commonly used medical pumps [2]. The results showed that no EMI would be expected to occur unless an apparatus with extremely strong output power were used.

Seventy-two client terminals are connected with servers using an IEEE 802.11a wireless LAN at each ward. These terminals are used only by the medical staff for browsing information, reviewing the medical charts of the patients with barcode scanning, and to immediately record medications and transfusions given at bedside. Reasons for choosing IEEE802.11a were its high rate data transfer and freedom from 2.45GHz band electromagnetic noise. To keep personal information security high, the SSID value is different on each floor and connection attempts using the SSID as "Any" are refused. Also, authentication with an ID and a password has been added and all communications are logged. The AP-5100 (ICOM Inc.), which has an OCB AES (128 bits) cipher system and a Media Access Control (MAC) address filtering function, were adopted as the access points.

Mobile voice communication for staff members [3]

In the target hospital, both landline telephones and the Personal Handy-phone System (PHS) are used for voice communication between staff members. PHS is a totally digital mobile communication system that was developed in Japan. The output of a PHS terminal is a maximum of

80mW. Almost no EMI with medical devices caused by the signals emitted by PHS terminals was found [4]. In many Japanese hospitals, PHS is used instead of the traditional nurse call system terminal. PHS is well-known for increasing efficiency, improving patient service, and raising the level of medical safety among Japanese nurses.

Doctors and some nurses working in the target hospital have had access to a public PHS terminal since November 2004. A red strap is connected to the PHS terminal to serve notice that the terminal has been registered for use in the hospital. Installing a public PHS service means no in-house telephone exchanger is needed. This results a great reduction of cost. The initial cost of this system was only about 4,500 U.S. dollars for the use of 280 PHS. If an in-house exchanger were to be installed, more than 100,000 U.S. dollars would be required. To determine the effectiveness of the public PHS system, the number of calls received on a fixed-line telephone in a ward was compared 7 days before and after the introduction. Total number of calls received was reduced from 1,908 to 997 (47.7% reduced). The number of calls received at surgical rooms increased, possibly because carrying mobile phones, including PHS, into surgical rooms is forbidden. Two years later, PHS handsets were given to every chief nurse. Also, a PHS handset that can make calls with PHS freely is provided to every ward to make it easier to contact doctors. Totally, 440 PHS handsets were in use in the target hospital at the end of November, 2006.

Mobile communication as a service for patients/visitors

In Japan, the use of cellular phones in business has been widely promoted as they are now recognized as being indispensable for doing business. The free use of phones by inpatients can decrease stress and the sense of isolation caused by hospitalization, thus raising the Quality of Life (QOL) [5].

The target hospital has permitted the use of cellular phones in unrestricted zones since January, 2004, with the following rules; “Cellular phones can be used only in visitor lobbies, single bed sickrooms, and in dining areas”, “The medical staff can use cellular phones at nurse stations and in conference rooms”, “Cellular phone use is not allowed within 50cm of medical devices”, “Patients connected to medical devices are prohibited from using cellular phones”, “After a set time for turning out sickroom lights, the use of cellular phones is prohibited”, and “Staff members are not allowed to use a cellular phone during rounds, while walking, or during explanations to patients or their family”. These rules are widely displayed and are given to inpatients. The co-operation of patients and staff members has been requested, and no EMI has been observed since these rules were put into effect.

Discussion and conclusion

In Japan, other than the target hospital, there are no hospitals with more than 600 beds using wireless communications for both data and voice communication at the end of December 2006. The main reason is the fear of EMI. However, by keeping cellular phones away from medical devices and by using mobile phones or wireless LAN apparatus with weak electromagnetic wave output, it is possible to stop or minimize EMI with medical devices. Limiting the areas in which phones are allowed is important for the purpose of preventing EMI, controlling noise, and preventing medical accidents due to the inattentiveness of the caller [6].

Safe and Efficient Use of Wireless Communication in a Large Hospital

Eisuke Hanada[a], Hideaki Nakakuni[b], Takato Kudou[c], Corbet Vernon Sullivan[d], Emiko Hata[e], Hideko Yakuni[e], Michiko Yoshioka[e], Shusaku Tsumoto[b]

a) Division of Medical Informatics, Shimane University Hospital
b) Department of Medical Informatics, Shimane University, School of Medicine.
c) Department of Electrical and Electronic Engineering, Faculty of Engineering, Oita University
d) Language Education and Research Center, Kyushu Sangyo University
e) Department of Nursing, Shimane University Hospital

Wireless Communication in The Target Hospital

- Installed systems
  1. Wireless data communication
     - Wireless LAN in wards
  2. Wireless voice communication for staff
     - PHS (A kind of cellular phone)
  3. Wireless voice communication for patients/visitors
     - Partial permission for cellular phone use
- The Target University Hospital
  - A university hospital located in western Japan
    - 616 beds and 21 specialized departments
    - 1 building for inpatients
    - 12 wards of about 50 beds each
      - Each ward has 8-10 daytime/ 2-3 night nurses
    - Most accommodate from 2-6 persons
    - About 300 doctors and 350 nurses

Safety of Wireless Communication Use in Hospitals

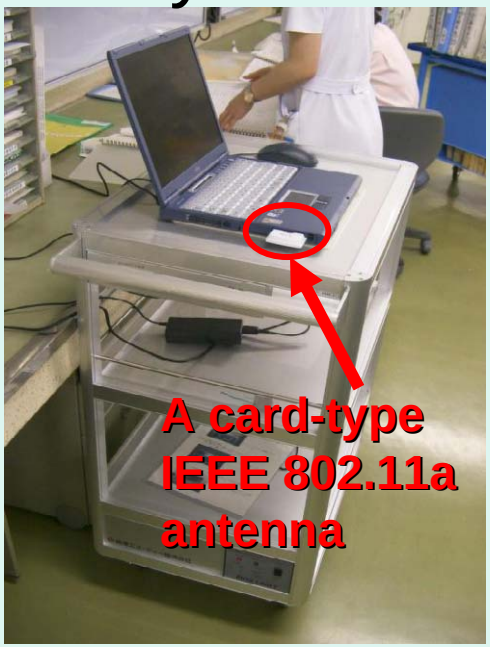
- No EMI was observed for 5.2 GHz radio waves until extremely high output power (3 W or higher) was irradiated [1]
- The power of the signal is limited by Japanese law

System	Output power (from the terminal)
2nd. Gen. Cellular phones	0.6~0.8W
3rd. Gen. Cellular phones	0.20~0.25W
IEEE 802.11b wireless LAN	10 mW / MHz (total output: 130~160 mW, approx.)

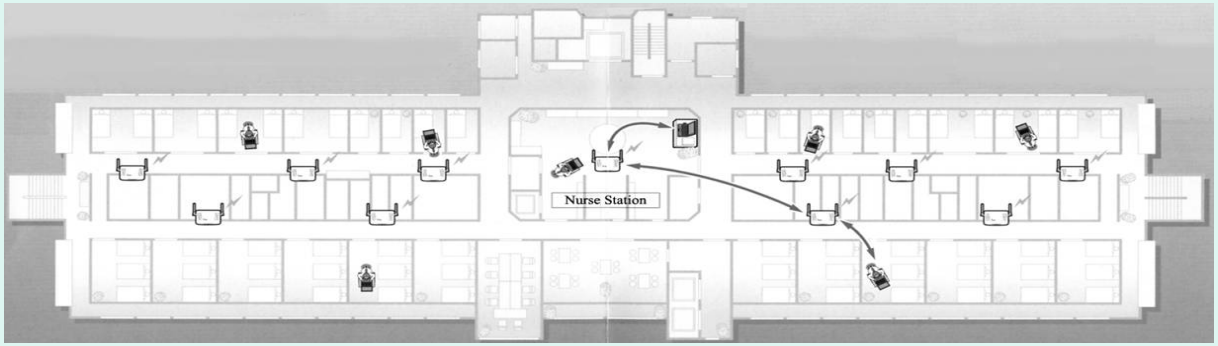
◎EMI will NOT occur when using PHS or wireless LAN in the Japanese legal setting

Wireless LAN System in the Target Hospital

- 72 HIS client terminals are connected with servers using wireless LAN
  - Terminals are limited to use in the wards by the medical staff
- IEEE802.11a standard is used
  - Apparatus that emit electromagnetic waves in the 2.45GHz band are often found in hospital wards
    - heaters, microwave ovens…
  - The data transfer rate is higher than that using IEEE802.11b/g



A notebook-type PC with an IEEE 802.11a antenna on a wagon



An image of the location of access points on one floor

Settings/Employment

- Security Settings
  - Connectable Media Access Control (MAC) addresses are registered for each access point
    - Only permitted PCs can connect to the hospital LAN
  - SSID value is different on each floor
    - An “Any” setting of the SSID is refused
  - OCB AES (128 bits) was adopted as a cipher system
    - High-speed encryption/decryption available
  - HIS user authentication with ID/passwords
  - Communication logging
- Currently used for
  - Patient ID confirmation with bar-codes
  - Entering patient information into an HIS at bedside
  - Browsing of patient data by doctors during rounds

Access Point
AP-5100 (ICOM inc.)

Improvements with wireless LAN

- Medical efficiency
  - Inputting patient information at bedside
  - Reviewing medical treatment charts
  - Sharing information
    - With an electronic patient record system, every staff member has access to registered information anytime/anywhere
- Medical safety
  - Reference to required medical information at the bedside is possible
  - Patient checks using barcode/tag scanning
  - Protection against input failures/mistakes
    - Eliminates the need to move from bedside to fixed terminals in the nurse station
- Personal information protection
  - Reduced use of paper memorandums

Wireless Voice Communication for Staff Members [2]

- Doctors have access to a public PHS terminal (WILLCOM, Inc.)
  - Cost effective service
    - US $8/month for use
    - US $4,500 to install 280 Terminals
      - Calls can be received freely
      - A limit is set at 3 numbers, designated for each handset, that can be called
- PHS (Personal Handy-phone System)
  - Uniquely developed in Japan
    - Completely digital
    - Frequency of radio waves: 1.9 GHz band
    - Handset output : 80 mW maximum
  - System structure is almost the same as for cellular phones
  - Public service available in some other Asian countries including China and Thailand

A PHS terminal for doctors in the target university hospital (WILLCOM Inc.)

Productivity Improvements with PHS

- Makes it unnecessary for nurses and pharmacists to physically search for a doctor
- Makes possible quick queries and feedback to the queries
- Number of terminals increased from 280 at start (Nov. 2004) to 440 (at the end of Nov, 2006)
  - Terminals provided to every chief nurse/every ward

Section received	Calls before introduction	Calls after introduction
Wards	1216	588
Visitor sections	458	356
Other sections	116	212
Total	1790	1126

Number of calls on weekdays (5days)

- Calls received at “other sections” increased, possibly because surgeons could not carry PHS into surgical rooms

Section Placing Call	Pharmacy	Clinical Lab.	Hosp. Affairs Section	Others
Before Installation	118	92	111	982
After Installation	23	66	38	412
Number Reduced	95	26	73	560
Rate Reduced (%)	80.5	28.3	65.8	57.0

Number of calls received in wards during working time by the section placing call

Mobile Voice Communication as a Service for Patients/Visitors

- Growing demand for the use of cellular phones
  - Over 100 million cellular phones are in use in Japan
  - Cellular phones are seen as indispensable for doing business
- Raising the Quality of Life (QOL) for inpatients
  - Free use of a phone can decrease stress and the sense of isolation
- Other factors
  - No reports of malfunction of medical devices have been made in recent years
  - Medical devices have improved protection against electromagnetic waves

Partial permission for the use of cellular phones is a welcome service for inpatients/visitors

Conditions for Cellular Phone Use in the Target University Hospital

- Cellular phone use is NOT allowed within 50cm of medical devices
- Cellular phones can be used only in visitor lobbies, single bed sickrooms, and in dining rooms
- The medical staff can use cellular phones at nurse stations and in conference rooms
- Patients connected to medical devices are prohibited from using cellular phones
- After a set time for turning out sickroom lights, the use of cellular phones is prohibited
- Staff members are not allowed to use a cellular phone during rounds, while walking, or during explanations to patients or their family

Discussion/Conclusion

- Mobile telecommunication systems in hospitals
  - Can be installed SAFELY with sufficient consideration
    - Cellular phone use should not be permitted in restricted areas
    - PHS is one of the safest and most convenient voice/data communication systems
  - Are very convenient and useful for staff/patients, but the **following problems must be addressed** [3]

1. Prevention of EMI with medical devices by signals
2. Prevention of noise caused by people talking on telephones
3. Prevention of accidents caused by lack of attentiveness of operators of communication tools
4. Prevention of private information leakage when using the camera or recording functions

Health*Connect* NT Point to Point Electronic Messaging and Electronic Transfer of Prescriptions Service

Leonie Katekar[a], Stephen Moo[b]

[a] *Top End Division of General Practice, Chief Executive Officer and Project Director, HealthConnectNT Point to Point Service, Australia*
[b] *Chief Information Officer Northern Territory Department of Health & Community Services and Director HealthConnect Northern Territory, Australia*

Abstract

The Point to Point Service provides enhanced clinical communication through standardised electronic clinical messaging between all health providers in the Northern Territory, including the public and private sectors and including specialist and general medical practitioners, allied health professionals, pharmacists, pathology and diagnostic imaging companies. The service supports integrated models of care supported through comprehensive referral management, diagnostic imaging results reporting, electronic transfer of prescriptions and transmission to the HealthConnectNT Shared Electronic Health Record.

The Point to Point Service is part of a national change management strategy to improve safety and quality in health care by establishing and maintaining a range of standardised electronic health information products and services for health care providers and consumers. Many IT projects fail in their implementation particularly in health, and the point to point service demonstrates some practical techniques which have ensured its success with clinicians.

Keywords:

Health*Connect;* E-Health; electronic mail; automatic data processing

Introduction

The Top End Division of General Practice (TEDGP) commenced the development of software to enable secure electronic messaging between health providers approximately eight years ago. The original innovative idea of the software, called Argus, was to fully integrate with the clinical desktop software packages to ensure maximization of business continuity in the clinical care environment and enhancement of clinical communication.

TEDGP commenced installing ArgusConnect software into the providers in the Top End region of the Northern Territory in September 2005 and currently there are over 115 health providers engaged in the messaging service in the private sector including the pathology providers as well as the public hospitals in the Northern Territory. The Point to Point service also links with the Northern Territory's Shared Electronic Health Record[1]

In addition, the Point to Point Service is undertaking the first electronic transfer of prescriptions trail in Australia which further enhances the comprehensiveness of the electronic messaging service. The implementation strategy has been developed in conjunction with the pharmacy, general practice and community sectors to ensure a smooth transition of the technology into the clinical environment as well as consumer acceptability.

Methods

The model chosen by the Northern Territory government was to entirely contract out the implementation of the Point to Point and Electronic Transfer of Prescriptions Service to the Top End Division of General Practice with an implementation pathway driven by the primary health care sector needs. Divisions of General Practice in Australia are uniquely placed in the primary health care sector as by the nature of their work, they have developed long standing working relationships with the multiple parties and providers across both the private and public sectors as well as engaging with the acute care hospital sector.

This choice of eHealth implementation provider is consistent with the findings outlined by Sittig[2] and findings of the Connecting For Health in the United Kingdom[3] which emphasizes the importance of clinician involvement and support by senior organizational management in e-health implementation to ensure that the e-health is driven by clinicians and not by technology.

Results

Over fifty health care sites have been connected by the point to point service with over 115 providers receiving electronic communications. General Practices are receiving and sending over 500 messages per week. The implementation of the Point to Point Service in the Northern Territory is achieving the following major outcomes:

- *Enhanced clinical Communication through standardized clinical messages*- single, comprehensive e-

messaging service with standardized templates for referral management and receipt of electronic communications;

- *Integrated model of care supported through referral management services, diagnostic results reporting and electronic transfer of prescriptions* – improved quality and safety in clinical practice with improved business performance, reductions in duplication and transcription errors and reduction of medication errors and misadventure.
- *Passing the Patient Safely Back to their Community* – the generation of electronic discharge summaries for inpatient and Emergency Department attendances.
- *Breaking Down the Distance Barriers by Improving the Co-ordination and Delivery of Health Services to Indigenous Populations* – engagement and maximisation of health providers participating in the point to point service, targeting remote indigenous communities, Aboriginal Medical Services operating in remote and major urban centres and small regional centres and towns across the Territory;
- *Establishment of the first electronic transfer of prescriptions in the aged care sector enabling streamlined prescribing, dispensing and administration of medications between a pharmacist, GP and aged care facility* - Prescriptions and aged care facility medication charts are both sent electronically and digitally signed.

Discussion

TEDGP was established in 1994 and thus has over 10 years experience building relationships with general practitioners and the broader primary health care providers. This enabled the implementation pathway of e-messaging to be driven through primary health care sector needs where the majority of e-messaging between independent clinicians and health organizations occurs on a daily basis

Critical success factors for implementation have been:

1. TEDGP implemented the point to point service under a capacity building model which developed Information Management (IM) Culture and Infrastructure within a general practices. Principles included assumption of little IM integration into general practices; Support of clinical leaders to assist other clinicians; Drawing together all IT/IM initiatives in the primary health care sector; and Linking IT/IM with patient care outcomes especially in chronic disease management.
2. Clinician participation in the development of innovative software that is functional within the complex health care environment and is acceptable to busy clinicians in both urban and rural settings;
3. Ensuring that the Point to Point Service was comprehensive and captured all e-messaging needs of the clinicians. Early work was needed to obtain agreement between the multiplicity of health care providers to proceed with implementing P2P within their environment;
4. Working closely with the Australian government on changes to the legislative and regulatory frameworks that govern health to permit electronic communication as a legally acceptable documentation pathway.

Conclusion

The Health*Connect*NT Point to Point and ETP Service implementations will continue to build on the successful development and implementation of its e-messaging service. The Northern Territory's HCNT Point to Point and Electronic Transfer of Prescriptions Service implementations are the most advanced Health*Connect*NT service implementations of their kind in Australia in terms of range of services, service coverage, provider and consumer participation. There is clear evidence that providers have embraced the concept of e-clinical messaging with sites receiving increasing number of messages and continuing requests from providers to be connected to the point to point service. There is also clear evidence of potential benefits in community medication management in reducing medication errors and misadventures for consumers and streamlining work processes and improving workplace productivity for GPs, pharmacists, other health providers such as those working in indigenous health organizations and aged care facilities. There is realization of benefits for a highly mobile Indigenous population through improved co-ordination and quality of health service delivery spanning vast distances, in some of the remotest areas in Australia. In conclusion, the Health*Connect*NT Point to Point and Electronic Transfer of Prescription Service is now demonstrating the impacts and benefits that may be realized in clinical practice across the primary health sector through innovative e-health reforms

eReferral – Using ICT to Improve Patient Care in a Major Health Service

Rosamund Green[a], Phil Joyce[b] , Mark Arnold[c]

[a] *Health Information Services, Barwon Health, Geelong, Australia*
[b] *School of Information and Communication Technologies, Swinburne University of Technology, Melbourne, Australia*
[c] *Nursing Services, Barwon Health, Geelong, Australia*

Abstract

The referral of patients from one type of health care to another is a primary business of health care, and by incorporating ICT into clinical process we have improved the flow of patients around the service, reducing waiting times and increasing the level of care and quality of patient clinical outcome.

Keywords:

referral, ICT, health care

Introduction

In the industry equivalent movement of patients would be identified as a supply chain issue and authors such as Lee (1) suggest that for an organization to succeed processes that are agile, adaptable, and aligned must be developed.

As an adaptive organization, prepared to take on innovations in Information Communication Technology (ICT), during 2002 Barwon Health upgraded the patient administration system (PAS) to a best of breed database. Not only is this PAS modular providing software meeting specific clinical process requirements, it also provides the ability to create data entry tabs and data fields in house for local data needs and government reporting requirements. This software flexibility supports the redesign of a process to be incorporated into the main organisational software with minimal delay or cost, as the configuration is done in-house. In addition because this PAS is used across the region, the common healthcare problem of isolated islands of information is not encountered (2). Therefore information can be developed into reports that are delivered or made available electronically to the acute and sub-acute areas as appropriate.

Method

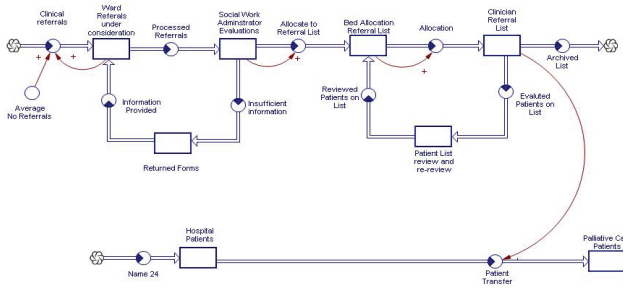

Figure 1 - Referral to sub acute care

The first and foremost issue with the paper based process is that it evolved over many years. The process was then effectively set in stone with the attitude that "this is how it has always been done" without consideration to changing needs of the organization for data, reporting, or the unnecessary complexity that had been incorporated into the evolving process.

Evolution of a process vs design

The traditional paper based process required a paper referral to be completed by the staff on the acute ward. This paper referral was transferred to the social work department via internal mail. The clinical and social information entered was often insufficient for to determine the appropriate referral to sub-acute care, so the referral was returned to the ward delaying sub acute services awareness of the potential patient. Once the referral was completed details were entered into as spreadsheet and a phone call made to the sub-acute center where a further spreadsheet was maintained. Sub-acute services then organized a senior clinician to access the patient at the acute center for the appropriateness of the referral, clinical date they will be ready to move from acute to sub-acute care and develop a treatment plan. This data flow is simply illustrated in Figure 1.

Locating the patients in the acute hospital can also be a challenge for the visiting clinicians who come to the acute site for patient assessment. Patients are often moved between wards to achieve a best patient mix on each ward. This can add time unnecessarily to the visit of the clinicians as they search for patients. The referral software has

been added to the Patients Administration System (PAS), so reports reflect patient movement as soon as the data is entered.

Information on the patients clinical needs can become quickly out of date on the referral paper. This regularly provides a challenge of information sharing between the acute and sub-acute staff. Common implications of when the information sharing breaks down include; patient condition deteriorates and they are no longer appropriate for sub-acute care, a nursing home bed becomes available and the patient is inappropriately transferred to it to clear the acute bed resulting in further disruption to the patient when they eventually get transferred to the sub-acute bed. Patients also may be transferred to the sub-acute hospital before all diagnostic tests are completed. Once again this initiates disruption to the patient and costs to the health service from unnecessary inter-hospital transfers.

The process was complex including many steps as the paper physically moved around the organisation. Analysis of the big picture and transparency of data had never been addressed. The intrinsic requirement that clinical assessment is required of each patient nominated to move from acute to sub-acute care, has not varied in the process change. This is to ensure that sub-acute care is the appropriate care for this person after their acute stay. For some patients sub-acute case is not required because they have adequate care available at home or have other medical or social complications that mean the patient requires alternative higher level of care such as nursing home.

Complex paper based process that are the result of evolution rather than design require specific staff for the process to work, with a break down of process during times of leave common. With the practice of redundant data entry by staff in different locations the ability to teach other staff to cover roles even for planned absences is difficult and time consuming as well as prone to failure due to lack of intimate familiarity with day to day tasks.

Advantages of ICT approach for clinicians

Intranet web based reports provide a single point of reference of referral information, which has met with clinician satisfaction. The clinicians buy in to the process of entering data real time and viewing reports with updated information rather than waiting for clerical staff to enter data into spreadsheets locally and then to be notified, has exceeded expectation and been sustained with minimal input in the six months since implementation.

Patient tracking as they move between wards, changes to clinical condition and inpatient procedures such as surgery are automatically provided by the ICT process assists clinical decision support (3). Removal of redundant steps with paperwork, lengthy phone calls comparing lists and faxing of referrals no longer required. These factors combine to ensure that the patient referral is received and acted upon faster than during the paper based process era. The minimum days to review has decreased by 50% from two days to one day and the average minimum days determined by day of week of referral has decreased from 3.9 to 2.6 days (Figure 2).

	Paper Based Internal Mail	ICT Approach
Minimum days to review	2	1
Average minimum days	3.9	2.6

Figure 2 - Change in time from referral to review in paper based versus ICT referral

Advantages of ICT approach for patients

Early planning of patient care with up to date patient clinical information has improved the level of care patients received because clinicians are supported in their decision-making in a timely and accurate manner. This provision of timely information supports objective decision making so that the right patient is in the correctly located bed at the right time, receiving the appropriate clinical level of care. Incorporating ICT into the process added more clinical information to the referral including previous admission details and current admission surgeries. In particular as the current admissions are updated in real time clinical readiness for transfer to sub-acute is monitored without seeing the patient saving clinicians time by reducing the number of reviews they do each Tuesday and Thursday. Saving time not seeing inappropriate patients allows for more quality time to be spent with patients who are appropriate for transfer.

Analysis "Mythbusters"

Sub Acute referral information following the computer referral implementation is freely available to other areas of the organisation in the form of web-based reports where in the past it was not transparent hidden in local spreadsheets. This facilitates strategic planning for beds as trends can be seen in the number of sub acute beds required, and analysis of peak times of demand for beds can be made objective. Both clinicians and administrators have appreciated dialog based on the same objective data. At a glance the clinicians can see the trends of patients waiting for transfer for the types of sub acute care.

The rate of rejected referrals to sub acute care has long been considered a problem for the organisation due to the sub acute clinician time. However the magnitude of the problem has been anecdotal and unsubstantiated through lack of objective statistical information. While referrals may not be accepted for unavoidable reasons such as unanticipated clinical deterioration or indeed death of the patient, the rate of acceptance is of prime relevance. With the data available so far the results show a statistically sta-

ble percentage of between 71% and 76 % from a monthly cohort of around one hundred referrals. Future review and analysis will include a break down of accepted referrals by referring ward to evaluate if the average 73% referral rate is constant across the wards, and inappropriate referrals are prevalence on particular wards requiring education.

Conclusion

The use of ICT to change the process by which patients are referred from Acute to Sub Acute care has had positive clinical and administrative outcomes. Patient referrals reach clinicians in a timelier manner, as there is no delay waiting for paper-based mail to be transported between hospitals. Clinicians also make better use of their time on the acute site spending it with patients rather that searching wards for patients who have moved. The administrative workload is also reduced as the previous handling of referral information by two sets of administrators has been eliminated by the direct clinician-to-clinician contact and web based monitoring of patient load. The foresight of appointing a project manager who had a vested interest in seeing cultural change and assisting clinicians with the change is the prime contributing factor to the success of the project. It goes without saying that the top-level management support that proposed the project was also a contributor to success. This collaboration provides the clinicians and administrators data to monitor the same cohort of patients each from their own perspectives. This information is available in real time, without subjective interference facilitating improved clinical decision-making and administrative decisions to provide the appropriate level of care as clinically dictated for the best advantage of the patient and organisation.

eReferral – using ICT to improve patient care in a major health service

Rosamund Green[a], Phil Joyce[b] , Mark Arnold[c]

[a] *Health Information Services, Barwon Health, Geelong, Australia*

[b] *School of Information and Communication Technologies, Swinburne University of Technology, Melbourne, Australia*

[c] *Nursing Services, Barwon Health, Geelong, Australia*

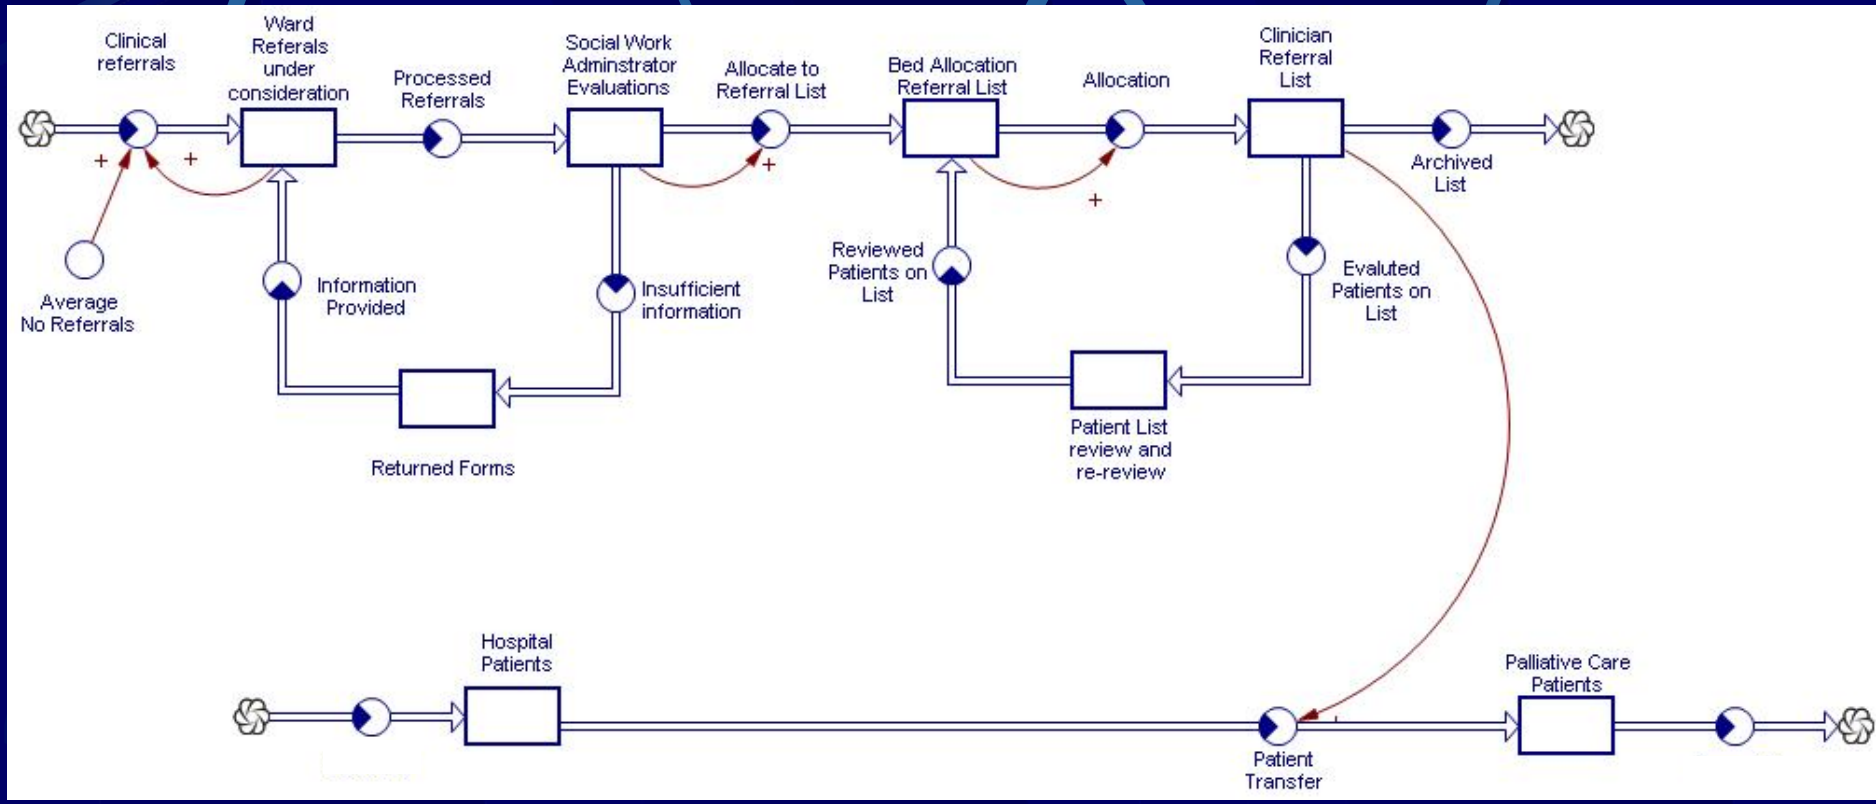
Introduction

- Patient movement an example of supply chain.
- For success processes: agile, adaptable and aligned.
- In-house flexible software supports redesign of process.
- Change management integral to combat “that’s how we’ve always done it”.

Evolution of a Process vs Design

- Evolution of a paper based process.
  - Redundant steps.
  - Out of date data.
  - Slow knowledge transfer.
- Design of an ICT process.
  - Facilitates evaluation of data flow.

Referral to Sub Acute Care



Advantages of ICT approach for Clinicians

- Reports available at any computer.
- Data up to date.
  - Changing clinical condition .
  - Ward and bed location.
- Referrals available real time, not waiting for triage by social work.
- Patients seen sooner & referred for appropriate treatment.

Advantages of ICT approach for Patients

- Clinical decisions made in a timely and accurate manner.
- Provision of wider range of data facilitates a more accurate clinical decision.
- Appropriate clinician able to spend more time with appropriate patients.

Minimum Time from Referral to Clinician review

Paper Based

Day Of Week	Sat	Sun	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue	Minimum Days from referral to first review
Patient A	■			▒		▒					▒	3

An Interactive Shared Decision Making System for Dental Treatment Planning

Hee-Chul Choi[a], Seon Gyu Park[a], Dong Hwan Lee[b], Hai-tao Zheng[a], Hong-Gee Kim[a]

[a]*College of Dentistry, Seoul National University, Korea*
[b]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Korea*

Abstract

Patients would be more satisfied if they are involved in the decision making process for the medical treatment. In reality, however, since the decision making process is time-consuming and complex, it would be hard to make full interaction between doctors and patients in terms of shared decision making. We propose a prototype system by combining two techniques: namely, Ontological Engineering and Analytic Hierarchy Process (AHP). The ontology provides machine processible conceptualization that bases interoperation and collaboration and, the AHP gives instant evaluation of health care options in a subjective manner. Our system is designed to support an optimal treatment planning for dental restorations. The proposed shared decision making system can consider diverse values of dental restorations: time, cost, esthetic and quality values.

Keywords:

patient-centered care, AHP, permanent dental restoration, communication, ontology

Introduction

Frosch and Kaplan define the concept of shared decision making as a process in which the patient and clinician consider outcome probabilities and patient preferences to reach a mutual agreement on the appropriate health care decision[1]. The decision making process could be time-consuming and complex; doctors and old patients would be less satisfied than young patients if the process got long and complicated [1-3]. To solve these problems, the interview or interaction should be simplified in the shared decision making procedure.

To build simple and agile interactions with patients, we combined two techniques, an ontology and an Analytic Hierarchy Process (AHP)[4]. An ontology provides machine processible conceptualization that bases interoperation and cooperation among different systems. The AHP is the technique to satisfy subjective needs of decision maker, and the availability of AHP is also extensible used in shared decision making area [3, 5].

In this paper, we propose a shared decision making system prototype that interacts with patients and a doctor based on an ontology and the AHP. This system is designed to make optimal treatment planning for dental restoration. The system helps both patients and a doctor interactively consider various patient conditions such as financial status and preference of a patient as well as patient's problems.

Method

An ontology is a basement to serve proper information for both of human and system. We define classes about dental restoration method and related information. The classes have various properties to make an effective use of a decision making process, AHP.

The instance of an ontology makes knowledge that can adapt to different situations. Instances of this ontology could be crated for one hospital or one patient. Figure 1 shows an instance of AmalgamRestoration. A value of hasFinancialConstraint can be changed for different hospital that has a different price system. A locatedIn property presents a location of problem tooth that depends on each patient.

We use AHP to suggest the best treatment option for each patient. First, we import the ontology and make alternatives from instances of TxOption class and subclasses. Second, we use common properties of those instances as criterions. Third, we visualize overall expected outcomes and detail properties of each alternatives. Finally, we give a user-interface to change the relative importance of criterion.

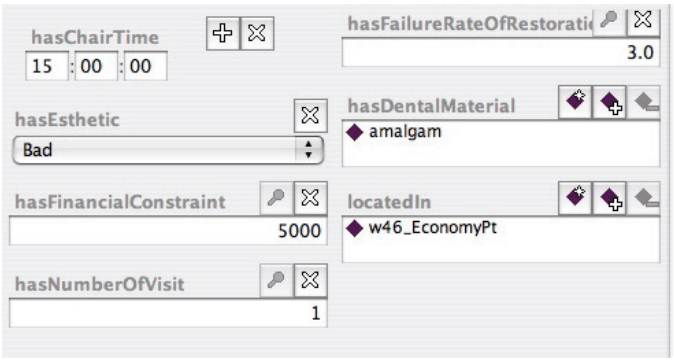

Figure 1 – An instance of amalgam restoration class

Implementation

The prototype was implemented using a described architecture to support a dental restoration treatment planning. The sub-goal of this system is providing an effective user-interface to be understood and interact with a patient.

This system is implemented as a multi-platform system based on Eclipse RCP[1]. We use a part of the JAHP[2] as a module to support the AHP. Each part of this system is described as following:

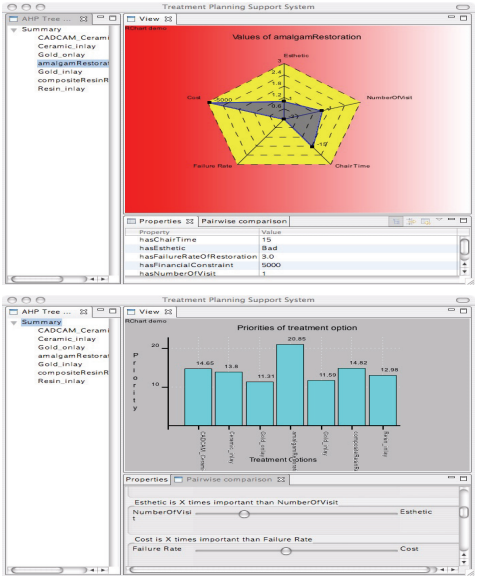

Figure 2 – Interfaces of implemented system

- Alternative Tree View
- Alternative Tree View is comprised of summery item and alternatives sub items. When the item is selected, graph and properties view will be updated to show proper graph and properties of alternative.
- Graph View
- Graph view visualizes current state by user-friendly graph. Radar graph summarizes merits and demerits of alternative at a glance. Bar graph shows expected outcome to compare treatment options.
- Pairwise comparison view
- Pairwise comparison view helps human to make pairwise comparison matrix that represents relative importance of properties. In this view, relative importance is visualized by slide bars and user can easily modify them by dragging. It affects bar graph immediately. It can be used iterative process of user to find proper solution.
- Properties View

  Properties view describes properties of treatment options based on ontology. Each property represents a characteristic of alternatives. It gives more detail information than graph view.

Conclusion and Future Works

In this paper, we built a prototype system using an ontology and an AHP technique to support an optimal treatment planning for dental restorations. This system showed: (1) A system can give instant evaluations of the treatment options for dental restorations; (2) A system can consider diverse values of dental restorations: time, cost, esthetic and quality values.

More generally, we showed the prototype architecture that an AHP integrated with an ontology: it could provide simple and agile interactions for shared decision making, and interoperations with other systems.

We have limited the scope of research to choose a best option among the provided options. Meanwhile, medical examinations could be collected from medical equipments; a reasoning functionality of an ontology could extract possible treatment options for a patient from the medical examinations. The development of these processes would help us to make a complete treatment support system for dental restorations.

Abstract

Promotion of telemedicine services is an important political issue in Japan. The most important factor in determining the quality of telemedicine services is communication infra-structure. With the spread of the IP network, broadband prices have fallen and take-up has increased, but the study of the platform of medical information systems has not yet been fully developed.

This paper first proposes two requirements for the telemedicine information system: 1) to provide the best-quality transmission service with limited communication bandwidth, and 2) to widely share medical information in an integrated and secure manner. Next, it outlines the two themes of our study to achieve these requirements: 1) an on-demand medical information network system, and 2) a highly efficient Region of Interest (ROI) image coding.

The results of the study will contribute to the promotion of telemedicine services on the IP network.

Keywords:

medical information system; telemedicine; region of interest; on-demand network; IP network

Introduction

Asahikawa Medical College Hospital in Hokkaido, to which my group belongs, started a telemedicine service for ophthalmology clinics in 1994, and is now providing approximately 150 diagnostic telemedicine services per year for 22 eye clinics in Hokkaido [1][2]. Currently, this service is also provided to radiology, pathology, surgery and internal medicine departments on a daily basis.

The system of telemedicine services uses transmitters, receivers and communication lines that link between them. The most important factor that decides the quality of the service is communication lines, which are actually less established in the areas that need more remote medical services. Although this constraint is being eased thanks to the recent spread of the broadband network, the establishment of an effective communication infrastructure has not yet been achieved in mountainous areas and remote islands.

Against this backdrop, our group has been involved in various studies and developments relating to a system to improve the quality of telemedicine services. This paper outlines our study according to its main themes.

Purposes

Our study aims to develop a system that meets the two major requirements essential for an effective telemedicine information service. These requirements are: 1) to provide best-quality transmission under limited bandwidth conditions, and 2) to widely share medical information in an integrated and secure manner.

Methods

To achieve the above purposes, especially requirement of 1), the study has been conducted under the following two themes. Meanwhile, regarding of the 2), we have studied and developed the P2P medical information sharing system [3].

(1) Prioritization of medical information transmitted on the IP network

The IP network is generally based on the best-effort service, and communication bandwidth and destination are determined by the contract conditions with communication carriers on the leased line service. However, telemedicine services require a certain level of communication quality in order to operate efficiently, enabling it to prioritize medical information in an emergency. To meet these needs, we have studied and developed an on-demand medical information network system, which controls traffic by prioritizing user requests on the MPLS network.

(2) High-quality transmission of video information according to communication bandwidth

Video information plays a significantly important role in telemedicine services. However, because of its extremely large volume compared with numeric and character information and its need to be transmitted in real time, its quality can be affected by network conditions. Therefore, we have studied and developed highly efficient image coding using Region of Interest (ROI) technology so that efficient transmission can be realized according to network conditions and communication purposes.

Results

Following are the outline and results of our study on each theme.

(1) On-demand Medical Information Network System

To control the network bandwidth, it is necessary to synchronize the data transmission on users' access lines with the transmission on the core network, which links the MPLS routers. The local administrator (LA) manages users' applications and access lines, which exist between users and the core network, as a local resource. The application gateway (APGW) controls the requests from each LA, and forwards the requests to the MPLS router via the router controller (RC) to secure the resource of the core network.

In response to user requests, the LA and APGW decide the application to be prioritized and pass the result to the network control. At that time, they consider a priority policy prepared for each application and the priority level specified by users, using the analytic hierarchy process (AHP) method, to comprehensively decide the order of priority. The user specifies the priority level by stipulating the level of the emergency (urgent or normal) together with the necessity level (5 to 1), based on medical guidelines. The network is controlled so that highly prioritized applications can preferentially secure the bandwidth, and routes are arranged appropriately.

(2) Highly efficient ROI Image Coding

With limited communication bandwidth, we figured out a method of image transmission that, as much as possible, maintains the quality required from the receiver. This method, called ROI image coding, compresses the ROI specified by a rectangle on the image into high-quality data and the outside (non-ROI) into lower-quality data. As giving prominence to characteristics, the quality levels of the ROI and non-ROI are automatically decided depending on the network bandwidth.

Discussion

When the communication bandwidth is broad enough to send and receive data, the receiver has no problem in retrieving information to provide medical support for its patient. However, it is rare to have such a communication environment. In reality, telemedicine services are requested from an area that does not have sufficient communication bandwidth. For such areas, the method of highly efficient ROI image coding is useful to ensure the transmission of the minimum required medical information on the best-effort type IP network.

Telemedicine services are particularly useful in case of emergencies such as disasters and accidents, but the requested information should be preferentially transmitted on the network. This would be similar to how ordinary cars move aside to offer an open road for approaching emergency vehicles. The study of the on-demand medical information network system enables the flexible control of communication quality according to applications and user requests, and secures smooth data transmission even on a congested communication network.

Conclusion

This paper has described our study themes, the on-demand medical information network system, the highly efficient ROI image coding system as the basic study of a telemedicine information system. We believe this study will ensure the quality improvement of telemedicine services on the IP network.

Developing a Digital Form Generation Systemfor Ubiquitous Computing Environments of EMR

Hae-Ran Lee[a], Myung-Chul Yang[a], Nam-Hyun Kim[b], Hye-Ryung Kim[a], Jae-Suk You[a]

[a]Development and Research Center, SoftNet Cooperation, Republic of Korea
[b] Dept. of Biomedical Engineering, College of Medicine, Yonsei University, Republic of Korea

Abstract

Recently, several hospitals have changed their systems from legacy system using paper to electronic medical record (EMR) system for inpatient and outpatient. There are several obstacles to this change such as user resistance; expense of education, time spent due to entering data, and etc. So there is a significant need for easy and user-friendly data entry system using digital pen for collecting electronic medical record. Also flexible form for digital pen must be promptly created by clinical staffs. The purpose of this study is to develop the digital form generation system using digital pen to support outpatient treatment rapidly. So we implemented the digital form generation system which is consisting of digital form generator interface and digital pen data entry system. To evaluate the digital form generation system we developed prototype of EMR system and tested data processing procedure. We expect this system using digital pens can be the helpful and the easiest migration tool in successful adaptation of the EMR.

Keywords:

electronic data entry system, image, digital pen, electronic patient record, digitalized data

Introduction

The effort for computerization of the medical record has been accelerated rapidly in recent years. However, computerization of the medical record is the repetition of trial and error due to the complexity of medical record and the very nature of medical environment, which is different from computerization of other industry areas.

According to NCA (National Computerization Agency) CIO REPORT (June, 2006) of Korea National Information Society Agency, EMR system introduction rate of Korea is only 2.6%, and it is mainly conducted by giant-scale University hospitals. The main issue related to medical informatics of Korea is rigidity of hospital organization against change and expenditure [1].

Some hospitals have developed electronic data entry system and let their staffs enter data at the time of medical treatment. But the systems are used only for some limited departments. The reasons EMR systems of some hospital could not be used for the entire hospital are assessed as follows. First, it is not easy for the clinic staffs to input prescriptions and medical treatments after reviewing history and medical record. Time is the critical issue here. Second, most health care systems still use some combinations of electronic medical records and paper charts because some kinds of sheets are inefficient to become electronic data via keyboard entry system. Last, electronic medical record system does not have reliability, stability, enough scale, and fast response time to support outpatient treatment smoothly [2]. To overcome the rigidity of organization against change and to ensure the reliability, and fast response time to support outpatient treatment, EMR systems should be kept in electronic form with various input devices (i.e., Personal Digital Assistant, Digital Pen, Tablet PC, etc.). Recently, digital pen is used as one of the EMR data entry devices, and electronic medical data entry systems using digital pen are researched and developed in Europe and America [3].

According to recent researches, the digital pen is an easy, fast, and cost-effective tool, supporting rapid adaptation of EMR. At the Lineberger Comprehensive Cancer Center in USA, Elodia Cole and her fellows (2005) accomplished a comparative study to determine the speed, accuracy, ease of use, and user satisfaction of various electronic data entry platforms for use in the collection of mammography clinical trials data. Four electronic data entry platforms were tested: standalone personal digital assistant (PDA), Tablet PC, digitizer Tablet/PDA Hybrid (DTP Hybrid), and digital pen. Research shows that Tablet PC and digital pen were equally fast and easy-to-use data entry methods that were well tolerated by radiologist users. Handwriting recognition review and correction for the digital pen were significantly faster and more accurate than secondary manual keyboard and mouse data entry. Also, digital pen showed much(or significantly) lower expenditure of hardware cost and higher satisfaction than other devices [4].

Martin Schiavenato (2006) remarked on his review paper "Technology Brief: Digital Pen and Paper" about Digital pen and paper systems as an expedient and innovative way of adapting the familiar handwriting medium into the EMR. She thought the advantages of the digital pen and paper system are ease of use and small need for training. An example of Cherokee Indian Hospital case is cited. The

hospital reported savings in its insurance processing transactions using a digital pen and paper system on a per form basis from $2.00 to $0.50[5]. Martin Schiavenato recognized the digital pen and paper as a potential and promising element in the evolving pursuit of the application of technology in healthcare. And she came to the conclusion that this system can transform the familiar process of pen and forms into an expedient and effective way to document and process clinical, research, and financial/ administrative data [6]. Bethesda Emergency Associates (2006) implemented the BARTCHARTS ™, a comprehensive, paper-based template charting system using digital pen. This new system provided emergency department physicians the power of electronic documentation with the ease of paper and pen. On the other hand, Robert R. Rothstein, MD, Medical Director of BEA(Bethesda Emergency Associates in the United States of America) explained the efficiency and ease of use as following statement: “None have been as easy to use or actually have improved my efficiency like this. Within 5 minutes of sitting down with the digital pen solution for eBC I was documenting 100% of my charts." [7].

Still now, Cherokee Indian Hospital (USA), Hôpitaux Universitaires de Genève (HUG, Swiss), Royal Ottawa Healthcare Group (Canada), etc have used digital pen for the effective and easy adapting method into EMR [8-9].

In Korea, some hospitals adopted the digital pen systems from the beginning of the EMR system design, especially for reducing resistance for EMR systems, effective recoding of the physical assessment data, and for the completion of the consent [10]. The extension of adaptation area was asked by many users for several times during two years. But it takes approximately one month for collecting proposals, implementing and printing new forms. And sometimes forms for digital pen system (the following of paper - digital form) are changed for some reasons, so printed digital forms became useless. Prompt digital form generation in hospital by user and time saving for developing and printing to add new forms at existing digital pen system are requested.

So, I suggest a digital form generation system which enables clinical staffs to use digital pen and digital form at ubiquitous computing environment of EMR system. Through this system the digital form can be promptly created and printed by clinical staff.

Methods

1.Anoto functionality

Anoto functionality is technology related to digital pen and paper, which is supported by Anoto AB in Sweden. This technology allows man to continue using pen and paper to capture information and digitalize the data. This technology, entailing interpretation and transmission of handwritten texts and images, is based on a special digital pen and a paper printed with a pattern that is invisible to the eyes. The pattern consists of small dots (100 μm in diameter) arranged with a spacing of approximately 0.3 mm on a square grid. The dots are slightly displaced from the grid, each dot in one of four possible positions. It is the pattern that makes it possible for the pen to know what is written and where it is written. Each dot carries two bits of information and since the pen registers positions by reading an area of 6 x 6 dots (which can have 46 x 6 = 436 = 272 unique combinations) unique pattern is ensured on a very large area. The displacement of the dots makes it possible to uniquely identify each pattern area [11]. In this study, Anoto Functionality is used for entire system construction.

2. System Configuration

Logitech® io™2 pen was used as digital pen, and Anoto Functionality(software development toolkit, form development toolkit, pattern license) of Anoto AB is used for developing digital pen data entry system and postscript file for printing. AFPL Ghostscript 8.54 and GSview are employed to print PS (Postscript) file.

C#.NET was used for software language. Visual studio 2003 was used as a language tool. Operation environment was the Windows XP with Microsoft.NET Framework version 1.1. Microsoft.NET Framework essentially was installed first in order to install Logitech® io™2 pen. Microsoft SQL database was used for saving the vector and result value, which is recognized and converted via recognition process.

3. System development

First of all, we mapped out a scenario for hospital setting (Figure 1). We designed digital form generator to load the existing clinical documents (ex. Hangeul (Korean editor), PowerPoint, Excel, Word file). After the existing document file loaded, user can set the user-area for saving the pen-data

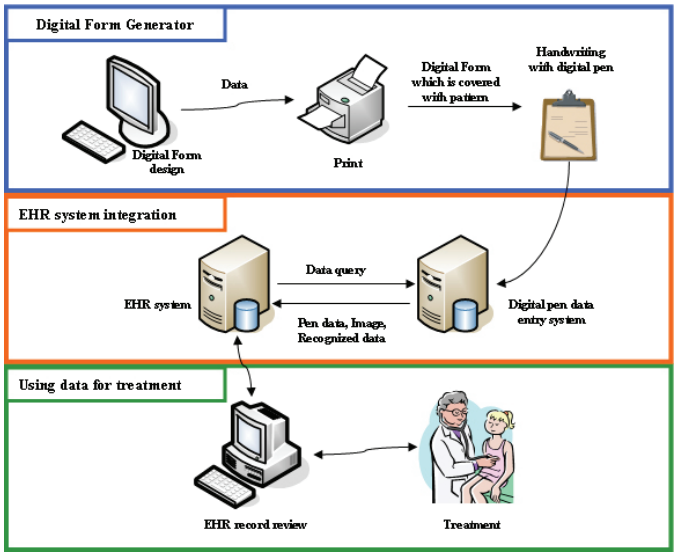

Figure 1 - System scenario

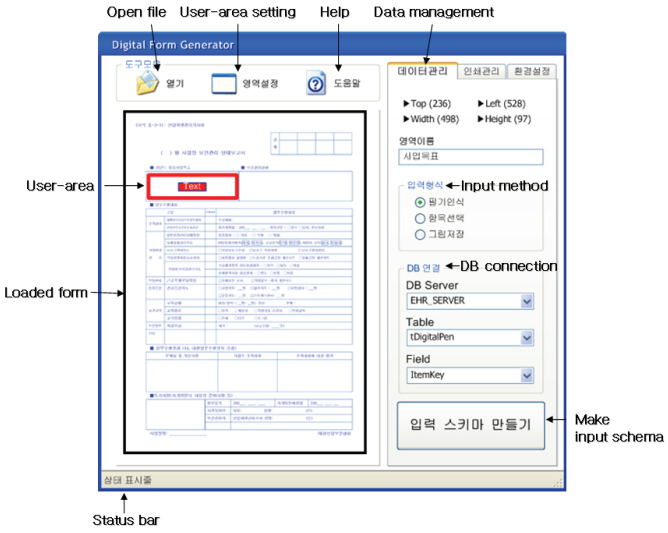

Figure 2 - User-area setting in Digital form generator

After user-area setting via digital form generator interface, digital form, which is covered with patterns would be printed out. Then the user can write treatment result or physical assessment data on the digital form freely. When the user put the digital pen into the cradle, which is connected to local PC by USB cable, the data synchronizing would be aroused and pen data would be converted into images, recognizing data and saving these in EHR system server. These data could be reviewed and used as treatment data or research data. On the base of this scenario, we planned to develop the digital form generation system, which is consisting of digital form generator interface and digital pen data entry system. To evaluate the digital form generation system, we developed prototype of EMR system and tested data processing procedure.

Results

1. Digital form generator

The user can load the existing form and easily set the user-area with dragging red box and can view the area size and position information via right side bar. The data management tab provides three ways for setting the input method (Handwriting recognized data, check box data, image) for each user-area. Database connection part shows the database server, table, field name of EMR server. As the making input schema button pressed, PAD file including user-area information and INI file for database information is generated (Figure 2).

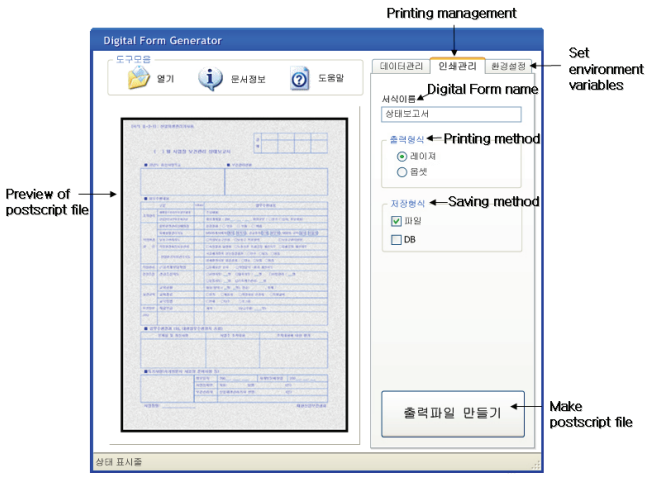

Figure 3 - Make postscript file in form generator

At the printing management tab, user can select the printing method. When user wants to print at the local or network printer, laser option could be selected. But when user wants to print a large amount of digital form at once, offset option should be selected (Figure 3).

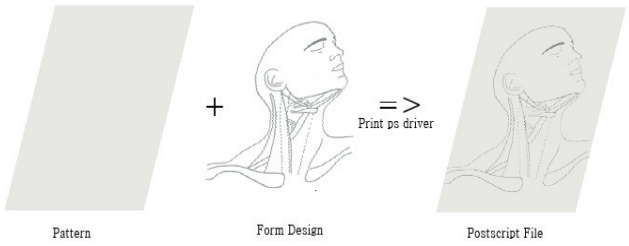

Figure 4 - Postscript output

When making postscript file button pressed, the existing form and Anoto pattern are merged and a postscript file is created for printing using postscript printer driver (Figure 4).

As the result of digital form generator, PAD file, INI file, and postscript file are generated. The digital form is printed by using postscript file.

2. Digital pen data entry system

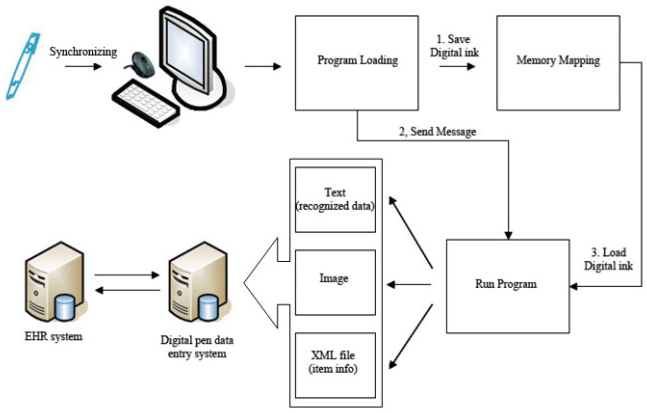

Figure 5 – Data digitalizing process

EHR system integration part of scenario can be explained as data digitalizing process perspectives. After the user handwrite on the digital form and put the pen into the cradle, the new instance of digital pen data entry system is loaded. The instance reads digital ink using address of memory map, which is transmitted to windows message. The application handles the pen data for various formats (handwritten recognized data, check box data, and image) according to input schema. After data handling is completed, the event message is transmitted to EHR system. Then EHR system reads the saved data from digital pen data entry system.

We implemented the digital form generation system, which enables user to generate digital form easily, and print whenever it is needed. This system converts handwriting data to digital data automatically, and put these into EMR database at once.

At first, we developed the digital pen generator in order to print digital form. Digital form generator interface is developed to allocate the user-area for recognition and to save data into database.

Secondly, digital pen data entry system is developed. When user uses digital form with digital pen, digital pen data entry system enables handwriting data saved as a recognized text data, image into database automatically. After handwriting and putting the digital pen in the cradle, pen data are transmitted to PC as vector format.

Conclusion

The digital form generator is an independent solution from EMR system. So when it adapted to other EMR system, less initial expenditure and more rapid adaptation are expected. Especially, in cases of questionnaire of patient symptom, consent, physical patient assessment using background image, this system would be very useful for digitalizing the patient records. The immediate use of the collected patient survey data for the patient treatment would be available. User satisfaction for EMR system would increase when this system is embedded to EMR system, because the user can create and print digital form when it is needed. Also, economic migration toward EMR system would be achieved because the repository is not necessary, and there is no need to buy another special printing system. If the printer dpi is over 1500dpi, any printer can be used. The clinic staff, even the ones, who are not familiar with a computer, would accept the collecting the electronic health record as easy and fast task. We have a plan to integrate this system with real EMR systems. We hope this system to contribute rapidly and smoothly to support medical treatment and to computerize the medical data with low cost.

Abstract

The u-Healthcare is a new healthcare paradigm based on the Internet and ICT. Healthcare service using mobile devices includes sensor devices using measured biosignal data and home health network. The biosignal monitoring service is one of the monitoring services in ubiquitous healthcare. Methods of inputting, transferring, and managing biosignal data are so various that device interfaces need to be expanded. A transferred data format also needs a data transmission standard like Health Level 7. We implemented the sender/receiver interface using three devices including a PDA, a desktop computer, and a digital pen. Also the HL7-based biosignal message template and its database were designed. In the user input interface, patient/doctor's interfaces were developed separately and they enabled the user to review graphically the accumulated data. We adopted a digital pen having a powerful user-friendly input interface to develop the self-record manage application.

Keywords:

biosignal, Interface, Transmission, Database, Health Level 7, XML

Introduction

The healthcare services using mobile devices include various devices using measured biosignal data, home health network, electronic home appliances, and so on. The biosignal data management system usually monitors, analyzes and manages the biosignal data of wireless medical devices like blood pressure, pulse and ECG data, etc. In this system, some essential techniques are needed for the system functions of sending to the server wirelessly, storing, and managing the measured data. We tried to find how to input the wireless biosignal data and how to send them to the management system by an efficient data transfer method. First, to make the system construct easily and reuse the data, we referred to common data formats and transfer methods. Secondly, to full use of recent data input devices, we should expand input interfaces in ubiquitous environment. We considered several standards for EHR and applied Health Level 7(HL7) Version 3.0 to our application. We thought that HL7 was accepted medical informatics relatives as general standardized data transmission protocol. We had implemented the web-based patient monitoring system using HL7 Version 2.5 as a preliminary study in 2005. This research aimed the improvement of the previous study and it was new approach by adding user interface devices and applying the new version of standardized data transmission protocol.

Methods

The whole system are composed of 4 major parts: the client input interface of three devices, the server interface of sending/receiving data, and the user interface including a graphic view and a digital pen interface. First, we designed and implemented HL7 Message Sender/Receiver Interface. In the Message sending module, Blood pressure, pulse, respiration, temperature, SpO2 and general information of patient were input into the application program. The message receiving module was the server application of HL7 V3.0 message receiver. The server received a message from the client program and sent a HL7 V3.0 acknowledge message to the client program. The database was developed with Microsoft Windows 2003 Server, Visual C#, SQL Server 2000 and XML. It stored and managed the data in XML documents. The application program of home self-recording was implemented by a digital pen.

Results

1. **Design of HL7 V3.0 RIM-based Biosignal Database**

The Biosignal Database was designed using the RMIM (refined message information model) that was the restrained model of the HL7 RIM. The cMET schema for the measured data with texts, REPC_RM000130 (ObservationVitalSigns.xsd) was applied. It was able to easily transfer the received data into the server system. The database stored and managed them within XML format messages. We made basic messages of biosignal data with the general information of the patient, and composed the input XML template. The standard model was reflected on tables and attributes.

2. Design and implementation of message sender/ receiver interface system

When the data were input into sender devices, a desktop computer, a PDA phone, the sender interface system made HL7 3.0 XML files of them. Multiple files could be sent to the server simultaneously. The sender interface on desktop computer has the user interface of data input and sends the data into an each device and shows the converted XML files to the user. When the user enters his name and password for login on a PDA, the sender converts the written biosignal data to XML files and sends to the server database. Then the server sends an acknowledge message to the PDA application, and sends the data within XML files to the database.

If HL7 V3.0 XML files received from the sender interface are valid, the message receiver stores them to the integrated biosignal database in the server application. Each an acknowledge message (ACK) toward each valid HL7 message is sent to the sending interface. When an invalid message is received or when a communication error is occurred, the system sends the ACK message with a specific value of the error.

3. Web-based Biosignal Data Management

This application has a query function to review the accumulated biosignal data by data itself and graphics. After the program registers to the web server, users enter their name and password for login in a web site or a device interface and they can inquire or review their accumulated data by a web browser. The main function is that users can inquire their data sorted by time and data types in the table or graphic format.

The patient can review his accumulated data and view graphically by PDA phone application program. After the data inserted to the database, the patient can't edit them. After login, the doctor can monitor his patient's data anywhere.

4. Expanded input interface: digital-pen application

We designed the self-record manager program as a Windows application by C#. Self-records at home were composed with personal identification items, biosignal data input items, and a memo item that the patient could input any comment or any question to his doctor. The manager can recognize a user using the pen ID in the personal information register items, and the user doesn't need to enter its personal information each time. It makes the data store individually. The written pen data is converted to selected image types (jpg, png, pdf) and is stored. When a user selects the data, it is converted to a HL7 3.0 message XML file and is sent to the server.

We added and expanded another function to self-recorded papers in home, the program could autonomously input a date and time item, and a respiration input item. Figure 7 shows self-management record manager.

In the record format using a digital pen, about 80% character recognition was caused of presence of various handwriting patterns. So we added a correction function, and users could review and correct their written data. The push of the recognition button in the lower review window shows written data and users may correct and store them.

Discussion

We implemented input biosignal data interfaces on a desktop computer and a PDA phone. The user interface was different user screen according to the patient or the doctor. The measured biosignal data from each medical device was converted a standardized message format and sent to the data management system server wirelessly with the standardized transmission format.

The points of this study were the wireless biosignal data transmission and the application of standardized transmission protocol (HL7 V3.0). During the implementation of the applications, we faced with many problems again for using a general standardization protocol. Because items of HL7 message tags were so detailed that we were not easy to apply these items to the real message. The types of data are limited in this study. We have a plan to expand them and to expand applications of data transmission standards to other related studies. The database inquiry will also use the standardized message format. The future study of data transmission standards and technologies will be followed.

This study was one part of the Ubiquitous Biosignal Device Center Project in Korea. The project aims at developing everywhere-anytime healthcare system. By minimizing medical equipments and making the users (patients, doctors and nurses, etc) to carry them all the time. Our team is looking for the technology of standardizing and interfacing body information.

The biosignal data were continuously generated by mobile devices or wearable sensors. We started from pre-assumption that the data were already measured by sensors and the user wanted to enter them on his screen interface in this study. Finally all implementations were connected each other sub-study.

Conclusion

In ubiquitous environment, various user interfaces are needed to introduce biosignal data sending/receiving, test and expand. We implemented the user interface with a desktop computer, a PDA, and a digital pen using a standardized data transmission method. The standards are not easy to implement real situation but they will be a trend in healthcare delivery system. But they are so essential to

share the healthcare data and they can make software applications simplify. The technology-assisted application with a new device is convenient and potentially powerful complement to user-led management. The device easily to use can encourage users to self-manage their healthcare information.

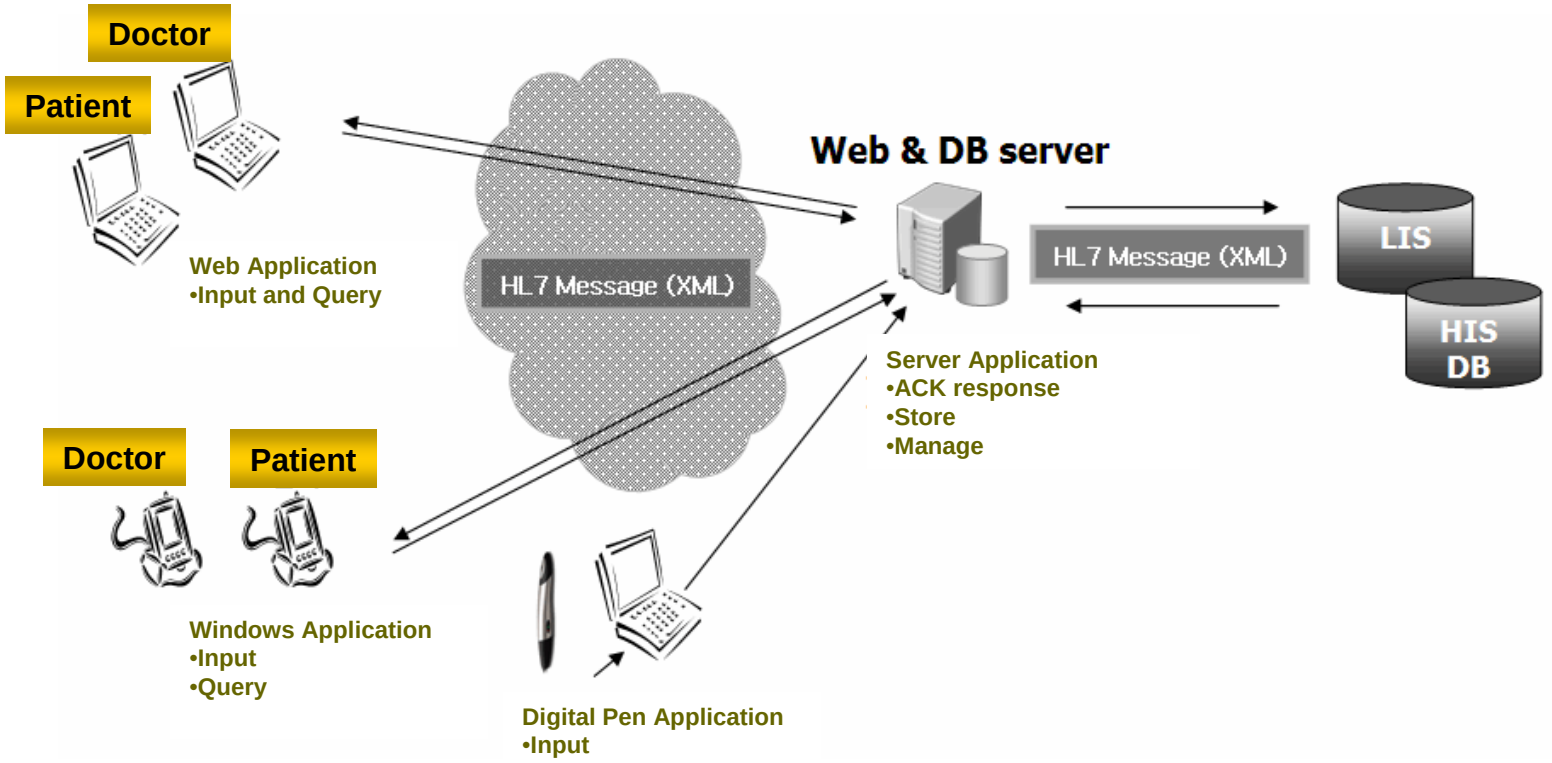
System Architecture

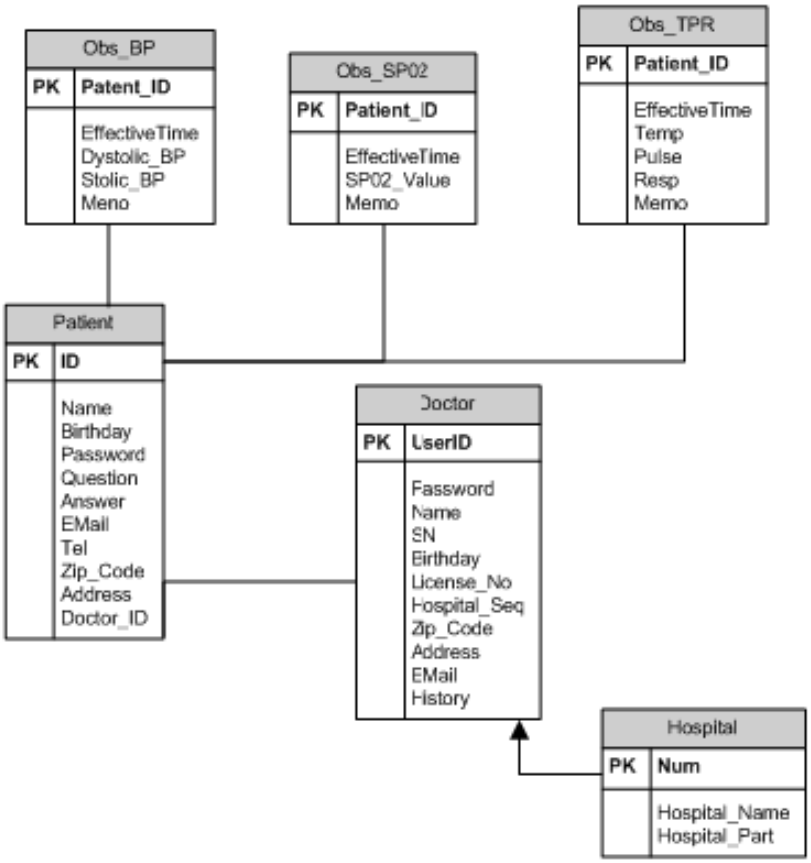


4 major parts:
the client input interface of three devices, the server interface of sending/receiving data, the user interface including a graphic view and a digital pen interface

Methods

1. Design and implementation of HL7 Message Sender/Receiver Interface for sending/receiving biosignal data and standardization
   - Message sending module of biosignal data
   - Message receiving module
   - Developed by MS Windows 2003 Server, Visual C#, SQL Server 2000 and XML
2. Web-based personal biosignal data management in a desktop computer
   - Standardized messages in user login and new user creation at the web-based interface
3. Application program for the home self-recording with digital pen
   - ioPen produced by Logitech was used

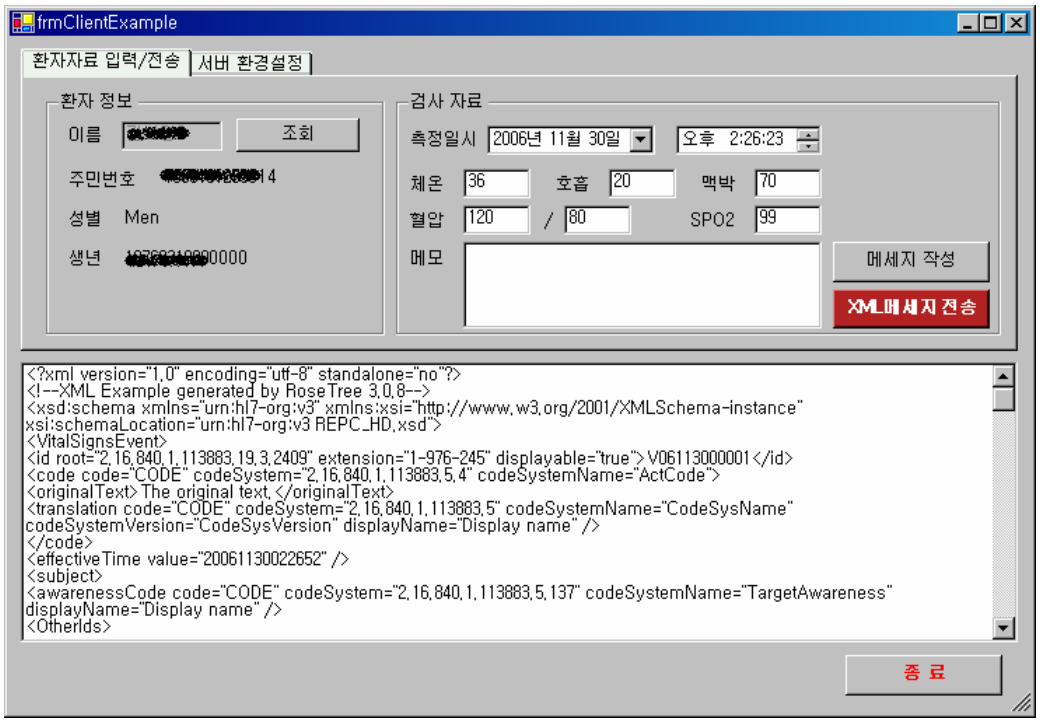
HL7 V3.0 RIM-based Biosignal Database



- The cMET schema for the measured data with texts, REPC_RM000130(ObservationVital Signs.xsd) was applied.
- The tables for other information were added.

Message sending/receiving interface

1. HL7 Message Sender Interface in the desktop computer



- The user interface of data input and sends the data into an each device and shows the converted XML files to the user.
- When the user presses the red button, the converted data can be confirmed in the lower box and are sent to server.

Message sending/receiving interface

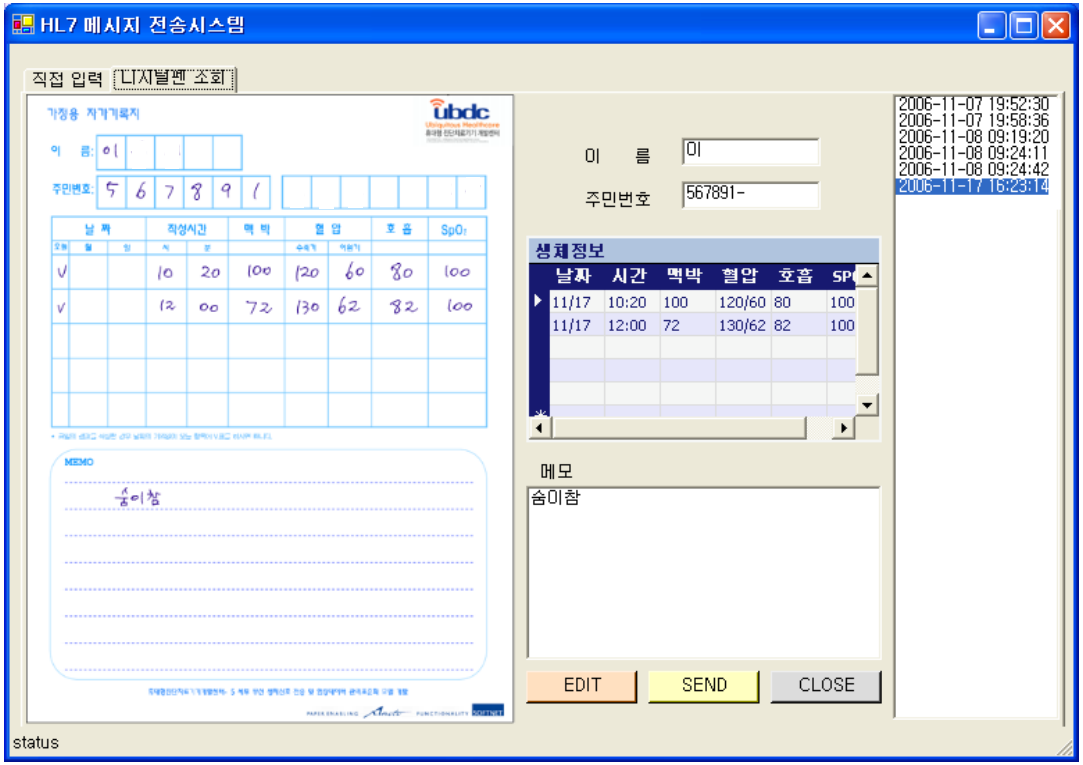
2. HL7 Message User Interfaces in the PDA phone

Inserting of Data

Inquiry of Data

- When the user enters his name and password for login on a PDA, the sender converts the written biosignal data to XML files and sends to the server database.
- The server sends an acknowledge message to the PDA application, and sends the data within XML files to the database.

Self-recording Manager by the Digital pen



- The written digital pen data is converted to selected image types (jpg, png, pdf) and is stored.
- Self-records at home were composed with personal identification items, biosignal data input items, and a memo item that the patient could input any comment or any question to his doctor.

Discussion

- The points of this study were the wireless biosignal data transmission and the application of standardized transmission protocols.
- During the implementation of the applications, items of HL7 message tags were so detailed that we weren't easy to apply these items to the real message.
- The biosignal data were continuously generated by mobile devices or wearable sensors.
- We started from pre-assumption that the data were already measured by sensors and the user wanted to enter them on his screen interface in this study. The types of data are limited in this study.
- We have a plan to expand them and to expand applications of data transmission standards to other related studies.
- The database inquiry will also use the standardized message format.

Conclusion

- By minimizing medical equipments and making the users (patients, doctors and nurses, etc) to carry them all the time. Our team is looking for the technology of standardizing and interfacing body information.
- The standards are not easy to implement real situation but they will be a trend in healthcare delivery system. But they are so essential to share the healthcare data and they can make software applications simplify.

In the Message sending module, Blood pressure, pulse, respiration, temperature, SpO2 and general information of patient were input into the application program. The message receiving module was the server application of HL7 V3.0 message receiver. The server received a message from the client program and sent a HL7 V3.0 acknowledge message to the client program. The database was developed with Microsoft Windows 2003 Server, Visual C#, SQL Server 2000 and XML. It stored and managed the data in XML documents. The application program of home self-recording was implemented by a digital pen.

Results

Design of HL7 V3.0 RIM-based Biosignal Database

The Biosignal Database was designed using the RMIM (refined message information model) that was the restrained model of the HL7 RIM. The cMET schema for the measured data with texts, REPC_RM000130 (ObservationVitalSigns.xsd) was applied. It was able to easily transfer the received data into the server system. The database stored and managed them within XML format messages. We made basic messages of biosignal data with the general information of the patient, and composed the input XML template. The standard model was reflected on tables and attributes.

Design and implementation of message sender/receiver interface system

When the data were input into sender devices, a desktop computer, a PDA phone, the sender interface system made HL7 3.0 XML files of them. Multiple files could be sent to the server simultaneously. The sender interface on desktop computer has the user interface of data input and sends the data into an each device and shows the converted XML files to the user. When the user enters his name and password for login on a PDA, the sender converts the written biosignal data to XML files and sends to the server database. Then the server sends an acknowledge message to the PDA application, and sends the data within XML files to the database.

If HL7 V3.0 XML files received from the sender interface are valid, the message receiver stores them to the integrated biosignal database in the server application. Each an acknowledge message (ACK) toward each valid HL7 message is sent to the sending interface. When an invalid message is received or when a communication error is occurred, the system sends the ACK message with a specific value of the error.

Web-based Biosignal Data Management

This application has a query function to review the accumulated biosignal data by data itself and graphics. After the program registers to the web server, users enter their name and password for login in a web site or a device interface and they can inquire or review their accumulated data by a web browser. The main function is that users can inquire their data sorted by time and data types in the table or graphic format.

The patient can review his accumulated data and view graphically by PDA phone application program. After the data inserted to the database, the patient can't edit them. After login, the doctor can monitor his patient's data anywhere.

Expanded Input interface: Digital-Pen Application

We designed the self-record manager program as a Windows application by C#. Self-records at home were composed with personal identification items, biosignal data input items, and a memo item that the patient could input any comment or any question to his doctor. The manager can recognize a user using the pen ID in the personal information register items, and the user doesn't need to enter its personal information each time. It makes the data store individually. The written pen data is converted to selected image types (jpg, png, pdf) and is stored. When a user selects the data, it is converted to a HL7 3.0 message XML file and is sent to the server.

We added and expanded another function to self-recorded papers in home, the program could autonomously input a date and time item, and a respiration input item. Figure 7 shows self-management record manager.

In the record format using a digital pen, about 80% character recognition was caused of presence of various handwriting patterns. So we added a correction function, and users could review and correct their written data. The push of the recognition button in the lower review window shows written data and users may correct and store them.

Discussion

We implemented input biosignal data interfaces on a desktop computer and a PDA phone. The user interface was different user screen according to the patient or the doctor. The measured biosignal data from each medical device was converted a standardized message format and sent to the data management system server wirelessly with the standardized transmission format.

The points of this study were the wireless biosignal data transmission and the application of standardized transmission protocol (HL7 V3.0). During the implementation of the applications, we faced with many problems again for using a general standardization protocol. Because items of HL7 message tags were so detailed that we were not easy to apply these items to the real message. The types of data are limited in this study. We have a plan to expand them and to expand applications of data transmission standards to other related studies. The database inquiry will also use the standardized message format. The future study of data transmission standards and technologies will be followed.

This study was one part of the Ubiquitous Biosignal Device Center Project in Korea. The project aims at developing everywhere-anytime healthcare system. By minimizing medical equipments and making the users (patients, doctors and nurses, etc) to carry them all the time. Our team is looking for the technology of standardizing and interfacing body information.

The biosignal data were continuously generated by mobile devices or wearable sensors. Evaluating Benefits of a Large Domiciliary Nursing Workforce Using Mobile Computers

Ian Cash, Julianne Oorloff

Information Services Division, Royal District Nursing Service, Melbourne, Australia

Abstract

In 2003, Royal District Nursing Service (RDNS) rolled out a Mobile Computing System (MCS) to approximately 800 domiciliary nurses and allied health staff working in the greater Melbourne Metropolitan area, providing real time access to client and visit information as well as email, intranet, internet and office suite applications.

In 2005 RDNS initiated a formal evaluation of the MCS which focussed on seven key themes: client care; work practice; use; satisfaction and value; system cost and saving, system management and support model and technical performance.

The detailed findings were gathered using an online survey ,workshops with clinicians, administration and support staff at regional Centres, accompanying clinicians "on the road", interviews with Managers and Executives and review of documentation. This paper will present a number of the outcomes that informed the key summary of findings of the RDNS MCS experience to date – telling it "As It Is":

1. There has been a very successful deployment of the MCS across RDNS
2. The nursing staff are positive about having and using the MCS. There is a large "bank of goodwill" towards it and they would welcome enhancements.
3. There have been issues with MCS reliability and functionality that degrade benefits, productivity and satisfaction
4. The MCS significantly achieves RDNS objectives in relation to visit management but there is more work to do in relation to the MCS improving client care.

The evaluation of the MCS has provided insights relevant to many health care providers looking to implement mobile computing to improve health service delivery. RDNS has achieved this on a large scale and our experience can help inform the planning of other health organisations wanting to make the best possible use of information, and communication technologies in a sustainable health system.

Keywords:

mobile computing, evaluation, nursing informatics

Introduction

RDNS' Mobile Computing System (MCS) has been fully operational with more than 800 field staff users since 2003. Heading into 2006/2007, RDNS faced an imminent and significant outlay to refresh the technology, particularly the portable computing devices (tablets). In this circumstance, it was prudent and timely for RDNS to undertake a comprehensive evaluation of the MCS as it is and to review possible future directions for the system.

RDNS engaged Opticon Australia to undertake the evaluation. Opticon has provided a comprehensive "As it Is" picture of the current MCS, a detailed assessment of the value RDNS is presently enjoying from the current MCS along with the value it can expect to extract in the future, and recommended actions RDNS should take in the short and medium term to assure the sustainability of the MCS in to the future.

How was the evaluation conducted?

The evaluation process was done in four stages, Information Collection, Analysis into Findings, Evaluation of the MCS, and Recommendations.

Information collection

Opticon partnered with the RDNS project team and a broad and deep cross section of RDNS personnel to collect comprehensive information to inform the evaluation. In a first stage, this included:

- A review of a large body of documentation;
- Interviews with senior management and persons in positions of key relevance to the MCS;
- Three workshops involving clinicians and administrative staff from a cross section of Centres;
- Field visits by Opticon consultants to four centres to observe first hand work-a-day use and issues relating to the MCS; and
- A comprehensive survey completed by more than 400 staff.

Since more than 400 field staff provided survey responses, the interpretation of the results assumes that the survey response is truly representative of all field staff.

The information collection provided a repository of material on which RDNS and Opticon believed analysis, evaluation and recommendations could proceed with a high level of confidence.

Analysing the information collected into findings

The survey statistics were interwoven with the qualitative information collected in the interviews, workshops, field visits and documentation review. This combination formed a comprehensive picture of the MCS "As It Is".

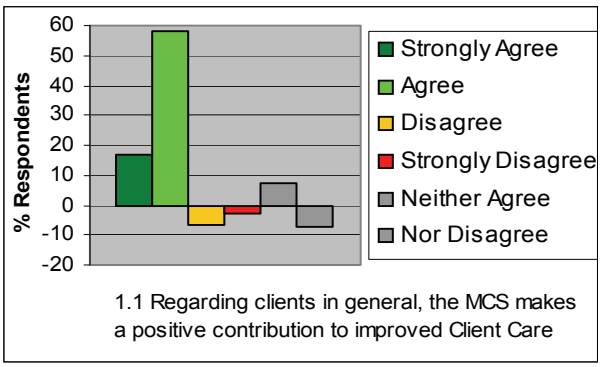
Introduction to detailed findings

The Detailed Findings are structured in line with the Themes and Key Questions specified by RDNS. These are shown in the table below.

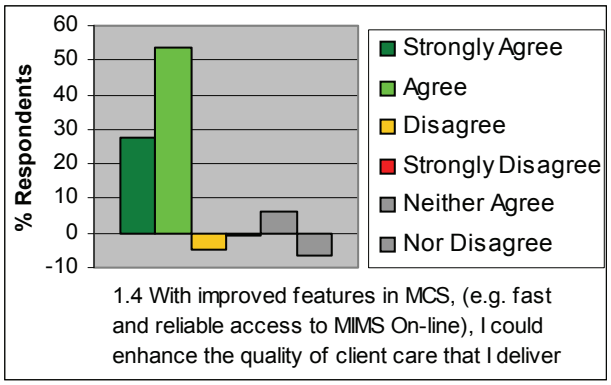
Theme	Key Question
Client Care	Is the system improving clinical care?
Work Practice	How has the system impacted work practices and stakeholders at RDNS?
Satisfaction and Value	Is the system judged to be useful and valuable to stakeholders?
System Cost and Savings	Is the system value for money?
Use	How usable is the system?
System Management and Support	How effective is the system management and support model?
Technical Performance	How well is the technology working?

Is the system improving client care?

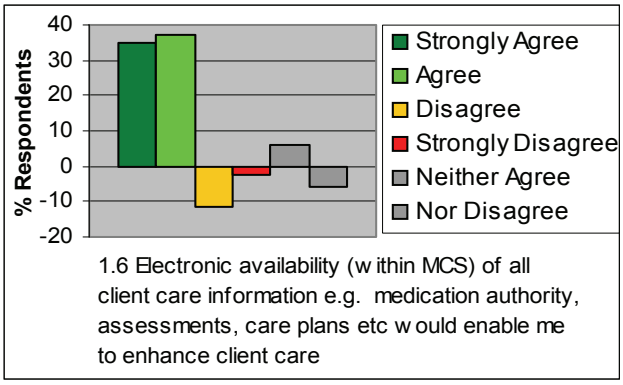
What we found is that there is a strong impression that MCS has improved client care in a general sense, as shown by chart 1.1.



1.1 Regarding clients in general, the MCS makes a positive contribution to improved Client Care



1.4 With improved features in MCS, (e.g. fast and reliable access to MIMS On-line), I could enhance the quality of client care that I deliver



1.6 Electronic availability (within MCS) of all client care information e.g. medication authority, assessments, care plans etc would enable me to enhance client care

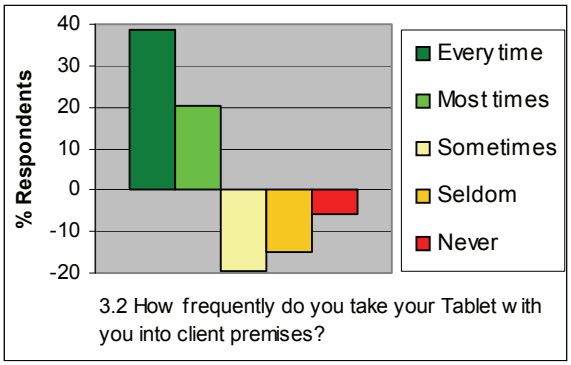
It was also found that the current system is more about static client information and visit management information but that enhanced functionality would further enable the enhancement of client care.

How has the system impacted work practices and stakeholders at RDNS

Using the tablet in the client's home

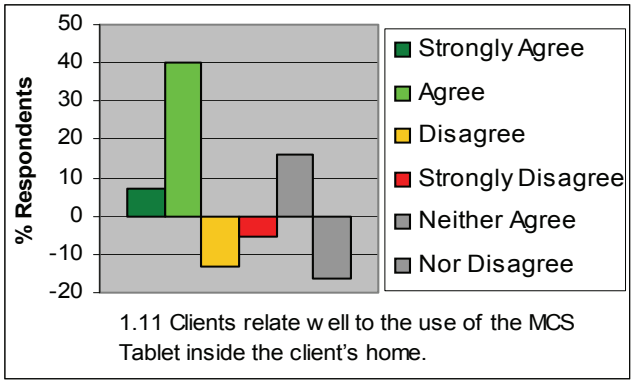
Information from workshops, field visits and the survey indicated that clinicians have mixed practices and views about using the tablet in the client's home.

Chart 3.2 shows that 60% of `clinicians take their tablet into the client's home most visits. But about 40% take the tablet in to the client's home sometimes, seldom or never.



3.2 How frequently do you take your Tablet with you into client premises?

Chart 1.11 shows clinicians have quite mixed views about how comfortable their clients feel about the clinician using the tablet ("a computer") in their home.



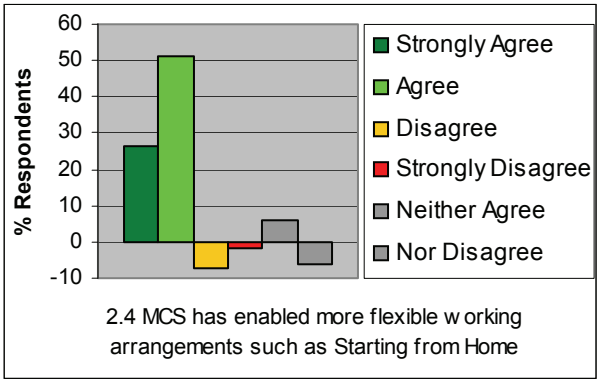
1.11 Clients relate well to the use of the MCS Tablet inside the client's home.

Feedback from the workshops and field visits provided some further insight into MCS usage during client visits. Participants reported on the one hand that MCS makes vital visit information available on site. On the other hand, they also reported that the tablet/MCS tends to become "irrelevant" in the face to face client interaction. The client interaction with the clinician is strongly identified as a trusted relationship. Clinicians voiced significant concerns relating to the potential of "with client" use of tablets creating a barrier or intrusion into that interaction.

Visit management work practices

In workshops and field visits, clinicians indicated that the MCS:

- Facilitated better visit management by making relevant information more accessible;
- Helps optimise staff resources – e.g. by facilitating client exchange 'on the road'; and
- By accurately recording travel time revealed that when not using MCS, travel time tended to be underestimated.

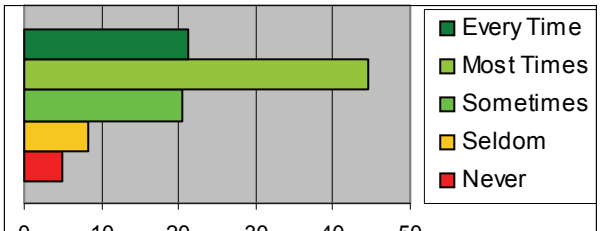


2.4 MCS has enabled more flexible working arrangements such as Starting from Home

Maintaining up to date information in MCS

An important issue for both clinicians in the field and Centre Support management in Centres and Head Office is maintenance of up to date information in MCS.

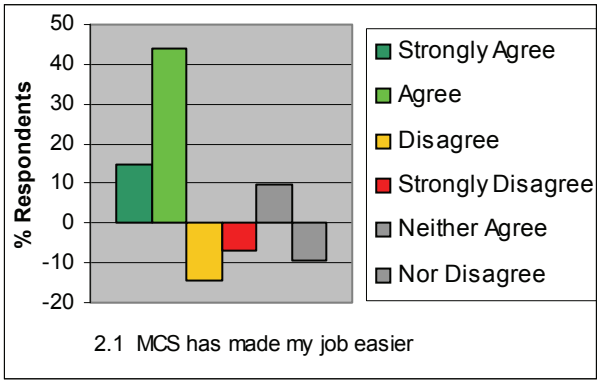
The preferred practice for field clinicians is that they update their schedule "on the road" at least once as well as at start and finish of their shift. Chart 3.6 shows that this standard is practiced by more than 80% of field staff.



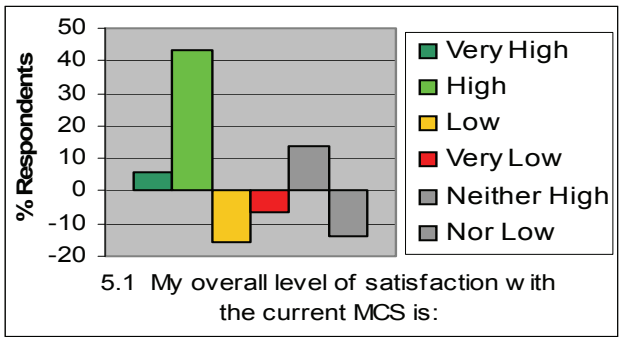
3.3 To what extent do you update client data in Gemino during or immediately after each client visit?

How satisfied are clinicians with MCS?

There was an overall positive feeling towards the MCS and staff generally felt it made their job easier.



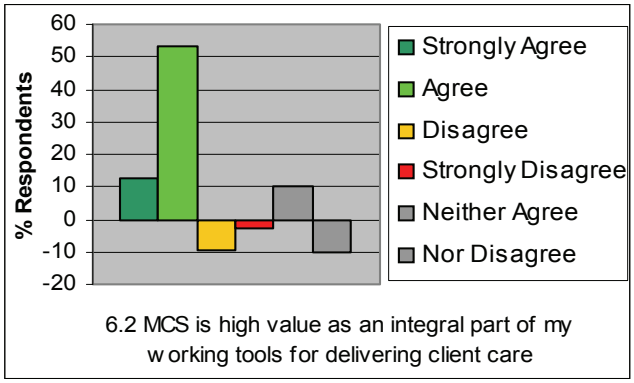
2.1 MCS has made my job easier



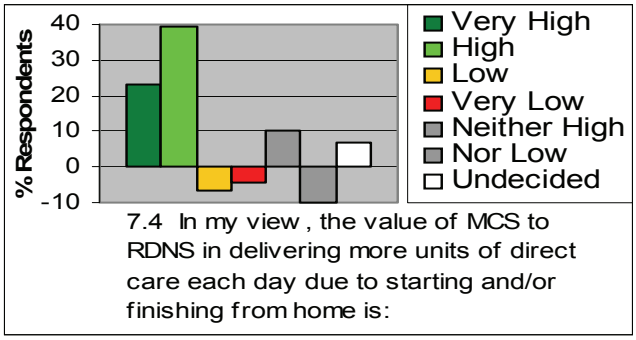
5.1 My overall level of satisfaction with the current MCS is:

Is the system value for money?

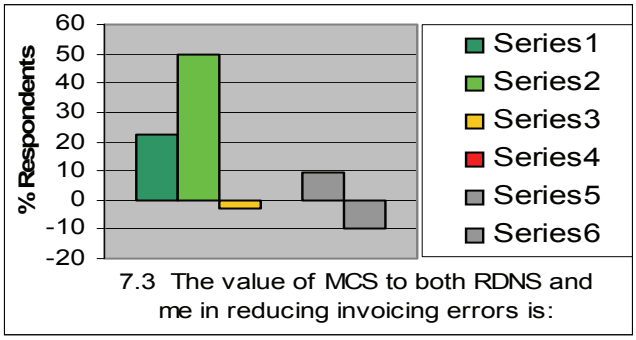
At the clinician level, chart 6.2 shows that MCS is regarded a tool with high value.



6.2 MCS is high value as an integral part of my working tools for delivering client care



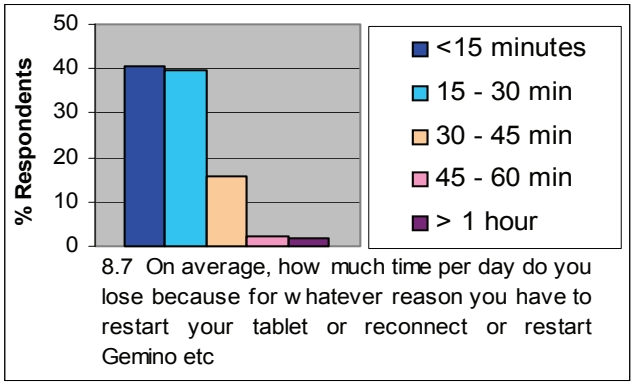
7.4 In my view, the value of MCS to RDNS in delivering more units of direct care each day due to starting and/or finishing from home is:



7.3 The value of MCS to both RDNS and me in reducing invoicing errors is:

How usable is the system?

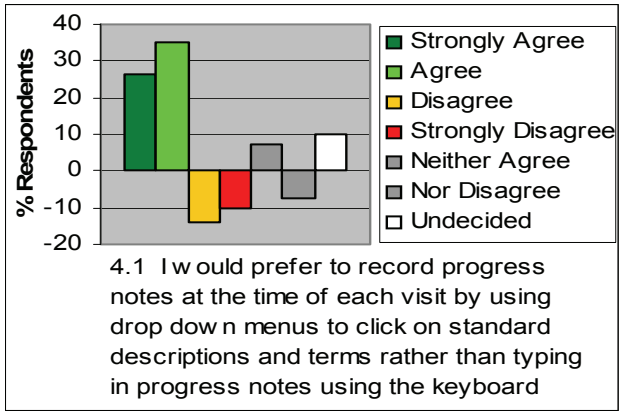
Perhaps the most telling finding in regard to usability is the amount of time clinicians expend each day dealing with various malfunctions in the MCS.



8.7 On average, how much time per day do you lose because for whatever reason you have to restart your tablet or reconnect or restart Gemino etc

What would improve usability?

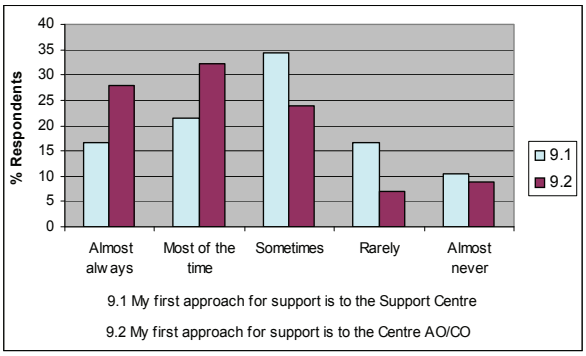
What would clinicians want to improve usability? Findings already reported have noted that the current MCS provides functionality more directed at visit management than client care. Chart 4.1 highlights clinician attitudes to some aspects of strengthening the client care toolsets in the MCS.



4.1 I would prefer to record progress notes at the time of each visit by using drop down menus to click on standard descriptions and terms rather than typing in progress notes using the keyboard

How effective is the system management and support model?

Under the RDNS model for system management and support, clinicians should go to their centre AO/CO for first level support and the IS Support Centre for second level support. In reality, practice seems to conform more to a free choice model.



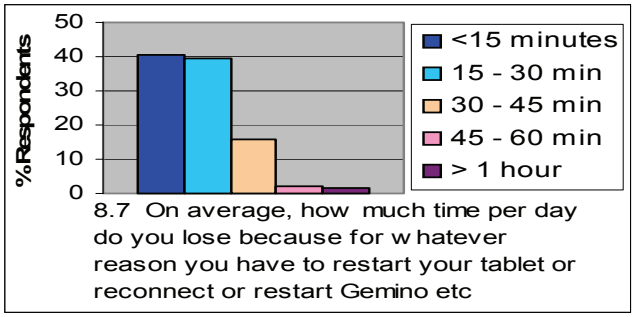
9.1 My first approach for support is to the Support Centre

9.2 My first approach for support is to the Centre AO/CO

How well is the technology working?

Reports from both the field and IS have indicated that tablets degenerate at an increasing rate as they age.

Changing batteries, re-entering data, restarting the tablet, unresponsiveness and re-attempting connections all not only add to the day's frustrations but take up clinician time. Feedback on recently replaced tablets was very positive.



Summary of findings – telling it "As It Is"

Four key big picture findings summarise the RDNS MCS experience to date:

1. In Opticon's view and experience, the successful deployment of the MCS across the 800-plus RDNS field staff is a great achievement;
2. Overwhelmingly, the field staff are positive about having and using the MCS. There is a large "bank of goodwill" towards it and they would welcome enhancements;
3. There are significant issues with MCS reliability and functionality that are frustrating to both users and support staff and seriously degrade benefits, productivity and satisfaction; and
4. The MCS significantly achieves RDNS objectives in relation to visit management but significantly under achieves RDNS objectives in relation to improved client care.

Conclusion

What RDNS has achieved in its MCS is a noteworthy success. There is widespread penetration and acceptance. The MCS has become an indispensable tool for visit management. Further, the significant bank of goodwill amongst users augurs well for introducing future enhancements.

At the same time there are performance issues and problems that detract from the positives There is also a shortfall in functionality that means the always-held ambition of using MCS to improve direct client care has not fully been realised and cannot be realised without further software development or replacement.

Information System for Clinical Organisations: from Hospital Information System to a Sustainable National Service for Treatment and Long Term Research in Wales

Hazel A. Bailey, Anthony J. Bater, David G.J. Howells, Dave Morrey, Wendy Jones.

Clinical Information Unit, Velindre Cancer Centre, Cardiff, United Kingdom

Abstract

Information System for Clinical Organisations (ISCO), originally developed as a clinical information system at the Velindre Cancer Centre in South East Wales, is now an All-Wales Electronic Health Record, primarily for cancer, serving 1000 users in 43 sites across Wales. Clinical information in ISCO is shared across organisations in Wales, improving communications between healthcare professionals and smoothing the patient pathway from referral to secondary care through to diagnosis, treatment and death. Data collected in the system is used to inform audit and research which in turn require the system to adapt. ISCO has proved to be a sustainable system in the medium term and its longer term sustainability should be assured by developments for Informing Healthcare.

Keywords:

Medical Records System, Computerised,
Hospital Information Systems,
Management Information Systems

Introduction

The Information System for Clinical Organisations (ISCO) is an Electronic Health Record (EHR) for cancer and other diseases across Wales, a principality within the United Kingdom. Designed to meet the audit needs of clinicians at Velindre Hospital in 1991, development of ISCO has always taken place with the full participation of clinicians and other users, as advocated by Protti [1]. Regular User Group meetings are held and ISCO has always had the support of the cancer centre management since its inception, ensuring financial stability.

A single casenote, multiple provider model was implemented in 1997 to meet users' and other organisations' needs, including palliative care [2]. ISCO as an EHR was born. Users may see a summary of patient care wherever it has taken place in Wales. For cancer patients the entire cancer history from screening to diagnosis, treatment and death is available. This is an individual health record event model as envisaged in the national information management and technology strategy[3].

The Cancer Information Framework has driven expansion of ISCO to include the All Wales Tumour Site Specific Cancer Datasets [3]. Cancer Services Units in hospitals across Wales collect cancer dataset information, for which purpose the system is known as Cancer Network Information System Cymru (CaNISC)[3]. Cancer data sets are used to monitor adherence to Cancer Standards and the statutory cancer waiting times.

ISCO now has 1000 users across 43 sites in Cancer Services, palliative care, Wales Cancer Trials Network, Wales Cancer Genetics, Wales Cancer Bank, Cervical Screening Wales for Colposcopy and Welsh Movement Disorder e-Network in South East Wales. There are over 338,000 individual patient records in the database.

Methods

System development and delivery

The prototyping approach is used for development where a working model of a new system module is given to users to evaluate, allowing early identification of any problems. The model is then improved incrementally according to the users' needs, as advocated by Heeks [4].

Requests for system developments, systems analysis, training, information and support needs are all met by the Clinical Information Unit (CIU) at Velindre Hospital where the critical nature of the application is well understood.

As "interoperability is the key... issue" [5], national and international standards are used where possible. There are plans to move to SNOMED CT coding in the near future.

As many organisational numbers as necessary can be stored for each patient as well as the NHS number. A unique internal system identifier and a rigorous registration process, using links to other patient databases, keep duplicate patients at a very low level.

The data structure is patient based, with logical separation of each care provider's information allowing a security model where system users can access the information they need but only edit information added by their own organisation.

Users outside of the hospital access ISCO via a web browser client. Access to the system is controlled by an authorised signatory system. Users receive training appropriate to their role before being issued a password to access the system.

Information use

The database structure allows reporting at the individual clinician level through to multi-disciplinary team, organisational and national level. Participation in United Kingdom national audits is possible by extracting the appropriate data. A set of data analysis tools allow users to validate data, perform their own analyses using a pivot table and run reports without understanding the underlying data structure. Ad hoc requirements are provided by CIU.

New innovations

Several innovative strands of work are underway in ISCO that should ensure the system's longer-term sustainability:

- a Multi-Disciplinary Team (MDT) module, supported by Informing Healthcare, enables attendance at meetings, patients listed for discussion, relevant patient information and the outcome of the discussions to be viewed and recorded
- pathology Integration and Electronic Sign Off of Results are automatically downloaded into ISCO using HL7, which is a healthcare messaging standard
- ISCO Today Sidebar, an alerter system, tailored to users, enabling them to be pro-active rather than reactive with patient pathway management and care
- an anonymised link between ISCO and The Wales Cancer Bank [6] database will allow future researchers to use clinical information matched to tissue samples from patients contributing to the development of more effective, targeted treatment for cancer.

Discussion and conclusions

The major challenges of a multi-purpose (clinical, administration and audit), local and national system are:

- organisational: robust administration processes need to be in place before new modules are implemented
- reconciling local versus national requirements
- data accuracy and consistency across all teams and organisations
- difficulties getting agreement for sharing data electronically between organisations.

Overcoming these problems has however encouraged closer working between all organisations involved.

ISCO has proved to be a sustainable system in a rapidly changing environment by:

- continually evolving to meet users' needs, with regular user group meetings
- being developed within a team that also provides users' information needs, training and support
- enjoying the support of local and national management
- providing good quality information
- investigating organisational issues before the release of new modules.

The linkage of present clinical information at a national level with future research as with the Wales Cancer Bank provides an important lesson for future sustainability. ISCO/CaNISC is to be mandated for collection of the cancer datasets and cancer waiting times within Wales and taken together with the support of IHC and the view that it is 'an EHR for Cancer' [3] should ensure its long term sustainability.

More Evidence of the Challenges of Determining ROI on Health Information Technology (HIT): A European Telecare Case Study in Four Countries

Abdul Roudsari[a], Denis Protti[a,b],Howard Leicester[a]

[a]*City University London, England*
[b]*University of Victoria School of Health Information Science, Victoria BC, Canada and City University London*

Abstract

Return On Investment (ROI) from novel uses of Health Information Technologies (HIT) is proving a methodological challenge. This was illustrated by an example Telecare service, linking remote patient monitoring to clinical advice and support. The service was introduced in distinct sites around Europe (London, Estonia and 2 in portugal) supporting commoner chronic conditions (diabetes, hypertension, asthma, advanced heart and lung conditions). Evaluations from patient, clinician and manager perspectives reviewed various sources (monitoring records, patient and staff progress forms, clinician activity diaries). Withdrawal rates were high. Persistent patients tended to be older and sicker. some patients were too sick to use the service, while many felt too well to warrant it. The service was never routine at any site. Adjustments were better at locations with local IT support. Work patterns did not change appreciably, though some administrative staff became more involved. Nevertheless, staff and patients were positive about the future for telecare. It still appears that investment in infrastructures of technology, trained staff and patients may be necessary before full benefits are identified and realised.

Keywords:

Telecare, telehealth, chronic disease, long term conditions

Introduction

For years the international debate has raged—is it possible to see a return on the investments on sophisticated clinical information systems? The question is an important one. The cost of these systems is enormous, easily ranging into the millions of dollars, and information technology is coming into its own at a time when the healthcare system around the world are in general financially burdened and concerned with sustainability.

As has been reported by many, the conundrum of measuring the HIT function is that:

- efficiency (“doing things right”) is easier to measure than effectiveness (“doing the right things”)
- since effectiveness ("doing the right things") and innovation ("doing new things") can not be readily quantified in terms of traditional outputs, improvements are not usually reflected in economic efficiency statistics
- new systems are often intended to change difficult to measure actions
- strategic systems elude measurement
- infrastructure investments cannot be cost justified on a ROI basis

As with any infrastructure, HIT infrastructure does not provide direct business performance. Rather it enables other systems that do yield business benefits. HIT infrastructure is strikingly similar to other public infrastructures such as roads, hospitals, sewers, schools, etc. They are all long term and require large investments. They enable business activity by users that would otherwise not be economically feasible. They are difficult to cost-justify in advance as well as to show benefits in hindsight. They require a delicate investment balance - too little investment leads to duplication, incompatibility, and suboptimal use; while too much discourages user investment and involvement and may result in unused capacity.

As Friesse points outs, some research has shown that hospitals can indeed experience powerful returns on investments, but those returns might not take the direct financial form that CEOs demand [1]. There is some anecdotal evidence of direct financial return from some electronic medical records systems in some hospitals. But what has been found more consistently over time is that most returns on investment are frustratingly intangible—though they may feed into the bottom line indirectly. This "soft ROI" includes increased workflow efficiencies, decreased medical mishaps, automated clinical decision support and the like. These improvements are clearly of tremendous value to patients and clinicians alike -- but exactly how valuable, in terms of raw dollars? The clues are enticing, but it is virtually impossible to determine objectively.

This paper will report on another HIT example of the challenge to find the evidence. The REALITY Consortium developed a representative remote monitoring service for patients with long-term conditions. The service was imple-

mented in four contrasting sites around Europe for periods of up to a year during 2004 - 2005.

Objectives

The REALITY Consortium of academics, clinicians and a technical partner developed a representative remote monitoring service for example long-term conditions. Supporting home medical and quality-of-life (QoL) monitoring and feedback to patients, the service was implemented at four contrasting sites around Europe for periods of up to a year. Socioeconomic evaluations adopted nominal viewpoints of patients, clinicians and managers. Patients were nominally most interested in technical usability and benefits of service usage. Clinicians were concerned with patient selection, training and everyday service organisation. The manager viewpoint focused on costs and wider organisational change.

The specific objectives were:

- O.G1. Develop a generalised framework for characterising and evaluating remote clinical and QoL monitoring implementations.
- O.G2. Provide information for European organisations to develop policies and guidelines.
- O.P1. Determine technology acceptance amongst diverse patient groups.
- O.P2. Determine the benefits of involving patients in collecting their own data.
- O.P3. Establish the impact of remote clinical and QoL monitoring on patients' overall well-being.
- O.M1. Provide comparative cost analyses with conventional care.
- O.M2. Identify optimal structures for future delivery.
- O.C1. Develop patient selection & training guidelines.
- O.C2. Clarify how healthcare professionals can work together to deliver services.

Methods

Figure 1 summarises the service introduced at each site. Patients were trained at clinics with home equipment to collect medical datasets specified by clinicians and Europe's generic quality-of-life (QoL) scale. Data were usually sent overnight to a central server by patients at home using telephone connections.

Clinicians could view the data and return messages of advice to patients via the server. Regular assessment of medical status and QoL factors were intended to prompt calls for face-to-face consultations or home visits by community services.

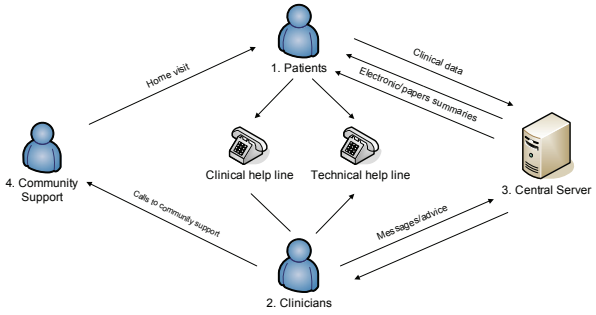

Figure 1 - Schematic summary of the REALITY service

Both patients and clinicians could communicate directly by phone and had access to technical support lines. Electronic and paper summaries of home data were provided for patients but only at Estonia.

Clinical Sites

Details on local populations and existing services were reported in [2]. Descriptions of national policies and achievements in provision for long-term conditions followed in [3].

All countries (Estonia, Portugal and England) were moving towards community care models, with varying degrees of implementation and success. Family/community doctors (GPs) were an historic feature in England. Restructuring had recently given them more powers to develop community services in combination with other health-related partners.

Results

Patients joined the project through a combination of local advertising and personal invitations. London recruited 29 asthmatics and 36 with diabetes and hypertension. 61 cases of hypertension and various heart diseases joined at Tartu. All 38 recruits at Lisbon had chronic lung conditions. Evora supported 21 asthmatics and 14 cases with advanced chronic respiratory diseases.

Most recruits had multiple medical problems. Some lived at home but most with partners/family. Conditions were often described as "reduced or inadequate".

In line with local population characteristics, several recruits at London were from ethnic minorities and many in Evora lived in rural areas. London patients appeared relatively younger and active compared to other sites. Majorities at London and Tartu were relatively well educated. The Portuguese cohorts tended to be older, sicker and rarely educated beyond primary school level.

London and Tartu had 7 doctors involved with the service. Number and roles of additional local staff at both sites were unclear. REALITY was delivered at Lisbon by a doctor-nurse team, and in Evora by a single consultant. No

staff involved from outside the main provider organisations was identified but, according to the activity diaries, Portuguese clinicians made home visits and appeared to serve in place of additional community services.

Stage of adoption

Base on interviews at site visits, two sites (London and particularly Tartu) had moved beyond constraints of novelty and early technical problems towards appreciation of consequences from new modes of service delivery. Both Portuguese sites had early technical problems, but were also thinking about wider benefits by the end of the study.

The consequences and benefits claimed were consistent across all sites (Table1). However, no example cases or documentary evidence were provided.

Table 1 - Service consequences/benefits claimed by clinicians.

For patients	Mutual	For clinicians
.	.	.
Psychological support and reassurance.	Increased communication.	More efficient use of clinic time.
.	.	.
Improved access to care.	Increased opportunities for joint decision making.	Availability of historic clinical data.
.	.	.
Increased knowledge about and understanding of their condition.	Increased quality of care (enhanced information to support clinical decision making).	Created time to address other patient concerns or health promotion.
.	.	
Increased capacity for self-management.	Increased continuity of care.	
.	.	
Increased involvement in decision-making.	Access to continuous information enabled fine tuning of treatments or dosages between scheduled appointments.	
.		
Increased motivation or reinforcement of lifestyle changes.		

Determine technology acceptance amongst diverse patient groups (O.P1)

Numbers starting with the service were lower than the recruited numbers at all sites. Numbers persisting also fell, most notably at London and Tartu. Compared to the other sites, proportions of persistent patients in Portugal collecting clinical data were relatively high and tended to complete QoL returns more regularly.

General usage results suggested that sicker patients, and those who were relatively fit but had clinically abnormal measurements for key variables, embraced the service. Delays in receiving equipment, and some early technical problems, discouraged some patients. A minority found the whole approach too complicated. Proportionately more patients from urban areas persisted, and Portuguese cases

with learning/memory problems appeared more likely to continue than those with sensory problems at London and Tartu.

Two usage features seem particularly important. Some patients were too sick to use the service while others felt too well to warrant it. Certainly, significant numbers at London and Tartu reported "lack of time".

Determine the benefits of involving patients in collecting data (O.P2)

No patients at Portugal passed beyond mid-term clinical visits without retraining in at least one category of technical service usage, and often in multiple areas. The same was true for at least half of the persistent cases at London and Tartu.

Assistance with accessing clinical messages and using the basic home unit were primary retraining needs. Help with third party devices was also prominent at Portugal because of connection problems between oximeters and the home unit.

Long gaps with no daily records were common at London, middling at Tartu, and relatively rare at Portugal. Key clinical variables were returned most frequently by persistent patients, but collection rates on lifestyle and medication compliance indicators appeared low across all sites and diagnoses.

Accuracy concerns were raised by the retraining needs identified above. When sites were asked at meetings about home data reliability, London stated that particular values or patterns may prompt independent tests and discussions at a patient's next visit. Notably at this site, medication was never changed on the basis of remote monitoring alone.

Clinicians found QoL data useful at two sites but "not readily available" or difficult to interpret at the others (London, Evora). Some patients found the questions difficult to answer, and several found them too general.

Relevance of the QoL data - as additional information to support calls on community services, or home visits by clinicians in Portugal - remains unclear. There were also no data on the nature of messages sent back to patients to illustrate how data may have influenced electronic advice.

Establish the impact of remote clinical and QoL monitoring on the patients' overall well-being (O.P3)

Independent analyses of persistent and low service users were expected by diagnostic groups at individual sites. Poor data availability - attributed to problems with electronic forms rather than clinical sites - restricted the tests to small groups.

There were no statistically significant changes according to the formal QoL instruments. There were, however, some clinical improvements at London (despite low sample sizes) and at the Portuguese sites. Changes were statistically significant but not necessarily clinically meaningful (e.g. a 1% increase in oxygen saturation at Lisbon).

Example case data examined in detail illustrated that some patients did make marked improvements while others appeared to worsen. With no data on clinical messages sent to the relevant patients or details from clinical visits, the contribution of the service as a whole is unclear.

Patient comments did suggest that basic measurement feedback educates and motivates some individuals, possibly with only minimal input from clinicians. But some patients were alarmed by seeing their abnormal measurements on a regular basis.

Point measurements at arbitrary times before, during and after an evaluation period may be misleading. There is measurement error, natural variation and, possibly above all for patients with long-term conditions, appreciable changes from day to day. These complicating factors are in addition to patients' basic skills to use the equipment.

Persistent patients (and/or carers), after at least the required four months' experience with the service, found the technology relatively easy to use. Large majorities reported improved relations with clinical staff and a greater sense of support. The psychological benefits are worth particular note, as they rarely appear in health related QoL scales.

Provide comparative cost analyses with conventional care (O.M1)

REALITY was an addition to existing services. Costs were automatically higher than conventional care and, apart from patients' sense of support and future potential for clinicians, there were few additional benefits identified over the study period.

Equipment, training and data viewing accounted for most of the additional cost/cost-related activities. Other uses of time appeared to be part of existing practice.

Numeric estimates and descriptions below might be put in context by patient numbers and progress categories involved (Table 2). Costs per patient increase if withdrawals are ignored; and retraining was a common activity at all sites.

Site expenditure on equipment and facilities and supported by the REALITY server ranged from 49,000 to 64,000 euros (Table 2). Compared to other sites, total Portuguese costs were substantially higher and costs per recruit were double. The differences were attributed to provision of oximeters with special links to the Docobo unit [4], and additional software handling firewalls at both Portuguese hospitals.

Costs include: the main Docobo units and server facilities; oximeters at Lisbon and Evora; peak flow meters at London and Evora.

Table 2 - Equipment and technical service costs (Euros) for the clinical sites

	London	Tartu	Lisbon	Evora
Total (€)	49,000	49,000	63,224	53,041
Official number of recruits	65	61	38	35
Mean cost per recruit(€)	754	803	1,664	1,515

Records via Evaluation Forms at mid-term and final clinical visits may have contained double counts. Nevertheless, visits to other clinics/hospitals were extremely high at London; and emergency hospital admissions at Lisbon were around 26-36 over the study period compared to around 2 at each of the other sites. Since these analyses, Lisbon has provided records of emergency hospital use by all their patients, to be included in ongoing work to improve evaluation methods (see S4 in particular).

There were few calls for face-to-face consultations and, notably, no recorded home visits by additional community services. In addition, regular visits to the London clinic by patients seeking feedback on data were not entered on Evaluation Forms. (Note: only Estonia patients received automated summaries, and experience at London suggests that messages to patients were not used to give such feedback).

Site activity logs (and server use by clinicians).

Logs of a "representative period" from all sites except London illustrated the 1-2 hours required to commission and initially train a patient. Tartu clinicians did not visit patients. But home visits in Portugal lasted some time and, particularly at Evora, involved considerable travel. Phone calls to patients appeared commonplace. They were short at Tartu (5mins) but almost as long as clinical visits at Lisbon (15mins compared to 20).

Clinicians appeared to access patient data in block sessions of over an hour. Records did not identify viewing practices for individual patients, but Portuguese clinicians seemed more likely to send messages back to patients (substantially more messages sent more frequently).

Summarising notes/documentation was a major activity at all sites, It was a regular three hour process at Evora though performed only once at Tartu over the logged period. In common with most of the recorded activities, time spent summarising notes specifically for the new service was unclear.

Discussion

Patient numbers fell significantly at most sites. Those who persisted felt a greater sense of support, although group data showed no improvement in health status. Clinicians had positive views about the future, but different approaches for different disease severities were not formalised and the general service was not embedded into local practice at any site.

Stronger conclusions are limited by lack of data. Obtaining costing details and independent clinical indicators for the service in operation was particularly difficult. Details on local service organisation and individual patient/carer circumstances - putting other information sources into context - were missing. Moreover, accuracy of data returned by patients was never demonstrated while specific actions by doctors to improve health or QoL status were not necessarily related to the new service and, in any case, not recorded.

Researchers believe that the technology and local service organisation required longer periods to resolve problems and adjust before formal evaluations and detailed data collection were justified. This seems true in particular for Evora where all responsibilities rested on one consultant. Perhaps clinicians at Lisbon provided the best overall summary:

"Remote monitoring can be a very important tool for patients with chronic respiratory diseases, particularly if they live alone and far from the medical services. This study showed the first steps - but there is a long way to run"

Conclusion

Patients with long term conditions tend to be older and sicker. Reporting a greater sense of support, they wished the service to continue. However, available information did not show group improvements in health status, reflect true costs, or explain the relatively high withdrawal rates at two of the four sites. Notably, some patients were too sick to use the service while others felt too well to warrant it.

Clinicians were also generally positive. In practice, though, the service was not integrated into other local operations at any site, and views appeared to reflect future possibilities rather than direct experience. Clinicians themselves concluded that "this study showed the first steps - but there is a long way to run".

There is still debate over what constitutes "evidence" and how best to obtain it in a field where technology is constantly changing and studies are relatively short. The methods raise their own difficulties. Economists, make assumptions about individual or continuous treatments

with long-term effects while poor characterisation of populations limits public health assessments. It also appears rare for organisational change to be examined with rigor.

Acknowledgments

AR and HJL wish to acknowledge, with thanks, the support of all their colleagues in the Reality project. The research described has been partly funded by the EU – Framework V – QLG7 – CT – 2002 – 02657. DP has been supported by the City University Strategic Development Fund.

Abstract

Clinical Quality indicators can be a powerful tools of improving the effectiveness of patient care. For 18 months, 20 specialists at each disciplinary developed total 34 Clinical Quality indicators and build data marts based on the EMR system, then electrically constructed clinical data warehouse system. Through the clinical data warehouse system, real time retrieval and monitoring of Clinical Quality indicators was achieved.

Keywords:

quality indicators, data warehouse system

Introduction

Clinical Quality indicators can be powerful tools of improving the effectiveness of patient care. There is no consensus about indicators for measuring quality of Hospital care in Korea. Therefore, a systemic process was initiated recently to develop and monitor indicators for the measurement of quality of hospital care through data warehouse system.

Materials and methods

The research, developing a clinical quality indicator and constructing the computing system, was processed as follows for 18 month from April 2005 to September 2006.

1. Development of a clinical quality indicator.

We organize 20 field experts of a task force team and developed a clinical quality indicator through setting a specific definition of a clinical quality indicator and inter-departmental conference. And we also made standard format to develop clinical quality indicator for each field.

2. Data mart construction

To construct a clinical quality indicator data mart we went via data refining course after through investigation of electrical clinic record. After that we construct a clinical quality indicator data mart in the data warehouse system and accumulate data by complementing of document and developing new document.

Fig.1 explains the structure of CDW. CDW DB server consists of CPU:1GHz*4, OS: UNIX-AIX5L 5.1, DB:ORACLE 9.2.0.4 and web server is made up of CPU: 1.4Ghz, OS:Window2000 Advanced SERVER, DB: MSSQL2000. MicroStrategy 7i is used as OLAP. Oracle ODBC is used as a linking method between OLAP Intelligence Server and Oracle Metadata Server, and TCP/IP is used to link OLAP/Web Server and user.

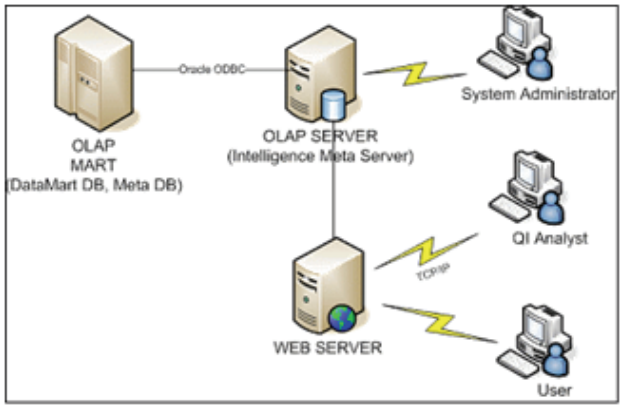

Figure 1 - Overall system configuration

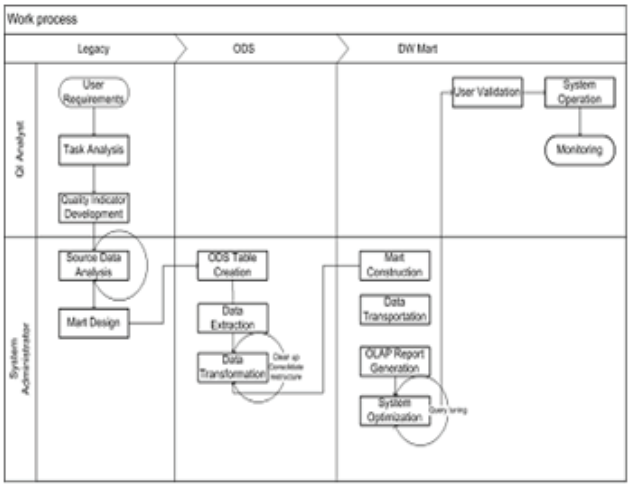

Figure 2 - Work process

3. Clinic-quality-index data warehouse system construction

A clinical quality indicator computing system is sort of data warehouse system developed by using MicroStarategy 7.2.3 Tool. Because of the task personality of a clinical quality indicator computing system, it is used for the analysis rather than a real-time process. So we used the database separately with the actual operation system.

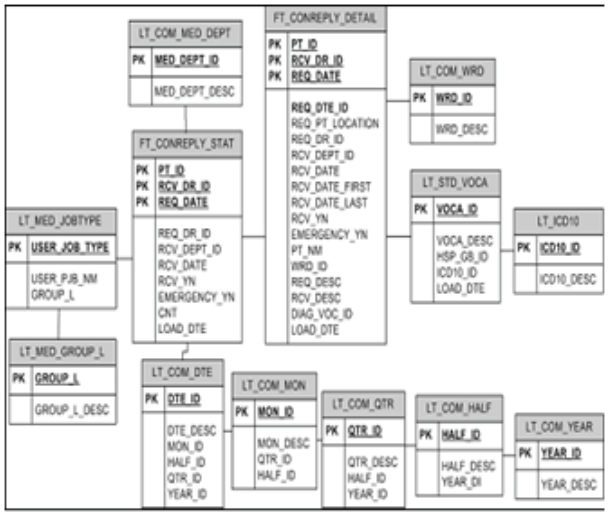

Figure 3 - Sample of ERD modeling

Results

We developed 34 clinic quality indexes and construct the data mart and did the computerizing it as a data warehouse system. The 34 clinical quality indicator item is listed on the table 1.

Table 1 - Lists of Clinical Quality Indicators (example)

domain	subdomain	clinical quality indicator
general	operation	waiting days for operation
		unexpected reoperation
	consult	response time to consult
	emerency room	readmissions to ER within 48 hours of discharge
	transfusion	return and disuse of blood
		RBC single unit
		side effect of transfusion
	CPR	survival after CPR
	mortality	mortality
		Deaths in hospital within 30 days of cystectomy surgery
		Deaths in hospital within 30 days of gastrectomy surgery
		Deaths in hospital within 30 days of prostectomy surgery
		Deaths in hospital within 30 days of nephrectomy surgery
	antibiotics	using days of antibiotics
specific	IM	(AMI patient) Aspirin at arrival
		(AMI patient) Aspirin at discharge
		AMI mortality
	AN	hypothermia after surgery
	nursing	pressure ulcer

Figure 4 - CDW system menu

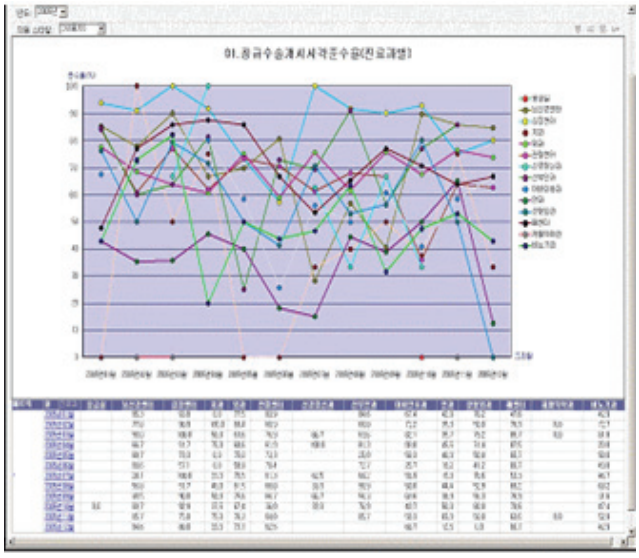

Figure 5 - graph showing the variation for a period

The screen of a clinical quality indicator of a parameter unit was implemented in data warehouse system. For its specific function such as detail data query facility in a specific total data, A annual or monthly trend query facility through the graph, optional query facility of grid and graph form, it can be possible to do real-time monitoring on specific clinical quality indicator.

Conclusion

Through the process of developing clinical quality indicator and constructing a data mart and computing system, we evaluate the possibilities of managing and applying clinical quality indicator with computing system.

The first feature of a clinical quality indicator computing system of Seoul National University Bundang Hospital is sufficient application of data that is based on electrical clinic record.

We used medical examination and treatment order, medical examination and treatment record, nursing record, inspection result as a real-time information. For its promptitude, we could investigate data easily. So many clinical quality indicator setups are expected to be possible. Also the time to be required could be reduced than the expected by using data which is coded and recorded in standardized term without further clinic-record query. Especially the possibility of practical using of formatting medical treatment and nursing records was a foundation of a clinical quality indicator computing setup.

Secondly we construct data mart and data warehouse in the system, which is separated with operating system. As a result a link information analysis that integrates data, stable refining and maintaining of latest information came to be possible. Also various analysis techniques are possible which use the graph and diverse analysis by patient, disease, and region. We prepared the basis to construct a disease-forecasting model through the data mining and expect to construct the screen of the report form afterwards.

The limit of a clinical quality indicator computing system setup is a precision verification side of the computing clinic record. In other words, wrong and missing record can be reflected as it is at a clinical quality indicator. But this problem can be solved by vocabulary system maintenance and continuous computing-clinic-record form supplementation.

Through this research, the simultaneous feedback and monitoring of many clinical quality indicator came to be possible. And also improvement inducing of each department came to be easy. From this result we can say that it is important to manage and monitor clinical quality indicator to induce a qualitative enhance of the medical treatment. We expect to develop and relate Critical pathway with Clinical Practice Guideline through the computerizing of developed clinical quality indicator.

The Application of Integration Approaches through Biomedical Informatics in Health

Medical Bioinformatics Dept., Institute of Health "Carlos III", Madrid, Spain

Abstract

INFOBIOMED is an European Network of Excellence (NoE) funded by the European Commission within the sixth Framework Programme. The main objective of this collaborative project is to create an stable and lasting European structure in Biomedical Informatics (BMI). This new discipline is based on the synergy between Bioinformatics (BI) and Medical informatics (MI).

Using all the relevant information, from the clinical records level down to the genomic, proteomic and molecular information levels, BMI is providing the technical and scientific infrastructure, as well as the necessary knowledge to develop new useful instruments and methods to improve healthcare advancing towards individualized medicine.

The main challenge of INFOBIOMED is to infer, based on the direct application in four pilots, the line of action and collaboration for BMI to fully export the synergies between BI and MI. In this paper, we describe the facts that support the consolidation of BMI as a relevant discipline for future European healthcare.

Keywords:

Biomedical Informatics, Genomic Medicine, INFOBIOMED

Introduction

The technology and resources, the increased knowledge extracted from large amounts of genetic and proteomic and phenotypic data are transforming the practice of medicine mostly characterized up to now by treating symptoms but also looking into the most fundamental causes and understanding the mechanisms of diseases [1]

In this context the EU funded the Network of Excellence (NoE) INFOBIOMED in order to consolidate the challenge of "Structuring European Biomedical Informatics to Support Individualised Healthcare" setting a durable structure for a collaborative approach at the European level and mobilising the critical mass of resources necessary for enabling the collaborative approach. This NoE consists of a consortium of 17 groups related with BI, MI and BMI research areas, that supports the consolidation of BMI as a relevant scientific discipline to be taken into account for future healthcare [2].

This is, BMI provides the technical and scientific infrastructure, as well as the necessary knowledge to produce new useful instruments and methods to improve healthcare in order to advance towards individualized medicine.

Further information about INFOBIOMED project is available through its web page http://www.infobiomed.org/

Materials and methods

The network has been structured by activities that cover all the significant aspects that are relevant to both MI and BI and that have the potential to provide a space for synergy between them. These aspects are envisaged for promoting integration of the research carried out in the fields of reference and they can be included in blocks of activities or workpackages (WP): NoE management (WP1); dissemination and communication (WP2); training and mobility (WP3); Data interoperability (WP4); methods, technologies and tools (WP5) and pilots applications (WP6).

Work Packages 4 and 5 have a horizontal design, the former dealing with data interoperability and the latter concerned with methods, technologies and tools. WP6 of the NoE introduces a novel vertical approach to biomedical research and healthcare.

The work in WP6 can be summarized as the application of data interoperability and management and the development of methods, technologies and tools in four pilots as 'proof of concept' of the pursued integrative vision of BMI that aim to cover the whole range of information levels from molecule to population.

Considering the different levels of heterogeneity due to BI and MI perspectives, the INFOBIOMED consortium aims in WP4 to integrate genomic, proteomic, clinical and population databases. Responding to the needs, different approaches have been made according to information linkage, data and query translation. Several of these databases containing all information levels related with the research of the diseases of interest were developed.

Due to the importance and success of ontologies in scientific research, data integration is evolving towards

ontology based methods that can solve the problems associated with syntactic and semantics gaps across data sources. This task is also relevant in INFOBIOMED and it has been developed an specific tool called Ontofusion.

INFOBIOMED efforts related with key technologies, methods and tools (WP5) were directed towards three main goals:

1. Data analysis and information retrieval: to identify, define and index the computational tools required for database integration, using and developing techniques of data and text mining, machine learning, knowledge extraction and other systems.

Diseasecard is an example of an information retrieval tool for accessing and integrating genetic and medical information for health applications (http://www.diseasecard.org) along multiple databases. Also, INFOBIOMED partners have developed the PIANA (Protein Interactions And Network Analysis) software framework that facilitates the work with protein interaction networks.

2. Image visualisation and analysis in order to enhance and develop image analysis approaches related with medical and genetic imaging techniques, like the DIA application (Dental Images Analyser) that extracts information from digitised radiographs that have been converted to the DICOM standard. Radiographic data in DICOM can be accessed by any computer system, which may be an important advantage in the studies of complex diseases, where multiple databases exist.

3. Information systems and decision support tools to extract knowledge from clinical and genomic available data sources. New models and systems to computerize clinical practice guidelines that will be a step towards genomic based enhancement of clinical decision making.

There are complementary activities for promoting integration of BMI research like dissemination and communication activities and training and mobility programmes in order to spread the knowledge generated in BMI. In this area some tools have been adapted to the needs of INFOBIOMED such as the LINK3D application (www.link3d.net). It can be used as a research tool to allow researchers to hold virtual meetings in a secure way. The INFOBIOMED website houses the European Biomedical Informatics Gateway for the BMI community and other stakeholders. It provides a central repository of reference materials and a notice board for announcing BMI events worldwide.

Results

There are four pilots in INFOBIOMED WP6 that represent the demonstration of the BMI approach to biomedical research and medical practice. The four INFOBIOMED pilots were based on several clinically relevant areas like pharmainformatics, genomics and microbiology, genomics and chronic inflammation and genomics and colon cancer.

Pharmainformatics (WP 6.1) carries out research on the impact of BMI in the drug discovery process, focussing in two case studies (Complex Regional Pain Syndrome and Nuclear Hormone Receptors) that establish an information continuum from pathology to pathway to target to ligand/ approved drug.

The approximation given by this pilot is mainly an example of translational research since its discoveries begin at "the bench" with basic research—in which scientists study those diseases at a molecular level—then progress to the individual level.

Genomics and Microbiology (WP 6.2) focuses its BMI activity on the study of comparative and functional genomic approaches combined with proteomic strategies in order to improve clinical evaluation strategies through a comprehensive pathway-related with host/pathogen interaction. The pathogens selected for this pilot are Cytomegalovirus and HIV.

In this pilot application, INFOBIOMED concentrates its efforts on the interferon pathway, combining host and virus genotype data with clinical data in order to find new markers of host immunity and viral therapy resistance. For this reason this study tries to improve clinical management obtaining information from molecular to individual level.

Genomics and chronic inflammation (WP 6.3) investigates the susceptibility to adult chronic periodontitis. A data warehouse was built combining many different causes that contribute to this complex inflammatory disease: genetics, infection, environment, intermediate phenotypes and disease phenotype. In order to gain more insight in periodontal disease, to design new treatment strategies and to devise preventive methods, this pilot focussed on the clinical management and disease prevention approach from the population to the molecular level information.

Genomics and colon cancer (WP 6.4) studies Hereditary Non Polyposis Colon Cancer. It uses the accumulated knowledge to build an infrastructure based on standards (e.g transmission of pedigrees including geno and phenotypes) that have been developed in XLM. To facilitate the use of this tool in different countries it is based on the international standard HL7. This pilot is mostly oriented towards public health, in particular towards prevention and exchane of information from the population to the molecular level.

Conclusions

The INFOBIOMED Network of Excellence is contributing to create a stable and lasting European BMI structure to

support individualised healthcare. Overcoming the obstacles and deploying the promised benefits of genomic revolution to society by combining the experience in both BI and MI developments, the methods and technologies used within the BMI integrative approach allow a direct application in the development of genomic medicine.

Abstract

Biomedical research needs to process and integrate large amounts of data, obtained from different biomedical disciplines, to research complex, multigenic diseases where the interaction of both genetic and environmental factors play an important role. It is essential to study the interactions among all the health information levels - population, disease, patient, organ, tissue molecular and genetic-. Biomedical Informatics is the discipline that provides models, methods and computer tools to integrate genetic, clinical and environmental information. In this paper we describe the successful results of INBIOMED, the Spanish Cooperative Research Thematic Network on Biomedical Informatics funded by the Spanish Ministry of Health, which is a perfect example of this line of work. INBIOMED members developed a technological platform to manage, integrate, model and analyze clinical, genetic, epidemiological and image data, for the research of any complex pathology. They also worked in the quality, security, communication and training aspects, to disseminate Biomedical Informatics in Spain. The work performed by INBIOMED was recognized as Excellent by an International Committee of Experts, who recommended its continuity and strengthening.

Keywords:

ICT in Biomedicine, Biomedical Informatics, INBIOMED

Introduction

The publication of the results obtained by the Human Genome Project has produced huge advances in biomedical research in the last years. This information has contributed to the development of new disciplines aimed at researching all factors that have an influence in diseases. Most diseases are caused by genetic and/or environmental factors, and to completely understand their causes it is essential to know patients genetic characteristics and life habits as well as the environmental agents to which they are exposed [1].

However, these data are obtained from very different biomedical disciplines, which often use them exclusively. The integration of these data is essential to be able to research complex, multigenic diseases in which environmental factors have a strong influence. It is also important to study interactions among all the information levels - population, disease, patient, organ, tissue and molecular or genetic-.

In this sense Biomedical Informatics, a recent discipline between Medical Informatics and Bioinformatics, has a relevant role in the integration of these new data and providing new approaches to old health problems, as you can see in figure 1. It does this by providing the models, methods and informatics tools to integrate information about genetics, clinics, and environmental aspects. Thus, Biomedical Informatics facilitates the development of Genomic Medicine, a new scientific discipline that aims towards the development of personalized treatments and therapies for groups of patients with common genetic characteristics[2].

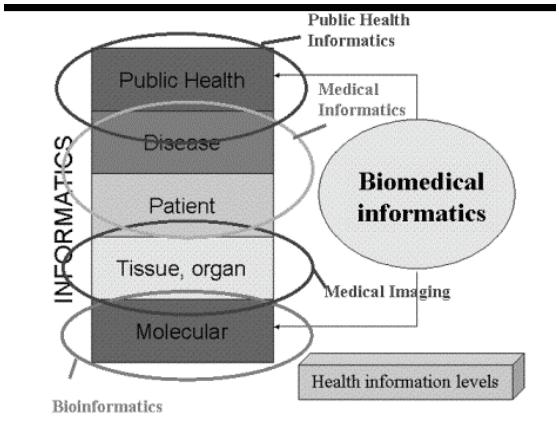

Figure 1- Integration of the health information levels

Biomedical Informatics has increased in the last years worldwide. Each year new initiatives appear in Europe mostly through the EU Framework Programmes and in the USA through the National Centres for Biomedical Computing funded by the US National Institutes of Health. All these initiatives support research in Biomedical Informatics, which is one of the most promising areas to diagnose and treat diseases in the future.

In this paper we describe the work and results obtained by INBIOMED, the Spanish Network of Cooperative

Research on Biomedical Informatics. It was one of the first technological projects in this line of work promoted by the Spanish Scientific Research, Development and Technological Research Plan from 2003 to 2006. This Plan followed the directives of the Europe Union Sixth Framework Program, which consisted of promoting cooperative research and initiatives combining elements from different disciplines. The Network developed a technological platform to store, manage, integrate, model and analyze clinical, genetic, epidemiological and image data that could be used to research any complex pathology. INBIOMED members also developed useful informatics tools, procedures and methods that have been included in the platform (SNPs and genes text mining systems, processing of biomedical images, data analysis of arrays, clinical decision support system, automated questionnaires to evaluate the diet and other environmental factors such as smoking habits). They also developed more specific tools targeted towards solving some of the problems encountered by the "bio-user" nodes. INBIOMED also made important efforts in quality, security, and communication aspects, to communicate and disseminate its results to the scientific community and other stakeholders. Moreover, due to the shortage of training offer in this area in Spain, INBIOMED members have organized Biomedical Informatics Specialization Training Plans and courses directed to researchers.

INBIOMED was formed by 13 biomedical research groups from 11 centres geographically distributed around Spain. INBIOMED coordinated relevant groups in Biomedical Informatics together with technological and pathology research groups that have a multidisciplinary character (Genomic Epidemiology, Pharmacogenetics, Molecular and Image Diagnosis), where the integration and analysis of clinical, genetic, epidemiological and imaging data is needed.

These groups were:

- Polytechnical University of Madrid. Faculty of Computer Science. Medical Informatics Group.
- Municipal Institute of Medical Research. Research Unit on Clinical and Molecular Epidemiology of Cancer.
- Municipal Institute of Medical Research. Research Unit on Biomedical Informatics.
- Sanitary Corporation "Clinic". Medical Informatics Group.
- University of "La Coruña". Faculty of Computer Science. Department of Information and Communication Technologies. Laboratory of Artificial Neural Networks and Adaptative Systems. Medical Informatics and Radiological Diagnosis.
- University of "Santiago de Compostela". Faculty of Pharmacy. Department of Pharmacology. Pharmacogenomics in Drug Research and Development Unit.
- University "Jaume I." Department of Languages and Informatics Systems. Research Group on Integration and Systems Re-engineering.
- University "Jaume I." Department of Technology. Engineering and Design. Informatics Engineering Faculty.
- University of Valencia. Faculty of Medicine. Department of Preventive Medicine. Research Unit on Molecular and Genomic Epidemiology.
- University Hospital "Virgen de las Nieves." Department of Computer Science.
- University of "Castilla-La Mancha." Department of Electric, Electronic and Automatic Engineering.
- Polytechnical University of Valencia. Biomedical Informatics Group. Faculty of Computer Science.
- Institute of Health "Carlos III". Biomedical Informatics Unit.

To achieve its objectives INBIOMED groups were organized in nine different work committees, as you can see in figure 2: Training, Quality and Ethics, Communication, Knowledge Representation, Image Analysis, Structured Data Analysis, Text Analysis, Technological Platforms and Bio-Users (Pharmacogenetics and Neuropsychiatry, Genomic and Cardiovascular Epidemiology and Cancer Epidemiology). Each Committee was composed by different research groups and was directed by a coordinating Committee, responsible for its production and quality. All the research groups were coordinated by the Department of Medical Bioinformatics of the Institute of Health Carlos III.

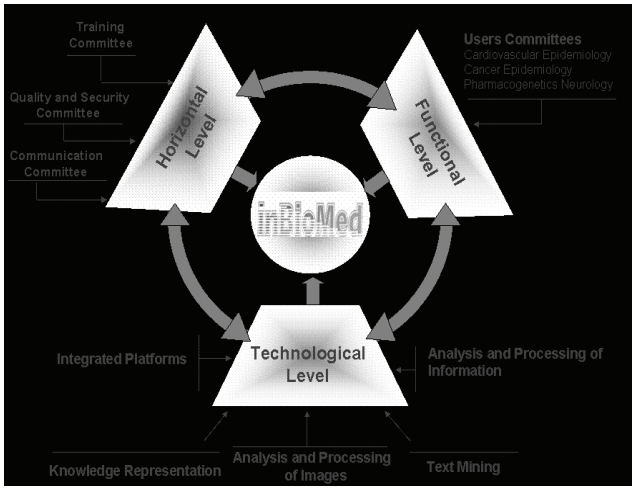

Figure 2- INBIOMED Work Committees

The structure of the cooperative work was defined in such a way that the technological platform aimed to provide solutions to the "bio-user" nodes. The platform was developed by the technological groups and updated with new solutions implemented following the proposals of the "bio-user" nodes.

Methods

The INBIOMED platform

After the creation of the INBIOMED network its members realized that the project had some drawbacks that had to be analyzed. The research groups had problems when they needed to cooperate or share information with other research groups. All the information generated in the laboratories or the gathering or collection of clinical data was very difficult to manage because of their volume. In addition, the Internet provides a huge amount of public relevant information, but in very different formats and the same problem occurred with the analysis and data processing tools.

The solution happened to use an infrastructure based on SOA (Service Oriented Architecture) that makes easy the interaction between all the research groups and the integration of their processes and data. It has a common information model to make a standard way of using the available analysis tools and getting results. To meet these needs, INBIOMED deve- loped a platform based on the development of three layers, as you can see in figure 3:

a) **Client applications** (user interface): This layer implements only the User interface with their input forms and the results presentation, delegating the responsibility to query, store and process the information as much as possible in the other two layers.

Taking into account the Web and Desktop targets, two client applications have been developed so that most of the researchers could use the platform:

1. Windows Desktop *Inbiomed Nexus Workbench* [3] to have the richest client user interface available.
2. Web based *Inbiomed Nexus Site*, it is developed under web technologies using ASP.NET 2.0 exploiting Web-Parts technology that allows the user personalize his framework.

The most interesting functionalities ready to be used are: complete management, shared relational data exploration and query, semantic query on ontology, integrated applications (but others can be developed), design and execution of Workflows, embedded IronPython, execution of IQL scripts and a lot more.

This platform has integrated the last web technologies and it is able to use ontology as data sources in both interfaces. Even those user interfaces have used an ontology to integrate diffe- rent data bases as only one. An example of this are hospital minimum basic data set (MBDS), Each hospital has his own codification language but in order to get a good and complete result many times you have to make several queries so with this integration you only have to query once to the different MBDS.

b) **Web Services Layer** (logic): This layer provides the logic of the platform, providing an easy way to query and process the information. In order to improve the cooperative spirit of INBIOMED, every research group contributes by making available his node to the others.

The main platform site implements a special web service to receive requests, to query and process data in a language oriented to batch execution called IQL [3]. It has, also, to allow the management of users, data sources, access to the other web services…

The IQL engine executes every received request in a separated thread and in a sequential way. All the data manipulation is done by using an ADO.NET data type called DataSet [4]. It manages temporal and persistent variables. For complex tasks it is possible to declare procedures containing other IQL sentences.

The platform provides support for cooperative process management and coordination through the ability to design and run workflows. INBIOMED workflow activities allow sha- ring the data repositories and executing processing tasks hel-ping human and computer based interactions in cross-groups applications to success. Also, it offers pertinent information about workflow execution progress supporting long-time transactions.

c) **Data Sources Layer** (storage): all the database servers are located in this layer. It contains the information sources accessible through the platform (public or private). Data warehouse technology plays a fundamental role guaranteeing that the information stored in the databases and finally published to the platform is well consolidated and oriented to be queried.

The main goal of the platform is to support efficient heterogeneous and distributed information sharing. The INBIOMED platform grants direct access to published relational data sources, but also solves the structural and semantic heterogeneity conflicts with the use of ontologies that define not only concepts and their relations but also mappings of concepts and entities to the published physical relational data.

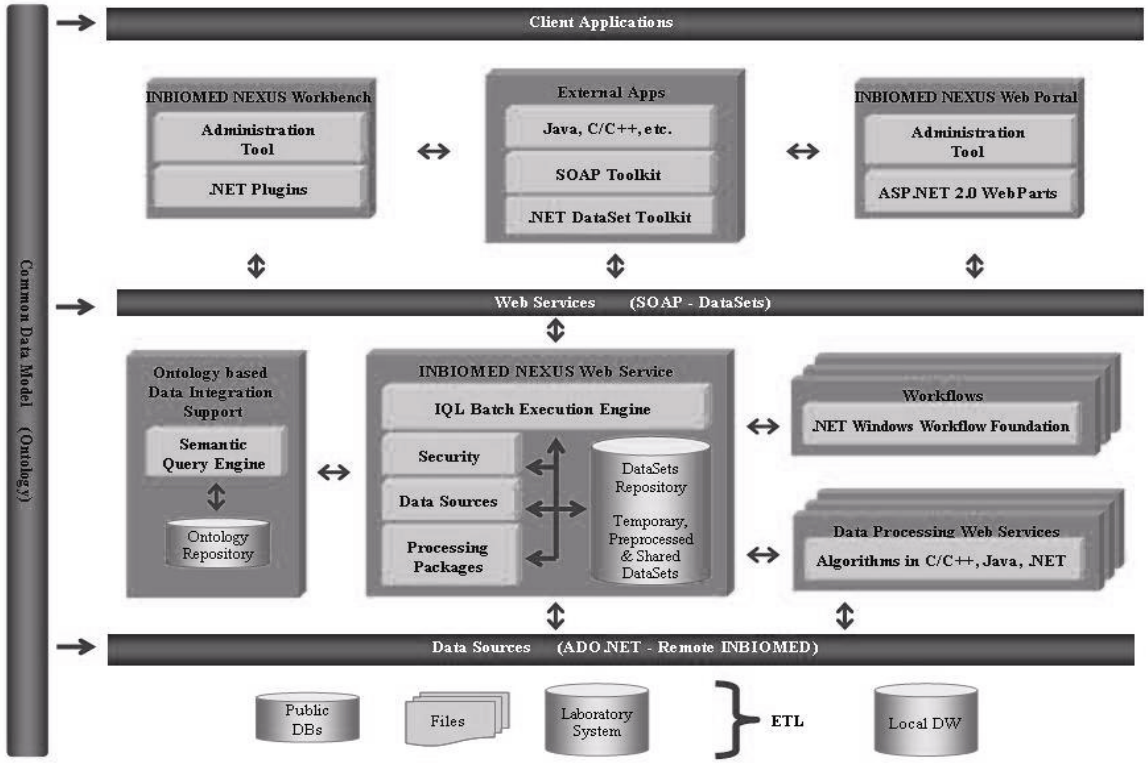

Figure 3 - INBIOMED Platform Layers

Tools

INBIOMED technological groups developed useful informa- tics tools to be used by the "bio-user" nodes and that were included in the platform. These tools include SNPs and genes text mining systems, tools to process, analyze and visualize biomedical images, clinical decision support systems, automated questionnaires, and others. The most relevant tools developed by INBIOMED are the next:PANGEA, a system to share clinical registers and obtain electronic clinical history of the patients.

- ZEHUTI, an algorithm for the calculation of the conceptual similarity between two texts by the projection of concepts into an ontology.
- Bussub, a virtual amplicon retrieval software.
- OSIRIS, a tool for the retrieval of articles from MEDLINE related to the sequence variants reported for a human gene [5].
- SeqPacker and Enzyme-Digest: tools for the analysis of nucleotides sequences.
- [2] DNASqueezer: a tool to compress DNA and RNA sequences.
- Blast2go: a tool for annotation, visualization and analysis in functional genomics research[6].
- SOC: a distributed system for the decision of clinical diagnostic
- SIREN Project: a computerized system to make inquests in Genomics Epidemiology.

Results

INBIOMED's main objective was to solve the needs of the "bio-user" groups. Each "bio-user" group had different pro-blems which required different solutions and strategies. These are detailed below by researches areas:

Cancer epidemiology

This task was leaded by Dr. Nuria Malats, head of the Research Unit on Clinical and Molecular Epidemiology of Cancer, Municipal Institute of Medical Research.

In response to the needs of the group, INBIOMED has solved in this way:

- In data analysis the researches have developed data mi-ning techniques and comparison of different data mining strategies in data analysis.

- In image visualization and analysis, it has been processed and stored biomedical images that the research in this specific area has created.
- In information retrieval, the members of this group obtain the automation and integration of heterogeneous clinical and pathologic information from hospital databases.
- In SNP searching area it has been produced an utomated search and selection of genetic polymorphisms and the use of OSIRIS to identify articles related to polymorphisms identified in genes of interest.

Pharmacogenetics in neurology

This task was leaded by Dr. Mabel Loza, chief of the Department of Pharmacology. Pharmacogenomics in Drug Research and Development Unit of the University of "Santiago de Compostela". This group had some specific needs related to schizophrenia disease that were solved as described below:

- The SNP searching was solved by automated identification of articles related to polymorphisms in genes of interest and the automation of this SNPs search was facilitated by the use of some informatics tools, like OSIRIS, SNPator and PupaSNP [7]
- A Web format database was created in order to process, store and interchange the images that were generated from several types of formats.
- The management of the Galician Computerized Biobank was improved to use its data and samples.
- The development of algorithms to set genetic expression profiles applied in microarrays assays. By this way the effectiveness predictive model of treatments with neuromedicines can be used in vitro.
- INBIOMED has developed ontology based methods that can resolve the problems associated with syntactic and semantics gaps across data sources. This ontology was created to define keywords used in schizophrenia's pharmacogenomics research and by this way to makes possible to set class relations between these keywords.
- To classify basic and clinical scientific publications according to their conceptual similarities, INBIOMED has developed the ZEHUTI algorithm.

Cardiovascular epidemiology

This task was leaded by Dr. Dolores Corella, chief of the University of Valencia. Faculty of Medicine. Department of Preventive Medicine. Research Unit on Molecular and Genomic Epidemiology. This group presented a different set of needs from the other "bio-user" groups, which are described below.

Informatics systems were developed to facilitate the efficient automatic recruitment and follow up of patients (CITAGEST), the management of biological samples (ALIGERA), the epidemiologic data collection by designing computerized questionnaires, and finally the automation and validation of information about food consumption and its conversion to nutrients by SIREN and VALFRECO.

This area of interest also shared similar needs with the other "bio-users" groups like SNPs search, information retrieval and visualization and analysis of images.

Conclusion

In this paper we have described the work done in INBIOMED, the Spanish Cooperative Research Thematic Network on Biomedical Informatics. This project was a successful example of cooperative research between different disciplines to study complex diseases. Along the three years lifetime of this project an important number of collaborations among the different nodes have taken place. The existence of Biomedical Informatics groups has allowed the setting up of a common ground and a common language between technological and biomedical research groups. The work performed by INBIOMED was recognized as Excellent by an International Committee of Experts, who recommended its continuity and strengthening.

Factors Affecting Electronic Health Care Records Adoption (EHR) and Success in Three Developing Middle Eastern Countries; Lebanon, Syria, and Jordan

Hala Badredine

School for Health, The University of Bath, United Kingdom
Project Manager USAID/AMIDEAST, Beirut
President of Lebanese Medical Informatics Association

Abstract

"The lack of access to basic healthcare continues to stifle social and economic advancement in many parts of the developing world." [1] Moreover, IT improved many industries according late research (2004- 2006) in developing countries but not in the health care industry. This even applies to developed countries.[2] Thus, this research seeks to further our knowledge of Healthcare Information and Communication Technology Systems (EHCR) adoptions in Fertile Crescent countries of the Middle East (Lebanon, Syria, Jordan, & Iraq). Researching EHCR factors leading to successful adoption in The Fertile Crescent countries will create a panoramic and practical picture and vision for healthcare executives, healthcare IT professionals, healthcare researchers and officials in the governments responsible for finance and health policy in these countries as well as agencies and other international organizations to take action towards bridging gaps for achieving optimal and affordable health information and communication technologies as EHCR. As a conclusion, this research will promote collaborative efforts for creating a reliable, timely, high quality and affordable health care in the region.

Keywords:
electronic health record

Introduction

It is argued that there is an identifiable cluster of factors that "predispose" hospitals to adopt EHCR in general [3, 4]. In particular, this investigation focuses on assessing and estimating the relationships between Environmental factors (economic, political, etc..) and "extent and success of EHCR adoptions" and the relationships between organizational factors and "extent and success EHCR adoptions" in the hospitals of which is nearly most inclusive and representative sample of the region's hospitals that treat approximately three quarters of the population. Moreover, it focuses on the relative importance of environmental and organizational factors with respect to "extent and success of EHCR adoptions".

Methods

Descriptive multivariate hypotheses are proposed, hence multivariate regression analysis are employed in order to evaluate factors' correlation magnitude with EHCR adoption and success in the Fertile Crescent region. The two main dependent variables are the "extent of EHCR adoption" and "EHCR adoption success". The former refers the measure of adoption as sum of percentages of adoption levels and components of EHCR-supported functions performed in a hospital because it reflects the level of commitment to EHCR adoption and the factors associated with it. The latter is a summary percentage measure of the extent to which EHCR functions is perceived to be hospitals' needs[5].

Data collection includes the use of on-site structured and open ended interviews of hospital departments' managers of "A" five stars accredited 200> beds' hospitals within counties of the region. Thus the sample includes hospitals whose clients account for more than 75% of the population of these countries.

Results

2006. So real conclusions will data analysis, results, discussion and conclusions will be updated at the end of June2006

Abstract

This research furthers **knowledge about factors** affecting individual managers actual individual usage of Electronic Health Care Records; (AIU-EHR), in hospitals i.e. in three developing countries of middle east. EHR is a **generic** term which incorporates several classes of systems. This research defines EHR as a scientific discipline concerned with cognitive information processing, as well as concerned with the communication tasks of health care, health care research, and education, respectively.

This investigation **focuses** on how the **independent variables** affect the dependent variable (AIU-EHR) [2,4,5,6]*:

- **Individual personality characteristics**
- **Attitudes and habits**
- **Characteristics of individuals according to their organizations**
- **EHR usefulness**

6-Van Bemmel J.H., (1997). Handbook of Medical Informatics: Springer.]

Subdivisions and Classes of EHR

The classes or subdivisions of EHR were defined in 1997.[2,,4,5]*

1. Administrative and Clinical Information Systems

2. Management Information Systems

3. Health Care Organization Information Systems

4. Patient-Centred Administration Systems

5. Medical Knowledge and Decision Support Systems (interactive systems)

6.Transaction Processing Systems

7. The Internet

But in this research EHR is handled as a discipline not as classes.

4- Pagliari et al., (2005) Scoping Study. Traditional Review. Draft.
5-Reznikoff, M., C.H. Holland, and C.F. Stroebel. (1977). Attitudes toward computers among employees of a psychiatric hospital. Mental Hygiene 51 May: 419 – 425.]

Background

Background: "The lack of access to basic healthcare continues to stifle social and economic advancement in many parts of the developing world."[5]

This applies to developed countries. [6]

Researching EHR factors leading to adoption in The Fertile Crescent developing countries will create a panoramic and practical picture and vision for healthcare executives, healthcare IT professionals, healthcare researchers and officials in the governments responsible for finance and health policy in these developing countries.

This also applies for agencies and other international organizations to take action towards bridging gaps for achieving optimal and affordable health information and communication technologies as EHR.

Data collection & Analysis

- **Data collection** includes a questionnaire. The researcher completed it. The researcher uses on-site interviewing of Healthcare organisations managers from macro to micro levels. The respondents are managers from healthcare departments in the three Middle Eastern countries mentioned.

- **Structural Equation Modeling SEM [1]* & Ideamap [3]*** data analysis techniques will be conducted. The measurement model in this research uses factor analysis to assess the degree that the observed variables load on their latent exogenous and endogenous constructs respectively. SEM literature defines the independent variables as endogenous factors while the dependent variable is an exogenous factor.

- The research uses in the analysis AMOS which is an add on SPSS application. As well as, Ideamap that also tests a large number of variables horizantally and vertically, in a similar way to AMOS.

*[1- Bollen, K. A. (1989). Structural Equations with Latent Variables. New York, NY: John Wiley & Sons.
3-Moskowitz H. (2007). Ideamap. New York, NY. www.ideamap.org]

Methods

- **Methods:** Based on a socio-technical approach the research approached nearly most inclusive and representative sample of the region's hospitals in each country.
- The aim of the **sampling methodology** is to arrive at a sample that is representative of individual health care professionals in organisations (size mentioned) in the countries under study. The number of individual health care professionals of health care organisations from any one country is determined on the basis on the **country's proportionate share** of all individual health care professionals in health care organisations in the studied countries.
- Research presents the number of individual health care professionals of the number of their respective hospitals in the region by country.

Syntax: Paths connecting contexts or variables in the diagram

1- The paths connecting the four independent variables (exogenous); **Individual Personality Characteristics (CS)**, **Attitudes (GA), EHR-Usefulness (AC)** and **Individual Organisational Characteristics (Yrs)** with the dependent (endogenous) variable; **AIU-EHR** as the independent variable are represented by **π (Pi)** coefficients.

- 2- The shared matrix between the four independent variables; **Individual Personality Characteristics**, **Attitudes, EHR-Usefulness** and **Individual Organisational Characteristics** with each other are represented by **Φ (PHI)** coefficients**.**

- 3- The path between an observed variable and its latent independent variable is represented by **δ (Delta)** coefficients.

- 4- The path between the sub-observed variable and its observed variable is represented by **λ (Lambda)** coefficients.

- 5- The path between the late sub-observed variable and its sub-βobserved variable is represented by **β(Beta)** coefficients.

The one dependant variable:

AIU- EHR: The actual individual usage of EHR
It is defined as the average time each EHR function is used per week by the specific personnel in charge if the EHR system is used.

The main four independent variables:

I- Individual Personality Cx:
It is defined as the Cognitive structure of every manager **(CS)**

II- Attitudes:
It is defined as The General Attitudes of each manager **(GA)**

III- Individual Organisational Cx:
It is defined as the years spent by a manager in an organisation **(Yrs)** No# of years.

IV- Usefulness of EHR
It is defined as attitudes towards contribution. **(AC)**

Results & Discussion

- **Results-**
  - The four **Π** correlational analysis coeficients and AIU-EHR are significant.
  - The six **Φ** Correlational coeficients are significant.
  - Out of the ten δ Correlational coeficients, number 2,4,5,6,8,10 are significant.
  - All the **Λ** Correlational coeficients are significant.
  - Only **β1** Correlational coeficient is significant.

- **Discussion**- This study has made major contributions:
  - **described the type of institutions that use EHR**.
  - **presented EHR usage within the context of the three developing countries of the middle east health care delivery systems and the policies**
  - **paved the way for future research that can focus on the management of EHR, as an outcome.**
  - **presented a tool for measuring individual usage of EHR in hospitals, w**ith a few modifications and refinements. This instrument can be used elsewhere and as a means for comparison across hospitals and/or countries.

- **Limitations**- however, the study is not without limitations, even in what was attempted here. For example, the dependent measure AIU- EHR is an oversimplified measure which should be re-operationalized in future research. Nevertheless, it was considered provisionally adequate given the exploratory nature of this research.

[e]*Massachusetts eHealth Collaborative,Waltham, MA, USA*

Abstract

The Massachusetts eHealth Collaborative is an effort to get all providers in the state to begin using electronic health records (EHRs), to implement clinical data exchange, and to get hospitals to begin using computerized provider order entry (CPOE). The Collaborative has implemented pilots in three communities in the state, and in this report we describe the evaluation of this effort, which is intended to inform strategies to spread EHRs, clinical data exchange, and CPOE across the entire state, with the aims of substantially improving the safety, quality, and efficiency of healthcare for the residents of Massachusetts. The evaluation will address how EHRs are used, the impact on the medication error rate, correlates of and barriers to adoption, whether an intervention aimed improving proficiency is beneficial, the impact of the EHR on quality, and an economic evaluation.

Keywords:

electronic health record, adoption, quality, safety, efficiency

Introduction

While electronic records are being used increasingly widely in developed nations, their impact on safety and quality has been variable [1-8]. Many features of EHRs, including electronic prescribing, interoperability and decision support, reduce opportunities for medical errors during the provision of care and have the potential to also improve quality. While implementation of an EHR system has the potential to enhance the quality and effectiveness of a physician's practice, many physicians have encountered a variety of barriers that dissuade them from electing to utilize this tool in their practices. These barriers include financial, technological and other challenges [5, 8-17].

The Massachusetts eHealth Collaborative (MAeHC) is a multistakeholder group which was formed with the aims of enhancing EHR adoption in Massachusetts, setting up clinical data exchange, and encouraging hospitals to adopt CPOE. Established with a coalition of 34 stakeholders who champion health information technology, and initial financial support from the Blue Cross Blue Shield of Massachusetts, the largest medical insurer in the state, MAeHC is working to improve the quality and safety of ambulatory care in the state through widespread EHR adoption and use.

In 2005, the MAeHC completed a proposal process for selection of three Massachusetts communities as pilots for full statewide EHR implementation. The state of Massachusetts has over 6 million residents that are cared for by approximately 20,000 physicians in about 6000 practices. The three selected communities represent over 150 ambulatory practices with over 400 clinicians. Currently, the MAeHC has implemented full EHRs in nearly half of these practices.

The eventual intent of the MAeHC is to implement EHRs and set up clinical data exchange statewide, but to do this will require significant investment and necessitate an array of policy changes. To inform this effort, we are performing an evaluation of the impact of the Collaborative in the pilot communities.

Methods

The evaluation focuses on four aims related to the implementation of EHRs. The first aim is to assess the ways that EHRs are used by physicians, ranging from those who use them proficiently to those who are just starting to use EHRs. The second is to assess how EHR use affects medication errors and overall quality of healthcare. The third is to identify physician characteristics that are correlated with the rate of EHR adoption, such as age, gender, innovational characteristics, in addition to practice characteristics such as a practice's financial health. Another aim is to facilitate EHR use through an intervention based on academic detailing [18], in addition to usual implementation strategies, and to assess whether academic detailing will accelerate EHR adoption and physician EHR proficiency. An economic evaluation is planned to calcu-

late the return on investment for EHR implementation. Finally, a preliminary evaluation of health information exchange (HIE) is planned for the final stages of the implementation effort. Evaluation across these aims will include assessment of the areas discussed below.

Effectiveness of intervention on rate and extent of adoption of EHRs

To assess the current rate of EHR adoption in Massachusetts, in 2005 we sent a one-page baseline office practice survey to the office practice managers of a random sample of 1829 ambulatory physician practices, representing approximately 30 percent of all practices in Massachusetts. A follow up survey is planned for mid 2007, after the full implementation of the EHRs in MAeHC's pilot communities. In addition, through the MAeHC, we have arranged to assess post-implementation EHR usage rates for specified features, as well as assess the planned health information exchange effort in the MAeHC communities.

Effects of EHR use on medication error rates

This aspect of the evaluation will compare errors found in handwritten prescriptions with those prescribed through the electronic health record system. Thirty physicians participated in the baseline measurement by using duplicate prescription pads for two weeks of data collection. A research pharmacist reviewed the prescriptions for medication errors, and performed subsequent chart review to clarify potential near misses and adverse drug events. A physician panel subsequently reviewed all near misses and adverse drug events.

After half of the participating practices have implemented EHRs in 2007, we will export electronic copies of prescriptions from each EHR. The other half of the physicians will serve as a control group by repeating the duplicate prescription protocol completed at baseline. The research pharmacist will review both the electronic and duplicate prescriptions for medication errors. Chart reviews and physician review panels will also be performed. Comparison analyses will be done to assess any differences in prescribing errors between paper prescriptions and e-prescribing through the EHR.

Effects of EHR use on quality of care

Quality of care has often been measured by claims-based data collection. Studies have indicated that EHRs can improve the quality of medical care, though their impact has been mixed [2,5,19]. To assess the effects of EHR implementation on quality of health care in community-based practices, the study team will obtain both pre-EHR implementation and post-EHR implementation claims-based quality data from the Massachusetts Health Quality Partners (MHQP). Comparisons between the two years are planned. These data will be linked to the physician characteristics collected in the physician survey to measure EHR usage and its relation to quality.

Studies have also suggested that EHR data exports present a unique opportunity to get faster and potentially better quality data [3]. To evaluate this potential, the study team plans to collect and assess quality data elements exported from the EHRs and compare EHR-derived quality measurements with claims-based quality measurement.

Physician use of EHRs

To assess physician characteristics and practice characteristics, we mailed an 8-page survey to 1884 randomly-selected physicians in Massachusetts, representing approximately 10 percent of physicians in the state. The questions in the survey addressed office characteristics, physician attitudes toward health information technology (HIT), barriers to EHR adoption, facilitators of EHR adoption, among others. For those who had EHRs in their practice, questions focused on EHR functionalities and degree of individual usage. A similar post EHR-implementation survey is planned for mid 2007.

Effectiveness of academic detailing on implementation

While many physicians welcome the addition of EHRs to their practices, some have greater difficulty adjusting to the EHR. In order to accelerate physician fluency with EHRs, the evaluation includes an academic detailing intervention. Academic detailing is a method of changing physician behavior that has been effective in improving prescribing behavior.[20] Using the same methodology, the intervention group (~ 15 physicians) will receive two academic intervention sessions to help them acclimate and adjust to their new EHR system. The control group will receive the usual technology support offered through the MAeHC and the EHR vendor. After the intervention, both groups will be assessed for EHR usage and satisfaction.

Economic evaluation

The planned evaluation also includes an overall economic component, which will assess the costs, savings, and return on investment related to MAeHC's implementation, interoperability, and data exchange. With respect to data exchange, we will count the number of pieces of data of various types (laboratory results, prescriptions, radiology results) moving within the communities. The eventual plan is to link the data exchanges with a statewide data exchange.

Results

The implementation effort and associated evaluation are both currently underway. Results available to date are described below.

Results from office practice survey

In our baseline survey, sent in April 2005, forty-six percent (847/1829) of office practices responded.[10] The survey was addressed to the office practice manager at each site. Weighted responses indicated that 18 percent of these practices had EHRs at the time of the survey.

Adoption rates varied slightly by type of practice, with 23 percent of primary-care-only practices, 25 percent of mixed practices (both primary care and specialty care), and 14 percent of specialty practices reporting having EHRs. The rate in specialty practices was significantly lower than the primary-care-only and the mixed practices ($P<0.01$). Practice size was also significantly correlated with EHR adoption, as smaller practices reported less EHR adoption ($P<0.001$).

EHR users were asked about functionalities that were available in their system. The most common functionalities available were visit notes, lab test results, and medication lists. However, when asked about which functionalities the majority of physicians used, laboratory and radiology result retrieval capabilities topped the list, with 87 percent of practices reporting that the majority of clinicians actively used both functionalities.

Of the practices that reported not currently having an EHR, 13 percent reported having plans to adopt an EHR within the next year, 24 percent reported plans for implementing an EHR in the next 1-2 years, and 11 percent in the next 3-5 years. Fifty-two percent of practices currently without EHRs reported having no plans to adopt an EHR in the foreseeable future.

One challenge to conducting this part of the evaluation was the unavailability of a list of statewide practice manager names. We sent the mailings to the "attention of the office practice manager" at each physician's office. Having the actual names might improve response rates.

Results from the medication error rate evaluation

Data collection for this evaluation is nearly complete. We were able to gather over 4000 prescriptions from 30 ambulatory, primary care physicians; nearly 200 chart reviews were performed to assess whether near misses (prescription errors with the potential to cause harm) were actually adverse drug events (prescription errors that did cause harm).

Our plan for this part of our implementation evaluation encountered some challenges. In comparison with our previous studies in academic settings, a larger proportion of physicians opted out due to a variety of concerns. Applying for Institutional Review Board (IRB) approval from hospital-based community IRBs was also more complex than usual, in part because less research is traditionally conducted in these settings. Also, the participating physicians came from many small independent ambulatory practices, making communication with all the various stakeholders a challenge.

Results from the quality of care evaluation

We have received HEDIS data on approximately 80 percent of the primary care physicians from our statewide physician survey sample. Analyses comparing quality of care with reports of EHR usage are underway. The methods for this part of the evaluation involve using HEDIS measures via claims-based data from the Massachusett Health Quality Partnership, which involves a long time delay (1-2 years post data collection).

An additional aim of this part of our evaluation is to examine the feasibility of gathering quality data directly from the electronic health records. This methodology for assessing quality generated concerns around physician identifiers, as well as numerous technical challenges to extract these data from multiple EHR vendors.

Results from physician survey

We also performed a statewide survey in June of 2005; a total of 1345/1884 physicians responded (71%).[9] When weighted to represent the distribution of practice size, specialty, and whether the practice was hospital-based, 23 percent of practices reported having EHRs. Practice size was strongly correlated with EHR adoption. Only 14 percent of solo practices reported having an EHR, while fifty-two percent of practices with 7 or more physicians reported having an EHR. However, due to the large number of practices with more than 7 physicians in Massachusetts, 45 percent of the physicians in the state, ranging from 10 percent in solo practices to 72 percent of large practices, reported having EHRs in their practices (see Figure 1). Practices that engaged in teaching medical students or residents and hospital-based practices both reported higher rates of EHR adoptions.

Not surprisingly, physicians reported that financial considerations present the greatest barrier to implementation. Loss of productivity was also a concern for physicians, with 81 percent of responders selecting it as a barrier. Physicians not currently using EHRs more often reported financial barriers as "major barriers" as compared with physicians who had EHRs.

Additional analyses are underway that focus on the characteristics of practices that have EHRs, as well as analyses that compare the statewide survey data with data collected in each of the intervention communities.

We believe that the high response rate was achieved because we used express mail delivery with $20 cash incentives, and multiple mailings. In addition, all envelopes were addressed to the physician specifically, and any

returned mail was researched (and re-mailed, if possible) using multiple statewide databases.

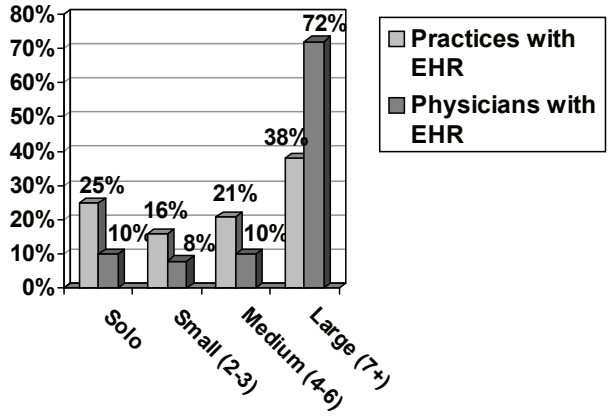

Figure 1 - Distribution of physicians and practices with EHRs by size of practice

Results from the academic detailing intervention

To date, we have been able to hire and train clinicians local to the communities participating in this intervention. This component of the evaluation is dependent upon EHR implementation, and the trained clinicians will begin the intervention in early 2007.

Discussion

The aims of this effort are to better understand more about EHR adoption in ambulatory settings, what can be done to get physicians to high levels of proficiency after adoption, how EHRs affect medication safety and quality performance in communities, and what the impact of EHR adoption and interoperability are on quality. Although we are still early on this path, we believe the preliminary results are of interest.

The results from both of our statewide surveys indicate that the rate of EHR adoption in Massachusetts in 2005 was higher than in other states in the U.S.. Practice size, as well as teaching practices and hospital-based practices, were all correlates of EHR adoption. The high response rate achieved in the physician survey suggests that our protocol, and specifically the cash incentives, can be a valuable method of obtaining high response rates from busy physicians.

EHR adopters reported various degrees of functionality within their systems. Visit notes and lab tests were the most common functionalities available. However, though many practices report having specific EHR functionalities, physicians were not necessarily using them in their practice. In our office practice survey, office practice managers reported that their physicians were using certain functionalities less than 50% of the time, or even none of the time. In 25% of practices who had clinical decision support (alerts, warnings and reminders) within that practice's EHR system, respondents reported that less than 50% of the clinicians were using that functionality. This would indicate that though physicians have functionalities within their EHR system, they don't necessarily use all of them. Some functionalities that they are not using, like clinical decision support, are important for quality improvement efforts.

Therefore, decision support standards need to be developed that will aide the availability and use of key quality-enhancing features in EHR systems. Additionally, physicians need to be trained and appropriately motivated to take advantage of the EHR.

EHR non-adopters have slightly different attitudes and weigh the challenges differently from EHR adopters. In our physician survey, non-adopters scored financial considerations as a greater barrier than did those with EHRs in place. Also, non-adopters' plans for implementation vary greatly, with the majority reporting having no plans to adopt EHRs in the near future.

Challenges in conducting this type of multi-faceted evaluation include physician concerns about privacy and security, issues related to conducting research in small communities that are not accustomed to academic research, and logistical and technical difficulties associated with independent EHR vendor systems.

Building trust in the participating practices is a key component to overcoming these challenges. For each study component, investigators and staff explained protocols and plans at the local level. Clear communication and community leadership from the coordinating organization, the MAeHC, has proven to be essential to the success of the evaluation. Their support of this research, as well as their relationships with the physicians and the vendor systems, has facilitated study operations.

An early conclusion from the work to date has been that the community-oriented approach to interoperability appears to be especially important. Our impression is that the involved practices would not have moved nearly as rapidly to setting up community data exchange without the Collaborative. In addition, we are hopeful that we will be able to identify practices that are not using the EHR to its full extent, and move them to higher levels of use than would have occurred without the Collaborative.

Conclusions

Measuring the impact of a fully-funded EHR implementation program requires a multimodal evaluation approach. This evaluation will be comparing quality, adoption rates, and correlates of EHR adoption across the state. This

Massachusetts evaluation has the opportunity to compare pilot communities that have comprehensive support to implement EHRs with EHR adoption in the rest of the state. Information collected as part of this effort will inform implementation in the rest of the state, as well as both national and international audiences. While many countries have made investments in EHRs that far exceed those made by the U.S., it is easy to have implementations that do not deliver full value. Evaluations such as this one may help justify future investments and policy choices in particular around relatively new areas such as interoperability.

Introduction: EHRs and MAeHC

- Use of Electronic Health Records (EHRs) is increasingly widespread [1-8].
- Features of EHRs, such as electronic prescribing, interoperability and decision support, may enhance the safety, quality and effectiveness of healthcare.
- Barriers to EHR adoption include financial, technological and other challenges [5, 8-17].
- Massachusetts eHealth Collaborative (MAeHC):

  A coalition of 34 stakeholders, formed with aims of enhancing EHR adoption in MA. USA, setting up clinical data exchange, and encouraging hospitals to adopt computerized provider order entry (CPOE)
- In 2005, MAeHC proposed to implement EHRs in three MA communities, representing over 150 ambulatory practices with over 400 clinicians, as a pilot for statewide implementation.

Aims: Evaluating the Impact of MAeHC in Three Pilot Communities

- Assess the ways that EHRs are used by physicians, ranging from those who use them proficiently to those who are just starting to use EHRs
- Assess how EHR use affects medication errors and overall quality of healthcare
- Identify physicians characteristics that are correlated with the rate of EHR adoption, in addition to practice characteristics
- Facilitate EHR use through an intervention based on academic detailing and assess whether academic detailing will accelerate EHR adoption and physician EHR proficiency [18]
- Calculate the economic return on investment for EHR implementation
- Preliminarily evaluate health information exchange (HIE)

Evaluation Methods

- Rate and extent of EHR adoption with intervention:
  - Baseline office practice survey of EHR adoption in MA in 2005: random sample of 1829 ambulatory physician practices (30% of all practices in MA)
  - Follow-up survey is planned for mid-2007, as well as an assessment of usage rates for specified EHR features.
- Effects of EHR use on medication error rates:
  - Baseline analysis on the medication error rate in duplicate paper prescriptions collected from 30 physicians over approximately two weeks
  - After EHR implementation, analysis will be performed on 15 physicians' duplicate paper prescriptions and 15 physicians' electronic prescriptions, as compared with the baseline data.
  - Chart reviews and physician review panels aid this analysis.
- Effects of EHR use on quality of care:
  - Comparisons of pre-EHR implementation and post-EHR implementation claims-based quality data from the MA Health Quality Partners (MHQP)
  - Collection and assessment of quality data elements exported from EHRs

Evaluation Methods (cont.)

- Physician use of EHRs:
  - In 2005, an 8-page survey was mailed to 1884 randomly-selected physicians in MA (10% of physicians in the state), assessing office characteristics, physician attitudes toward health information technology (HIT), barriers to EHR adoption, facilitators of EHR adoption, etc.
  - Post-EHR implementation survey distributed in Spring 2007
- Effectiveness of academic detailing on implementation:
  - Academic detailing is a method of changing physician behavior that has been effective in improving prescribing behavior. [20]
  - An intervention group (~15 physicians) will receive 2 academic sessions to help them acclimate and adjust to their new EHR systems. A control group will receive the usual technology support offered through the MAeHC and the EHR vendor. Both groups will be assessed for EHR usage and satisfaction after the intervention.
  - At this point in time, clinicians local to the communities participating in this intervention have been hired and trained to serve as the academic detailers. Timing of the evaluation is dependent upon EHR implementation. Trained clinicians will begin the intervention in 2007.
- Economic evaluation:
  - Assessment of the costs, savings and return on investment related to MAeHC's EHR implementation and data exchange

Results: Office Practice Survey

- Out of a sample of 1829, a total of 847 completed surveys were returned, yielding a response rate of 46%.
- Overall, 18% of practices reported having an EHR.
- All results are weighted to better represent statewide trends.
- Reported having EHRs:
  - 23% of primary care practices
  - 25% of mixed practices (both primary care and specialty)
  - 14% of specialty practices
- Smaller practices reported less EHR adoption.
- Of the practices that reported not currently having an EHR:
  - 13% have plans to adopt an EHR within the next year
  - 24% in the next 1-2 years
  - 11% in the next 3-5 years
  - 52% reported having no plans to adopt an EHR in the foreseeable future

Figure 1: EHR Functionality Usage

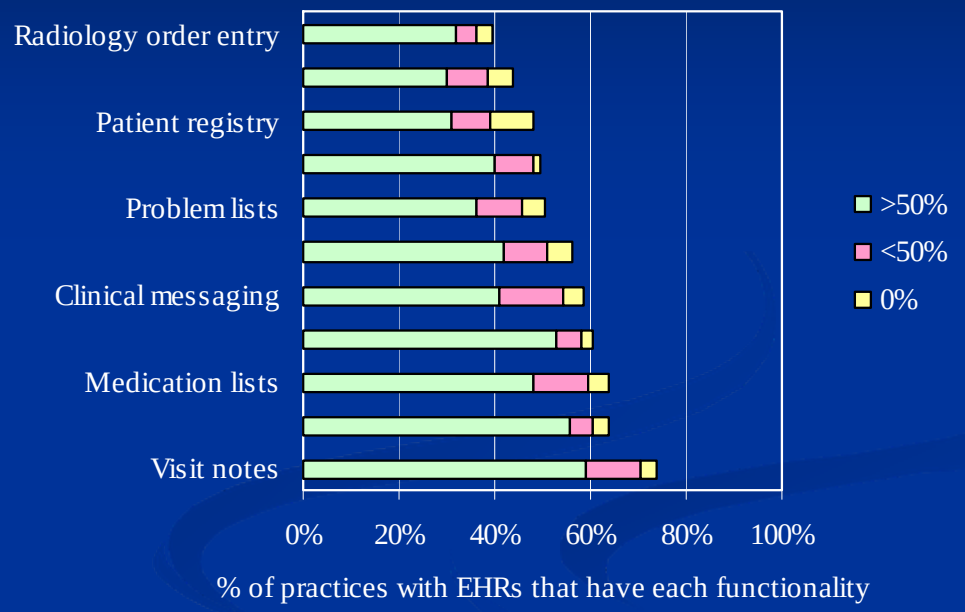

Figure 1: Availability and use of individual EHR functionalities among office practices with EHRs. The length of each bar indicates the percentage of practices that have each functionality available within their EHR system. The component segments of each bar reflect the proportion of practices in which 50% or more of the clinicians regularly use the functionality (green segment), less than 50% of the clinicians regularly use the functionality (yellow segment), and none of the clinicians use the functionality (blue segment).

Status: Medication Error Rate Evaluation

- Data collection is almost complete, with over 4000 prescriptions gathered from 30 ambulatory primary care physicians.
- Nearly 200 chart reviews were performed to assess whether near misses (prescription errors with the potential to cause harm) were actually adverse drug events (prescription errors that did cause harm).
- Challenges:
  - Many physicians opted out.
  - IRB approval processes were complex.
  - Communication with various stakeholders was difficult, since physicians came from many small independent ambulatory practices.

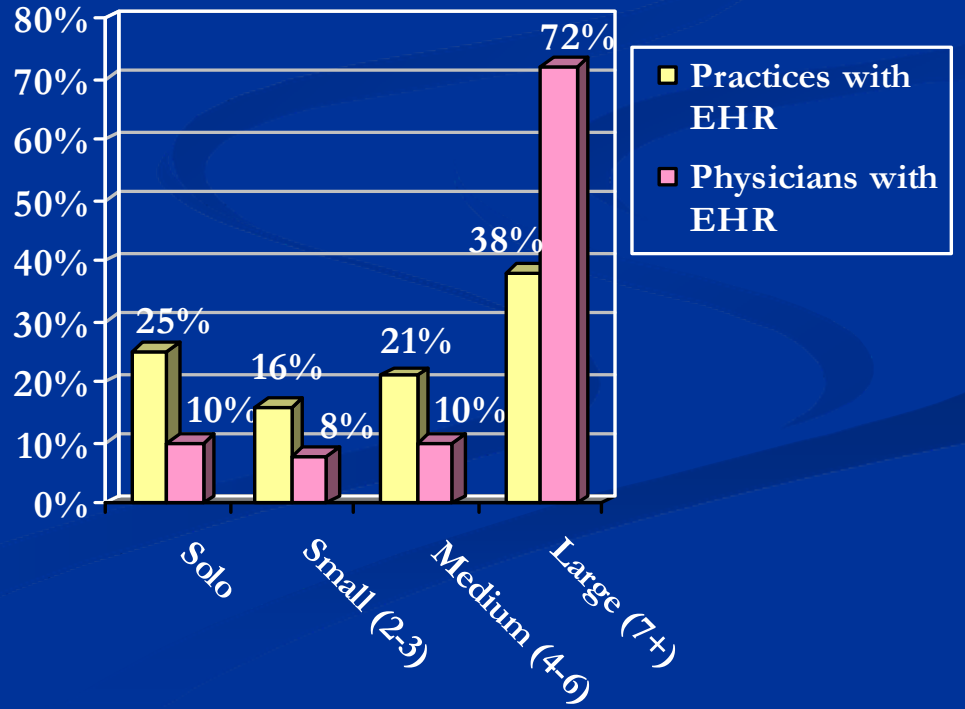
Status: Quality of Care Evaluation

- HEDIS data on ~80% of primary care physicians from our statewide physician survey sample have been received.
- Analyses comparing quality of care with reports of EHR usage have begun.
- Part of this evaluation involves using HEDIS measures via claims-based data from MHQP which requires 1-2 years after data collection to construct measures.
- We are in the process of determining methods for direct electronic data extraction from multiple EHR vendors.

Results: Physician Survey

- 1345/1884 physicians responded (71% response rate).
- Practice size was strongly correlated with EHR adoption (see Figure 2).
- Financial considerations were reported as the greatest barrier to implementation. Physicians who do not currently use EHRs more often reported this as a "major barrier" as compared with physicians who had EHRs.
- 81% of responders also reported that loss of productivity was a barrier.
- Additional analyses focusing on the characteristics of practices with EHRs and analyses comparing the statewide survey data with intervention communities are underway.

Figure 2 – Distribution of physicians and practices with EHRs by size of practice



Discussion

- Our survey results indicate that the rate of EHR adoption in MA in 2005 was higher than in other states in the U.S.
- Larger practice size, teaching, and hospital-based practices were correlated with EHR adoption.
- Visit notes and viewing lab test results were the most commonly available EHR functionalities.
- Though many physicians report *having* specific EHR functionalities, physicians were not necessarily *using* them in their practices.
- Decision support standards, additional training and appropriate motivation will aid the availability and use of quality-enhancing features in EHR systems.
- Many EHR non-adopters cite financial considerations as the main barrier to EHR adoption. Their plans for implementation vary greatly, with the majority reporting having no plans to adopt EHRs in the near future.
- Challenges in this evaluation include:
  - Physician concerns about privacy and security
  - Issues related to conducting research in small communities that are not accustomed to academic research
  - Logistical and technical difficulties associated with independent EHR vendor systems
- A community-oriented approach to interoperability and data exchange appears to be important.

Conclusions

Based on these preliminary results of ongoing research, measuring the impact of a fully-funded EHR implementation program requires a multimodal evaluation approach. The evaluation will be assessing quality, medication safety, adoption rates, and correlates of EHR adoption across the state. This Massachusetts, U.S. evaluation has the opportunity to compare pilot communities that have comprehensive support to implement EHRs with EHR adoption in the rest of the state. Information collected as part of this effort will inform implementation in the rest of the state, as well as both national and international audiences. Many countries have made great investments in EHRs, and it is important to understand the value of these systems. Evaluations such as this one may help justify future investments and policy choices, particularly pertaining to relatively new areas such as data exchange.

From Activity Analysis to an User Interface Navigation Structure for an Electronic Patient Record (EPR)

Jens Lauber

Department of Medical Informatics

University of Amsterdam / University of Heidelberg

Outline

- Introduction
- Objectives
- Methods
  - Activity Analysis
  - Workflow Modelling
  - Implementation of the Navigation Structure
- Results
  - Activity Analysis
  - Workflow Modelling
  - Implementation of the Navigation Structure
- Discussion & Conclusion
- References

Introduction

- At the Academic Medical Center (University Hospital in Amsterdam) a new EPR will be introduced
- Our project will give proposals for the new user interface design
- We looked into the workflow of the department of gynaecology
- Clinicians must be involved in the system development for best acceptance

Objectives

What patient data and in what context do physicians search for information and what resources are used therefore ?

Methods:
1. Activity Analysis

List all activities and its

- Roles (who is acting)
- Reason (why the action is conducted)
- Information (what is transferred)

Modelling by

- Activity
- Input
- Output
- Resource/ Method
- Control/ Constraint

Methods:
2. Workflow Modelling

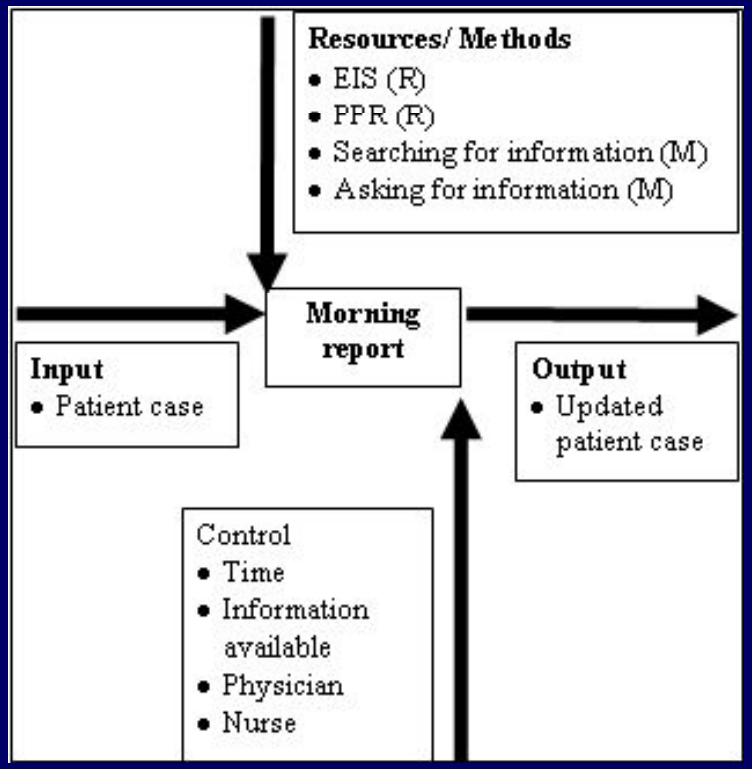
Define in chronological order the medical information reviewing process into four parts:

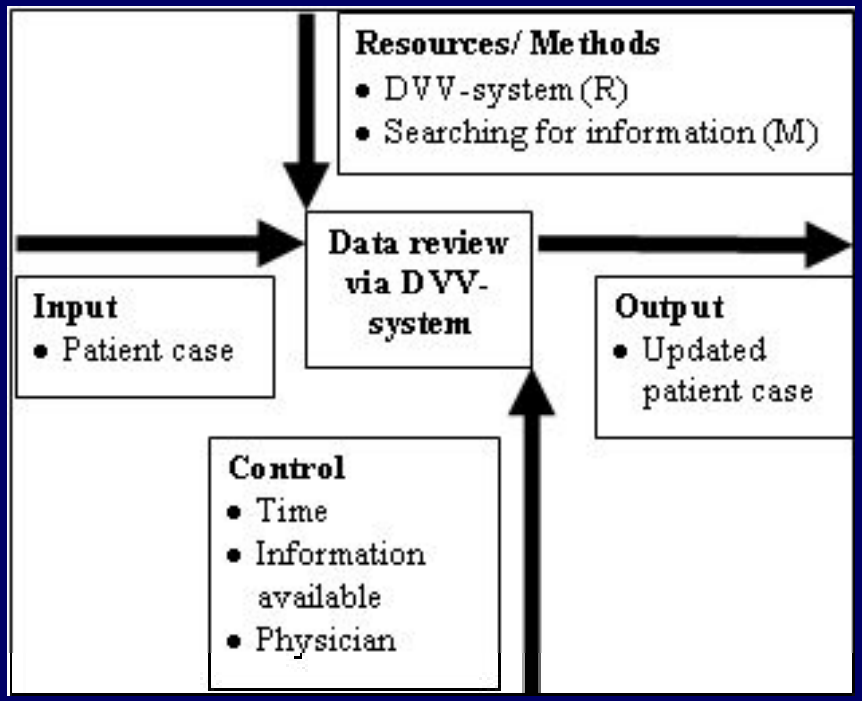
- patient summary / patient history
- actual patient status
- examinations
- daily controlled data

Methods:
3. Implementation of the Navigation Structure

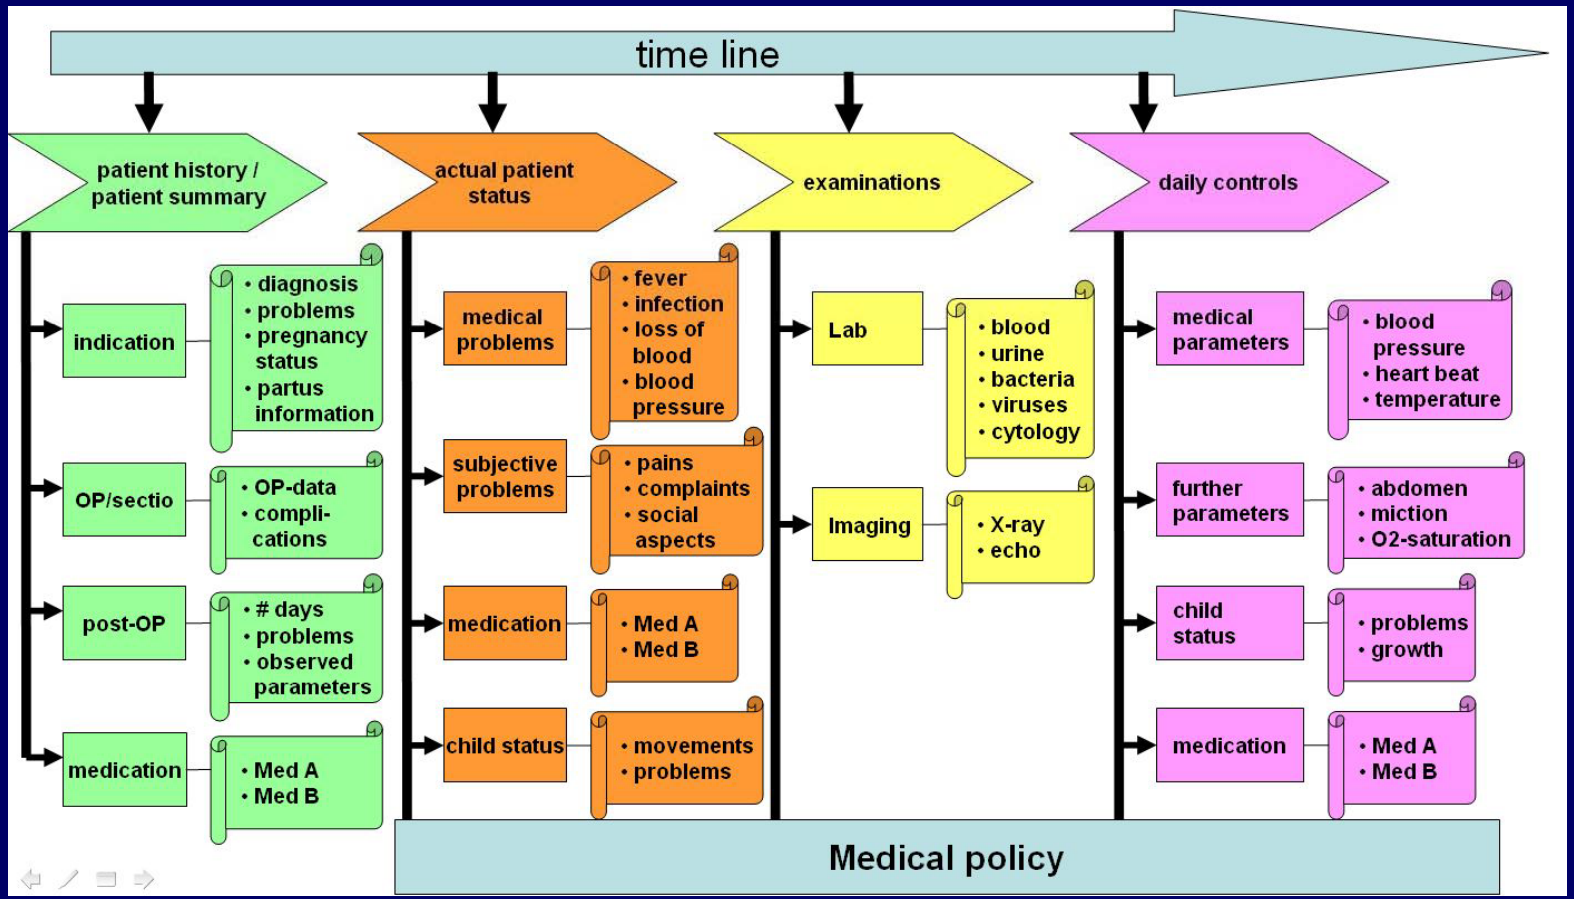
- Workflow model leads to navigation structure
- Results of Workflow modelling was mapped onto the EPR-prototype
- Navigation structure was adapted to the new workflow results obtained from the models

Results:
1. Activity Analysis





Results:
2. Workflow Modelling

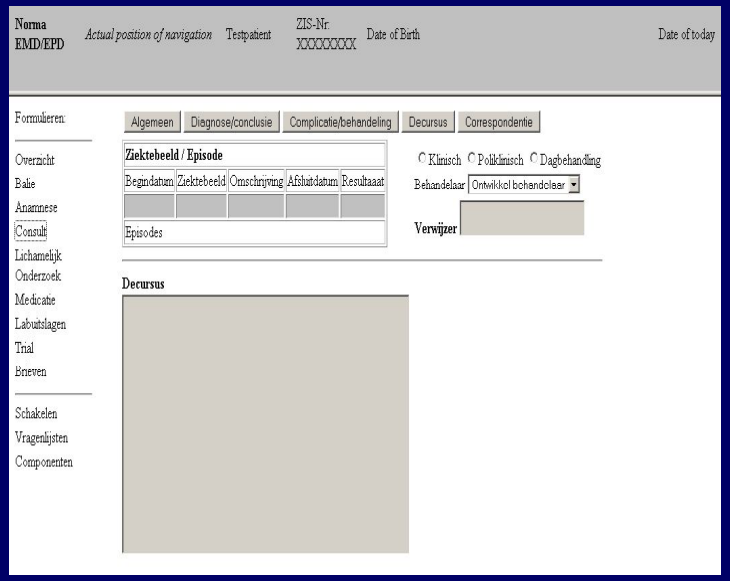


Results:
3. Implementation of the Navigation Structure

Old:

One text field

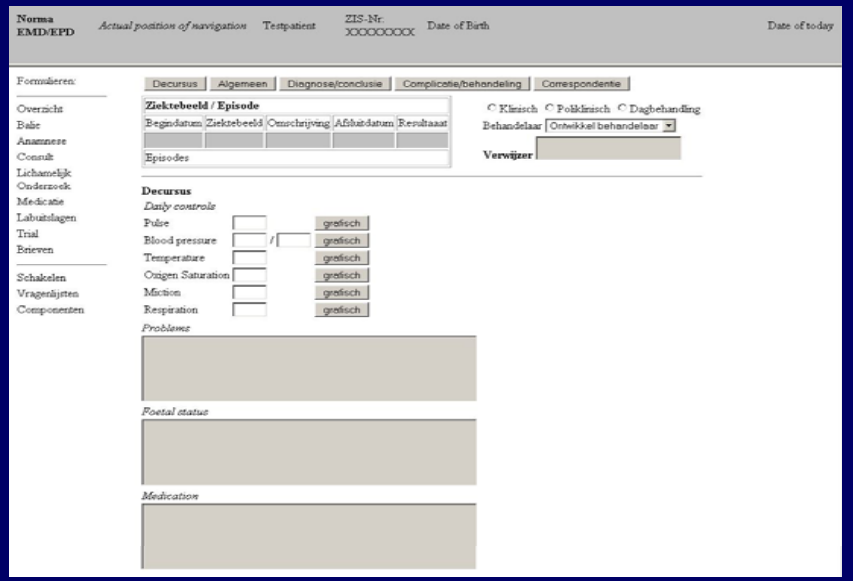
Bad overview



New:

Process driven fields

Better info searching



Discussion & Conclusion

- Some EMR-system have low acceptance
  - Tailored system by integration of the end-user
  - **Acceptance ↑**
- Perspective of data input is common in EMR
  - Focus on data retrieval / data review behaviour
  - **Better modeling** of the real scenario
- Media cracks through the use of conventional systems mixed with electronical systems
  - Investigation of the workflow streamline to find an efficient supporting navigation structure
  - **Patient safety ↑**

Abstract

Medication discrepancies occur frequently at hospital admission and discharge. Medication reconciliation is recognized as an essential process to reduce medication discrepancies and improve prescribing practices.

The University Health Network has developed an electronic tool that is integrated with the electronic patient record (EPR) and facilitates the medication reconciliation process. The tool was developed by first creating a structured, multi-disciplinary medication reconciliation strategy.

The Electronic Medication Information Transfer Tool (EMITT) is populated with patient demographics, allergies and medications from the patient chart. The tool facilitates medication reconciliation documentation as well as the coding of medication discrepancies. EMITT is integrated with the electronic discharge summary application and is able to generate an electronic prescription upon discharge. The tool also generates a medication letter, a patient medication grid and a medication wallet card.

The success of this project is attributed to the high degree of clinical leadership and involvement throughout the entire design and development of the electronic tool. It is anticipated that similar electronic models can be easily adopted at other healthcare institutions.

Keywords:

medication reconciliation, electronic prescription, preventing medication discrepancies, electronic medication reconciliation tool, medication safety

Introduction

The Canadian "Safer Healthcare Now!" initiative and the Institute for Healthcare Improvement "100K Lives" campaign have both identified medication reconciliation as an essential process to prevent medication discrepancies. The Institute for Healthcare Improvement defines medication reconciliation as "a formal process of obtaining a complete and accurate list of each patient's current home medications - including name, dosage, frequency and route - and comparing the physician's admission, transfer, and/or discharge orders to that list. Discrepancies are brought to the attention of the prescriber and, if appropriate, changes are made to the orders. Any resulting changes in orders are documented" [1].

The Canadian Council on Health Services Accreditation (CCHSA) has also recognized the importance of medication reconciliation by including it as part of the Patient Safety Goals and Required Organizational Practices (ROPs). As part of the accreditation process healthcare organization in Canada are required to:

- "Reconcile the patient's medication upon admission to the organization, and with the involvement of the patient." [2]
- "Reconcile medications with the patient at referral or transfer, and communicate the patient's medications to the next provider of service at referral or transfer to another setting, service, service provider, or level of care within or outside the organization." [2]

Canadian hospitals must meet the CCHSA requirements to be considered an accredited healthcare organization. Passing the accreditation process indicates that "the organization was assessed by its peers, met or exceeded national standards of excellence, and continues to strive for high quality health care" [3].

Many healthcare organizations are now faced with the challenge of incorporating the medication reconciliation process with current workflow practices. Some of the challenges that organizations may face include [4]:

- How to integrate reconciling meds with current workflow and prescribing practices?
- How to standardize the collection of data?
- The amount of time required to reconcile medications.

To address challenges with reconciling medications, the University Health Network has developed an electronic

tool that is integrated with the electronic patient record (EPR) to facilitate the medication reconciliation process.

Methods

Project Objectives

This project worked towards developing a web-based tool that is integrated with the hospital's electronic EPR and can facilitate the medication reconciliation process. The tool must be able to facilitate medication reconciliation throughout the entire inpatient stay and capture the Best Possible Medication History (BPMH), admission medication reconciliation, and discharge medication reconciliation. It is also essential that the tool is able to generate the best possible discharge medication list, electronic prescription, a medication letter for community clinicians and a medication grid and wallet card for the patient.

Requirements Gathering

A multi-disciplinary team comprised of pharmacists, physicians and IT professionals worked closely together to decide upon the functional requirements for the web-based application. The team was involved with a separate project that conducted a literature review, needs assessment and a baseline measurement of discharge prescription medication discrepancies to develop a structured medication reconciliation strategy [5, 6]. The results of the structured medication reconciliation strategy would provide direction of the requirements needed for an electronic medication reconciliation tool.

Technical Development and Testing

The Medication Reconciliation application known as the Electronic Medication Information Transfer Tool (EMITT) was built in-house by developers in the hospital's IT department. All required database and user interface work was also completed by the same technical team.

The application was thoroughly tested by both the technical team and pharmacists who were involved with the project. The application also underwent additional usability testing by the Human Factors team in the labs located on site at the Centre for Global eHealth Innovation.

Results

Technical Specifications

The EMITT web-based application was built using PHP, Javascript, and AJAX; it resides on an Apache server and has an Oracle database. The application is integrated with the EPR and is pre-populated with patient demographics, allergies and medications. The application is also integrated with the electronic discharge summary. Figure 1 is an example of how EMITT is integrated with the EPR and the discharge summary application.

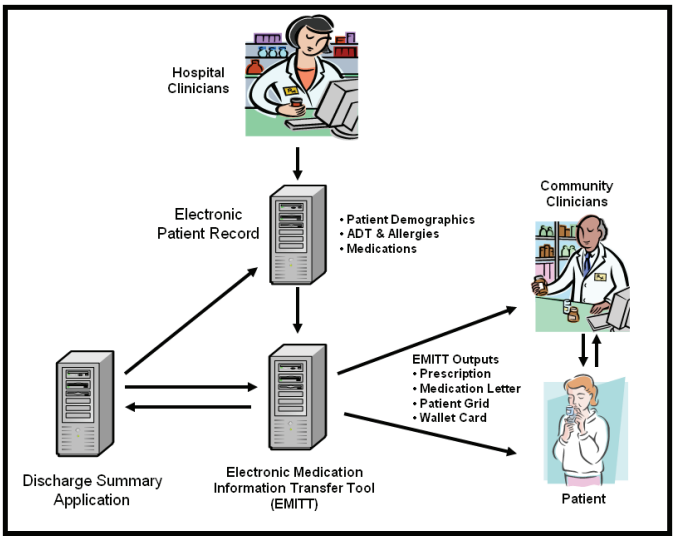

Figure 1: EMITT dataflow diagram

Application Design

The EMITT application was built to facilitate the medication reconciliation process from admission to discharge and to improve prescribing practices. The application is sub-divided into seven pages that guide a user through the Medication Reconciliation process:

Allergies and BPMH – This page allows a clinician to document and print the BPMH for both prescription and non-prescription medications. The clinician is also able to document the sources of information used to obtain the BPMH. Allergies are automatically populated from the patient's chart if available in the EPR. Figure 2 is an example of how the BPMH is documented.

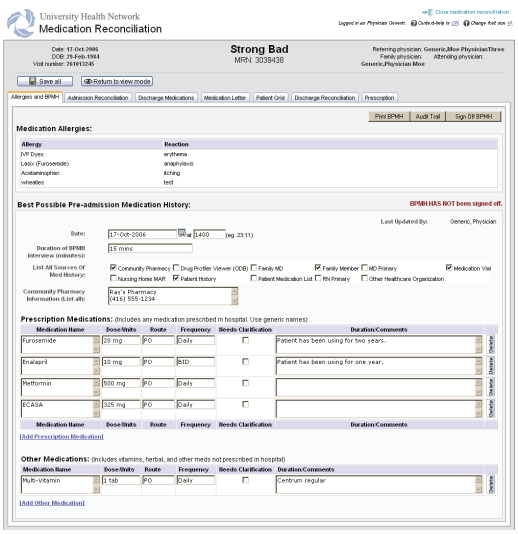

Figure 2 - Screen capture of the allergies and BPMH page

1. Admission Reconciliation – This page allows clinicians to compare the BPMH to admission orders and reconcile the medications. The BPMH medications are automatically pulled across from the previous tab and the medication admission orders are automatically populated from the EPR. On this tab the clinician is required to reconcile admissions orders and code any discrepancies according to the Safer Healthcare Now! recommendations. This tab also allows clinicians to document any issues that require follow-up. Figure 3 is an example of how clinicians would reconcile admission medications.

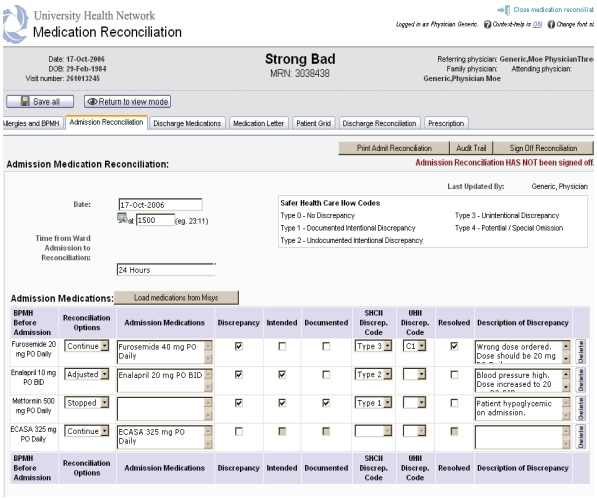

Figure 3 - Screen capture of the admission reconciliation page

2. Discharge Medications – This page allows clinicians to reconcile the BPMH with the current active in-hospital medication list. This process generates the best possible discharge list and an electronic prescription. The discharge medication list is also used to populate the medication letter and patient grid. This page is integrated with the discharge summary application and provides physicians with a recommended discharge medication list if available.
3. Medication Letter - This page is used to generate a medication letter for the patient and/or community clinicians. All of the reconciled medications on the medication letter are automatically populated from the discharge medication page. The medication letter contains a list of the patient's current medication regimen and any adjustments (with rationale) that have been made since the patient was admitted to the hospital. The medication letter also contains a description of any outstanding medication related issues to be followed up in the community.
4. Patient Grid – This page allows clinicians to generate a medication grid that outlines why a patient is taking a medication and when s/he should be taking it. All of the instructions on the patient grid are in lay terms to ensure that patients understand their medication regimen. The patient grid medications are automatically populated from the discharge medication page.

5. Prescription – The electronic prescription is generated from the reconciled medication on the Discharge medication page. This page allows the clinician to view and print out the prescription. The electronic prescription not only contains the medications that are to be dispensed, it also includes a summary of any new, adjusted, discontinued, and medications to be continued. Figure 4 is an example of how a completed ePrescription will appear.

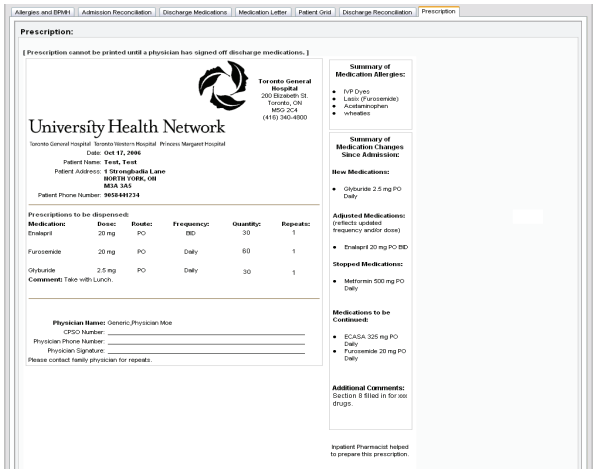

Figure 4 - Screen capture of the prescription page

6. Discharge Reconciliation – This page allows clinicians to reconcile the BPMH, the last day impatient medications and prescription medications. The BPMH and prescription medications are automatically populated from previous pages and the last day meds are populated from the EPR. This page also allows clinicians to document and code medication discrepancies.

Built into EMITT are several security features. Clinicians log into the application via the EPR which prevents an additional login and ensures that only the appropriate users have access to the application. A secondary authentication check is done on the application end to verify security. If a user does not have the appropriate security they are denied access to the application. In addition to the security checks, the application also keeps detailed audit logs of who accesses, edits and signs off on any of the pages within the application for each patient record. To improve the quality and accuracy of data within the application all fields that are currently available within the EPR are automatically populated.

Adoption and usage

The EMITT pilot has been well received and adopted by the General Internal Medicine (GIM) pharmacy team at Toronto General Hospital. Pharmacy is currently completing a study to validate and formally measure the impact of EMITT on medication reconciliation and prescribing practices. From January 2007 to March 2007, 135 patient discharge medication lists were created using EMITT in GIM at Toronto General Hospital.

The project team is currently working on a communication and education strategy to safely introduce EMITT to the other inpatient units at the University Health Network.

Conclusion

The University Health Network has developed a web-based tool that facilitates the medication reconciliation process. EMITT is integrated with the EPR and has been built to meet the medication reconciliation requirements of both the CCHSA and the Safer Healthcare Now! campaign.

EMITT is a single web-based platform that is integrated with the electronic discharge summary. The ability to populate EMITT with data from the EPR improves the accuracy and quality of data collection. EMITT is used to document the BPMH and reconcile medications at admission and upon discharge. EMITT is also used to generate an electronic prescription, medication letter, patient grid and medication wallet card.

Discussion

Healthcare organizations are constantly challenged to improve patient safety and the accuracy of medication orders. Throughout the development of EMITT the technical team worked very closely with a multi-disciplinary team of clinicians to understand the challenges with implementing a new workflow process. The ability to involve clinicians throughout the entire design, development, and implementation process allowed the technical team to develop a product that meets clinical needs and is minimally disruptive to current workflow practices.

One of the biggest strengths of this project is the amount of research and design work that went into the application before development even began. Before beginning discussions of what the application would look and how it would function, research was completed to identify what information clinicians would require to reconcile medications effectively. Additional research of UHN's current medication prescribing practices upon discharge was also completed to identify areas for improvement that could easily be incorporated into the application.

The ability to integrate EMITT with the hospital's current EPR allowed the application to leverage information that is electronically captured. This process alone minimized

the amount of duplicate documentation needed and decreased the amount of time required to reconcile medications.

The EMITT application is built on a web-based platform that could be adopted and implemented at another health-care institution. The application is fully functional even if information, such as medications, cannot be electronically leveraged from a separate data source.

EMITT provides an electronic framework for reconciling medications and guiding prescribing practices.

Acknowledgments

We would like to thank all of the clinical and technical contributors to this project. Without all of your leadership, expertise and guidance this project would never be successful.

Project Objectives

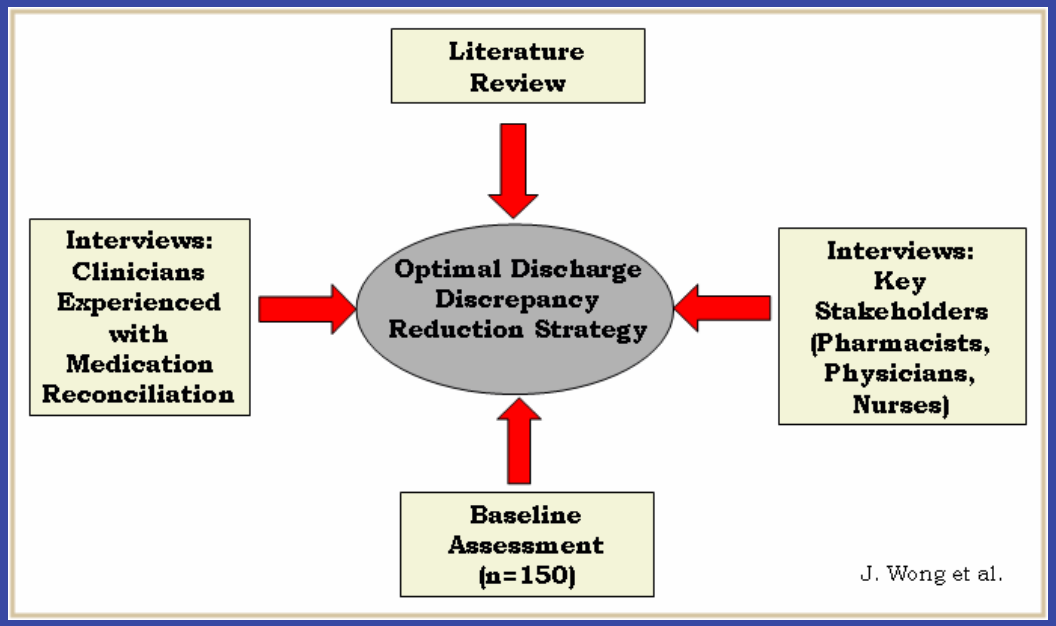
- To develop a web-based tool that integrates the hospital's electronic patient record (EPR) and facilitates medication reconciliation

- To develop a process to guide clinicians through the medication information transfer process, and help prevent discrepancies by improving prescribing practices

University Health Network

Methods

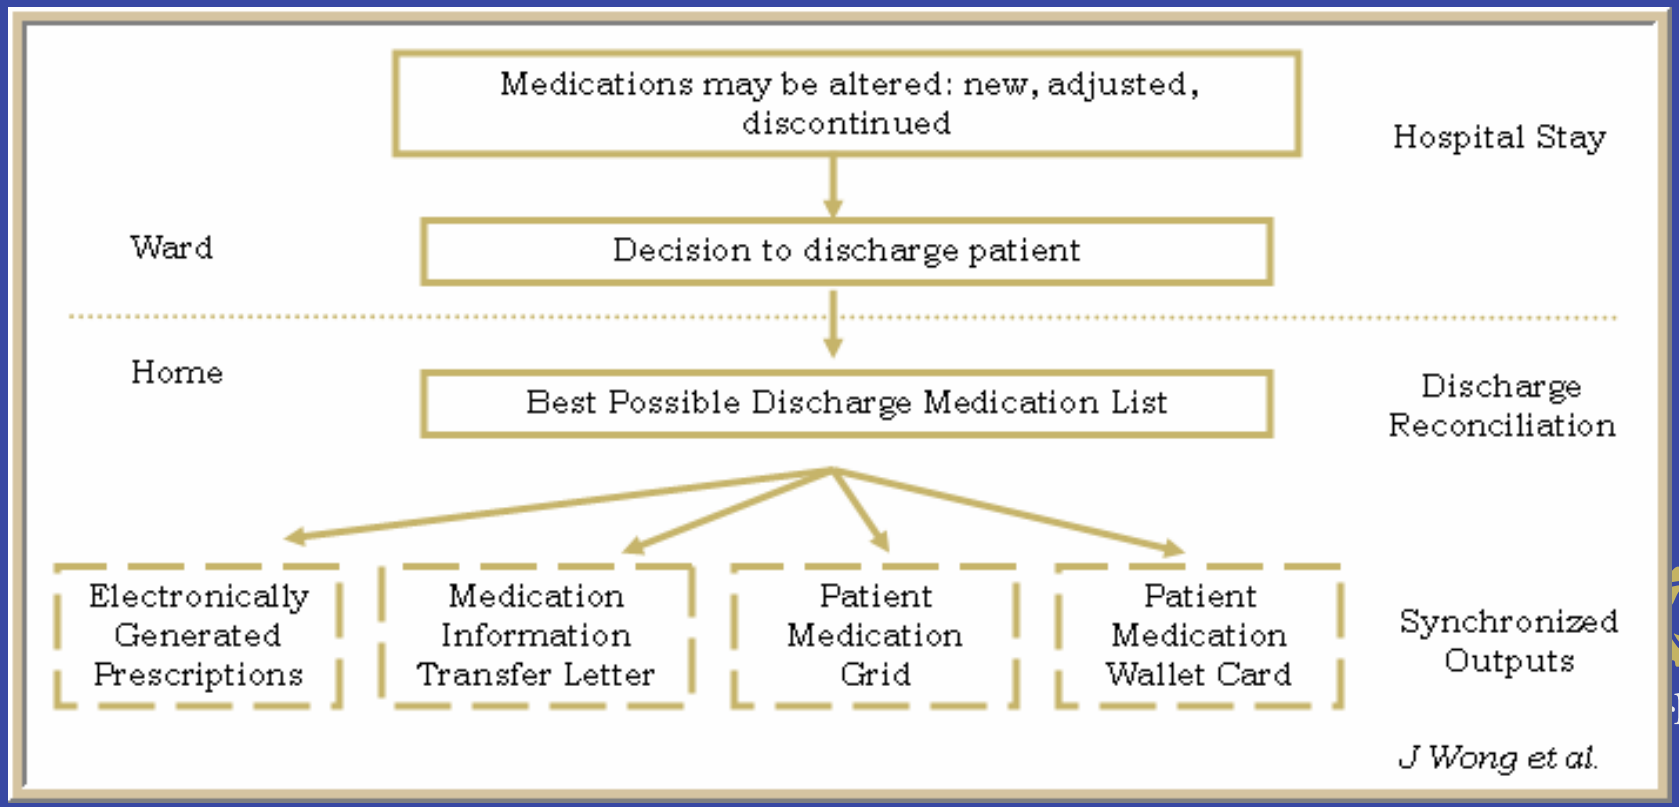
- A multidisciplinary team conducted a literature review, needs assessment and a baseline measurement of prescription discrepancies.
- The Electronic Medication Information Transfer Tool (EMITT) was built internally by developers in the hospital's information technology department.



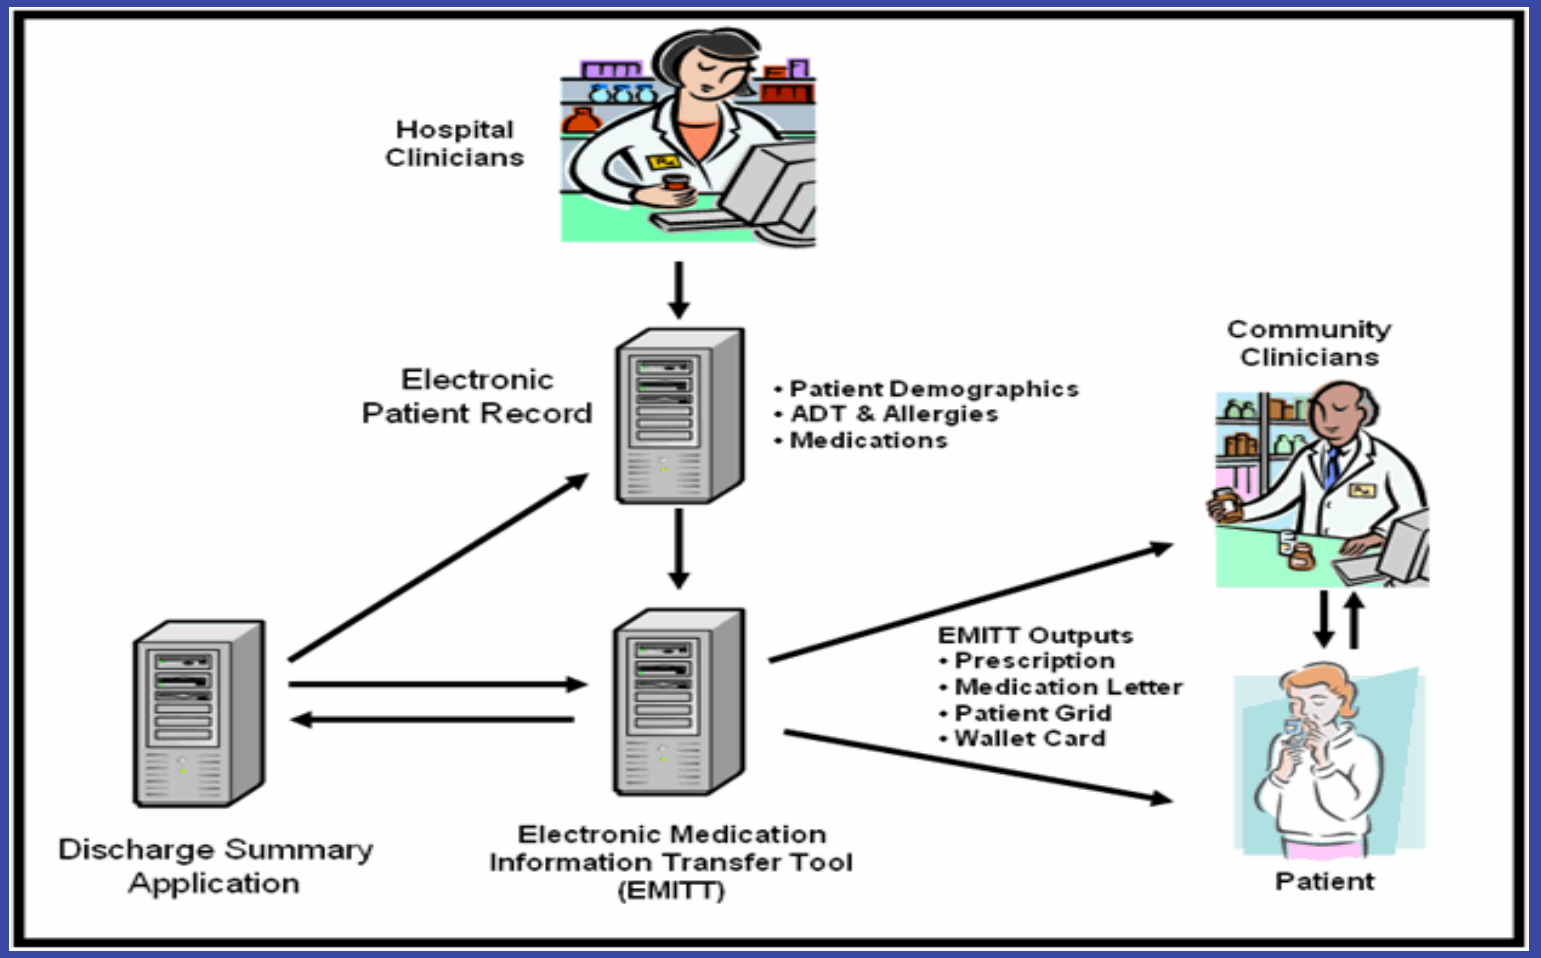
University Health Network

Results

- EMITT facilitates the collection and reconciliation of medication information from admission to discharge.
- It also allows for the coding and the documentation of medication discrepancies.



Results – System Design



University Health Network

Innovative Features

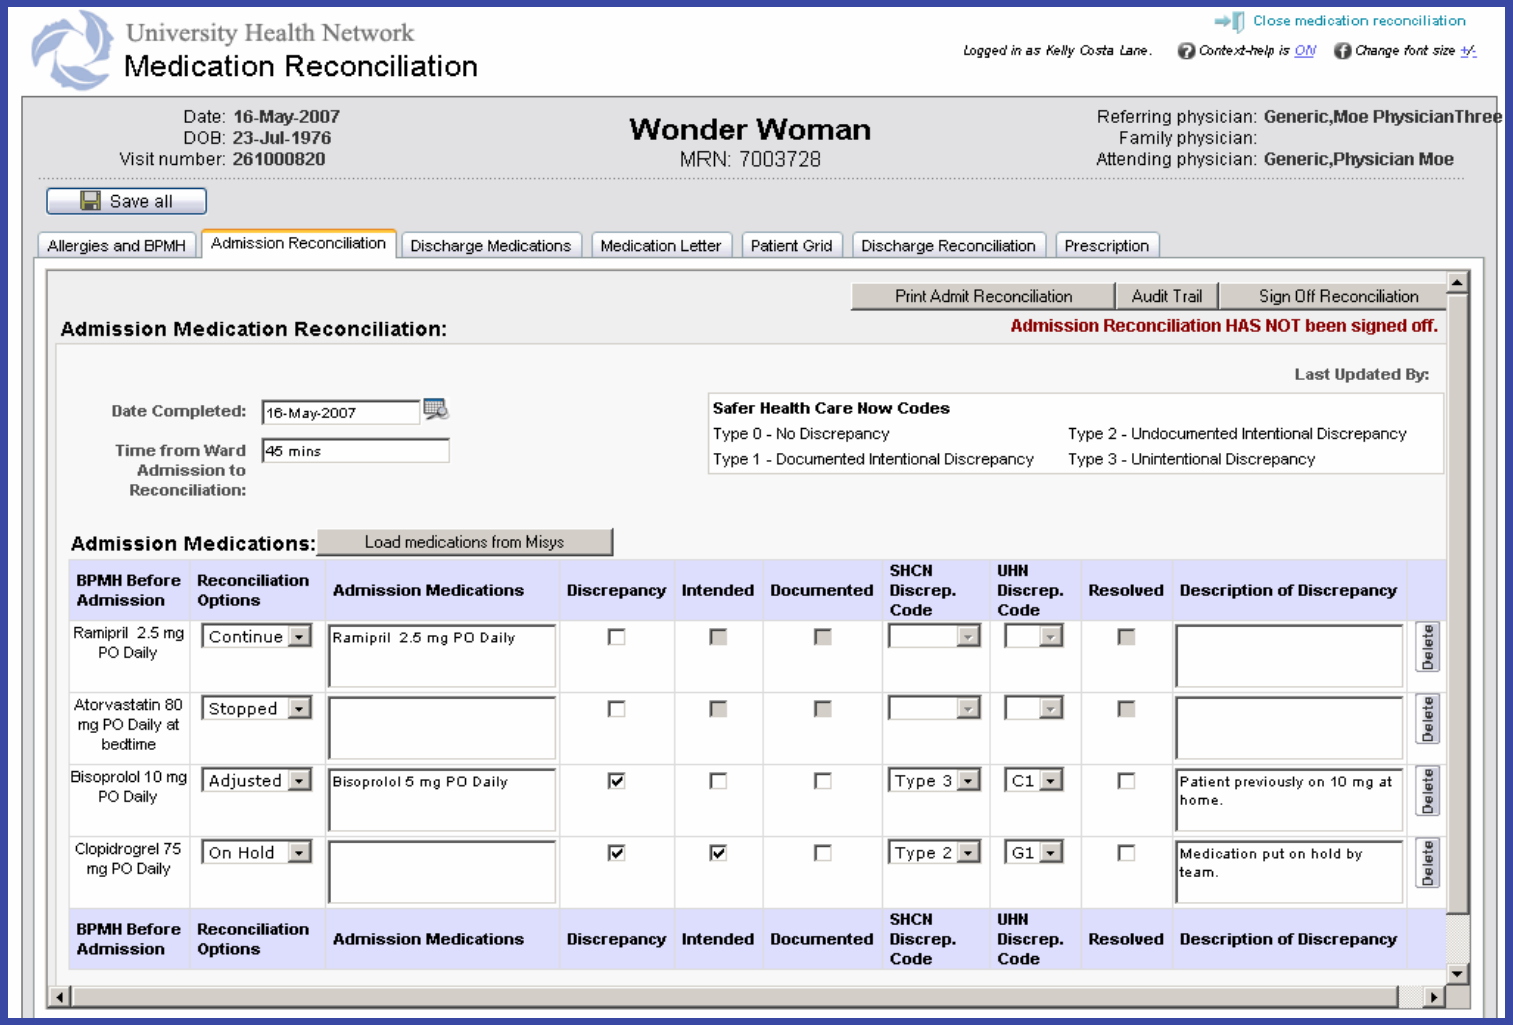
- Medications are automatically populated by the hospital's EPR to eliminate the duplication of documentation
- Medications auto-align themselves by name for easy comparison and reconciliation
- The application follows the Institute for Safer Medication Practices guidelines and eliminates unsafe abbreviations
- EMITT is integrated with the hospital's Online Discharge Summary application
- EMITT automatically uses the best discharge medication list to generate synchronized outputs:
    - Electronically generated prescription
    - Medication Letter
    - Patient Grid
    - Medication List and Wallet Card

University Health Network

Benefits of an Electronic Tool

- Communicates patient's complete medication regimen to community clinicians post discharge
- Ability to leverage real-time data captured in the EPR
- Guides clinicians through the medication reconciliation process
- Eliminates the need for duplicate documentation
- Capability to generate reports and identify potential safety issues
- Addresses areas of potential prescription discrepancies upon discharge
    - Quantity and repeat fields are mandatory for prescription medications
    - Electronically generated prescription is clear and legible
    - Flags clinicians to write Limited Use (LU) codes on prescription

Screen Capture – Admission Reconciliation



University Health Network

Screen Capture – Discharge Medications

PRESCRIPTIONS TO BE DISPENSED

Medication:	Dose:	Route:	Frequency:	Quantity:	Repeats:
Acetylsalicylic Acid	81 mg	PO	Daily	30 Days	0
Ramirpril	5 mg	PO	Daily	14 days	0

Comment: Take with food.

Physician: Dr. Physician Moe Generic
CPSO Number: _____
Physician Phone Number: _____
Physician Signature: _____
Please contact family physician for repeats.

Summary of Medication Allergies:

- No Medication Allergies

Summary of Medication Changes Since Admission:

New Medications:

- Acetylsalicylic Acid 81 mg PO Daily

Adjusted Medications: (reflects updated frequency and/or dose)

- Ramirpril 5 mg PO Daily

Stopped Medications:

- Clopidrogrel 75 mg PO Daily

Medications to be Continued:

- Atorvastatin 80 mg PO Daily
- Bisoprolol 10 mg PO Daily

Inpatient Pharmacist helped to prepare this prescription.

Conclusions and Lessons Learned

- A thorough understanding of current practices is essential for developing an effective application that addresses medication information transfer issues.
- The ability to leverage information currently stored in the EPR may improve the accuracy and quality of the data being used to reconcile medications.
- It is anticipated that this electronic framework can be easily adopted at other healthcare organizations.
- Multi-disciplinary engagement is necessary throughout the entire design and development of the application.
- The ability to leverage information for the electronic patient record is only beneficial if the information is real-time and changes as the patient's care is modified.

Abstract

This article describes the challenges and results of the application of videoconference technology to support family practice professionals in the Northeast of Brazil. The NUTES – telehealth network was established in 2003, connecting four cities in the state of Pernambuco. Continuing Health Professional Education (CHE) and Teleconsultations were available to five videoconference rooms connected in this network. The Videoconference CHE Program was highly demanded but the Teleconsultation Program not. From August 2003 to December 2005 eighty five videoconferencing educational sessions were held with two thousand and three hundred participants, and until November 2006 a hundred and twenty sessions. In conclusion, besides the barriers to acquire technology in a poor region of an under development country, cultural barriers have to be undertaken by health professionals and by health managers to achieve full potential of telehealth technologies.

Keywords:

telemedicine, videoconferencing, public health, family practice

Introduction

Pernambuco is a state located in the Northeast of Brazil, it has 98,311.616 Km^2, 185 cities and around 8,5 million people living in this state, most of them on poverty condition. [1]. Providing healthcare in to so many remote locations is a difficult task. Considering access to specialist's expertise and access to high complexity exams is out of question. Several problems arise from this logistics. Hospitals in Recife (Pernambuco's capital) cannot support all demand from the state. Trying to minimize this problem a national program implementing family practice started in 1994, the Health Family Program (PSF) [2]. This program is under implementation in several cities in the country, but the goal of solving 80% of theirs income health problems has not been achieved resulting in several inappropriate patient referrals. The UFPE University Hospital, Clinics Hospital (HC) based in Recife, admits around 1,000 inpatients and provide assistance to 13,000 outpatients per month [3]. A great number of patients come from cities of Recife's metropolitan area. Beside the lack of specialized and tertiary healthcare units in the country area, another great number of patients come from remote locations. Travel is a major limiting factor even inside the metropolitan area, financial expenses, time off from work and poor public transportation system conditions are major obstacles to patients access specialized care. Based on these facts, a telehealth service was introduced to provide support to family practice professionals and reduce referrals to HC-UFPE leading to faster and better care of high complexity level medical cases.

Methods

Using videoconferencing technology, PSF professionals from Recife and other three metropolitan area cities were connected to specialists at the HC-UFPE. In 2003, a telehealth network, Rede de Núcleos de Telesaúde (NUTES) of Pernambuco, was established as a pilot project coordinated by TIS-UFPE (Health Information Technology research team), and financed by Brazil's Ministry of Health. A main telehealth center NUTES-HC-UFPE coordinates the telehealth network and four additional partner sites were connected: a PSF in Cabo de Santo Agostinho, a PSF in Camaragibe, a PSF in Igarassu, and Lessa de Andrade Policlinic in Recife. These four cities were chosen based on referral information from the epidemiology department of HC-UFPE. Two videoconferences services have been offered, a Health Continuing Education (HCE) Program and teleconsultation on demand. In each partner one videoconference room was deployed with: a videoconference dedicated system (point-to-point), a TV, a document camera, a personal computer, a printer, a webcam, a scanner and a digital camera. At NUTES-HC-UFPE the videoconference system is multipoint bridging the partner sites. The sites are connected using ISDN lines

(Integrated Services Digital Network) at 384Kb/s rate. The videoconference HCE Program is provided once a week over an annual agenda based on cities epidemiological profile and theirs local health priorities. On the other side, the speakers, most of them from HC-UFPE, were identified based on the agenda themes.

Results

From August 2003 to December 2005 eighty five videoconferencing sessions were held with two thousand and three hundred participations, most of them, physicians and nurses. A set of artifacts was introduced to follow-up the program: presence notes, videoconference agenda spreadsheet, speakers register, assessment questionnaire and spreadsheet statistics. The first videoconference session was in August 2003 about child abuse. Since then until November 2006 a hundred and twenty (120) sessions occurred: 15 in 2003, 35 in 2004, 35 in 2005, and 35 in 2006. Several specialties have presented videoconference sessions, most of them on Medical and Nursing fields. The most frequent specialties were Pediatrics (30%), Nursing (20%) and Obstetrics (16%). A survey was conducted from January 2004 to December 2005. About one thousand questionnaires (50% of attendance) were collected analyzing technical and educational aspects (such as infrastructure, devices, support team, content and speakers) and more than eighty (80%) percent of the attendance classified the sessions as “good” or “excellent”.

Discussion and conclusion

This project was originally designed to focus on teleconsultations, but results demonstrated that continuing education was far more used by health professionals. Several reasons could justify this finding. At a continuing education activity, you can ask questions to the specialist only if you want to, while teleconsultation is a direct confrontation with a specialist. Besides that, if the teleconsultation schedule is not introduced as a regular routine in the service, it is easier to order a referral using just a piece of paper with patient name, health problem and specialist required. Informing regular teleconsultation schedules could facilitate this process [4]. Most speakers were specialists and there is a significant gap between family practice and hospital practice. There are different protocols and resources to assist the patients. In 2006, the Residency of Family Physicians was created at HC-UFPE and was engaged on the videoconference sessions. The audience satisfaction has increased once the videoconference session has achieved more practical approaches than those presented by specialists. Some success factors should be considered in a telehealth program for family practice in public health. First, health department’s managers should be strongly involved and understand the requirements and benefits of a telehealth program to their communities. Telehealth must be included in health policies of the city, allowing financial support for these initiatives as a way to achieve sustainability. While in other countries, telemedicine services are financed [5], in Brazilian public health system it is still not a reality. A strategy to get a better professional engagement on telehealth services is first to introduce in their routine a videoconference program for educational purposes. A teleconsultation service should be introduced only after they get used to videoconference technologies. Technical aspects should consider not only acquiring equipments, but also maintaining and training staff in telehealth. Communication lines should achieve a good cost benefit ratio concerning the proposed service. It is also important to make consulting staff understand the possibility of reducing inappropriate referrals using a telehealth program, once it is possible to help the primary care professionals solving common clinical problems within their communities. In addition, both consultants and primary care professionals can better qualify themselves to assist their patients. Telehealth is a strong weapon to provide solutions to solve local problems and benefits all players involved.

INTRODUCTION

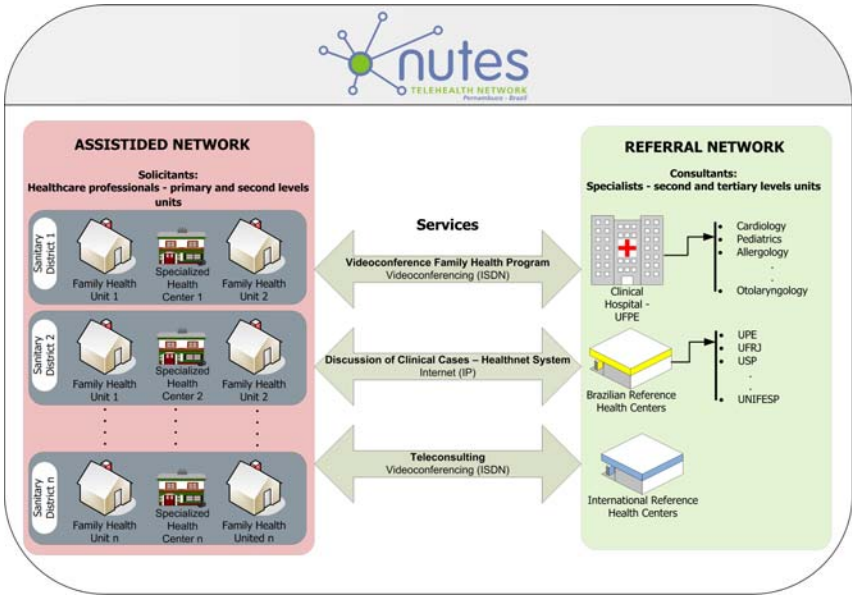
- **Pernambuco is a state of Brazil, located in the northeast region, it has 98,311.616 Km2, 185 cities and around 8.5 million people, most of them living on poverty condition.**
- **Several communities are challenged by geographic and social barriers. Family practice has only been introduced in the last decade in our state, furthermore most cities do not have specialized medical care.**
- **The only solution for health departments of these cities is to provide transportation to their patients so they can receive medical assistance at Recife, capital of Pernambuco.**
- **Several problems arise from this logistics, first, hospitals at Recife cannot support all demand from the state, besides they are supposed to assist only high complexity medical cases. Nowadays, patients suffering from common conditions have been treated at these hospitals resulting in over demand.**

INTRODUCTION

- **Therefore, a telehealth service was proposed to provide support to family practice professionals and reduce referrals to the University hospital leading to faster and better care of high complexity level medical cases.**
- **In 2003, a telehealth network, Rede de Núcleos de Telesaúde (NUTES) de Pernambuco, was established as a pilot project conducted by a research team named TIS (Health Information Technology group) and financially supported by governmental federal funds.**
- **Using videoconferencing technology, family practice professionals at Cabo de Santo Agostinho, Camaragibe, Igarassu and Recife (metropolitan area cities) were connected to specialists at the UFPE University Hospital, in Recife, Brazil. These four cities have been chosen based on referral information provided by the epidemiology department of the Clinics Hospital (HC) at UFPE.**

METHODS

- **A main telehealth center NUTES-HC coordinates the telehealth network and four additional partner sites were connected:**
  - NUTES - PSF Manoel Vigia (Cabo de Santo Agostinho)
  - NUTES - PSF Bairro dos Estados (Camaragibe)
  - NUTES - PSF Santo Antônio (Igarassu)
  - NUTES - Policlinic Lessa de Andrade (Recife)
- **A network among healthcare providers was established involving primary, secondary and tertiary level of care.**
- **Two videoconference based services have been offered to partner's cities, a health continuing education program and teleconsultation on demand.**



METHODS

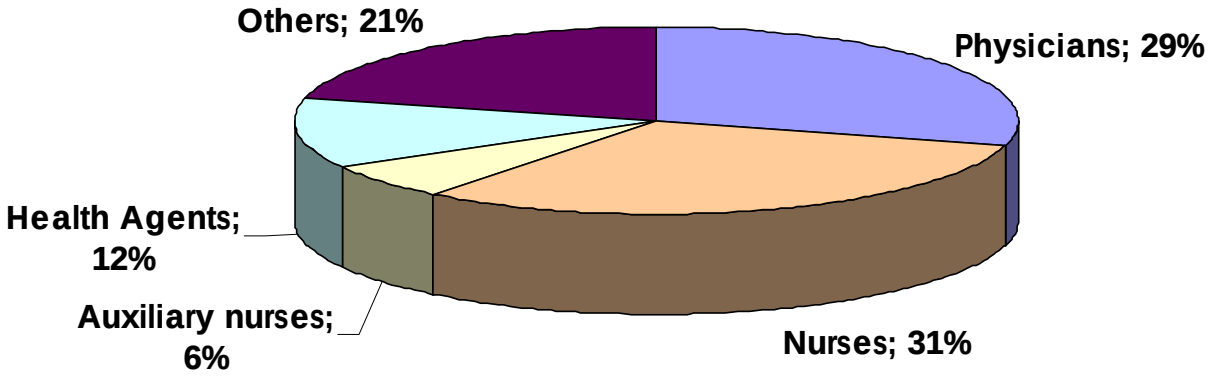
- Each partner's videoconference room is composed by a videoconference dedicated system (point-to-point), a TV, a document camera, a personal computer, a printer, a webcam, a scanner and a digital camera.
- At NUTES-HC the videoconference system is multipoint bridging the partner sites.
- The sites are connected using ISDN lines (Integrated Services Digital Network) in a 384Kb/s rate.
- Partner videoconference rooms have capability of 10-15 people, while NUTES-HC has capacity to accommodate 25 people.
- Technical assistance is available on every partner videoconference room. At NUTES-HC a team composed by information technology, healthcare students and professional, is available to set up the NUTES services.

- Videoconference health continuing education program is provided weekly. Content choice is based on local partners epidemiological data. Most speakers are faculty members. A survey was collected on every session analyzing technical and educational aspects.
- Besides continuing education, our videoconferencing equipment have been used to support clinical care, courses, administrative and clinical meetings, as well.

RESULTS

From August 2003 to December 2005 eighty five videoconferencing sessions were held with 2,300 participations.

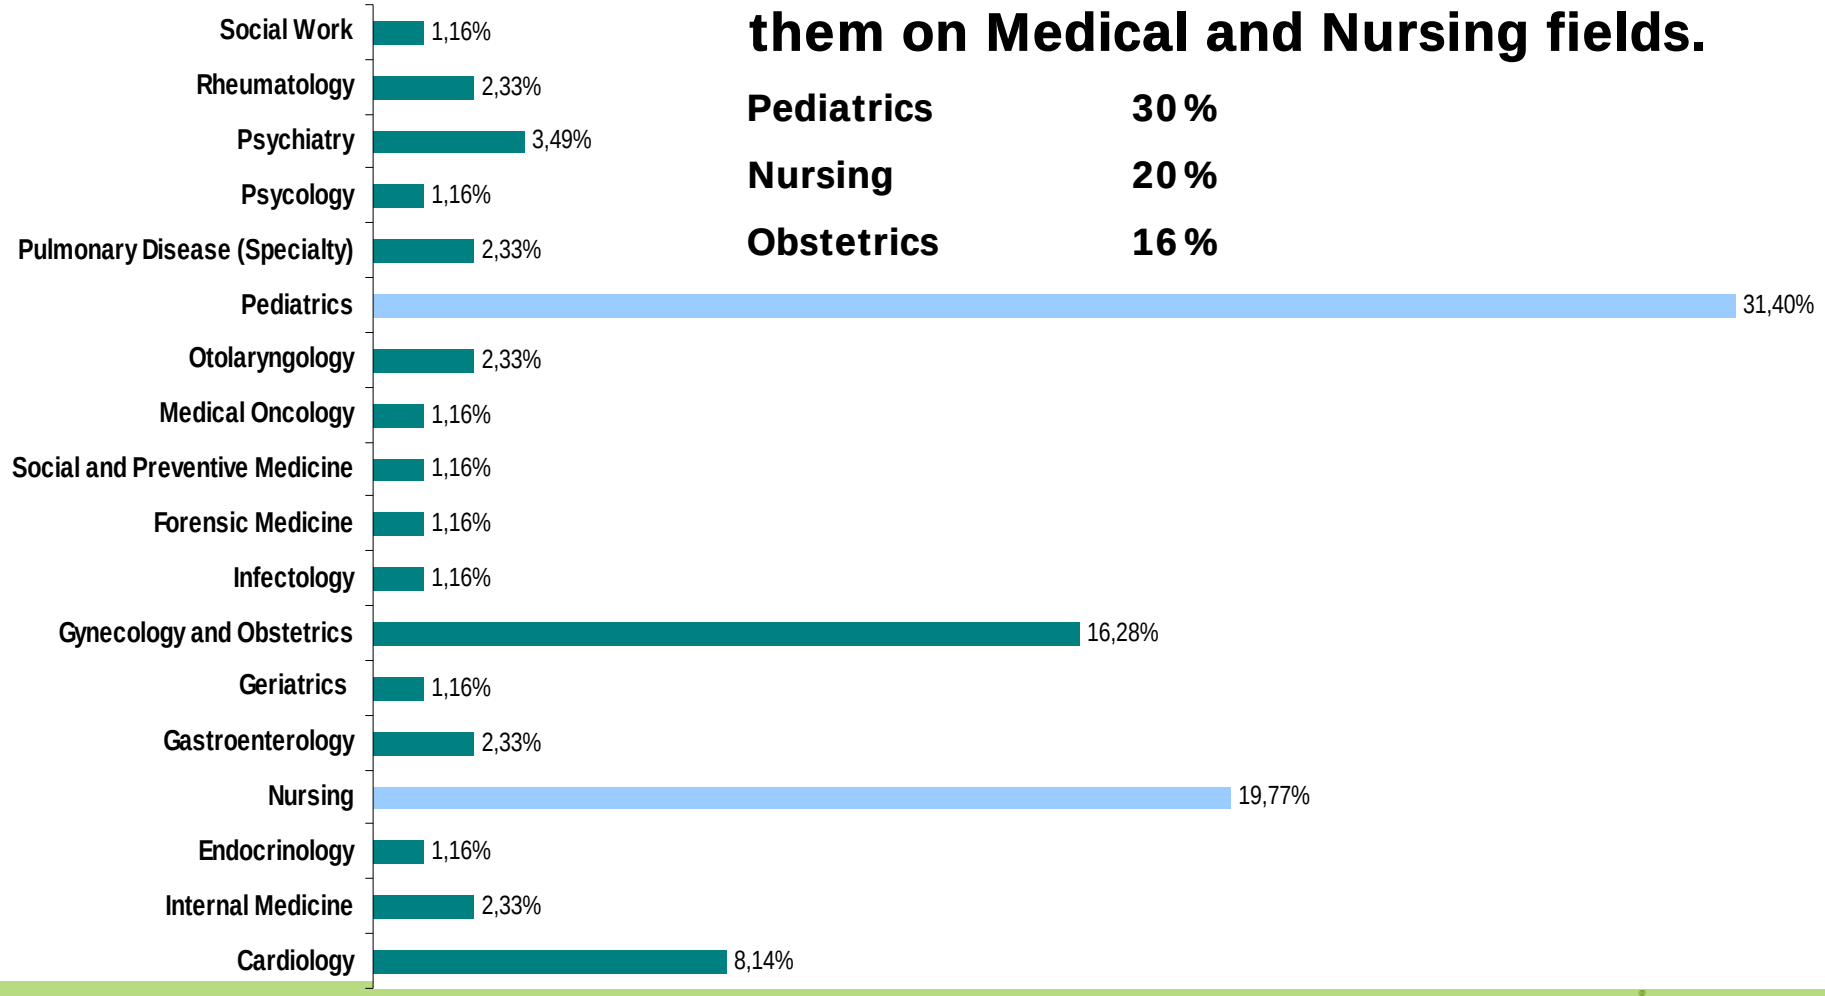
Physicians	**29%**
Nurses	**31%**
Auxiliary nurses	**06%**
Health agents	**12%**
Other health and administrative professionals	**21%**



RESULTS

Several specialties have presented videoconference sessions, most of them on Medical and Nursing fields.

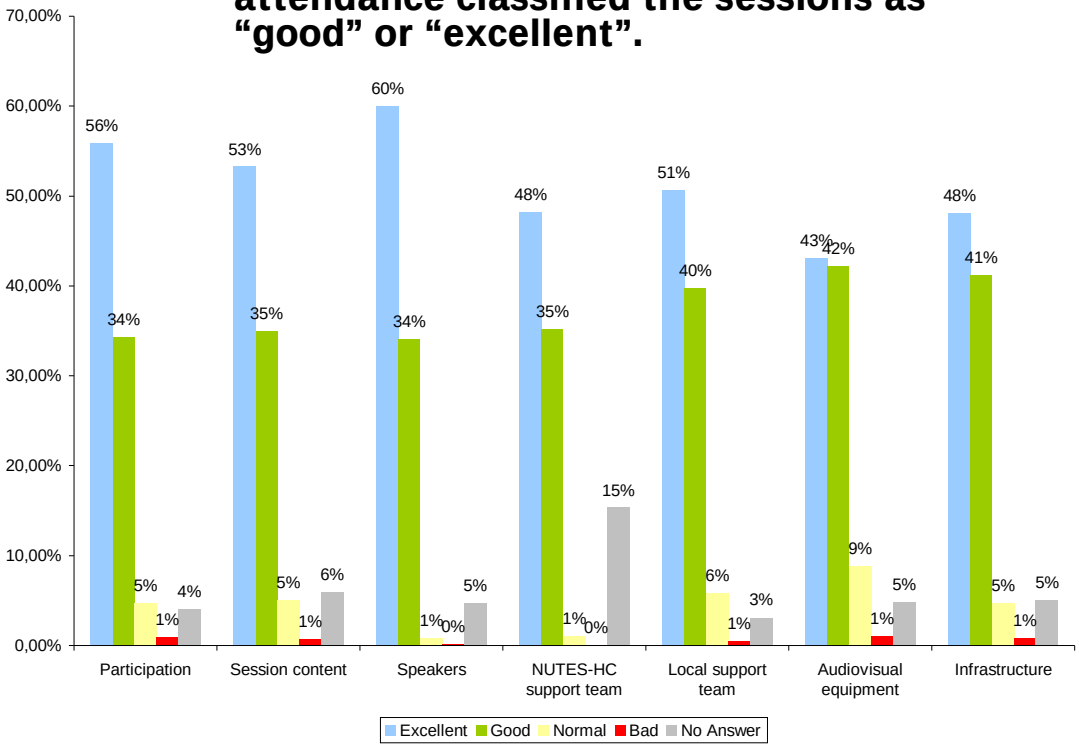
Pediatrics	**30 %**
Nursing	**20 %**
Obstetrics	**16 %**



RESULTS

- **Some examples of presented themes:**
  - Dengue, how to strike?,
  - Fever, how to treat?,
  - Bone tumors,
  - Filariasis,
  - Vaginitis/Vaginosis during Gestation,
  - Cholera,
  - Viral Hepatitis,
  - Hemogram Interpretation,
  - Parasitic Diseases,
  - How to manage Hypertension and Diabetes in FHP (HIPERDIA),
  - Asthma,
  - Schistosomiasis mansoni,
  - Tuberculosis,
  - Breast Feeding: healthy women and baby,
  - Obesity,
  - Leptospirosis,
  - Pregnancy in adolescence,
  - Malnutrition,
  - Diarrheas,
  - Violence,
  - Vaccination in first year of life, etc.

- **From January 2004 to December 2005 a survey was conducted**
- **More then 1000 questionnaires were collected analyzing technical and educational aspects (such as infrastructure, devices, support team, content and speakers)**
- **More than eighty (80%) percent of the attendance classified the sessions as "good" or "excellent".**



DISCUSSION

- **This project was originally designed to focus on teleconsultations, but results demonstrated that continuing education was far more used by health professionals.**
- **Some professional were not comfortable in exposing their lack of knowledge to the specialist.**
  - At a continuing education activity, you can ask questions to the specialist only if you want to, while teleconsultation is a direct confrontation with a specialist
  - Besides that, if the teleconsultation schedule is not introduced as a regular routine in the service, it is easier to order a referral using just a piece of paper with patient name, health problem and specialist required
  - Informing regular teleconsultation schedules could facilitate this process
- **Family practice professionals from remote locations tend to change jobs very rapidly; several teams had to be trained in telehealth every time new professionals were admitted to the unit.**
- **Most speakers were specialists and there is a significant gap between family practice and hospital practice. There are different protocols and resources to assist the patients.**

CONCLUSION

- **Some success factors should be considered in a telehealth program for family practice in public health.**
  - A strategy to get a better professional engagement on telehealth services is first to introduce in their routine a videoconference program for educational purposes. A teleconsultation service should be introduced only after they get used to videoconference technologies.
  - Health Department's managers should be strongly involved and understand the requirements and benefits of a telehealth program to their communities.
    - Telehealth must be included in health policies of the city, allowing financial support for these initiatives as a way to achieve sustainability.
  - Technical aspects should consider not only acquiring equipments, but also maintaining and training staff in telehealth. Communication lines should achieve a good cost benefit ratio concerning the proposed service.
  - Consulting staff have to understand the possibility of reducing inappropriate referrals using a telehealth program, once it is possible to help the primary care professionals solving common clinical problems within their communities.
    - With telehealth both consultants and primary care professionals can better qualify themselves to assist their patients.
  - Telehealth is a strong weapon to provide solutions to solve local problems and benefits all players involved.

Abstract

Interpersonal communications within specialized community palliative care consulting teams are fundamental to patient care. However, the process of communication has not been well supported technologically. We developed a network-based information system to improve communication within team. The Network Tool is a database system developed using FileMaker Pro® (File Maker, Inc., CA, USA), which utilizes the wired/wireless network and the mobile computing system. It enables interactive communications between the office headquarters and professionals over the intranet. This database comprises information relevant to the patients including details on their family, home, medication, and actual clinical status assessed by each professional. It is designed to improve clinical information, facilitate an interdisciplinary team approach, and allow collecting structured clinical data in general practice on a daily basis. The system has been successfully implemented and used, especially to improve communication within the interdisciplinary team. This system supports practices that are consistent with improvements in the quality of care. An infrastructure that shares the database of patient's records was developed for home-based palliative care.

Keywords:

delivery of health care, palliative care,
Computerized Health Record

Introduction

In recent years, information and communication technology (ICT) support system has been recognized as a tool for improving care delivery, symptom assessment and communication between medical staff and patients/families in palliative care settings [1-3]. However, the efficient sharing of information and the process of communication within interdisciplinary teams has not been well supported technologically in the delivery of home-based palliative care. To ensure that home-based palliative care is provided reliably and sustainably, we developed a network-based information system for specialized palliative care consulting teams in the community. The objectives of this project are: (1) to improve the efficiency of visiting clinicians and nurses who are overburdened with paperwork and frustrated with bottlenecks in the information exchange process, and (2) to improve the sharing of information within interdisciplinary teams by using a network-based information system (computerized medical records).

Materials and methods

We have deployed the information system on the Okabe Clinic Regional Palliative Care Program since July 2003.

The Information System

The network tool is a database system using FileMaker Pro® (FileMaker, Inc. CA, USA), which utilizes the wired/wireless network and the mobile computing system.

This system provides the connectivity required to enable complete workforce mobility. Team staff can carry their mobile computers when working in the field. More importantly, with integrated modem, wireless LAN capabilities, and fast 10/100 Ethernet, the mobile computer allows users to stay connected at all times. This enables interactive communication between the office headquarters and each professional over the intranet.

This database comprises information relevant to the patients including details about their medical history, family, medication, administrative function and actual clinical status as assessed by each professional. It also includes narrative visit notes by each interdisciplinary expertise, physician orders, prescriptions, care plans and laboratory data. It was designed to improve clinical information, facilitate an interdisciplinary team approach, and enable the collection of structured clinical data in general practice on a daily basis.

During each visit, a professional briefly assesses the symptoms, side-effects, and other key problems of the patient

and enters this information into the system. Most importantly, visiting nurses measure vital signs including pain score [4] based on numeric rating scale (from 0 to 10). They also assess patients' symptoms including general fatigue, anorexia, nausea, dyspnea at rest, edema, dry mouth, drowsiness, insomnia, anxiety, bed sore, dysphagia, depression and delirium based on symptom intensity score (from 0 [absent] to 3 [severe]).

Subsequently, when other professionals access the patient's electronic medical record from any remote location, a window containing the patient's complete assessment information is displayed.

Physicians and managers receive updates regarding the quality of treatment being received by the patient. Each patient's identifiable data is securely and confidentially maintained on the server located at the office headquarters.

Results

The system has been successfully implemented and used, especially to improve communication within the interdisciplinary team. Using this system, field staff can electronically submit their clinical visit notes – a process that was previously done on paper, mostly in a narrative form. Since the users are required to fill out the information in a structured electronic format, we can accurately and efficiently collect a considerable amount of valuable data for future analysis and develop superior structured care plans before each patient visit. Further, the system also complements an interdisciplinary team meeting and offers 24 hours/ 7 days assistance.

After deploying this system, we have been able to improve patient care by reducing the administrative work load of our mobile workers. Clinicians and nurses can now focus on delivering high quality care, thereby significantly improving their own quality of life. In addition, field nurses may be able to make three or four additional visit each week. This system also assists in the operation of home-based palliative care during night and over the weekend; this has led to an increase in the number of patients under each team. To date, this system has been used for more than 50 advanced cancer patients and approximately 200 chronically ill patients.

Discussion

By equipping field staff with this system, we have enabled them to increase the time spent in providing care at patients' homes and less time in completing their paperwork. Now, as field staff makes their daily visit to patients' homes, the mobile computers ensure that they have all the required information with them. Hence, patient records, including medical and care history, medications, and insurance information are just a few clicks away.

The interdisciplinary team approach has been widely accepted as appropriate in the palliative care setting. The team approach, which involves shared decision making, the efficient sharing information, and the mutual understanding of the role of each member, is different from the sequential multidisciplinary care that frequently characterizes "usual" hospital care. In order to promote interdisciplinary team care, the information system we developed led to an expansion of each professional role and function, advancement of knowledge and techniques, and improvement of sharing information within team.

In this project, we did not consider the quality of symptom control and the cost of care in relation to this system. Further studies should assess symptom control as well as patient's and family's satisfaction. Cost of care also needs to be addressed in future researches.

Conclusion

An infrastructure that facilitates sharing of the database of patient's record was developed for home-based palliative care provided by the interdisciplinary team.

As a result, we now have access to all patient-related data collected by the interdisciplinary team and can leverage this data to develop new treatment plans and processes that will further enable the consistent delivery of high-quality patient care across the community.

Acknowledgments

This project was supported in part by grants from the Sasakawa Health Science Foundation, Tokyo, Japan.

RESULTS

The system has been successfully implemented and used, especially to improve communication within the interdisciplinary team. With this system, our field staff can electronically submit clinical visit notes – a process that had previously been done on paper, mostly in narrative form.

By requiring users to fill out the information in a structured electronic format, we can accurately and efficiently collect a wealth of valuable data for future analysis and develop superior structured care plans before each patient visit. It also complemented an interdisciplinary team meeting and offered 24 hours/7 days assistance.

After deploying this system, we have been able to improve patient care by reducing the administrative workload of our mobile workers. Clinicians and nurses can now focus on delivering high quality care, significantly improving their own quality of life.

In addition, field nurses may be able to make three or four additional visits each week. This system also assists the operation of home-based palliative care in the night time and over the weekend; these has led to an increase in the number of patients per team.

To date, this system has been used for more than 50 advanced cancer patients and approximately 200 chronic ill patients.

DISCUSSION

By equipping our field staffs with this system, we have enabled them to spend more time providing care in patients' homes and less time filling out paperwork.

Now, as our staffs make their daily rounds to patients' homes, they have all the information they need right at their mobile computers. Patient records, including medical and care history, medications, and insurance information, are just a few clicks away.

In this project, we did not take quality of symptom control, cost of care and this system into consideration. Further studies should assess symptom control as well as patient and family satisfaction. Further research should also address cost of care.

CONCLUSIONS

An infrastructure that shares the database of patient's records is developed for home-based palliative care performed by the interdisciplinary team.

As a result, we now have access to all patient-related data collected by the interdisciplinary team and can leverage that data to develop new treatment plans and processes that will further enable the consistent delivery of high-quality patient care across the community.

A Primary Care Physicians Web-Space

Shirley L. Fenton[a], H. Dominic Covvey[a], Douglas W. Mulholland[b], Donald D. Cowan[b]

[a] *Waterloo Institute for Health Informatics Research, University of Waterloo, Canada*
[b] *Computer Systems Group, University of Waterloo, Canada*

Abstract

The Primary Care Physician Webspace (PCPW) is intended to provide a physician community with an array of support services. It provides an environment that augments and complements typical clinical management systems (CMS), links to them, and links physicians to each other, to the University of Waterloo, to regional healthcare facilities, and to local and remote information resources. CMS tend to lack Community of Practice (CoP) support, and portals tend to ignore the existence of a CMS. The PCPW addresses CoP in depth using advanced technologies built into a rapid development environment that provides software agent support for interaction with other systems, thereby addressing both challenges.

Keywords:

web-based system, communities of practice (CoP), consumer e-health, workflow, clinical information system

Introduction

Small and medium sized organizations underutilize modern information and communication technologies for communicating with their communities[1]. Relational databases, mapping, notifications, agents and advanced web-based technologies such as dynamic prototyping, are all examples of capabilities that could benefit organizations like a primary care physician's practice. The cost and complexity of deploying and maintaining such systems are major barriers to their more widespread use. The community that would benefit includes rostered patients, the general public, partner practitioners, associated staff, allied professionals, other service deliverers in the community such as pharmacies and hospitals, and, where applicable, medical residents and students.

The Centre for Family Medicine (CFFM), in Kitchener, Ontario, Canada - http://www.family-medicine.ca is a family health team[2] comprised of primary care physicians, their staff and allied professionals that, until recently, made no significant use of web-based technologies for communicating with their community. The team had chosen and deployed a CMS, but no public web site and no technology to support a broader, online community communications strategy had been acquired or designed.

In partnership with the University of Waterloo's Waterloo Institute for Health Informatics Research, the Computer Systems Group, a research group within the David R. Cheriton School of Computer Science at the University of Waterloo and the J.W. Graham Information Technology Trust, a Primary Care Physician's Webspace was created with the CFFM to help to address the Centre's online community communications needs.

Methodology

The following major steps were taken:

1. Establish an advisory panel of primary care physicians.
2. Identify the goals and objectives of primary care physicians related to Community of Practice (CoP) support as well as integration with other systems.
3. Analyze these goals and objectives and collaboratively define the needs of the physicians and the required capabilities of the system.
4. Design the system and review this with the advisory panel and a key primary care practice.
5. Using a locally-developed advanced rapid prototyping toolkit called the Web-based Informatics Development Environment (WIDE), create a demonstrable version of the system.
6. Evolve the system using the advisory panel and practice feedback through several iterations.
7. Demonstrate the system.

A key part of step two was to identify the various user communities and their corresponding information needs from the system. It is also important to note that some of the steps and sequences of steps were repeated several times. As the capabilities of the system became better understood by the advisory panel, their objectives shifted and so the requirements for the system changed.

Discussion

Communities served

Four communities are served by the system:

1. Rostered Patients and the General Public including Newcomers and Immigrants
2. CFFM Staff and Professionals

3. Prospective Medical Residents and Students
4. Other Physicians and the Medical Community

Rostered patients and the general public including newcomers and Immigrants

The cities of Kitchener, Waterloo and Cambridge and the surrounding townships that comprise Waterloo Region in Southwestern Ontario, Canada, are designated as underserviced by primary care professionals, according to the Government of Ontario[3]. Almost all doctor's offices in the region maintain a roster of patients who can make appointments to visit the office. For a family health team in Waterloo Region, such as the Centre for Family Medicine, rostered patients are their highest priority community. When the needs of that community have been met, any extra capacity within the team can be used to serve the general public. For example, the CFFM offers an extensive series of educational seminars on topics such as nutrition and diet, exercise, diabetes management and general health promotion. These seminars are first made available to rostered patients but anyone can ask to be registered if space permits.

In the PCPW the highest priority community to communicate with is the community of rostered patients. Basic information about the CFFM itself, including educational events and special clinics such as those for flu shots is of high importance to this community. As well, the PCPW provides directories of local pharmacies, medical labs and physiotherapists that are of use to this community and the general public. These directories include detailed contact information and maps that can produce driving directions. This information is especially valuable to residents of small and rural communities. Similarly, information for newcomers and immigrants is particularly valuable as Waterloo Region has the fifth highest per capita immigrant population of all urban areas in Canada, behind only Toronto, Vancouver, Hamilton and Windsor[4].

CFFM staff and professionals

Although the CFFM has an extensive e-mail system and makes very good use of it, it is a challenge to keep ten physicians and between twelve and fifteen other associated staff and professionals informed of special events, meetings and presentations. As an added complication, the CFFM physicians work from four offices in the cities of Kitchener and Waterloo and the village of Wellesley, Ontario which is approximately 27 kilometers (17 miles) from the downtown Kitchener site. The PCPW can significantly reduce the challenge of keeping the group informed of upcoming events. As well, the CFFM staff can see immediately what patients and the broader community are being told about upcoming CFFM events.

For after-hours calls from local pharmacies, physicians usually fax their on-call hours and contact information to a list of organizations. The PCPW includes a capability to provide that information to these organizations in a more secure and reliable manner.

Prospective medical residents and students

Waterloo Region has a great deal to offer prospective medical residents and students in the context of the CFFM. Residents who seek a placement in what is primarily an urban setting but also want to experience a rural community can find the CFFM to be ideal. The PCPW contains extensive links to community information about topics as diverse as regional hiking and biking trails, bus routes, arts and cultural information and social services. After attending a public lecture at the Perimeter Institute for Theoretical Physics or spending an evening with the Kitchener-Waterloo Symphony, a CFFM resident could attend a clinic in the village of Wellesley that serves a large old-order Mennonite community whose residents frequently arrive at the doctor's office in a horse and buggy.

Other physicians and the medical community

Some of the physicians at the CFFM actively teach, research and write about innovative topics in the field of Family Medicine. The PCPW currently includes several presentations and papers on the topic of the environmentally friendly doctor's office. As well, documents have been prepared to present a range of options for presenting, accessing and participating in meetings and presentations over the internet. For example, one to one meetings where no patient information is discussed can often be presented using simple internet mechanisms such as Skype[5] or Windows Live™ Messenger[6]. Presentations with a wider audience might be broadcast with a system like ePresence[7] and an event that includes secure videoconferencing requirements might be best suited to a system that is based on the OTN/North Network[8] environment.

Requirements elicitation

As previously mentioned in the Methodology section, this project involved an extensive, iterative requirements elicitation process. The cost of such a process in a traditional, commercial consulting context would have rendered the process completely infeasible. Nevertheless, it did require several weeks of meetings and discussions to educate the advisory panel about the capabilities of and issues related to current information technology and to reconcile different goals and objectives amongst the members of the panel.

A key technology that was used in the creation of the PCPW is called "Model-Driven System Generation" (MDSG). This innovative technology, which is a feature of the WIDE toolkit[9], provides an environment where the application model and operational system are always synchronized – there is no architectural gap between the model and the implementation. In traditional software

development, the phenomenon of "model drift", where the model and implementation are initially synchronized but soon separate, is very common. Without MDSG it would not have been possible to create the PCPW without a much larger budget. It was essential to this project to be able to develop a rapid prototype of a proposed feature, explore how the feature operated with the advisory panel and then either discard it as undesirable or change the model to improve it.

Content

Content in the PCPW can be classified as either original or secondary material. Original material is created mostly by CFFM professionals and staff and secondary material is sourced externally. Of the secondary material, some is presented within the CFFM with appropriate credit and some is presented as links to external web sites.

Original material includes the following:

- information about the CFFM, including vision and plans, physical sites and pictures, hours and contact information
- frequently asked questions
- medical nutrition information for patients
- information about the basics of health care in the region
- research papers and presentations
- Secondary material presented within the site includes directories of:
- pharmacies
- medical labs, and
- physiotherapists
- Secondary material presented as links to external sites includes:
- community and social services
- arts and cultural resources
- community events
- transportation around the region
- Medical-resident matching services

For all of this content, sustainability was a key concern. Specifically, it was essential that the information always be as up-to-date, comprehensive, relevant and authoritative as possible. As well, maintenance of the information should be as easy and inexpensive as possible, ideally at no cost. The following sources of information that met the sustainability criteria were levered where possible:

- Waterloo Regional Arts Council (arts and cultural information)
- Community Information Centre of Waterloo Region

When no single source of information was available that met the criteria, the WIDE toolkit provided options for amalgamating several sources of information into a single result. For example, the directory of pharmacies was created and is maintained by amalgamating and monitoring ten different data sources:

- four brand-name drug store web sites
- two employer association web sites
- four community business directories

As is inevitable with such diverse data sources, inconsistencies have been discovered and are reported back to the maintainers of the original data.

As well, regular and comprehensive checking of the site is performed automatically. Broken links to external web sites, missing images and spell checking are all performed by autonomous agents without any administrative intervention and only the results are reported to the system administrator.

Future work

The CFFM would like to explore closer connections with the hospital information systems of the two general hospitals in Kitchener-Waterloo in order to provide the primary care physicians with better access to the medical records of their patients. This integration step is currently being investigated.

As the new Downtown Kitchener Health Sciences Campus of the University of Waterloo is built, the PCPW should be extended to communicate with and enhance the online systems of the new School of Pharmacy, the School of Optometry and the new Kitchener satellite of McMaster University's Michael G. DeGroote School of Medicine.

Conclusions

The Primary Care Physician's Webspace has demonstrated a capable primary care physician support solution that allows the augmentation of commercial Clinical Management Systems with advanced web-based capabilities. It shows what can be gained by using tools, such as the WIDE toolkit, that significantly reduce barriers to partner development and understanding, and allow frequent and rapid revisions. This is particularly important when new types of requirements, such as support for CoP and little user knowledge of potential solutions exist. The PCPW allows significant systems support in the primary care setting using internet-based, browser accessible technologies.

Integration of Evidence-Based Nursing Content: A Collaborative Study

Patricia S. Button, EdD, RN[a], Rosemary Kennedy, MBA, RN[b], Ida Androwich, PhD, RN, FAAN[c], Rebecca R. DaDamio, MBA, RN[b]

[a] *Zynx Health Incorporated, Los Angeles, California, U.S.A.*

[c] *Loyola University, Chicago, Illinois, U.S.A.*

Abstract

In 2005, Pinnacle Health System, Zynx Health, and Siemens Medical Solutions developed a partnership to conduct a study, exploring opportunities and challenges associated with integration of evidence-based knowledge within the Electronic Health Record (EHR) with the goal of creating repeatable methodologies for nursing knowledge integration. The two-phase study involved access to referential evidence-based content and integration of customized evidence-based plans of care within EHR documentation applications.

Key results, to date, of this ongoing study include identification of data model variations between evidence-based knowledge sources and hospital information systems that expose pre/post coordination challenges; greater insight into how structured data elements should appear to end users in terms of form, order, and context; staff nurse response to availability of evidence-based content in care planning and documentation workflow; and impact of customized evidence-based plans of care on organizational processes of incorporating evidence-based practices into clinical practice. Findings included general satisfaction of the content, validation of the importance of strong nursing leadership related to implementing evidence-based practices in the organization, the need for client vendor partnering, and data documenting positive impact of integrated evidence-based content on quality of care.

Keywords:

patient care planning, outcome assessment, evidence-based medicine

Introduction

Study objectives and questions

The overall goal of this evaluation study was to test the impact of an electronic health record populated with nursing knowledge and evidence for use by nurses in assessing, planning, evaluating, and communicating patient care. During the study, both referential and integrated knowledge and evidence populated clinical applications. Referential knowledge and evidence is defined as synopses of evidence and evidence sources classified according to type of study.

The referential knowledge and evidence was available through links from specific points in the clinical workflow within Siemens applications. Integrated knowledge and evidence is defined as evidence-based assessment tools, order sets, and nursing orders/plans of care that were integrated for use in the Siemens clinical applications.

The specific objectives of the study were to:

1. Gain an understanding of the technical factors related to providing access to Zynx Health knowledge and evidence from within Siemens applications;
2. Gather data regarding various nurse users' reactions to the availability of Zynx Health knowledge and evidence in these applications;
3. Identify the specific locations within the clinical system interface from which Zynx Health knowledge and evidence knowledge provides value for nurses; and
4. Identify requirements related to the integration of nursing knowledge within the electronic health record, specifically focused on knowledge structure, content, and components most valuable to nursing practice.

Methods

The study included two phases.

Phase I: Referential performance measures and quality indicators

The first phase of the study focused on providing links from Siemens clinical systems to Zynx Health referential knowledge and evidence. Links to evidence about four nursing sensitive performance measures, patient falls, acute pain, pressure ulcers, and smoking cessation, were provided to bedside clinicians. Users had the ability to link, via a display icon, from Siemens care planning and documentation screens to the Zynx Health evidence regarding the four patient problems and return to the care planning or documentation application.

Phase II: Customized evidence-based plan of care content integrated in care planning and documentation applications

The focus of Phase II was the customization of Zynx Health evidence-based plans of care for the Pinnacle organization and integration of the content of the plans in Siemens care planning and documentation applications. The project team chose six Zynx Care plans of care that addressed key patient problems at Pinnacle: pain management, prevention of surgical site infection, prevention of ventilator-acquired pneumonia, tissue perfusion, and fall prevention. Three teams of Pinnacle nurses including clinical nurse specialists, clinical educators, staff nurses, and an Information Systems nurse liaison were formed and each team customized two plans of care. The evidence-based plans provided by Zynx include comprehensive expected outcomes and interventions assembled using a strict evidence-based methodology. The plans also include evidence links to synopses of the evidence and classified references. The plans are available in a content management tool that supports creation of plan versions specific to a particular organization.

Results

The study showed that referential access to clinical knowledge provides the most value when there are numerous devices; access from any location within the clinical area; Google-type searches for clinical topics; contextual sharing of patient specific information; and access to "nurse dashboards" that provide access to evidence about common patient problems. Integrating the plans of care within the hospital information system revealed variations in data models between evidence-based knowledge sources and hospital information systems that exposed pre/post coordination challenges, requiring modifications in the codes used within the dictionaries in the hospital information system.

Phase I results

Results of Phase I included staff reports of the value of available evidence-based content in providing them with information they had forgotten or was new; variation in the frequency of using the links to access evidence; and, preference for evidence available during care provision, rather than during documentation. Phase I results also included observation of the critical importance of initial and ongoing involvement of the Chief Nursing Office as champion of the study as well as the Nurse Educators. Initial education regarding evidence-based practice and the study was provided by the Nurse Educators.

Phase II results

The teams of Clinical Nurse Specialist, Nurse Educators, bedside nurses, and informatics nurses who developed organizational evidence-based plans of care using the vendor model plans of care, content maintenance tools, and customization tool reported several key observations.

- First, they observed that the time to complete an organizational plan decreased to less than 12 hours compared to the previous approach that took several months.
- Secondly, they reported that the quality of the plans was significantly better because the plans were based on evidence developed with a strict methodology.
- Lastly, they reported the customization process itself was very positive because it engaged the members in interesting, clinically relevant discussions and fostered collaboration between Nursing and the Information Systems Departments.

Data on the impact of integrated evidence-based assessments and plan of care content included bedside nurse reported perceptions and quantitative data related to fall rates and frequency of pain reassessment. Bedside nurses reported that the integrated assessment and plan of care content expanded their knowledge; provided accessible information so that they did not have to go to books for needed information; and that the embedded content was accessible, detailed and specific, and provided the basis for more meaningful assessments.

Overall perception of the value of the evidence-based content implemented into plans of care for Pain – Acute, Mobility – Impaired, Infection – Risk of, Surgical Site Infection, and Falls – Risk of was favorable. Plans of care for Infection – Risk of, Ventilator-Associated Pneumonia and Tissue Perfusion – Cardiopulmonary, Altered were perceived to be less helpful to the end users' planning of patient care. Figure 1 depicts the statistical mean, based on a 6-point Likert Scale, regarding the end users' perceptions of the value of each specific plan of care content.

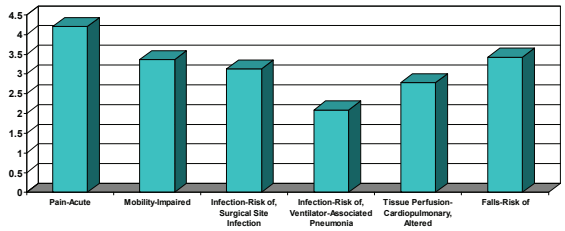

Figure 1- Value of specific content

In addition, it was observed that, following the implementation of integrated evidence-based pain assessments, fall risk assessments, and pain and fall risk plans of care, the documentation of pain reassessment improved from 76% to 94% compliance. Subsequently, there was a reduction in

the number of falls with sustained injuries noted in the organization.

Discussion and conclusion

This study demonstrated that positive value could be achieved through the integration of evidence-based knowledge within automated assessment and plan of care documentation, for use at the point of decision-making. The study fostered collaboration between clinical staff nurses and the information systems department and through this collaboration staff nurses were able to define with greater precision how structured data elements should appear to end-users in terms of form, order and context.

The study serves as a case example of a repeatable implementation model, starting with access to referential content while moving concurrently towards tighter levels of content integration within assessment and plan of care documentation functions. Success was contingent on five fundamental requirements: a strong partnership of the three organizations; strong nursing leadership, evidence-based content; tools to customize the content in accordance with institutional practices; a flexible hospital information system; and an inter-disciplinary team of experts from Pinnacle Health, Zynx Health and Siemens Medical Solutions. The implementation model can be replicated in other facilities.

Integration of Evidence-Based Nursing Content: A Collaborative Study

A Collaborative Study

Mutual interest in better understanding methods of making evidence based content available to clinicians at the point of care.

- **Pinnacle Health**
  - **Community based healthcare system**
- **Zynx Health Inc.**
  - **Evidence-based clinical content provider**
- **Siemens Medical Solutions**
  - **Broad portfolio in healthcare IT and modality systems**

Study Objectives: 2 Phase Study

- Gain an understanding of the **technical factors** related to providing access to Zynx Health knowledge and evidence from within Siemens applications;
- Gather data regarding various **nurse users' reactions** to the availability of Zynx Health knowledge and evidence in these applications;
- Identify the **specific locations** within the clinical system interface from which Zynx Health knowledge and evidence knowledge provides value for nurses; and
- Identify **requirements related to the integration of nursing knowledge** within the electronic health.

Phase I Methods

Phase I: Referential Access

Provided Links from Siemens clinical systems to Zynx Health referential knowledge and evidence regarding four key quality indicators.

- Patient Falls
- Acute Pain
- Pressure Ulcers
- Smoking Cessation

Phase II Methods

Phase 2: Evidence Based Content Integrated in Plan of Care and Documentation

Customization of Zynx Health evidence based plans of care for the Pinnacle organization and integration of the content of the plans in Siemens care planning and documentation applications, for:

- Pain Management
- Prevention of surgical site infection
- Prevention of ventilator-acquired pneumonia
- Tissue perfusion
- Fall prevention
- Impaired Mobility

Phase I Findings

Executive Champion | Facilitating Practice Standards | Future Work

- CNO as champion support was required throughout the project – not just at the ‘kick-off’.
- Nurse Educators provided additional ‘face-to-face’ education individually with staff nurses – after the initial educational session.

Phase I Findings

Executive Champion | **Facilitating Practice Standards** | Future Work

Staff Nurse Perceptions

- Provided information they didn't know or had forgotten
- Provided evidence for the "new" information reflected in the literature
- Provided valuable information that is not sought out due to lack of time during care delivery
- Information was useful during rounds and shift report
- Information was accessed most during care provision

Phase II Findings

Executive Champion | **Facilitating Practice Standards** | Future Work

Staff Nurse Perceptions

- Embedded content expanded knowledge
- Information more accessible – do not have to go to books
- Embedded content
  - Understandable
  - More detailed, expanded
  - Provides more options

Phase II Findings

Executive Champion | **Facilitating Practice Standards** | Future Work

- Improved documentation of pain reassessment by 76% to 94% compliance
- Reduced number of falls with serious injuries

Pilot Overall Findings

Success was contingent on several fundamental requirements.

- Strong partnership of three organizations
- Strong nursing leadership
- Evidence based content
- Tools to customize the content in accordance with institutional practices
- Flexible hospital information system
- An inter-disciplinary team of staff nurses, advance practice nurses, and nursing informatics specialists

Pilot Overall Findings

- This study demonstrated that positive value could be achieved by providing access to evidence based knowledge at the point of decision making.
- Study serves as a case example of a repeatable implementation model for integrated evidence based content within the electronic health record.
- Nurses in this study shifted from task based documentation to knowledge-based decision-making.

Alberta WebSMR – The Implementation of a Synoptic Report for Cancer Surgery

Walley J. Temple[a], David Stringer[b], Evangeline Tamano[c], Sarah J. Konschuh-Luc[d]

[a] *Tom Baker Cancer Centre, Alberta Cancer Board, Canada*
[b] *Cancer Surgery Alberta, Alberta Cancer Board, Canada*
[c] *Cancer Surgery Alberta, Alberta Cancer Board, Canada*
[d] *Cancer Surgery Alberta, Alberta Cancer Board, Canada*

Abstract

Cancer Surgery Alberta worked with Alberta surgeons to examine the need for standardized cancer surgery guidelines within the province. Consensus was reached on the development of an electronic synoptic report to replace the traditional narrative report for cancer surgery. Minimum data sets were established by surgeons for each tumor group converted into a web-based surgical medical record (Alberta WebSMR). By working with Alberta health regions, surgeons, and Alberta Health & Wellness, synoptic reporting for cancer surgery was introduced throughout Alberta. This application has been successful in recording cancer surgeries and providing a method for access to real-time clinical outcomes data. Implementation will continue throughout the province and the number of active templates will increase. The Alberta WebSMR provides an opportunity for surgeon education, data to support decision making, and ultimately improved surgery for cancer patients.

Keywords:

cancer , surgery, synoptic, computer, operative report, outcomes

Introduction

Medical oncology services, including chemotherapy and radiation have long been centralized across Canadian provinces. Surgical oncology, on the other hand, has not met that same level of standardization. Due to the resultant lack of well-defined and readily available treatment guidelines and outcomes data in cancer surgery, the Alberta Cancer Board consulted with the Alberta Health Regions, the Alberta Medical Association, Alberta Health and Wellness, and the College of Physicians and Surgeons of Alberta to develop Cancer Surgery Alberta (CSA). Along with the Canadian Strategy for Cancer Control, CSA identified a need to establish baseline surgical information in order to better understand the current status of patient outcomes of cancer surgery and enable benchmarking of surgical outcomes. CSA obtained consensus from Alberta surgeons on the development preformatted templates and synoptic reporting that makes outcomes analysis possible. Minimum data sets were developed by the surgeons and a pilot study was conducted. Upon ascertaining that a web-based synoptic report was advantageous in providing a complete picture of cancer surgery, and thus benefiting cancer patients, a web-based medical surgical tool was developed and deployed in Alberta.

Methods

Cancer Surgery Alberta held consensus workshops to address the lack of cancer surgery guidelines. As a result of these meetings, data elements were established to create a computer-based synoptic report for rectal cancer. A pilot study was conducted to compare the feasibility of such a system to the traditional narrative report. The study looked at elements for abdominoperineal resection and anterior resection. Examining waiting times, resource utilization, staging, decision-making, guidelines, functional information, and the technical details of surgery, the findings from this initial study showed that the synoptic report captured 99% of critical information in rectal cancer versus 46% of critical information obtained from the standard narrative operative report (Edhemovic, Temple, de Gara, & Stuart, 2004 [1]). There is a paucity of information in the literature about synoptic surgical records because this is a relatively new concept. Intuitively clinicians and outcomes analysts believe that such records will offer considerable advantages. However, there is little empirical evidence reported in the literature to support this widely held opinion. The few studies reported in the literature are unanimous in identifying the advantages and superiority of synoptic reporting over traditional narrative reporting. (Dougherty, 1999 [2]; Edhemovic, Temple, de Gara, & Stuart, 2004 [1]; Hemmings, Jeffery, & Frizelle, 2003 [3]; Sleszynski, Glonek, & Kuchera, 1999 [4]) Other than the report of the pilot study of the current initiative (Edhemovic, Temple, de Gara, & Stuart, 2004 [1]), only one study was found that reported the use of synoptic reporting for surgery (DeOrio, 2002 [5]) and that study reported synoptic reporting in orthopedics. No studies were found that reported on oncology surgery. However, after consulting widely, CSA concluded that the current practice of

dictating operative reports was inadequate and needed to be replaced with mandatory reporting of certain data elements that could be most easily achieved by a standardized electronically-generated operative synopsis. CSA contracted an independent software consulting group to develop a web-based surgical medical record (WebSMR).

In order to develop a successful province-wide system, CSA had to develop a multi-disciplinary team consisting of clinical, technical, and administrative members from all health regions

and concerned organizations. This included surgeons, the Alberta Cancer Board, health records, Alberta Medical Association,

Alberta College of Physicians & Surgeons, cancer registry, information systems, and the operating room. Once a foundation was developed, a CSA steering committee was established to provide leadership in working towards all of the CSA Goals identified. In addition, tumour site working groups (TSWG) were established for the development of each template. These groups were composed primarily of surgeons that work in the tumour site area for which a template was being developed. The TSWG defined data elements and formatted their tumor specific templates, approved standards for data definitions, defined outcome queries for the database, and recommended implementation to specific surgeons and health facilities. The surgeons who generated these data elements were the cornerstone of a successful computer synoptic system. There were also several other requirements essential to the success of such a program. Physicians and executive members were involved from the beginning to ensure leadership and user uptake. Individualized training of all users at their own site, coupled with open communication and regular feedback to the end users, has also facilitated successful implementation. In creating a province wide system, it was important to establish Information Management Agreements, Privacy Impact Assessments, and security clearances with each individual health region. Each health region also created an implementation team consisting of health records, OR managers, and information systems. After a template was deployed, surgeons provided feedback and suggested changes to the data. These recommendations were catalogued and would be discussed with the TSWG at regular meetings. Approved changes would then be used to create a new version of a template, and all surgeons would be advised of the update.

The Alberta WebSMR is a technology solution that provides healthcare institutions with a simple electronic means of capturing standardized data points and generating synoptic post-operative surgical records. Its simple interactive questionnaire design makes it easy for surgeons to file consistent reports from any computer with internet access and is limited only to what the surgeon knows at the time of surgery. The heart of the Alberta WebSMR is the Survey Administration Module (SAM), managed by CSA. It is within SAM that the templates are created using the minimum data sets established by each tumor working group. SAM is a dynamic tool, allowing each template to be customized while permitting regular updates to the data sets based on surgeon requirements. It is also from SAM that CSA staff run quality assurance checks on the operative reports and distribute the reports to all interested parties in a timely manner.

To ensure successful user uptake, the Alberta WebSMR is as comprehensive as possible. The system is available from the hospital, office or any other location with an internet connection. A surgeon selects a pre-entered patient, completes a series of survey-style questions, and electronically signs the document, thus eliminating the need for transcription, cutting down review time, and providing the opportunity for surgeons to obtain real-time outcomes.

In order to maximize interoperability, the Alberta WebSMR has targeted integration to other health care systems using a standards based approach. Health Level Seven (HL7) is used as the means to define the electronic messages that Alberta WebSMR uses to send and receive data to other healthcare information systems. As the standard for interfacing clinical data in many institutions, HL7 offers simple communication with many other systems. The application currently uses HL7 2.x and therefore can be interfaced with health information systems that are in use today, with a future target of HL7 3.0. Within the HL7 messages that WebSMR sends, the Clinical Document Architecture (CDA) standard is followed when sending the WebSMR surgical report to other healthcare systems. CDA will be utilized to provide the post operative surgical report in its entirety as a document, thereby replacing the classic dictation style in updating provincial/regional EHRs. At the data element level, the use of structured clinical vocabulary is imperative to enable comparison across sectors and jurisdictions within a pan-Canadian EHR. Aligning with a more widely adopted clinical terminology standard enables more effective data aggregation and transfer across sectors and jurisdictions than the current consensus based clinical vocabulary standard of WebSMR. WebSMR data elements can accommodate to SNOMED Clinical Terms (SNOMED CT) as well as to CCI and ICD 10.

Once surgical information is collected by the WebSMR database, a data table can be exported to the preferred statistical application. As soon as a WebSMR report has been approved, the data can be analyzed through this technique. Reports can be generated based on individual, health care facility, health region, or date range.

Results

The WebSMR currently has six active tumor groups in use (colorectal, breast, liver, sarcoma, melanoma, ovarian), with over 500 reports entered by 20 surgeons in four health regions since 2005. An electronic health record interface is currently in production which will expand the number of health regions using the Alberta WebSMR from four to ten. Thus far, feedback from surgeons has been mainly positive. Regular meetings and communication with surgeons and other steering committee members has facilitated the refinement of the application, with development of new template versions, format changes, and improved work processes. Login issues and timely development of interfaces with other health systems have been the largest challenges.

There have been several aspects of the Alberta WebSMR that have received approval. Namely ease of use, reduction in chart review, and faster turnaround time for reports. Perhaps the strongest response has been towards the availability of outcomes. Waiting times can be determined based on decision date and surgery date, and reasons for delays are also monitored. Several areas directly related to the surgery are also recordable, such as preoperative testing (table 1), clinical staging, patterns of practice (table 2) and use of neoadjuvant therapies. Sample outcomes from the WebSMR can be found in Tables 1 & 2.

Table 1: Breast Cancer Method of Detection

	# patients	Patient (%)	Imaging (%)	Doctor (%)
DCIS	28	0	100	0
IBC	127	43	47	10

DCIS: ductal carcinoma in-situ; IBC: invasive breast cancer

Table 2 - Rectal cancer outcomes

	Abdomino-perineal Resection (APR)	Low Anterior Resection (LAR)
# Patients	18	48
Tumor 1-5cm	94%	6%
TME – Total	100%	63%
TME – Subtotal	0	37%
Loop ileostomy	0	44%
Margins <2cm	5%	0
APR Rate	17%	n/a

TME: total mesorectal excision

Discussion

Surgeon uptake of the Alberta WebSMR has been successful with a limited number of users in four health regions. By March 2008, the application will be deployed throughout the entire province, with an increase to ten health regions and potentially 250 users. Therefore, it is important to utilize user feedback to enhance the system at an early stage. Although login and interface issues have proved to be challenges to this point, these issues will be rectified in the near future. In contrast, the ability to review and sign-off a chart and the elimination of transcription have been met with positive review. Such features allow a surgeon to provide more time in practice and less time with administrative issues. Following successful implementation of the Alberta WebSMR throughout Alberta, CSA will examine the potential for adoption of the WebSMR by other surgical specialties in Alberta, other clinical specialties that would benefit from synoptic reporting, and other provinces across Canada.

The quality of surgery is now linked with significant short and long term outcomes, which mandates that we accurately record and measure our procedures. As such, the Alberta WebSMR offers an excellent tool to obtain real time outcomes with the ability to reflect changes in patterns of practice. It can demonstrate the capacity to analyze aggregated clinical outcomes data related to oncologic surgery with the capacity to influence the adoption of changes in practice by providing practice based evidence. Following the completion of an operative report, updated outcomes can be obtained for all aspects of surgery. For example, the method of breast detection can be determined and the results can be used to analyze the need for increased public education, improved imaging practice, etc (table 1). This analysis can prove beneficial to many facets of cancer surgery. The template that guides the surgeons as they record the data points was developed by their peers and is a subtle but potent educational means of disseminating and refreshing surgeons' awareness of cancer surgery guidelines. The Alberta WebSMR is an important educational tool for surgeons by providing them with a dataset with which to self evaluate by analyzing techniques or outcomes to identify areas where continuing education and training may be valuable. For example, a surgeon may compare personal APR rates to those of all surgeons as a whole (table 2) and draw conclusions about his/her practice measured against the norm. The delivery of timely, accurate, and aggregated surgical outcomes information also has the potential to be a powerful decision making tool for surgeons, health managers, and policy makers. For example, waiting times and reasons for surgical delays can be generated from the Alberta WebSMR. Communication of patient information is one of the barriers to reducing waiting times. Prompt reports providing information on these issues to the appropriate positions

will enhance patient care by follow-up teams and family physicians along with workload planning for the tertiary cancer care centres.

Conclusion

The WebSMR process has been highly successful in defining the elements of a cancer surgery, providing an educational tool for the participating surgeon and providing an efficient mechanism for outcomes assessment. Defining important elements will lead to standardized guidelines for cancer surgery in Alberta, and possibly Canada. In turn, the education of participating surgeons will be strengthened. Increased surgeon knowledge will ultimately benefit the patient, who will receive improved care. Likewise, decision-making outcomes will lead to better resource management within health facilities and improve availability of quality care for patients. Future integration with other areas of cancer care, such as pathology, radiation oncology, and medical oncology will provide an excellent opportunity to understand the biology of cancer.

Acknowledgments

Cancer Surgery Alberta would like to acknowledge the continuing support of the Alberta Cancer Board, Dr. Anthony Fields, Softworks Group Inc., the Alberta Health Regions, Alberta Health and Wellness, the CSA Provincial Steering Committee, and all of the Alberta surgeons.

Intelligent Querying of Terminology Services: A Web-Based SNOMED© CT Servlet

Ignaz FA Reicht[a], Sebastian Garde[b]

[a] *University for Health Sciences, Medical Informatics and Technology, UMIT Hall in Tyrol, Austria*
[b] *Central Queensland University, Health Informatics Research Group, Melbourne, Vic, Australia*

Abstract

Clinical terminologies are playing a major role in realising Electronic Health Records (EHR). These terminologies are becoming increasingly complex and comprehensive to enable more detailed recordings of the patient. This may increase quality of documentation but is also time-consuming and error-prone if a clinician has to navigate through a "jungle of codes" as this is often the case in current systems. The purpose of this paper is to show how the power and features of terminologies can be made accessible to the clinician. For this we developed a dynamic JavaServlet application, which provides access to intelligent SNOMED-CT search queries registered with Ocean Informatics' Terminology Server. The architecture of the Servlet and provided Webservices will enable interactivity between user and Terminology and thus reduce the time and effort required by clinicians when coding using clinical terminologies. As our JavaServlet application demonstrates, user-friendly querying of complex terminologies – even if they constantly change and are getting more complex – is possible. Our service-oriented, web-based architecture appears to be reasonably stable and sufficiently fast.

Keywords:

SNOMED-CT, terminology, Electronic Health Records, computerized medical record systems, openEHR, archetypes

Introduction

Electronic Health Record (EHR)

The characteristics of EHRs are in general as follows:

- Patient-centered
- Longitudinal, this means a long term record of care would be preferable, in the best case from the cradle to the grave
- Comprehensive, which includes records of all care events and all relevant measurements
- Prospective, this provides instructions and goals in healthcare for the patient.

To implement these EHR characteristics Information Technology (IT) is a powerful instrument. It enables efficient communication supporting a high level of Data integrity – once recorded available anywhere – Information must be of high quality, correct, complete, reliable and flexible. However, without interoperability, correct and trustful interpretation of the stored data might lead to more complex and variable processes imposing additional workload and sources of errors on clinicians [1].

A systematic collection of patient relevant data including what, where, how, when, why and who took and takes care of the patient will empower the quality of patient care. But it depends on how clinicians and carers can handle the provided IT systems, and thus on their usability. If the symbiosis between them increases, both, clinicians and IT systems will benefit from higher quality. Clinicians will make serious usage of IT features, and thus symbiosis and evolution will continue.

During the last decades there have been huge efforts in research and development of terminologies. To fulfill desired requirements of users, clinical terminologies have become more complex and comprehensive. There is a need to create applications, which can enable the usage of complex and comprehensive features. To our knowledge usability of complex and comprehensive clinical terminologies is quite difficult due to current IT solutions do not consider socio-technical aspects very well.

The aim of this paper is to

- Briefly identify common problems with clinical terminology
- Describe the development of a webbased application (JavaServlet), which enables access to intelligent queries implemented on a SNOMED-CT Terminology Server and thus overcomes some of the identified problems with clinical terminologies.
- Discuss how this use of clinical terminologies fits together with the use *open*EHR archetypes as models of clinical content.

Materials and methods

To reach our goal, we had to investigate available resources, instruments and which applications and tools are compatible for our purpose. From a technical point of view, we tried to find the most innovative solution with the best performance for the development of the application in discussions together with members of Ocean Informatics, by studying specifications and manuals and developing prototype systems to experiment with specific approaches.

*open*EHR *and Archetypes*

For future-proof development of EHRs representation, context and semantic integrity are essential. The *open*EHR and Archetypes approach can cope well with this issue. *open*EHR is originally based on the GEHR projects (Good European/Electronic Health Record). The aim is to support the communication and availability of routine data and development of EHR. It focuses on data and semantic interoperability of complete EHRs. An Archetype is a smart specification which can represent one complete clinical concept by separating clinical data collection from the record keeping concerns. E.g. a blood pressure archetype represents a description of all the information a clinician might want or has to report about a blood pressure measurement [5].

Ocean Terminology Service (OTS)

According to the product specification OTS, consists of three components, Terminology Service, Terminology set query editor and application widget for clinical application use. The terminology service restricts the set of possible terms used to populate a given data field based on the constraints expressed in archetypes - while allowing browsing of the terminology within this knowledge environment. OTS is highly scalable and supports the comfortable usage of complex terminology in clinical areas [6] in our case SNOMED-CT. In this paper we use OTS to access SNOMED CT queries via webservices.

SNOMED-CT Model

The SNOMED-CT concept model supports both pre- and post-coordinated concept expression. Post-coordinated means, that an expression which is sufficient to define a concept representation but which has not been assigned a name by being used in a definition. Pre-coordinated is a named concept representation, which is either defined, or not. The fundamental design of the SNOMED CT concept model refers to the way in which the concepts in SNOMED CT are defined and related to one another. This includes features and limitations about concepts, relationships, characteristics and roles. Within the constraints of the Fundamental Concept Model Design, the way that particular attributes are applied has a significant impact on the way that SNOMED-CT concepts are defined and the ability to compare them. This includes the use of specific sets of released attributes for findings, context model attributes providing additional defining characteristics for context dependent concepts and role hierarchies [7].

Results

In the following, we will describe the mechanisms our Servlet uses and the concepts it is based on. These mechanisms solve typical problems inherent in many clinical terminologies as the following brief literature review about typical problems in clinical terminologies reveals.

Terminology

Clinical terminology concerns the meaning, expression, and use of concepts in statements in the medical record or other clinical information systems. During the last decades there have been huge efforts solving problems of standardizing medical language and terminology but it is unknown if the development and research will ever succeed in this case [2]. In this paper, Rector also mentioned 3 assumptions about the context in which terminologies are being used:

- The purpose of clinical terminology is to support clinical software
- All terminologies will have to support conversion to existing reporting and epidemiological coding schemes
- All terminologies will need to be multilingual

The more specific the terminology, the more complex and comprehensive its vocabulary in a given area. E.g. there are two kinds of burn – thermal, chemical – and 200 body locations, using pre-coordination we would get 400 codes for burns. If we add 3 thicknesses plus unspecified we have 1.600; if we add three extents plus unspecified we have 6.400; add three levels of recency plus whether or not the burn is complicated by infection the total amount will rise to 76.800 codes only for burn. Another problem is a fundamental conflict between the needs of users and the requirements for developed software. The way humans and machines process information is very different. Machines with their digital processing capabilities are intolerant, fixed and not flexible compared to human beings with analog data processing [2].

Above we have focused on the issue of "what" the terminology can express, but what is about "how" the terminology can express its content and how the vocabulary is organized in it. Cimino [3] describes 2 approaches. One is a systematic case description by choosing the suitable term. A Fracture for example – in the first round you choose between simple or compound, in round two you decide between greenstick, avulsion, compression etc. This avoids nonsensical combinations and avoids the large numbers of terms occurring through the explosion of combinations.

Another approach will allow the user compositional extensibility by combining all the atoms of the terminology into necessary coded terms. The problem within this alternative is, that the atom cannot only consists of its letters (e.g. the word / atom *"White"*) there is a need to add a characterization. For example with the atoms *"White"* and "*Conjunctiva"* you can formulate the term "*White Conjunctiva",* but how would you formulate "Wolff-Parkinson-*White* Syndrome"? [3]

By reading medical informatics research, Terminology-systems tend to dealing with the notion of concepts. That means, that each individual term refers to an individual meaning [3].

Afterwards many vocabularies and terms are organized into strict hierarchies. For example a concept with the unique identifier/code 1000 might be the parent of the concept with the code 1200 which might be the parent of the concept 1280 and so on. With computer interfaces querying for members of a class or concept become easier (search for "all codes beginning with 1" will retrieve codes 1000, 1200, 1280). But within a polyhierarchical terminology where one concept can also belong in more than one location in the hierarchy, a single hierarchical identifier is no longer possible. Therefore is it desirable, to have the unique identifiers for the concepts which are free of hierarchical or other implicit meaning. [3]

Now search routines have to be smart enough to cope with these complex hierarchical and concept identifiers. Nevertheless, front-end terminology applications (like terminology browsers) have to be simple, easy to handle and smart enough to identify what information the user requires in what context.

Terminology browsers allow users to search and navigate through the terminology without necessarily providing editing capabilities. E.g. MicroMeSH was one of the first tools created for interacting with complex standard terminology. This program provided a search assistant with a rich set of lexical look-up facilities and a tree walker to support navigation through terminology.[4]

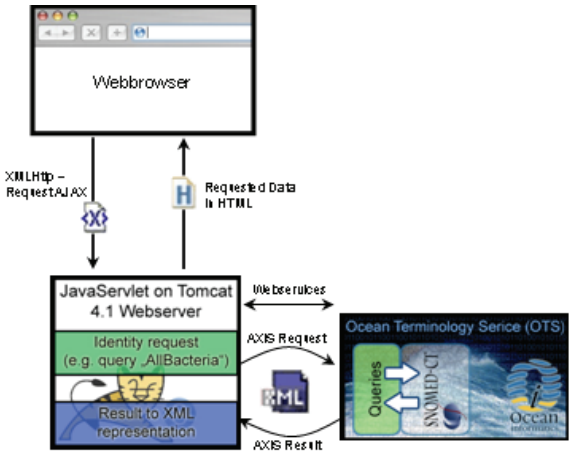

Figure 1 - Overview of the system architecture

After we made us familiar with typical problems of clinical terminologies for our development solutions and concepts have to be found, which overcome some of the problems mentioned above and can lead to innovative results. For development and research in this case, problems in interoperability have to be solved and the openEHR Archetype approach can lead to solutions. As the openEHR and archetype approach does not rely on big standardized terminologies but on "micro-vocabularies", it offers more flexibility during standardization and translation of clinical concepts and overcomes some of the shortcomings of terminology-focused approaches. Terms within an archetype can be bound to or constrained by any number of terminologies or, if highly specific to the archetyped concept, be specified within the archetype itself. To SNOMED-CT, archetypes provide the required structure for clinical concepts. Each term can be bound to a SNOMED-CT concept to specify explicitly that the archetype term and the SNOMED-CT concept have the same meaning. In addition each archetype term that is a text can be constrained by a terminology like SNOMED-CT, ICD etc., e.g. the allowed values (value set) for a diagnosis text in the archetype could be constrained by the appropriate subset of a terminology that deals with diagnoses. Archetypes in contrast to terminologies specify groups of data that as a whole are whole, discreet, highly related and clinically meaningful concepts like a blood pressure measurement consisting of the diastolic and systolic blood pressure, but also of any other information relevant for the interpretation of the readings, e.g. the position of the patient during the measurement [1].

The Servlet

In general the Servlet represents an interface between user and implemented Webservices for querying SNOMED-CT on OTS (Figure 1). The Servlet can manage two kinds of incoming data. First, information about desired commands

or queries, which will be handled within the application so desired processes can take action on OTS. In our case Webservices enable queering SNOMED-CT will be processed. After calling, OTS delivers results to our Servlet application which interpret and represents these in HTML via Webbrowser. As a consequence of this design, Bacteria for example, which are defined in Snomed CT at various locations, can be pulled together and presented coherently for a specific purpose.

It was quite difficult to access our desired information because of the abundance of different technologies and standards. In the following we present an approach to realize such an interface. The Webservices on OTS are based on .NET® and they are SOAP1 and SOAP2 compatible (SOAP: Simple Object Access Protocol) With SOAP you can exchange information between different systems. This technology is comfortable because it provides platform independency. The existing Archetype Finder (http://www.archetypes.com.au) already provides Apache AXIS1 based Webservices (Axis: Java and XML based Webservice framework, comfortable for creating interoperable applications). A couple of other specifications and tools like AXIS2, XINS (XML Interface for Network Services), JWSDP (Java Web Services Development Pack) and XFire were investigated, but AXIS1 was the easiest way to fulfill our motivation with a stable suite of webservices and we therefore used AXIS1 Technology also in our application. In addition, we chose a Tomcat 4.1 Webserver with JRE 1.4 (Java Runtime Environment).

AJAX(Asynchronous JavaScript + XML) and servlet functionality

To support high performance during querying the AJAX Technology provides the most suitable transmission architecture in our case. The big advantage of this Technology is in the *"XMLHttpRequest"* Object, which is responsible for transport of commands or actions a user wants to run on the Servlet. The Servlet connects to the Webservices on OTS and lists all available queries. The requested Data collected by the processed query will be represented as HTML by the Webbrowser (Figure 2).

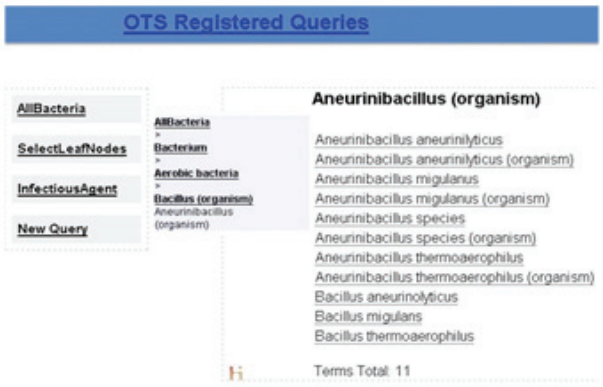

Figure 2 - The servlet in a web browser

To call a command on OTS for example to list all bacteria, we needed the definition of the Webservices on OTS. For programming the Servlet to transmit the required commands and information, the provided WSDL-file on OTS has to be converted to Java Classes by the open source tool CASTOR (so that the Servlet can take action). Now the "highway" to the Webservices is prepared, but we do not know what kind of vehicles (datasets) can drive on it to reach the Webservices. OTS defined the datasets by XML-Schemas (XML: Extensible Markup Language). The Webservices accept two different datasets: registered queries and defined terms. To implement and prepare the Servlet, CASTOR needs to be used again. After all these conversions the Servlet is able for correct interactivity and interpretation with the Webservices registered on OTS. Figure 3 shows all available queries. For example "*AllBacteria*" is a registered Query, which lists all Bacteria within the SNOMED-CT. All entries are grouped, so comfortable top-down navigation between the levels is given. First we can choose between different types of Bacteria. For example if we want to know all available entries of "Aerobic bacteria" (Figure 4) the AJAX engine will deliver a command to the Servlet to go one level deeper into "Aerobic bacteria". If you want to navigate one ore more levels higher AJAX will transmit a "go up" command to the Servlet. As you can see with AJAX is it possible to query only the requested data, this means the Servlet has not to re-query and rebuild already presented data and information.

These search routines, queries and navigation of the Servlet in cooperation with OTS Webservices will deliver fast and situation–specific results for clinicians and care professionals.

Discussion

The more detailed and specific terminologies are, the more complex and less comprehensible they get. Research of

terminologies provides huge potential for new and innovative approaches, but actually we are not able to define what will be the most suitable direction for the future [2]. However, we have to find ways and solutions to enable all features provided by terminologies, therefore considering socio-technical aspects of usability will lead to future orientated results. Without intelligent search strategies and navigation concepts, we believe that growing clinical terminologies are no longer handable leading to suboptimal quality of documentation. To prevent a lack of quality *open*EHR decided in cooperation with Ocean Informatics to construct services and applications, which can cope with the evolution of terminologies. As mentioned in results the *open*EHR archetype approach offers more flexibility and overcomes some of the shortcomings of terminology-focused approaches ([1], [5]).

Further, *open*EHR and Archetypes grant interoperability achieved by the 3 level definition. The *open*EHR reference model alone ensures syntactic (data) interoperability. Structural interoperability is achieved by the definition and use of archetypes. E.g. a blood pressure archetype will have the same meaning no matter where or in which EHR it appears. The third level describes semantic interoperability. In addition to archetypes and the reference model, archetype development must be coordinated through systematic governance. Incompatible, overlapping archetypes expressing the same concept for example have to be avoided[1].

An archetype specifying SNOMED-CT terms by including our Servlet is now available in EHR and can share its clinical knowledge and information can be safely interpreted by exchanging archetypes.

In our case all employed tools and programs to generate our Servlet served the purpose and provided correct and reliable results. The Servlet is running stable. The implementation of the AJAX Engine supports a convenient and easy to use search routine. It works quite similar to the *"GoogleSearch bar"*. If your cursor is in the search field and you are typing an "A", a list of available criteria starting with "A" will be shown nearly instantly.

Figure 3 - Registered Queries

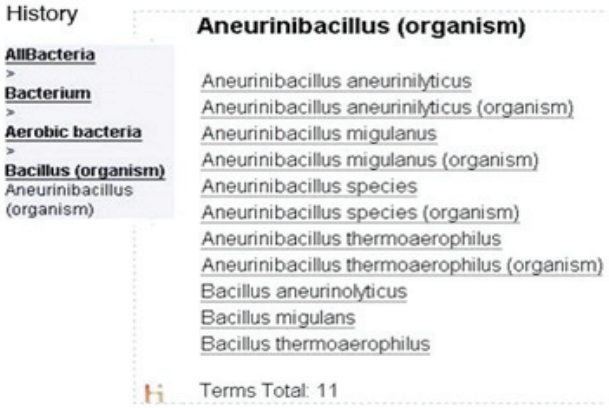

Figure 4 - JavaServlet querying "AllBacteria" on OTS; History box lists visited subcategories of "AllBacteria"; underlined terms processes to go down one more level and list terms

This proof of concept shows that the Servlet can enable available Webservices and queries on OTS and by these means improve the usability of clinical terminologies. The advantages of this approach are the following: First, the Servlet is flexible and dynamic, so there is no need to alter any parameter if queries are changing or moving. The second advantage is due to the web-based concept with a service-oriented architecture, which enables effortless integration into EHR applications. Together, this eliminates the need for directly integrating (hard-coding) clinical terminologies into software and the need for upgrading the software when the clinical terminology changes.

With regard to performance, to make our approach future proof, we need to explore the following approaches:

- Caching Results
- Cache Clustering (locate already loaded Data in cache of other users)

- Server Mirroring

The next goal will be the transport of required data into EHR applications. There is a huge range of possibilities and we will do research to find the most suitable one.

Conclusion

By means of our Servlet we were able to demonstrate that user-friendly querying of complex terminologies – even if they constantly change and are getting more complex – is possible. The technologies chosen for this purpose (Java Servlet technology, AJAX, AXIS in a service-oriented, web-based architecture) appear to be reasonably stable and sufficiently fast.

Integration of Clinical Data to Support HIV Research

William B Lober[a], Mari Kitahata[a], Dan Drozd[a], Michael Saag[b]

[a] *University of Washington, United States*
[b] *University of Alabama, United States*

Abstract and objective

Over the last 20 years computer science and medical informatics have evolved so that real-time data collection is now possible in the clinical practice setting, at the point-of-care. In 2004, we build a system to integrate HIV clinical data from six sites around the United States, developing an integrated clinical research cohort. The architecture and current status of the system will be described.

Keywords:

HIV, AIDS, data integration, CNICS

Introduction

The CFAR (Centers for AIDS Research) Network of Integrated Clinical Systems (CNICS) project is the first EMR-based resource network that will contribute to the contemporary HIV research agenda, and was implemented in 2004. As a clinic-based research network, CNICS directly reflects the outcomes of clinical decisions and management options made daily in the care of HIV infected individuals. Previous observational cohort studies have used structured data collection at three or six month intervals and medical record review to abstract relevant clinical data.. Unlike data collected in structured interviews or through retrospective medical record review, CNICS allows a broader range of information associated with the rapidly changing course of HIV disease management through collection of data at the point of care. The challenge for research using data from different care systems is to collect data with uniform definitions and quality. The CNICS project supports a data system that is a central repository of verified and quality-controlled data from the EMRs at six CFAR sites (the Universities of Washington, Alabama, & California/San Diego & San Francisco, Case Western Reserve, & Harvard/Fenway) EMR data are standardized and are thus available for population-based outcomes research.

Methods

Overview of the CNICS system

CNICS was built as a relational database using MySQL. The CNICS system uses a normalized relational database (SQL), Extended Markup Language (XML), and JAVA. The database server is secured with standard techniques including: strong access controls; institutional IT-support; software firewall; secure file transfer protocols; daily differential and full back-ups as well as off-site secure storage of backup media; and network-wide virus protection software. CNICS data are transmitted to the central repository using password-protected, encrypted, secure file transfer protocol. The automated parser-translator framework has been developed for demographics, clinical diagnoses, laboratory test results, and medications.

Results

The sources of data within the CNICS repository are the EMR systems at each participating CNICS site. While the EMRs at the six sites were developed independently, there is significant commonality among data elements across sites including clinical diagnoses, laboratory results, and medication data. The challenge of the CNICS project is to integrate clinical data from EMRs with uniform definitions, standards, and quality at the site level and within the CNICS repository. Therefore, a primary focus of the CNICS project has been establishing standards for terminology, format, data verification and quality assurance procedures for the CNICS group that can be used by other sites as they develop local EMRs.

CNICS contains fully integrated data on 9,311 patients, the majority of whom enrolled in the cohort after 1996 and thus, have been under care in the HAART era. Median follow up for the cohort enrolled through 2002 is four years. CNICS contains 3,210 unique observed AIDS-defining events since January 1, 1995. Among the patients in the CNICS Cohort, 3,435 (37%) had been treated with HAART (PI- or NNRTI-based regimen) prior to initiating care at a CNICS site and 2,715 (29%) received their first HAART regimen while in care at a CNICS site.

Conclusion

CNICS is a successful and unique resource for HIV clinical, translational, and basic research, poised to address the challenging and evolving issues in HIV care and research.

How to Represent the Medical Annotations?

Abstract

The medical practice needs an important collaboration of the health care professionals. This collaboration must be improved by efficient exchanges of information. Annotations (post-it, comments) are one of the strategies used by the practitioners to communicate in an informal way. In this paper, we want to describe precisely these annotations. This model can be used to design electronic settings (indexing or laying out annotations according to various points of view).

Keywords:

annotation, collaboration, electronic health record, knowledge engineering, patient safety, quality of care

Introduction

Health care professionals (HCP) use the paper and electronic documents of the health records to keep traces of their communications and of their acts. Most of the time, on paper, the documents are annotated. Indeed, the documents are structured and they are not sufficient for all the comments. Consequently, practitioners use annotations (post-it, comments) to communicate in an informal way. They have similar difficulties with the electronic documents but unfortunately the existing annotation tools are not sufficient. The purpose of this paper is to describe precisely these medical annotations for integrating them in the electronic settings.

Methods

In the DocPatient[1] project, we studied the existing annotation tools. We compared their functionalities with the paper practices of annotations. We chose 6 functionalities and we implemented them in the DocAnnot model [1]. We evaluated this tool with 20 practitioners. This evaluation allowed us to improve our tool and to understand how annotations are necessary for the HCP' collaboration. But we still need a better description of these annotations to represent and display them in our system.

We also collaborated with the LAMIH[2] who have similar problems when they study the semi structured information written in a textbook by the nurses during home care activities. We described in [2] a conceptual model of these communication notes. We propose four interpretation levels (contextual, perlocutory, locutory/illocutory and collaborative) to organize the concepts used when a note is produced or read.

In this paper, we apply this model to describe more in detail the annotations, which are a particular type of communication notes. Our aim is to answer to the following questions basing us on the notion of discourse structure, speech acts and collaborative activities:

- **Contextual level:** What is the context which leads the author to produce an annotation? Who is speaking or writing or drawing? when? Where? for who?
- **Perlocutory level:** In which way does the author want his annotation to be used and how the reader uses it?
- **Locutory/illocutory level:** What are the means used by the author's annotation to transmit his message? Which target? anchor? form?
- **Collaborative level:** What is the impact of the annotation on the activities?

Results

Contextual level: A medical annotation is written in a *spatio-temporal framework of creation* and is read in a *spatio-temporal framework of reading* (at a particular date, in the patient's room...). The *annotator* is a writer who belongs to the medical team (a physician, a nurse...). The annotator writes the annotation for one or more *targeted readers* (the annotator himself, several member of the medical team...) but, as the health record remains in the patient's box, all the medical workers are *potential readers*. The *real readers* are readers which can be targeted, potential or *collateral readers*. The *collateral readers* have not been envisaged by the annotator as a computer scien-

1 The DocPatient project (2002-2005 University of Amiens) is financed by the Picardy region. We worked with a pilot site (paediatric intensive care and neonatal medicine) and an industrial partner (UNI-MEDICINE).

2 http://www.univ-valenciennes.fr/LAMIH/

tist who studies the health records. An annotation deals with an *object of communication*, a topic.

Perlocutory level: The annotator produces a note according to an *intention of use*. We distinguished two objectives: (i) *the annotator writes the note for himself* but he can communicate the note according to the needs of the organization members (memos, personal notes, reports of actions, links); (ii) *the annotator writes the note according to an intention of communication for one (or several) targeted readers* (daily instructions, transmissions, requests for information, emphases of information). In addition, an annotation can correspond to several intentions of use. For example, a physician wants to *draw the attention* of the fellows by *linking* documents. Moreover, in the medical context, most of the annotations are written to collaborate. Consequently, most of them are *incidental reflections* which are not inevitably related to the documents but to the activities described in them.

Locutory/illocutory level: To annotate, the practitioners choose a *target* which can be can be a collection of documents, a document, a part of a document (a paragraph, an image…), or another annotation. He also chooses an *anchor* which links the annotation to the target (a line, a surrounded sentence…). Finally, he writes a *contents* which is a trace of one of his mental representations elaborated about the target. He adds a layout, a *shape* to this content (bold, coloured sentences...). The content of the annotation has an *illocutory force*, it can be used to achieve an act. Austin distinguishes the constative and performative utterances. The constative utterances assert or state something that can be judged as true or false and the performative utterances perform the actions mentioned rather than express a proposition about it. In the medical annotations, we rarely find constative utterances, but we find them in the documents to describe the patient's state. On the contrary, we find performative utterances in the annotations and in the documents because the practitioners use the annotations to keep traces of the actions which have been carried out or which will be carried out.

Collaborative level: To describe the annotations, we also used a collaborative point of view: the Hoc's architecture of collaboration [4] which proposes three levels: action, plan and meta-collaboration. We use the example of a physician who sticks a post-it "BG in two hours" to describe this three levels.

- **Action level:** When the physician sticks the post-it, he deliberately *creates a local interference*. The post-it facilitates his own task. The others worker are aware of his activity and will not schedule a care at the same time. The post-it also make easier the tasks of the others practitioners, who can be disturbed by this new task. A nurse reads this annotation and *detects the interference*. She had scheduled the bath of the child at the same time. She *identifies the goal of the annotator*. He wants to supervise the evolution of the blood gas. She *solves the local interference* by delaying the bath.
- **Planning level:** The nurse *updates her representation* of the child. She understands that the physician wants new blood gas because the child is ill. She also *updates her representation of the controlled process* (the evolution of the child's state) and *her representation of the controlled activity* (the cares). For that, she readjusts her *representation of the common goal* (to keep the child in a stable state), of the *common plan* (the blood gas have priority on the other cares) and of the *distribution of the tasks* (she must prepare the material for the physician).
- **Meta level:** The nurse uses the vocabulary of the field, a *common code*, to associate the abbreviation "BG" with the meaning "blood gas". In order to have a *representation* compatible with the physician's representation, she translates the post-it which is written according to the physician's level of expertise in her own level of expertise. To finish, she *updates his own representation and his representation of her partners*. She's used to work with the physician, so she can infer on the aim of this new BG. She also knows what the physician expects from her (to prepare the material).

The complexity of the collaborative activities must be underlined. A fellow analyses the same comment from another point of view and this note can induce others activities.

Discussion and conclusion

Usefully managing and laying out annotations is a challenge because their informal and unforeseeable nature makes them difficult to handle. Their description according to multiple points of views is a solution to consider their multiple facets. Our model is coherent with the implementation of our annotation tool dedicated to the electronic health record and will be easily integrated. Moreover, this representation is also satisfactory in respect of the evaluation carried out with the HCP. We of course need to collect more data to evaluate this model with various medical specialties. The following step consists in building a computational model directly usable by electronic settings, for example, to index the annotations or to lay out them according to various points of view. We evoke the possibility of building an ontology to represent this model. To conclude, a detailed modeling of these annotations allows not only their computerization but also their integration in the complex process of medical information management. The originality of our modeling comes from the way we take into account of some collaborative knowledge.

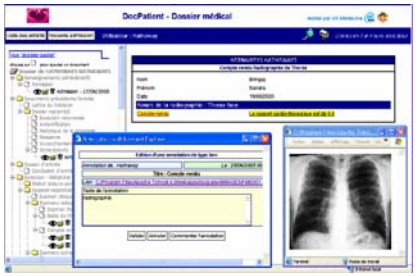
Introduction/Background: DocPatient Project

- **Initial report:**
  - Need of annotations to support the collaboration of the health care professionals in the documents of the health record

- **Methods:**
  - Study of the existing electronic annotation tools and comparison of their functionalities with the paper medical practices of annotations
  - Selection/Implementation of 6 functionalities in a model
  - Evaluation of the model with health care professionals



- **Results:** Specification of an annotation tool dedicated to the electronic health record to **support collaborative practices** [1]

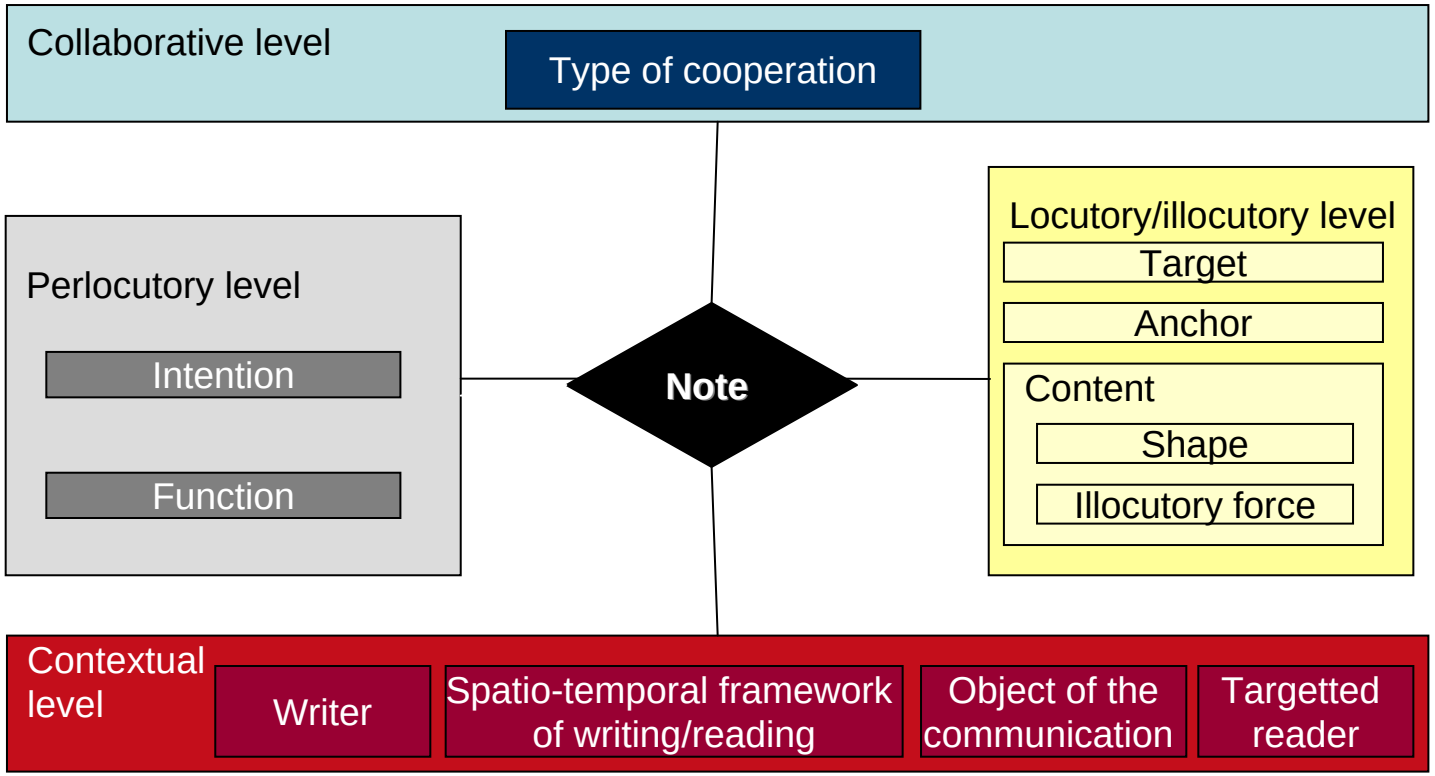
- **Need: A better description of these annotations to represent and display them in our system**

Introduction/Background: Collaboration with LAMIH

- **Initial report:**
  - Need of a description of the medical information

- **Results:**

4 levels to describe medical information [2]

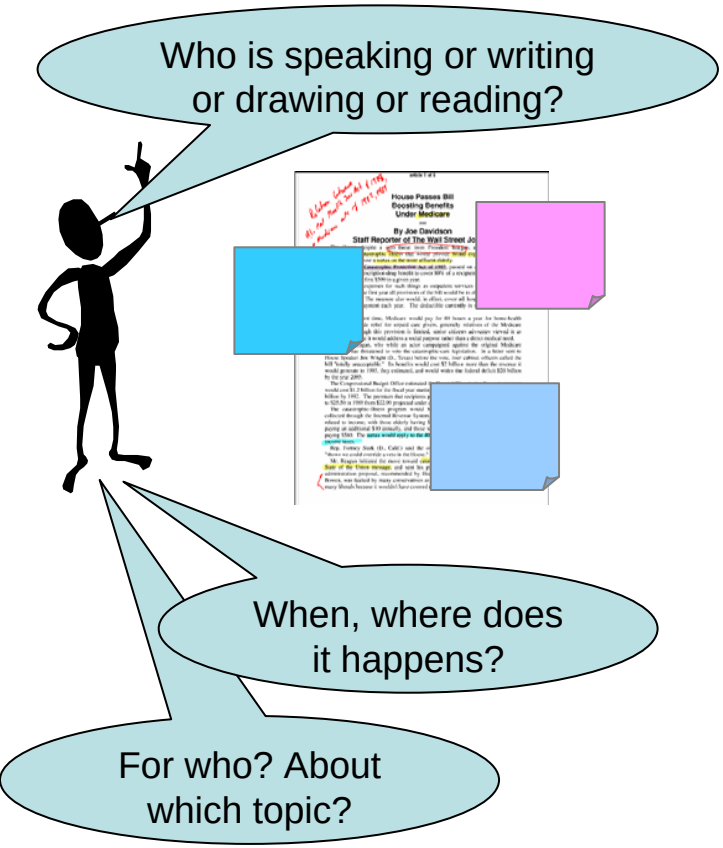


Objectives

- To improve collaborative practices
- Need of a detailed description of the annotations for a better integration in the Electronic Health Records (indexing and layout according to various points of view)
- Application of the model of the communication notes to the annotations of the health care records

Results: Contextual level

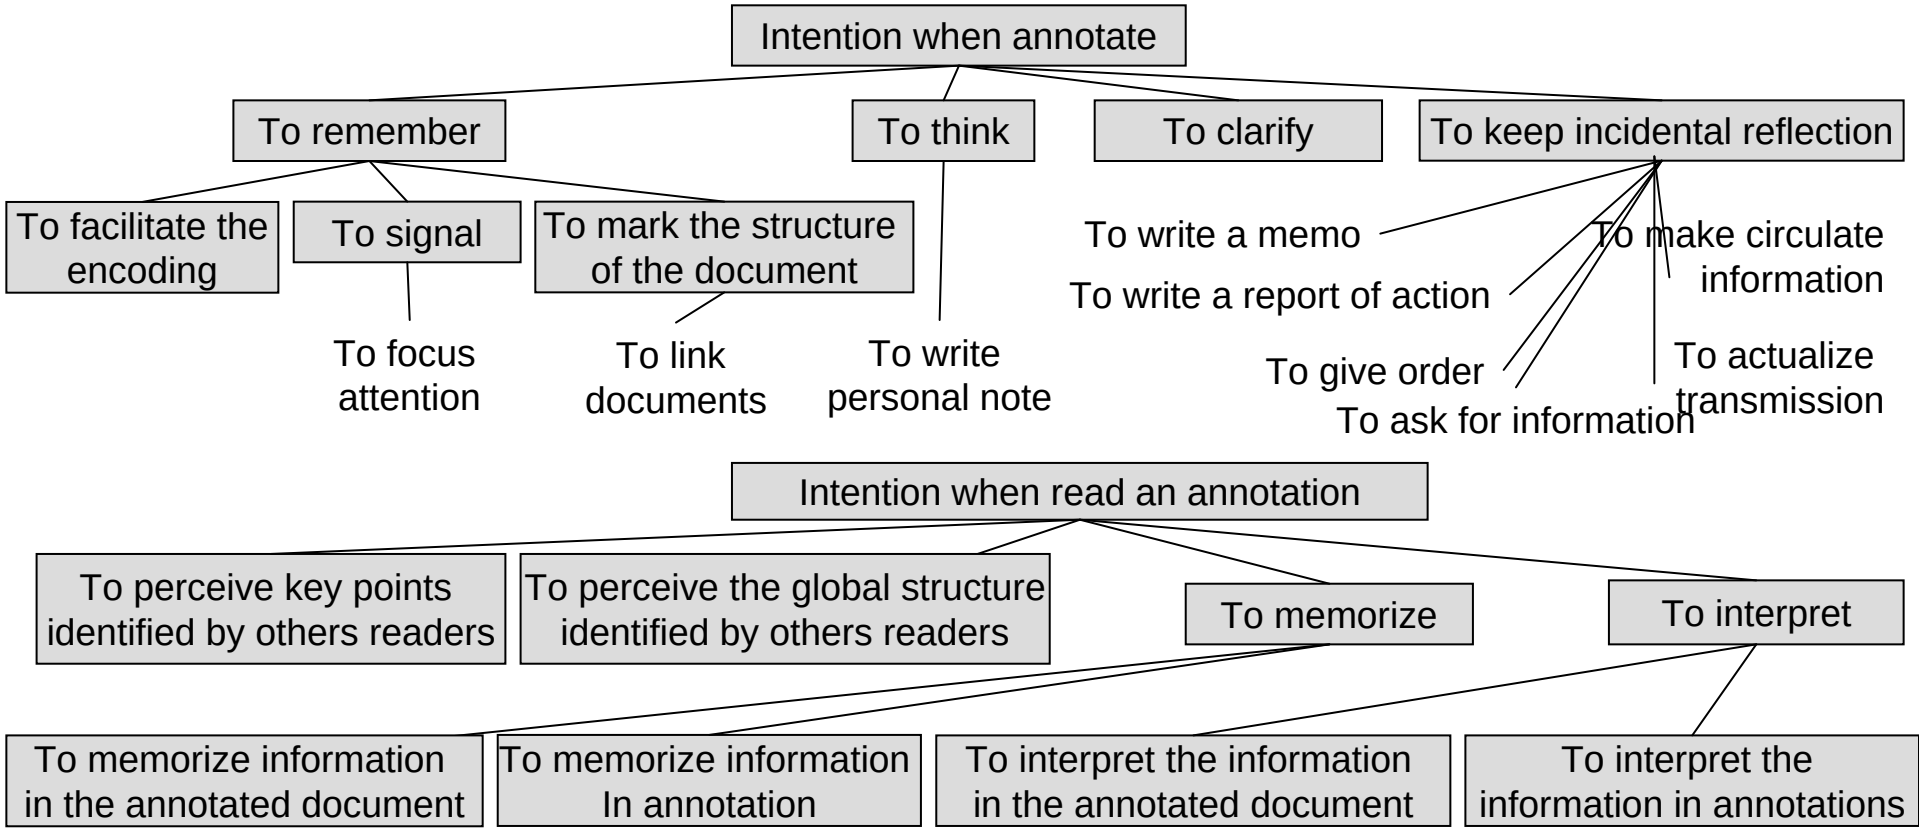
Contextual level: What is the context which leads the author to produce an annotation and what is the context which leads a reader to interpret it?



- ***Spatio-temporal framework of creation/reading:*** at a particular date, in the patient's room, in the physician's office...
- ***Annotator:*** writer who belongs to the medical team (physician, nurse, fellow...)
- ***Targeted readers:*** the annotator himself, one or several member of the medical team, the family...
- ***Potential readers:*** as the Health Record remains in the patient's box, all the medical workers
- ***Real readers:*** targeted, potential or ***collateral readers*** (readers who have not been envisaged by the annotator e.g. computer scientist who studies the Health Records)
- ***Object of communication***, a topic (patient's state, care planning)

Results: Perlocutory level

Perlocutory level: In which way does the author want his annotation to be used and how the reader finally uses it?



Results: Locutory/illocutory level

Locutory/illocutory level: What are the means used by the author's annotation to transmit his message? How does the reader interpret it? Which target? Anchor? Form? Illocutory force?

- ***Target:*** collection of documents, a document, a part of a document (a paragraph, an image…), or another annotation
- ***Anchor:*** link between the annotation and the target (a line, a surrounded sentence…)
- ***Contents:*** trace of one of the mental representations of the annotator elaborated about the target
- ***Shape:*** a layout added to the content (bold, colored sentences...)

This table gives the percentages of the practitioners who use annotations by professions and by types of annotations

	Physician	**Fellow**	**Nurse**	**Ad agent**
Post-it	80%	80%	80%	100%
Comment	100%	80%	100%	60%
Mark	100%	80%	80%	100%
Personal note	100%	100%	40%	100%

Results: Locutory/illocutory level

Locutory/illocutory level: What are the means used by the author's annotation to transmit his message? How does the reader interpret it? Which target? Anchor? Form? Illocutory force?

This table classifies the types of annotation according to the classification of speech acts mainly used to formulate the content

- ***Illocutory force [4]:*** action associated to the speech act (directive, commissive, declaration, representative)

Personal annotations which can be published	
Memo	Directives, Commissives
Personal note	Declarations
Report of action	Declarations
Link between documents	Representatives, Declarations
Emphase of information	Representatives, Declarations
Annotations writen to be published	
Order	Directives, Commissives
Transmission	Representatives, Directives
Request for information	Directives
Circulation of information	Declarations

Result: Collaborative levels

Collaborative level: This level exists only if the annotation is produced in the context of collaborations. What is the impact of the annotation on these activities? The reader integrates the annotation in his own tasks and he interprets it according to the various levels of collaboration mentioned by [5]

- **Example:** a physician sticks a post-it "Blood Gas in 2 hours"
  - **Action level :**
    - When the physician sticks the post-it, he deliberately ***creates a local interference*****.**
    - A nurse reads this annotation and ***detects the interference*****.** She had scheduled the bath at the same time.
    - She ***identifies the goal of the annotator*****.** He wants to supervise the evolution of the blood gas.
    - She ***solves the local interference*** by delaying the child's bath.

Result: Collaborative levels

Collaborative level: This level exists only if the annotation is produced in the context of collaborations. What is the impact of the annotation on these activities? The reader integrates the annotation in his own tasks and he interprets it according to the various levels of collaboration mentioned by [5]

- **Example:** a physician sticks a post-it "Blood Gas in 2 hours"
  - **Planning level :**
    - The nurse ***updates her representation*** of the child. She understands that the physician wants new blood gas because the child is ill.
    - She also ***updates her representation of the controlled process*** (the evolution of the child's state)
    - and *her* ***representation of the controlled activity*** (the cares given to the child). For that, she readjusts her ***representation of the common goal*** (to keep the child in a stable state), of the ***common plan*** (the blood gas have priority on the other cares) and of the ***distribution of the tasks*** (she must prepare the child and the material for the physician).

- **Complexity of the collaborative activities:** A fellow analyses the same comment from another point of view and consequently, this note induces others collaborative activities.

Discussion, Conclusion and Prospects

- **Usefully managing and laying out annotations** is a challenge because their informal and unforeseeable nature makes them difficult to handle.
- Their **description according to multiple points of views** is a solution to consider their multiple facets.
- When an annotation is described according to different the items of our model, an agent (man or machine) has the necessary knowledge to effectively use, exchange and lay out it.
- A detailed modeling of these annotations allows not only their computerization but also their integration in the complex process of medical information management.
- This **representation is coherent with the implementation of our annotation tool** dedicated to the Electronic Health Record and will be easily integrated.
- Moreover, this **representation is also satisfactory in respect of the evaluation** carried out with the Health Care Professionals.
- The originality of our modeling comes from the way we take into account of some **collaborative knowledge** which are not often used to build collaborative tools in medical situations.

Abstract

There are few implementations of automatic extraction of clinical data from Electronic Health Record (EHR) to clinical research data management system (CDMS). At the G.Pompidou European Hospital (HEGP), cardiovascular radiology reports are captured twice, first in the EHR and then in a national CDMS dedicated to clinical research in arteriography. The objective is to develop tools for producing both an HL7 CDA report for patient care and a CDISC ODM message for clinical research from a single multipurpose form. We adopted and compared two approaches: 1) implementing a single "care-research" form within the EHR and aligning XML structures of HL7 CDA document and CDISC ODM message to export relevant data from EHR to CDMS; 2) displaying a single "care-research" XForms form within the EHR and generating both HL7 CDA document and CDISC ODM message to fill directly both EHR and CDMS. The solution based on XForms avoids overloading EHR with irrelevant information. Beyond syntactic interoperability, a perspective is to address the issue of semantic interoperability between both domains.

Keywords:

HL7, CDA, CDISC, ODM, medical records systems, computerized, biomedical research; clinical trial

Introduction

Considerable efforts were realized for standardization and communication of medical information for both patient care (driven by HL7 (HL7 RIM, Clinical Document Architecture (CDA))) and biomedical research (driven by CDISC (Clinical Data Interchange Standards Consortium).

In 2004, CDISC initiated the Biomedical Research Integrated Domain Group (BRIDG) that addresses the issue of interoperability between systems that capture patient data, as Electronic Health Records (EHR) and clinical data management systems (CDMS) for biomedical research [1]. In addition, within the IHE (Integrating the Healthcare Enterprise) initiative, an integration profile called RFD (Retrieve Form for Data-capture) provides a method for gathering data within a user's current application to meet the requirements of an external system [2]. RFD aims at supporting the retrieval of forms from a form repository, display and completion of a form, and return of instance data from the display application to the source application.

Although there is an issue to connect patient care and biomedical research, nowadays, in practice, clinical trials or epidemiological studies often require specific manual entry of data, some of which already reside in the EHR [3,4].

Material and methods

Nowadays, in the G.Pompidou Hospital (HEGP), radiologists enter clinical data of arteriographies through a form of the EHR (DxCare®, Medasys©) and then fill another form of a national CDMS for clinical research in cardiovascular radiology (AIR On Line (AOL)®, Kika Medical©).

We used a two steps methodology to implement a solution to capture data for both patient care and research in the cardiovascular radiology domain.

Designing a multi purposes "patient care-research" form

Items required for patient care and for clinical research were analysed and compared.

A single multi purposes form was designed including all the required items for cardio-vascular radiology. Since we could only make changes in the EHR forms, to evade semantic interoperability issues, the items that were required in both contexts (patient care and research) were represented according to the research context. We took into account the data types, the modalities of answer and the data type controls of the CDMS for clinical research.

The multi purposes form was implemented on one hand in DxCare® ("Care-research" CV form(a)) and on the other hand using the standard XForms ("Care-research" CV form (b)).

Exporting data from EHR to clinical data management system (CDMS)

We analyzed the differences between the HL7 CDA [5] and CDISC ODM models on both a structural and organizational point of view (with regard to the context of data capture).

We implemented two approaches to export data from EHR to clinical data management system (CDMS):

The first approach consists in 1) generating for each instance of the "Care-research" CV form (a) implemented in DxCare® the corresponding HL7 CDA document and 2) aligning XML structures of HL7 CDA document and CDISC ODM messages to export relevant data from EHR to CDMS (figure 1).

The second approach, based on the IHE integration profile RFD, consists in displaying the "Care-research" CV form (b) implemented using XForms technology [6] within the EHR and generating both HL7 CDA document and CDISC ODM message to fill directly both EHR and CDMS (figure 2).

Results and discussion

The comparative analysis of clinical data captured in patient care and clinical research showed that, in the domain of cardio-vascular radiology, 93 clinical items are relevant for patient care and 136 for clinical research. The mixed "Care-Research" CV form contains 198 items.

The comparative analysis of both standards HL7 CDA and CDISC ODM showed that some differences are due to different contexts of data capture in patient care and clinical research. These differences intervene primarily in the representation of the patient's administrative data. With regard to the structure of the models, the HL7 CDA model allows representing clinical data according to an infinite depth of sections since CDISC ODM proposes only three levels of depth to represent clinical study data. The generic solution used to generate a CDISC ODM message from an HL7 CDA document including more than three levels of depth is to concatenate labels of items from the sections above section 3 and to group them under only one item group. « Section 1 » in the CDA document is aligned with the ODM « FormData » tag. Items of the last section in the CDA document (« section n ») are copied in the ODM « ItemData » tag. Label of « ItemGroupData » results from concatenation of items of the « section 2 » to « section n-1 ».

Tools were developed to implement two approaches to export data from EHR to clinical data management system (CDMS).

The tool developed according to the first approach uses the mixed "Care-Research" CV form implemented in DxCare (198 items) and produces a CDISC ODM message including 136 items for biomedical research (figure 1).

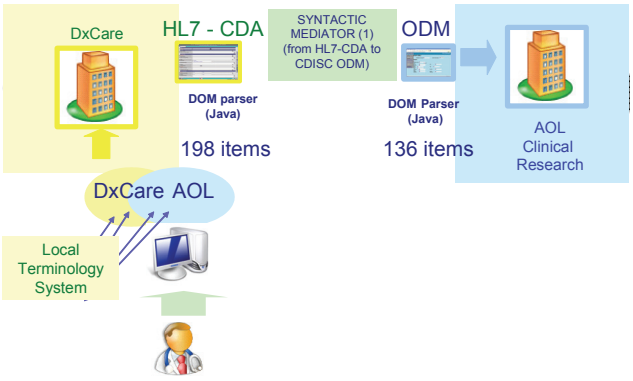

Figure 1- Production of a CDISC ODM message from a HL7 CDA document and using a mapping file

The tool developed according to the RFD profile produces an HL7 CDA document including 93 items dedicated to patient care and a CDISC ODM message including 136 items dedicated to biomedical research from the same single "Care-Research" form implemented in XForms (198 items) (figure 2).

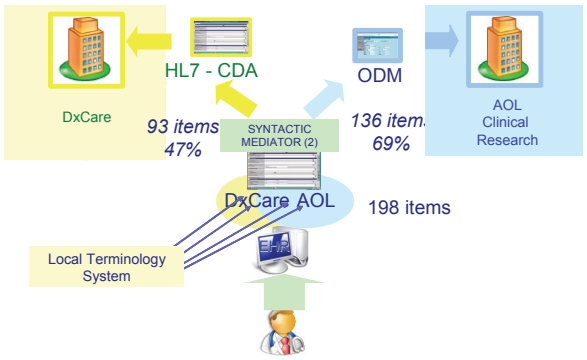

Figure 2- Production of a HL7 CDA document and a CDISC ODM message from a multi-purpose XForms form

We showed that it was possible to exploit for clinical research data captured in the EHR during patient care. The benefit for healthcare providers consists of the absence of time consuming and error prone double data entry, the automatic transfer of administrative and clinical data relevant for biomedical research towards a national CDMS and the storage of a structured data containing information necessary for patient safety in the EHR (for example adverse events).

A first limit of this work is that the tools were not tested in daily practice. We are working with Medasys© and a company developing CDMS for clinical research to implement

this workflow in HEGP. Another limit is that this experiment only addresses syntactic interoperability between standards of patient care and clinical research. There is an issue to solve semantic interoperability between applications while implementing integration profiles between patient care and research.

Further developments and lessons learnt

Further developments

- 200.000 translated and validated concepts ultimo 2007
- 30.000 translated concepts has been clinical qualified of ultimo 2007
- Initiation of a EHR test project ultimo 2007
- 280.000 SNOMED CT concepts translated and clinical qualified 2010

Calculated costs for the whole project: 6.000.000 USD

Lessons learnt

- Using concept based translation the national context can expressed
- Iterations and feedback-loops increases quality and must be integrated in the process
- Linguistic guidelines are needed to get harmonised results
- A tool handling the workflow and supporting a distributed translation process is required
- Provision of synonyms and subsets are crucial for clinical acceptance
- Exchange of experience is needed – IHTSDO.org will support this

Requirements for a structured EHR

Adapting SNOMED CT® for use in Denmark – the Tools and the Process of Concept Based Translation

Ulrich Andersen[a], Janni Lerche [a], Palle Gerry Petersen [a], Knut Bernstein[b]

[a]*National Board of Health, Copenhagen, Denmark*
[b]*MEDIQ, Copenhagen, Denmark*

Abstract

A common clinical terminology is a cornerstone for well structured documentation in electronic health records and a precondition for secondary use of data and semantic interoperability. The Danish authorities have selected SNOMED CT® as the main reference terminology for healthcare. The entire human medical domain of SNOMED CT® will be translated into Danish. Instead of just translating the terms, a concept based translation method is used. The terms' position in the terminological network, i.e. the relations and the attributes, are mapped to a corresponding Danish concept model. Professional translators, terminologists and domain experts are involved in the translation. A translation tool supporting all involved actors has been developed in order to manage this complex and distributed process. This paper describes the translation process and the developed translation tool.

Keywords:

SNOMED CT®, translation, terminology, electronic health record, software tool

Introduction

The use of information technology has a high penetration in the Danish society and in the healthcare sector. Hospitals, laboratories and pharmacies have implemented it-systems. Nearly all primary care doctors are using electronic health records (EHR), and around 50 % of all hospital beds are served by EHR. Electronic messages based on national standards are extensively used by all parties.

In order to harmonise the data content and structure in EHR, the National Board of Health (NBH) has developed a national model for EHR. The model supports a problem-oriented, longitudinal, cross professional and cross sectorial EHR for the purpose of continuity of care. The intention is to improve semantic interoperability using structured data for clinical documentation as well as secondary use of EHR data. A comprehensive and granular, multi professional clinical reference terminology then becomes a prerequisite.

Methods

NBH have assessed possible terminologies to support semantic interoperability. SNOMED CT® with it's more than 380.000 concepts, 900.000 terms and 1400.000 relationships, was found to be the most comprehensive and detailed terminology. The poly-hierarchy and different levels of granularity were seen as an advantage. The reference model for SNOMED CT® was considered robust and offered an evolutionary development, handling of multilingual use and language extensions.

However, it has been important ensuring the terminology is adjusted to Danish conditions and that professionals, patients and relatives can recognise and understand the terminology used. Therefore the entire human medical domain of SNOMED CT® will be translated into Danish. Instead of just translating the terms, a concept based translation method is used. The terms' position in the terminological network, the relations and the attributes, are mapped to a corresponding Danish concept model. This requires extensive use of healthcare domain experts in a distributed process.

A translation tool has been developed supporting the actors, manage the authoring process and monitor the quality.

The translation process

During the process, the National Board of Health (NBH) cooperates with a translation agency, language specialist, terminologists and Subject Matter Experts (SMEs). (See figure 1.)

Each month 10.000 concepts are selected for translation and distributed to the translators - a 1st translator and a 2nd translator for review. The 2nd translator can accept the suggested translation and forward it to NBH for approval. He may also ask the first translator to revise the term. If specific clinical knowledge is required, he may consult the SMEs. In more difficult cases, the editorial board may be consulted. The editorial board consists of terminologists, medical domain experts, and representatives from the NBH.

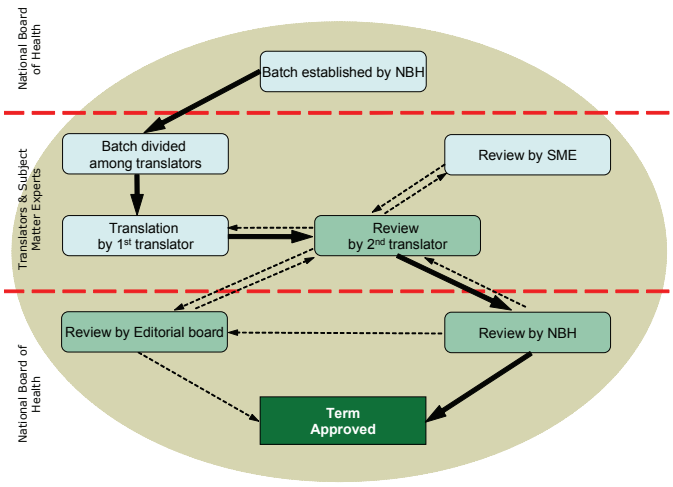

Figure 1 - The translation workflow process

The translation tool

The Danish National Board of Health has partnered with the IT supplier Carecom, to develop a web-based IT system, containing the functionalities necessary for the management of the entire SNOMED CT® translation: A common space for translators and the reviewers where all documentation of the translation takes place; Management of the translation workflow, showing the current stage for each term, and providing statistics on progress; Access to similar already made translations and supporting of addition of synonyms and modelling of new concepts for the Danish extensions; Development of discipline oriented subsets or subsets for specific purposes; Access to terminologies, updated translation guidelines, medical textbooks etc.

Results

The translation is progressing according to the plan with 10.000 concepts translated each month. In the first phase of the project only concepts are translated and only one term per concept is produced. In a second phase the synonyms will be identified. The entire human medical domain of SNOMED CT® is expected to be finished within 2-3 years with a cost of 6 million USD. By December 2007 200.000 concepts of the expected 250.000 are translated.

Approximately 80% of the concepts have been processed without problems, i.e. followed the direct path shown with broad arrows in figure 1. In case of doubt or questions were raised, the Editorial Board and SMEs were consulted. To avoid overload of the Editorial Board, precise translation guidelines were developed.

The translation is an intensive process, and especially the costs of the review board experts are substantial. To control the cost and achieve a high quality, the review feedback loop (between the 2nd translator, NBH, and the Review board) must be strictly managed and optimised.

Discussion

SNOMED CT® is today translated into Spanish, German and GB-English. There is an extensive experience of mapping between SNOMED CT® and other terminologies and meta-thesauruses as well as using natural language techniques. These techniques require that the "natural language" text and the terminology are in the same language. By processing bilingual parallel text corpora it has been possible to identify translations of medical terms in controlled vocabularies, including SNOMED CT®.

These methodologies have not been found to substitute the manual translation of SNOMED CT® to Danish, since the Danish work has been focusing on the concepts behind the terms. A similar focus has been demonstrated feasible in a project where ontology driven tools were used for bilingual translation of coding systems for clinical procedures.

To ensure the provision of scientific and psychological accepted terms is has been crucial to have a close cooperation with clinicians from different specialities and disciplines.

Earlier translation experiences have demonstrated the possibility of semantic drift when synonyms are translated. Therefore synonyms for the preferred Danish terms will be provided in a second phase of the translation.

Provision of synonyms and subsets/catalogues for use in specific situations is seen as crucial to get clinical acceptance. The maintenance of these as well maintenance of the terminology itself, will be a substantial task.

Exchange of experiences on SNOMED CT® translation and multilingual issues is needed. A new International Health Terminology Standards Development Organisation (IHTSDO) will support this. It has been established January 1st 2007 and is hosted in Denmark.

Conclusion

Health care provision is internationalised, and there is an increased demand for valid, structured, and globally standardised data supporting clinical and administrative processes.

Many countries need to manage translation process and the use translation tools, and it is imperative to evaluate the processes closely and exchange experiences. The newly formed IHTSDO is expected support this efforts.

The implementation of SNOMED CT® in practical use must take place in cooperation with the clinical community. Only if a structured terminology can facilitate clinical work processes and provide relevant decision support, the clinicians will produce valid data for the clinical documentation as well as secondary use, i.e. for quality development and management.

An Analysis of Skin Integrity Alerts Used to Monitor Nursing Home Residents

Gregory L. Alexander[a], Brian Hensel[b]

[a]*Sinclair School of Nursing, University of Missouri—Columbia, USA*
[b]*Department of Health Management and Informatics, University of Missouri—Columbia, USA*

Abstract

Few computerized systems have been implemented and evaluated in nursing home systems. The purpose of this descriptive study is twofold: 1) assess the frequency of active alerts occurring in two nursing homes implementing an electronic health record (EHR) with a clinical decision support system; and 2) determine if clinical responses of health care workers are different when a clinical alert is active versus not active. A secondary analysis of de-identified data was performed to derive conclusions about use of alerts to monitor residents' skin conditions in the nursing homes. The percentage of residents who had active skin integrity alerts ranged from 8% to 52%. The majority of time resident skin integrity alerts were active for 1-3 consecutive days. In one facility, 6% of the residents had an active skin integrity alert for 20 or > consecutive days. A total of 118 alerts were analyzed from 59 residents in the analysis of documented clinical responsiveness. No significant difference was found in clinical documentation for responses when alerts were active versus when alerts were not active (N=59, p=1.00). There were just as many clinical responses documented to conditions when alerts were active than when they were not active.

Keywords:

decision support, clinical, computers, handheld, nursing home, information technology

Introduction

Continuing concerns about quality, costs, accessibility, adequacy of oversight, and regulation of nursing homes are driving the need to implement computerized clinical information systems in these settings. Key capabilities of clinical information systems recognized in nursing home settings include improved patient safety, more effective delivery of patient care services, better management of chronic conditions, and greater efficiency [1]. However, in order for nursing homes to adopt and invest in clinical information systems more research and dissemination is need to understand how electronic environments affect clinical processes in the nursing home [2]. This paper describes a secondary analysis of de-identified resident level data obtained from an electronic health record, called One Touch Technologies (OTT). OTT had a clinical decision support system with an automated skin integrity alert system to alert nursing home staff of potential resident skin integrity problems and to facilitate clinical management. The purpose of this evaluation was to 1) describe the frequency of active skin integrity alerts occurring in two facilities during the seventh month (31 days) following implementation of the clinical information system; and 2) determine if significant differences existed between clinical actions documented by healthcare workers when alerts were active compared to when alerts were not active in the EHR.

Background

Technology is changing the way healthcare providers are performing clinical work [3]. Potential uses of computerized technologies in nursing homes include clinical decision support, improved financial analysis, and safety and quality improvement initiatives ([4;5]. Long term care strategists have placed a high priority on educating concerned citizens about the potential for nursing home technology and stimulating interest in the implementation of interoperable EHR's in long term care settings [6;7]. Historically, the process of adopting new technologies has been slow in long term care with as many as 14% of USA's 17,000 Medicare, Medicaid, and dually certified nursing facilities reporting having no computer system at all within the last decade [8;9]. However, this is changing as the benefits of computerization such as better recordkeeping and improved decision making are realized in other nursing systems [10;11].

Clinical Decision Support and Automated Alerts

A CDSS is a computer program that has the ability to facilitate a healthcare provider's clinical decisions. CDSS should aid in problem recognition and should lead to clinical actions that improve resident outcomes. In some cases, these mechanisms have shown to significantly improve clinical practice [12].

In nursing homes, resident assessment data usually associated with the long term care minimum data set is used to document resident conditions in the health record. Predetermined criteria or triggers within the resident assessment data can be used to build electronic decision support tools including alerting mechanisms. Few of these clinical information systems have been implemented in nursing homes.

Even fewer have been studied to determine there effectiveness to enhance clinical actions documented by nursing staff.

Nursing home technology

The OTT system uses wireless real time automated information processes at the point of care. This system incorporates electronic technologies not previously available to the nursing home industry, such as decision support. This new level of data manipulation should have positive effects on the quality of individual resident care by improving detection of potential resident problems through the automated alerts in the CDSS. Recently, evidence of the positive effects of CDSS has been found in healthcare practices using automated alerts to evaluate patient specific clinical variables and clinical decision making [12;13].

One of the defining features of the OTT clinical information systems is the ability to collect data at the patient's bedside using a handheld PDA at the point of care. The technology combines the use of magnetic technology located in the resident ID bracelet and caregiver ID badge to facilitate caregiver accountability for resident care and documentation while being alerted to individual resident needs. The PDA clinical modules provide a template for complete verifiable documentation and interactivity of specific items in the resident record.

The skin integrity alert in the OTT CDDS assists healthcare providers to identify when a resident may be experiencing a skin integrity problem. The skin integrity alerts have an electronic alert calculation that defines the triggers in the data that activate the alert. Alerts and triggers are incorporated into a relational database that uses detailed data elements to make an alert active or not active. Using the infrastructure of the OTT, the goal of this study was to describe the frequency of active skin integrity alerts during one month and to evaluate the skin integrity alert in the CDSS to determine if significant differences existed between clinical actions documented when alerts were active versus when they were not active.

Methods

Two nursing homes, A & B, participated in the study and ranged in size from 180 to 240 beds, respectively. Facility A was in a rural setting and was a government owned facility. Facility B was located in a urban setting and was a not for profit. Both nursing homes were participating in a larger federally sponsored research project designed to evaluate the use of bedside technology to improve quality of care [14]. According to the Centers for Medicaid and Medicare Nursing Home Compare database in February 2005, one month prior to the beginning date of collection, the lowest percentage of occupied beds was in facility A (72%) with the highest in facility B (95%). During this same time period as few as 40% (facility A) and as many as 80% (facility B) of the residents were categorized as having bowel and bladder control issues; these conditions could potentially predispose residents to an increased loss of skin integrity.

Data collection

De-identified data were collected for one month (31 days) following the 6 month post implementation date in both facilities. Data were provided by OTT after fictious, unique nursing home and patient identifiers were assigned in the data sets.

Data collection involved querying each facility EHR during the day at 0700 AM, the start of day shift, on the first day of the month and ending at 0700 AM on the last day of the month. Query data from the alerts was used to assess the average length of time that skin integrity alerts were active on consecutive days at 0700 AM. Finally, while controlling for periods when skin integrity alerts were active, time of day alert occurred, and resident, clinical actions documented in the EHR were counted. Six electronic administrative reports and clinical reports in the HER were used to determine clinical actions documented including: 1) care plan changes, 2) nurse assistant task lists, 3) skin and wound reports, 4) turning and repositioning reports, 5) toileting reports, and 6) progress notes.

Data analysis

To meet the goals of the research the analysis plan involved three steps. During the first step the average number of residents occupying the facility per day was determined, overall average frequency of active skin integrity alerts per day that were active at 0700 AM was calculated and the range of active skin alerts/day active at 0700 AM for all patients was recorded for each facility (Table 1).

Table 1. Frequency of active skin integrity alerts

Facility	Ave. Number of Residents	Ave. Frequency of Active Skin Integrity Alerts/day	Range of Active Skin Integrity Alerts/day
A	136	21	11 – 34
B	225	93	68 – 118

During step two the length of time skin integrity alerts were active on consecutive days at 0700 AM was tabulated. This step enabled us to calculate the number of residents in each facility that had no active alerts versus those that had 1 or more active alerts during the same period on consecutive days. Categories for active skin integrity alerts in consecutive days were operationalized by counting the number of days at 0700 AM when an alert was active; for example, if a resident had no active alert on

Monday, an active alert on Tuesday, and no active alert on Wednesday of the same week this episode was added to the 1-3 day category. Categories for length of time alerts were active were created where natural breaks appeared in the data. Categories included no alerts during the month, alerts that were active consecutively for 1-3 days, 4-9 days, 10-19 days, and 20 or greater days. The category no alerts, was an indicator of the number of residents who had no active alerts occurring during the 31 day period (Table 2).

Finally, in step 3 the frequency and types of clinical actions documented by staff during an active skin integrity alert versus when the alert was not active for the same resident was calculated. The day of the week and time of day alerts were active and not active was controlled for to offset any confounding affects of changing staff schedules during the week. For example, if an alert was active on Monday, a similar time period

Table 2: Length of time in consecutive days skin integrity alerts were active

Facility	Ave Number of residents	Total Number of Days in month	No Active Alerts	1-3 Days	4-9 Days	10-19 Days	20 or > Days
A	136	31	44	293	18	3	1
B	225	31	17	834	137	31	13

one week later when an alert was not active was selected to compare clinical responses documented on the same resident. Only alerts from facility B are analyzed here to minimize differences in documentation and clinical practices between homes. To test the hypothesis that there would be differences in the proportion of clinical actions during a period when a skin integrity alert was active versus not active a McNemars test was calculated. All statistical processes were performed using SPSS 13.0.

Results

Comparisons of the daily alert frequencies for home A and B were tabulated (Table 1). Facility A had fewer residents than facility B and also had few average active alerts during the day. The percentage of residents with an active skin integrity alert on their EHR at least once during the day ranged from 8% in facility A to 52% in facility B. The range of active alerts in facility B was also larger than facility A during the study period.

Results of the average length of time skin integrity alerts were active as measured by the number of consecutive days alerts were active in the EHR at the 0700 AM query are shown in Table 2. In facility A, 44 of 136 residents (32%) had no active skin integrity alerts during the month. Conversely, 78% of the residents had an active skin integrity alert in their record. The majority of those active akin integrity alerts in facility A occurred over 1-3 consecutive days. Only 1 resident had an active skin integrity alert for 20 or greater consecutive days at 0700 AM.

In contrast, only 8% (17/225) residents in facility B, which had a higher daily census, had no active skin integrity alerts during the month (Table 2). Ninety two percent of the residents had an active skin integrity alert; the majority of these were present for 1-3 consecutive days at 0700 AM. Thirteen residents (6%) had an active skin integrity alert over 20 or greater consecutive days. Skin integrity alerts had a very frequent change of status from active to not active with most lasting from 1-3 consecutive days.

The final analysis in this project compared clinical responses documented during periods when alerts were active and not active to determine if this could be a factor in the frequently changing status of the alerts activity. A total of 118 alerts were analyzed from 59 residents residing in facility B. Table 3 illustrates that there was no significant differences in clinical responses during periods when alerts were active versus when alerts were not active (N=59, p=1.00). There were just as many clinical responses documented to conditions when alerts were active than when they were not active.

However, further investigation using the administrative turning and repositioning reports in the EHR revealed that 39 out of 58 residents (67.2%) who had no documentation on the date a skin integrity alert became active had documentation on turning and repositioning when the alert was not active at the exact same time a week later. In comparison, electronic nurse assistant task lists,

Table 3: Analysis of Clinical Responsiveness to the Skin Integrity Alert

		Alert Active		Number residents	††Exact sig. *P*
		Clinical Response Absent	Clinical Response Present		
Alert Not Active	Clinical Response Absent	1	6	7	*1.00*
	Clinical Response Present	6	46	52	
Number of residents		7	52	59	

††McNemar's Test

used to communicate important resident tasks between nurses and nurse assistants, were used very little to delegate skin integrity care planning. Of 46 residents that had no documentation on the task list related to skin integrity when the alert became active, 100% had no documentation a week later when the alert was not active.

Discussion

The results of this study indicate there is substantial difference in the average daily frequencies of active alerts between the participating nursing homes. Even after adjusting for daily occupancy differences by calculating the average daily percentages of residents with active alerts, facility B had substantially more 41% than facility A (15%). One possible reason for the differences could be that 50% fewer residents had been reported nationally in NHC in facility A vs. facility B with bowel and bladder control issues [15]. Fewer residents with incontinence problems might reduce the frequency of skin integrity alerts that occurred in facility A. This makes intuitive sense since bowel and bladder voiding are two data triggers in the EHR relational database that can cause an alert to become active.

The frequent change of status in the alerting mechanism from active to not active could not be explained by the clinical responses documented by staff in the EHR. Documentation of clinical responses in care plans, skin and wound reports, toileting, and information in progress notes were not significantly affected by active alerts in the HER. Finding indicate a uniformity in clinical interventions whether alerts were active or not. Such consistency can contribute to quality assurance and prevention. It also raises questions about responsiveness to new clinical information generated by a CDSS.

An exception is seen in the administrative turning and repositioning reports. In more than half the cases where active alerts existed, it appeared that documentation on turning and repositioning residents occurred during a one week period starting with an alert being active and ending with the alert being not active. This is a positive finding because another trigger which can active a skin integrity alert in this specific EHR relates to the frequency of occurrence of turning and repositioning. Although there was not significance found between the clinical responses documented and active/not active clinical alerts, there was increased documentation on turning and repositioning following an active alert. However, interventions for skin integrity following an active alert, such as turning and repositioning, do not appear to be carried through on documentation contained in automated nurse task lists. This raises the question whether, ideally, alerts should automatically generate selected, evidenced based nurse aide tasks such as more frequent turning and repositioning for residents for which this is authorized by a nurse.

Prevention of skin ulcers is a central goal of nursing homes. This study contributes to knowledge about the potential role of CDSS technology in effectively pursuing this goal. Limitations of this study include the small sample size, small time frame for gathering alert data, and reliance on secondary data analysis to confirm clinical responsiveness.

Application

Widespread adoption of CDSSs such as OTT will largely depend on how much they contribute to effectiveness and efficiency of nursing care. Staffing levels in nursing homes make it challenging to meet all of the physical needs of residents. As compared to acute care, there is a higher proportion of nurse aides to licensed nurses and onsite physician visits are less frequent. CDSSs have potential to contribute to effectiveness in care by identifying and alerting nurses to patterns in EHR data that indicate possible resident problems, thus facilitating earlier interventions. They could contribute to efficiency by reducing nurse time in assessment and detection of some problems and by recommending and possibly even facilitating some interventions.

As an active [16] CDSS, the OTT alerts nurses to potential skin breakdown based on underlying risk factors. Such risk scenarios may sometimes otherwise be missed, leading to development or worsening of pressure ulcers. In this way, the CDSS functions as an additional intelligent processor of otherwise discrete data inputs in the EHR. Ideally, CDSSs are supplemental in assisting nursing home staff in delivering care.

In addition to assisting in assessment, CDSSs like OTT recommend and can even facilitate associated interventions. For pressure ulcers, more frequent turning and repositioning is one recommendation. This can be automatically added to nurse aide task lists, thus increasing efficiency for nurse case managers and possibly facilitating more timely response by aides. Other tasks that might be automated include ordering and increasing inventory levels of associated supplies. Furthermore, CDSS alerts may influence staffing assignments and allocation.

CDSS information, including alerts and associated responses, can potentially enhance a facilities quality assurance oversight and quality improvement analyses. CDSSs and other electronic documentation should reduce time otherwise involved in manually compiling summary information form chart reviews. In addition to improving quality, this may be helpful in meeting facility licensure and other regulatory requirements. To the extent that CDSSs contribute to quality, they may contribute to market demand for a facility and thus to its occupancy level and associated financial viability. Word of mouth about quality is the most important factor in nursing home selection [17].

Lastly, CDSSs may contribute to research-based knowledge of nursing home performance. Electronic documentation facilitates faster tabulation of data than manual chart review. This could contribute to research

with larger samples, thus allowing generalization and associated advancement of theory. CDSSs in particular allow for examination of process responses to alerts and recommended interventions, and their differential effects on clinical outcomes.

Conclusion

This study does not conclusively show that a CDSS with alerts is beneficial to nursing home residents and staff who care for them. Further research is needed to evaluate these types of electronic tools in nursing homes to determine effectiveness. Important considerations for future research using CDSSs for skin integrity include association of alerts and evidenced based clinical process responses with skin integrity outcomes.

An Analysis of Skin Integrity Alerts Used to Monitor Nursing Home Residents

by

[a]Greg Alexander PhD, RN
[b]Brian Hensel PhD

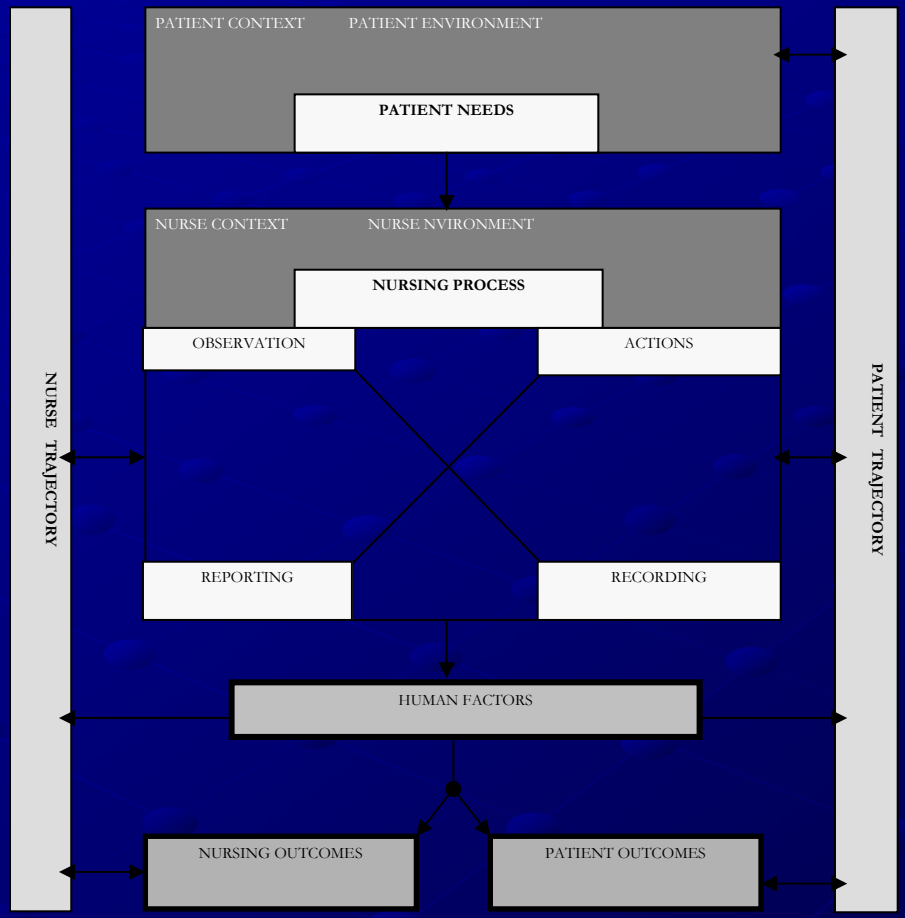
[a]University of Missouri-Columbia USA, Sinclair School of Nursing
[b]University of Missouri-Columbia USA, Department of Health Management and Informatics

Study Objectives

The objectives are twofold:

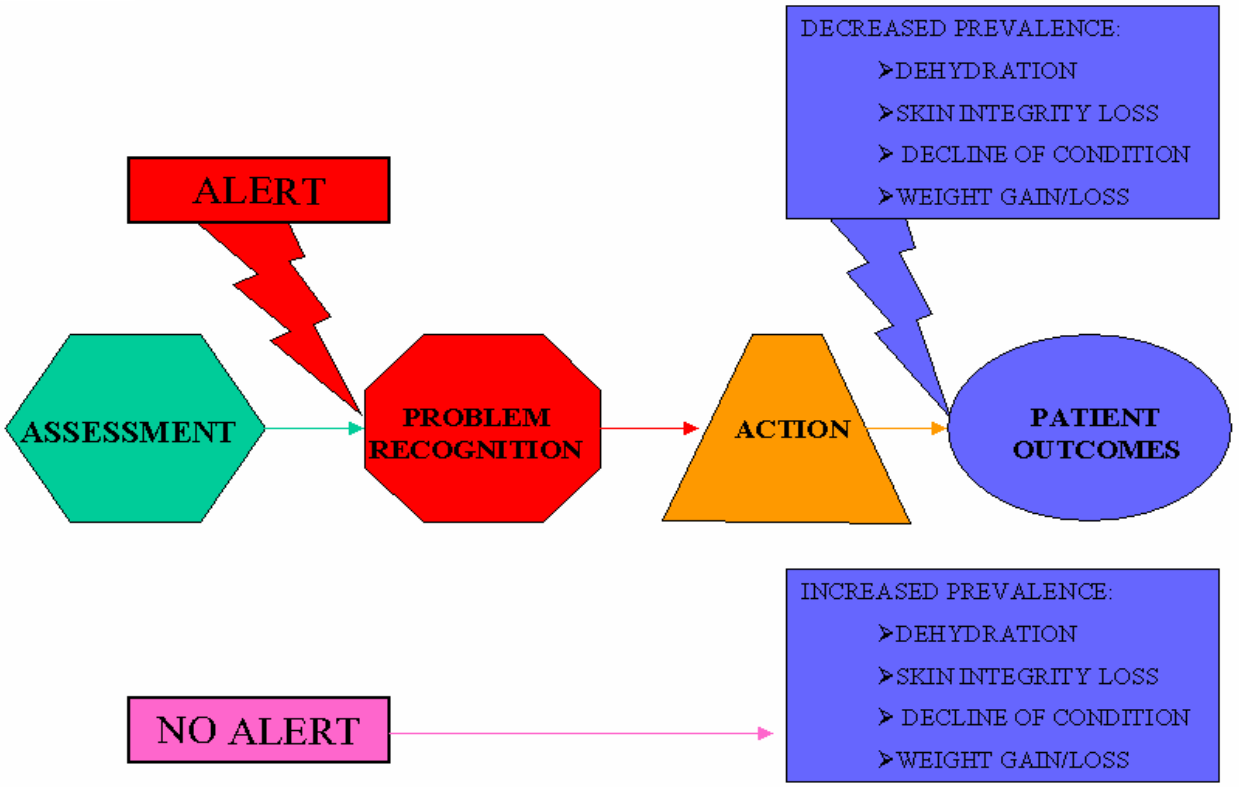
1) Assess the frequency of active skin integrity alerts occurring in two nursing homes implementing an electronic health record (EHR)
2) Determine if clinical responses of health care workers are different when a clinical skin integrity alert is active versus not active.

The Nurse-Patient Trajectory Framework



Alexander, GL (2007)

A Model for Clinical Decision Support Systems in EHR



Automated Clinical Decision Support in Nursing Homes

- Information systems using automation to direct nursing home staff are absent in most nursing homes
- There is limited research that considers electronic medical records (EMR) and clinical decision support in nursing homes.

(Schnelle, Bates-Jensen, Chu, & Simmons, 2004)

Background and Definitions

Clinical Decision Support System: Automated system that supports clinical decision making

Clinical Alert System: System that monitors a continuous stream of data and automatically generates a message (alert) in response to patterns that may require action

Clinical Alert: A decision support mechanism which serves as a part of an alert system that automatically detects changes in critical assessment data and notifies the healthcare provider

Example: dehydration

Trigger: Established criteria for when an alert will become active

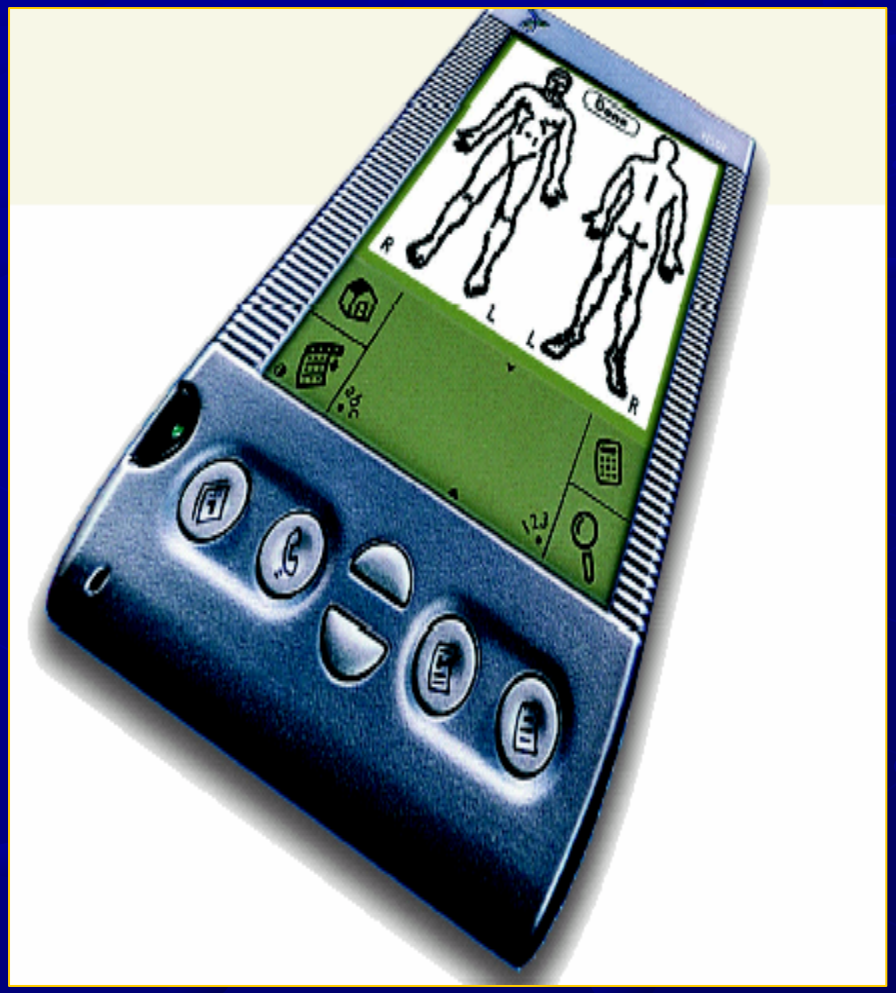
Example: Fever reported in last 24 hours

Description of Study

- Design: Descriptive analysis of 6 months of clinical alert data (beginning 6 month post implementation of OneTouch Technology)
- Setting: Two nursing homes
- Participants: Midwestern nursing homes where administrative staff had committed to implementing OneTouch clinical decision support system.

Partnerships in Nursing Home Technology

OneTouch Systems



- Bedside data collection using handheld and wireless devices
- Electronic charting and reporting
- Automated Minimum Data Set and Risk Assessment Protocols
- Accountability for caregiver activities and risk management
- Automated clinical alerts and triggers
- Electronic Medication Administration Record (eMAR) using wireless touchscreens on medication carts.

Results Objective 1

Table 1. Frequency of active skin integrity alerts

Facility	Ave. Number of Residents	Ave. Frequency of Active Skin Integrity Alerts/day	Range of Active Skin Integrity Alerts/day
A	136	21	11 – 34
B	225	93	68 – 118

Table 2: Length of time in consecutive days skin integrity alerts were active

Facility	Ave Number of residents	Total Number of Days in month	No Active Alerts	1-3 Days	4-9 Days	10-19 Days	20 or > Days
A	136	31	44	293	18	3	1
B	225	31	17	834	137	31	13

Results Objective 2
Clinical Responsiveness to Active Skin Integrity Alerts

		Alert Active		Number of residents	††Exact sig. *P*
		Clinical Response Absent	Clinical Response Present		
Alert Not Active	Clinical Response Absent	1	6	7	*1.00*
	Clinical Response Present	6	46	52	
Number of residents		7	52	59	

††McNemar's Test

Discussion

- There is substantial differences in average daily frequencies of active alerts in NH (Facility B had more than Facility A.)
- The frequent change of status in the alerting mechanism from active to not active could not be explained by the clinical responses documented by staff in the EHR.

Application

- Widespread adoption of CDSSs in NH will largely depend on how much they contribute to effectiveness and efficiency of nursing care.
- CDSSs have potential to contribute to effectiveness in care by identifying and alerting nurses to patterns in EHR data that indicate possible resident problems, thus facilitating earlier interventions.
- CDSS information, including alerts and associated responses, can potentially enhance a facilities quality assurance oversight and quality improvement analyses.
- CDSSs may contribute to research-based knowledge of nursing home performance.

Abstract

In 2004, the European Network of Excellence INFOBIOMED (http://infobiomed.org) (IST-507585) was set to consolidate a stable and lasting European network with BMI as an essential discipline for the future of healthcare through the work carried out in the four pilots in which the 17 European partners participated. INFOBIOMED had six work packages one of which was Dissemination & Communication that coordinated all the information policy of the NoE both to the scientific community and to other stakeholders. The objective of this paper is to describe the development and implementation of the INFOBIOMED Gateway, a repository for compiling, organizing and disseminating the latests news about Biomedical Informatics, mainly in Europe but also in the rest of the world.

Keywords:
bioinformatics, medical informatics, biomedical informatics, repository, INFOBIOMED

Introduction

The EU's sixth framework program that is about to finish (2002-2006) has had as one of its main priorities life sciences, genomics and biotechnology for health. In February 2003, the EU BIOINFOMED project (http://bioinfomed.isciii.es/) "Prospective Analysis of the Relationships and Synergy Between Medical Informatics and Bioinformatics" [1, 2] ended with the publication of a White Paper [3]. The document detailed 18 research lines identified and prioritized to help consolidate the integration of the genetic information in the field of public health through the application of the Information and communication technologies. It analysed in detail all synergies that take place between two well established disciplines, Bioinformatics (BI) and Medical Informatics (MI

The Network of Excellence (NoE) INFOBIOMED [4-8] titled "Structuring European Biomedical Informatics to Support Individualised Healthcare" is funded by the Information Society Directorate-General of the European Commission within the VI Framework Programme for Research and Technological Development. The Network is composed of 17 research groups from 9 different European countries. Its main objective is to establish a stable and lasting European network in BMI. With this objective in mind they designed 4 pilots in which collaborative work between heterogeneous (MI, BI, BMI, Health care) research groups is essential.

The network is divided into six work packages (WP): Coordination, Dissemination and communication; Training and Mobility; Data Interoperability & management; Methods, technologies & tools and Pilot applications. Under the umbrella of this work package some communication materials such as newsletters, web page, brochure, oral communications, posters, etc have been developed to disseminate the work carried out in the network. However, dissemination is a still a challenge when it is necessary to keep the community updated about the wide spectrum of possibilities available through the Internet. Lots of resources are necessary for this task.

The great variety of resources available, the heterogeneity, the geographic distribution of the different research groups and the large number of publications indexed in pubmed prompted the development of a tool that specifically gathers together all materials produced in the world about BMI.

Materials and methods

New Biomedical data is mainly reported through journals and conference proceedings. These publications do not present a structured pattern which would make possible the use of data mining or knowledge discovery techniques and tools to include in an automatic manner this new information into ontologies. It is also important to take into account the increasing number of publications with biomedical information. This makes it very difficult for human curators to extract all the information. Some companies are trying to tackle this problem, in particular IBM is working on the development of a Semantic Web for Life Sciences. The idea is to use lexico-syntactic patterns to find biomedical relations in the internet. [10]

The BIOINFOMED Study compiled a resources guide that listed a large number of biomedical information resources grouped into the following categories: Standards in BI, BMI and MI, Scientific Societies and Working Groups, Journals in BMI, Congresses in BMI, Groups and Projects,

Papers in BMI, Books in BMI, Training programs in BMI and Links in BMI.

One of the main objectives of the INFOBIOMED project is to keep the guide updated, as an essential tool for classifying, organizing and disseminating the ever increasing number of research projects, groups and articles about BMI. With that objective in mind basic aspects such as searches and storage of the information included in the guide has been notably improved. These processes are now more efficient that the traditional list of links in html web page, that had to be edited by hand.

Informatics specialists built for INFOBIOMED the "Biomedical Informatics Gateway", a database designed with SQL server and implemented with PHP so that it could grow indefinitely. It can be updated from any computer through a secure access protected by a user id and a password. The INFOBIOMED webpage is hosted in the servers of one of the partners, which is also the coordinator of the project, the "*Fundació IMIM"* (FIMIM), in Barcelona, Spain. Data capture in the data base can be done from any computer with an internet connection from the restricted area of the website. However most of the loading and filtering of the contents of the Gateway is done by the ISCIII. For this purpose and for preserving gathered data a secure access interface has been implemented.

Once the user has been validated, the user accesses the main administration screen, organized into four sections: *Events and Announcements, Training, Repository and Links*. Each section includes its own fields which will later be seen in the Gateway. For example, the fields included in the section *Events and Announcements* are table ID, that is the primary key, title, which also is the hyperlink to a webpage, date the event takes place, location, country, status (it shows if the entry has any information and whether it has been filtered by an authorised user), insert Date, last Updated, user that has updated the contents and Topics/ Entities. This is the only field that can be edited by the user through a pop up window. It provides information about the user that is validating the data, the title of the event which corresponds with the hyperlink to its web site, the dates and the location of the event. The filtering of the events is done by clicking on the boxes that characterise them and places them in their place in the Gateway.

The hierarchy of the resources was developed following two organizing criteria: topics & entities. There are 19 topics, 18 of which coincide with the 18 research lines initially identified and a general topic titled "Initiatives integrating several Research Lines".

The loading data in the Gateway can only be done by a authorised user but the information can be proposed for entry by any of project partners or any other stakeholder interested in their information appearing on the web. The filtering of the data captured by an authorised user taking into account the topics and entities is what determines whether or not the information will appear in the database and under what topic.

Results

The INFOBIOMED Gateway (http://infobiomed.org) is a free access tool for the compilation, storage and retrieval of biomedical informatics information. This is structured in a database and it is regularly updated. Queries are simple and direct through a web interface and are divided into two categories: topics and entities. The tool was developed with the idea of disseminating all activities carried out in the field of BMI to the scientific community in a filtered and organised manner. The topics coincide with the 18 lines identified in the BIOINFOMED project with the addition of another general line: *Initiatives integrating several Research Lines.* Through this we can retrieve all the information included in those entries in the database that involve several research lines simultaneously.

The interface of the Gateway resembles a chess board in which the topics are in the row and the entities are in the columns. There are different ways to make the queries: i) free-text query, there is a box for free text queries that opens a popup window with the results of the query if there are any; ii) query by topics: if you click over any of the 19 titles of the columns, you will get a new window that will show all the entities related to the subject, such as standards, congresses, working groups; iii) query by entities: it is possible to visualize all Congresses in all the topics if we click on the column titled "Congresses" and iv) individual queries: each of the squares makes an individual query for the chosen topic and entity. All queries are visualised by hyperlinks that take directly to the website to which they refer.

Conclusions

One of the main objectives of the NoE is to provide the bases for a stable and durable European structure in the field of BMI. The dissemination to the scientific community and other stakeholders of the objectives, work methodology and results help achieve this goal. This is usually done through the traditional channels but it has now also found in the Internet a way of globalising its discoveries and communicating information.

The easy access and the low cost of the infrastructures help publish and disseminate making it easier to share research results and all new information. However, with the increasing amount of information published, storing, organizing and disseminating all the available biomedical information are the new challenges faced by our society.

The INFOBIOMED Gateway is a tool that tackles this challenge and meets all the criteria: free and easy access through the Internet, updated information and specific to one field: Biomedical Informatics. It is a point of reference, just like the website, for finding the latest news about the 19 lines of research that were identified and detailed in the agenda developed by the BIONFOMED project and that are now part of the INFOBIOMED project.

Monitoring Clinical Pathways

Chris J.Kooijman[a], Elise Bijvank[b]

[a] *VU University Medical Center, Information Management, Amsterdam, The Netherlands*
[b] *VU University Medical Center, Quality Improvement Program Manager, Amsterdam, The Netherlands*

Abstract

This paper describes the development of a monitoring system for Clinical Pathways. Data are collected from existing data sources, which proved much more efficient than manual data collection. The DBC, the recently introduced Dutch equivalent of the DRG, proved to be a useful data source. With the system it is possible to monitor several indicators for a given pathway.

critical pathways, quality indicators, total quality management, information storage and retrieval, diagnosis-related groups

Introduction

Health care organizations are seriously challenged to deliver cheaper and better services. To achieve this goal, improvement programs are launched on the local or national level. An example of a national improvement program is 'Sneller Beter', Dutch for 'Quicker Better', which was launched in the Netherlands in 2004 [1]. The program started out in 8 hospitals, with 16 more in the following two years. These 24 hospitals were selected to set examples of good practice for the other 80 hospitals in the Netherlands.

Improvement requires measurement[2]. In all quality improvement methods, like Six Sigma or TQM [3], measuring plays an important role. Measuring can be done either manually or with the help of a computer. Of course, if automation is possible, this will be much more efficient [4].

A widely accepted method of improvement of hospital care is the implementation of Clinical Pathways. Clinical Pathways (also referred to as Critical Pathways or Care Paths) are multi-disciplinary plans of best clinical practice for specified groups of patients with a particular diagnosis that aid the coordination and delivery of high quality of care [5]. Just like other improvement methods, this method requires measurement to assess the standards of care as they evolve during and after the Clinical Pathway implementation [6].

In the Netherlands, the interest for Clinical Pathways was boosted by the 'Sneller Beter' improvement program. Many hospitals have started to develop Pathways within or outside of the 'Sneller Beter' program. However, many hospitals also struggle with the measurements that are needed. If this is done by hand, this poses a serious question to available resources. What if this could be automated?

The VUmc Hospital is one of the eight hospitals that participated in Sneller Beter from the very first start. The question of automation of measurements for Clinical Pathways came up at the end of 2005, when several Pathways were implemented, but there was no permanent monitoring of results, because manual data collection was too labor-intensive.

In this article the method of constructing such an automated monitoring system is discussed, with the difficulties encountered, and the results are shown.

Methods

The construction of a monitoring system for Clinical Pathways comes down to the following steps:

1. Selection of patients
2. Calculation of indicators
3. Presentation of indicators

An additional step is necessary beforehand, if the data that is going to be used is not available in an easy-to-access database. In that case extractions need to be built, to load the data from one database into another. In the VUmc we could use the hospital data warehouse, therefore this extra step was not necessary.

The three steps will now be discussed in more detail.

1. Selection of patients

Many hospitals implement Clinical Pathways, but do not run an automated Clinical Pathway planning system. The VUmc is not an exception. This makes the first step of building a monitoring system the hardest one. Which patients are 'in' the pathway, and which patients are not? Only if a correct patient selection can be made, it is possible to calculate indicators for these selected patients. There are several data sources available to solve this question. In the VUmc we used the recently introduced DBC, the Dutch equivalent of the DRG. DBC stands for Diagnosis Treatment ('Behandeling' in Dutch) Code. Linking DBCs/

DRGs to Clinical Pathways is not uncommon [7]. Table 1 shows the items which are included in the DBC registration. An exception is the last item, the DBC Profile. This is a collection of procedure data, which is automatically linked to a DBC by a special algorithm. We include it here, because we will discuss its usability for the monitoring system.

Table 1 - DBC items

Item	Description
Patient ID	Unique patient number for the VUmc hospital
Treating Medical Specialty	E.g. internal medicine, gynaecology, orthopaedic surgery
Opening date	The date of the first encounter with the medical specialist
Closing date	The date the specialist refers the patient back to the GP or to another specialist
Type of Patient	Either new patient or known patient
Diagnosis	A classification of the disease of the patient, on a slightly higher level of granularity than ICD9 or ICD10
Treatment	Depending on the specialty, e.g. operation with hip replacement. This item includes the setting, e.g. inpatient or outpatient
DBC Profile	all the necessary procedures which were applied for this patient, between opening date and closing date, for this medical specialty. On the basis of the DBC profile, the hospital is able to calculate the average cost of a certain DBC.

For the patient selection, the items Treating Medical Specialty, Opening Date, Type of Patient, Diagnosis and Treatment were used. Only "new" patients were selected, and for some pathways only those patients with an inpatient treatment.

The dashboard shows the results only for patients from the current year, therefore selection is also made on Opening date.

For every particular pathway, the selection criteria of DBC-items should be identified that match the pathway. However, this is not a single-step-process. After a first selection is made, the selected patients should be matched with some other data source. In the VUmc it was possible to use spreadsheet-administrations of nurses who had been assigned this task. If there is no matching data source available, then a doctor or nurse who is strongly involved in the Clinical Pathway should check the DBC patient selection. This matching process can be the basis for a refinement of selection parameters. After a new selection is made, the result should be validated again. The process repeats itself until a sufficient level of confidence in the DBC selection method is reached.

The results of the matching process in the VUmc will be discussed in the results section.

2. Calculation of indicators

There are several types of indicators for Clinical Pathways [8].

The most important are Clinical, Financial and Process indicators. In the Sneller Beter program, process indicators were the main focus of the CP development. Examples of indicators are waiting time for an operation and length of stay.

Many of the indicators are shared between Clinical Pathways. This means that if an indicator is developed for one Pathway, it can be used by many other Pathways, if appropriate patient selection is applied.

We searched the hospital database for appropriate data items.

One of the difficulties encountered here, was that Clinical Pathways are, in fact, multidisciplinary. Therefore it was not possible to use only procedure data from the DBC profile. DBCs are monodisciplinary, so only procedures from a single medical specialty are part of it. For this reason, database selection needed to be extended beyond the DBC data.

Table 2 shows indicators and data sources from which they can be drawn.

Table 2 - Indicators and data sources

Indicator	Data sources
Access time to first encounter with specialist	DBC Opening date, Outpatient planning system
Time to diagnosis	DBC Opening date, Procedure data
Number of visits before admission	Procedure data, ADT data (admission-discharge-transfer)
Waiting time for admission	Inpatient planning system
Length of Stay	ADT data
Time between diagnosis and surgical operation	Procedure data, operating system data
Time between diagnosis and radiotherapy	Procedure data
Costs	DBC profile
Readmissions	ADT data

Of course, similar as with the selection of patients, the quality of the data sources should be checked before they can be used. If, for instance, procedures are not properly coded in the hospital, a lot of these indicators cannot be calculated. Fortunately in the VUmc the quality of these data sources was sufficient. The 'Costs' indicator was limited to the costs of the DBC, used for the patient selection.

For some indicators the problem is not data quality, but simply the availability in electronic format. This was the case for the indicator 'number of complications'. The VUmc does not yet run an organisation-wide complication registration system.

The indicators are first calculated per patient, and then an aggregation is made to the level of the Pathway. The aggregates are calculated on the basis of

- median values (e.g. waiting times, length of stay)
- percentages (e.g. operated patients, readmissions)
- totals (e.g. number of patients in the pathway)

3. Presentation of indicators

We developed a dashboard based on Cognos [9] and HTML technology. For management information, this type of dashboards already existed in the VUmc hospital, showing indicators like production rates, absence ratio of personnel and average waiting time for admitted patients. This dashboard is accessible through the intranet. An important feature of the system is the possibility to enter target values, e.g. a length of stay of 4 days. If reality shows that the median value for length of stay is more than 4 days, a "red flag" is shown, indicating that length of stay is above the target level.

In the results section three screen examples are shown.

Results

At the time of writing of this article (November 2006) dashboards have been developed for three Clinical Pathways, Head-Neck Oncology, Carotid Surgery and Abdominal Aorta Aneurysm repair. These Pathways showed a good agreement between manual and automated (DBC) data sets.

An important finding was the fact that manual data collection did cost the nurses, who were assigned this task, up to 4 hours a week for a single Pathway. The development of the dashboard system for the three Pathways did cost about 200 hours (mainly from the first author, a database specialist).

We show three examples from the application. The indicator values which are shown are not completely based on reality, but are only provided for illustration purposes.

Figure 1 shows an example dashboard for head-neck oncological patients. The report shows three subsections: Financial, Logistics (which contains the most indicators) and Clinical. Every indicator line displays name of the indicator, target value, current value and previous value. At the right part of the screen there are 2 hyperlinks, which give access to additional information.

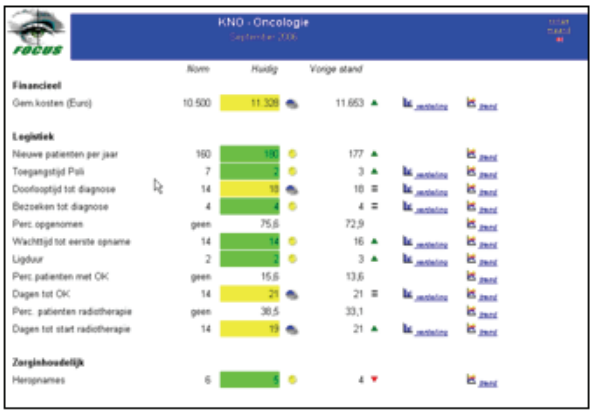

Figure 1 –Monthly overview of indicators for a certain Pathway

Figure 2 shows an example of what shows up from the first hyperlink, a bar chart of indicator values for all the individual patients in the Pathway. This particular graph shows the number of visits to the outpatient clinic, before admission. This graph gives a good insight in the number of outliers. Notably, not for all patients a value is presented. This is due to the fact that for this Pathway included patients do not need an inpatient period. If no inpatient period is found, then the indicator "Number of visits until admission", can not be calculated for this particular patient.

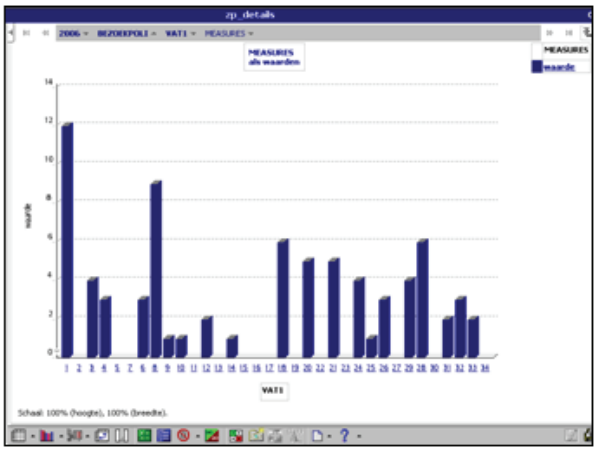

Figure 2 -Indicator scores per patient

Figure 3 shows the development of a certain indicator through the year, together with the target value (horizontal line). The values are based on aggregates (median values) for all patients from January up to the specific month. This example shows the access time for the outpatient clinic, which was seriously improved, but on aggregate still remained above the target of 7 days.

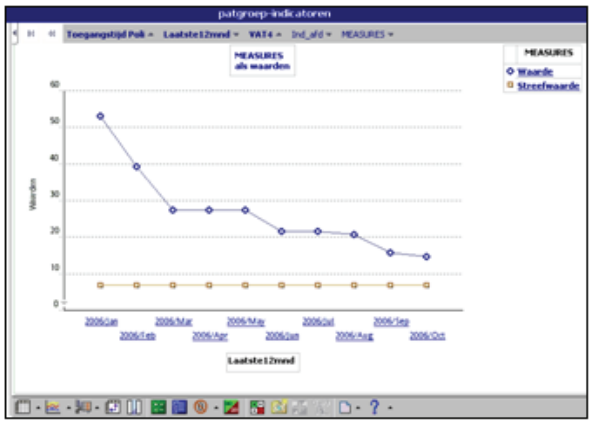

Figure 3 – Development of indicator through the current year

Discussion and future developments

From the hours estimated necessary for manual versus automatic data collection, it is clear that the investment in developing a system for automatic data collection is quickly returned. If for the three Pathways we estimate 10 hours of work a week by a nurse, then the 200 hours by the database specialist are returned in just 20 weeks. Moreover, the system can be used for additional Pathways, which will lower the cost per Pathway. As we described in the method section, once an indicator is developed, it can be used by all the Pathways defined in the system. However, additional effort will always be necessary for the first step of the process, setting up the right criteria for patient selection. The VUmc is planning to develop more than 100 Clinical Pathways in the coming five years.

A difficulty with the system is that it is not completely clear who its users are. Primary users of dashboards in general, are those who are responsible for the particular management unit. Because Clinical Pathways are multidisciplinary, it is not always easy to find an 'owner' of the Pathway, who is also a primary user of the monitoring system. This management question is still to be addressed by VUmc senior management.
Secondary users, who have an interest in the Pathways, but are not primarily responsible, are for example quality assurance staff, who are assisting with Clinical Pathway development, and senior management.

The system was first developed in the VUmc hospital, but another hospital, the Atrium in Heerlen, asked to do the same there. A prototype was developed, using the method as described above. The main difference was that the patient selection was not carried out on the basis of DBC data, but on planning data. However, no results are available from a matching analysis between automated and manually collected data, as carried out in the VUmc hospital.

A drawback of the system is that in the first part of the year, the number of patients will be relatively low, therefore indicator values will not be as reliable as in the second part of the year. This will be particularly true if registrations are lagging. For example, it can take a while before a DBC is completely coded. If this includes the items which are necessary for the selection for the dashboard, then the patient will be 'missed'. In the VUmc, the care administration staff has a major job in keeping the DBC registration up to date.

Conclusion

The monitoring system is a valuable tool for the VUmc to develop and maintain Clinical Pathways. Although in this case information technology does not bring any improvements to the care process itself, it does support the improvement potential of Clinical Pathway implementation. In this sense, it also contributes to the realization of a sustainable health care system.

Abstract

Physician Profiling is an analytical tool used to provide information on health care processes and it is based on the generation of different indicators whose purpose is to optimize clinical outcomes. The Hospital Italiano de Buenos Aires created a Physician Profiling Program for family physicians in its Health Maintenance Organization (HMO). The indicators used were based on the Health Plan Employer Data and Information Set (HEDIS). In order to generate and view those indicators, a software program that showed results of every indicator in graph format was developed. The aim of the present study is to describe the development and implementation of such software.

Keywords:

physician profiling, HEDIS, quality indicators, health care

Introduction

Quality monitoring and quality improving are usually related important issues in health care organizations. They both attempt to promote medical care through clinical guidelines and patients' satisfaction.

Deficiencies in healthcare account for the need of monitoring quality patterns. Quality monitoring is usually reported in the medical literature under three categories: (A) Patients who do not get health care benefits; (B) Patients who get unnecessary treatments; (C) Low-frequency use of some interventions [1].

Physicians' work overload as well as their multiple daily duties often result in small deficiencies in health care, which can be easily detected through monitoring tools. Health care quality can be measured either by watching health care processes (e.g. preventive practices delivery) or by health outcomes (e.g. morbidity and mortality rates) [2].

A useful tool for measuring health care processes is **Physician Profiling**, which generates information on health care processes usually by means of data from electronic transactions which provide medical care indicators.

The Hospital Italiano in Buenos Aires is a high-complexity University Hospital with 650 inpatient hospitalization beds and 23 outpatient health care centres distributed between the City of Buenos Aires and the surrounding metropolitan area. It has a pre-paid medical insurance plan called *Plan de Salud* with 140,000 members at present. It delivers 150,000 outpatients visits and 3,000 inpatients admissions monthly. Since 1998, both clinical and administrative issues are registered in a comprehensive health information system [3] . Due to the need to monitor the health care quality of our Hospital Italiano *Plan de Salud*, a physician profiling program has been implemented to measure the performance of interventions at our Institution. The program was created following HEDIS measurements and the indicators were shown to different primary health care physicians by means of a software program which allows for the graphic representation of these indicators. The aim of the present study is to describe the development and implementation of this tool destined to profile primary health care physicians at the Hospital Italiano in Buenos Aires.

Methods

In 2003, to carry out this project, the Family Medicine Unit together with both the *Plan de Salud* Quality Area and the Department of Medical Informatics started the development of a number of health care indicators based on Health Plan Employer Data and Information Set (HEDIS) measurements [4]. HEDIS was created by the National Commission for Quality Assurance (NCQA) in the USA to assess and compare different health plans.

In our case, we used HEDIS to measure intervention performance at the population level. It was not our aim to compare results with other institutions.

Fifteen HEDIS measurements –out of approximately 60— were selected for the creation of these indicators, which were based on cancer screening and control of most frequent diseases. Each indicator was determined by an

equation whose numerator and denominator emerged from an adjustment of the HEDIS measurement selected. For example, the indicator for screening breast cancer was composed as follows:

NUMERATOR: Women with a biannual breast echography or mammography.

DENOMINATOR: 40-75 year old women. No limit to number of patients.

Once indicators had been determined, data was collected and entered into a database. Collected data included patient identification and some other information like period of time measured, age, birth date, hypertension readings, diabetes, last glycosylated haemoglobin (HBGli), LDL and HDL measurement, etc. It later became necessary to establish the source of the data being fed into this database, namely, whether it came from clinical or administrative databases.

Having determined the parameters and collected the data, a web-technology-based interface was designed. The programming language used was PHP 4.0 and MySQL was used as a database. This interface allowed for the graphing of indicators over a year both from the individual viewpoint of each physician and from the institutional standpoint. Figure 1 shows the graph that depicts indicators and their local outcomes in one column (Outcomes) and the desired outcomes according to the bibliography in the other (Goal).

This software was accessible from the Personal Information Section of the Hospital Intranet. For Privacy and Confidentiality reasons regarding personal information, and in order to avoid either political or personal conflicts between our professionals, each physician had access to his/her own results only.

Results were presented in a radar graph, where each axis represented one of the 15 indicators selected.

On the other hand, it was also possible to establish comparisons through a dispersion graph in which the results of a particular physician were compared to the results of the rest of the physicians at our Institution.

Discussion

The tool developed allowed to assess the performance of interventions under the *Plan de Salud* of Hospital Italiano in Buenos Aires. This information was then fed back to the physicians to analyse indicators outcome and to discuss with them the implementation of strategies for continuous improvement. In addition, many of the indicators were deemed difficult to improve solely from the primary health care standpoint and so, other strategies, like Programs for Chronic Disease Management were supported.

At present, work on stratification according to the different profiles is being carried out. The following criteria are being taken into account:

- Health care effectiveness indicators.
- Taking part in institutional resources, like using the Electronic Medical Record (EMR), participating of training courses, making presentations at the hospital discussion groups, attending congresses, etc.
- Scoring health care received (user's degree of satisfaction) through the different available tools.

Another strategy proposed for improvement consisted of making indicators dynamic, even to have hidden indicators for a strategically monitoring in order to avoid the risk posed by the use of profiling indicators, namely, that of working only in terms of the information provided by the indicators and leaving aside other aspects of health care.

In the future, this tool will hopefully enable us to measure the impact of having implemented the Support Systems for the Decision-making Process, which includes alerts or reminders on preventive practices.

HOSPITAL ITALIANO de Buenos Aires

Department of Medical Informatics

Introduction

- Physician Profiling is an analytical tool used to provide information on health care processes and it is based on the generation of different indicators whose purpose is to optimize clinical outcomes.

- The Hospital Italiano de Buenos Aires created a Physician Profiling Program for family physicians in its Health Maintenance Organization (HMO).

- The Hospital Italiano de Buenos Aires is a high-complexity University Hospital with 650 inpatient hospitalization beds and 23 outpatient health care centres.

- It has a pre-paid medical insurance plan called Plan de Salud with 140,000 members at present.

- It delivers 150,000 outpatients visits and 3,000 inpatients admissions monthly.

Introduction (cont.)

- Due to the need of monitoring the health care quality of our Hospital's Plan de Salud, a physician profiling program has been implemented to measure the performance of interventions at our Institution.

- The program was created following HEDIS measurements.

- The indicators were shown to different primary health care physicians by means of a software program which allows for the graphic representation of these indicators.

Objective

- The aim of the present study is to describe the development and implementation of this tool destined to profile primary health care physicians at the Hospital Italiano de Buenos Aires.

Methods

- In 2003 started the development of a number of health care indicators based on Health Plan Employer Data and Information Set (HEDIS) measurements.
- HEDIS was created by the National Commission for Quality Assurance (NCQA) in the USA to assess and compare different health plans.
- We used HEDIS to measure intervention performance at the population level. It was not our aim to compare results with other institutions.
- Fifteen HEDIS measurements –of approximately 60– were selected for the creation of these indicators

Methods

Indicators	Description
CA COLON	Colorectal cancer screening
CA Mama	Breast cancer screening
DBT BMI	Documentation of BMI in Diabetic patients
DBT HbGli	Request for Glycosylated Haemoglobin
DBT HbGli < 7	Percent of diabetic patients with HbA1C < 7%
DBT HbGli < 8	Percent of diabetic patients with HbA1C < 8%
DBT LDL	Request of LDL-c in DBT population
DBT LDL<100	Percent of diabetic patients with LDL cholesterol <100mg%
DBT LDL<130	Percent of diabetic patients with LDL cholesterol <130mg%
EnfCor LDL	Request for LDL-c in (IAM-CRM-PTCA)
EnfCor LDL<100	Percent of coronary heart disease patients with LDL cholesterol <100mg%
HTA Controlados	Percent of hypertensive patients under control (140/90)
HTA Registro TA	Documentation of BP measurement
PAP < 65	Cervical cancer screening < 65 years old
PAP < 75	Cervical cancer screening < 75 years old

HTA: Hypertension. CA: cancer. DBT: diabetes. HBGli: glycosylated hemoglobin. BMI: body mass index. Enf Cor: coronary disease PAP: PAP smear. LDL: low density lipoprotein. IAM: acute myocardial infarction. TA: arterial tension. CRM: myocardial revascularization surgery.

Methods

- Each indicator was determined by an equation whose numerator and denominator emerged from an adjustment of the HEDIS measurement selected. For example:

Breast Cancer Screening

$$\frac{\text{Women with a biannual breast echography or mammography}}{\text{40-75 year old women. No limit to number of patients}}$$

- This web-technology-based interface allowed for the graphing of indicators over a year both from the individual viewpoint of each physician and from the institutional standpoint.

- Results were presented in a radar graph, where each axis represented one of the 15 indicators selected.

Ontology Design for the Development of Semantically Interpretable Clinical Practice Guidelines

Fernando Díez, José Mª Fuentes, Álvaro Valera, Luis Martín, Laura Hernández, Pablo Castells

Escuela Politécnica Superior, Universidad Autónoma de Madrid, Spain

Abstract

Clinical practice guidelines (CPG) are becoming an essential help tool in medical care. Despite their continuous evolution and dissemination, their application in the context of the new Information and Communication Technologies is not sufficiently developed. A fair amount of work still remains to be achieved in the area of CPG execution, and as a consequence, it is difficult to find even medium sized repositories of formalized and executable CPG. In this context, we present an initiative for modeling and executing clinical guidelines, named SCPG, where a new, ontology based approach is proposed to fill this gap. The proposed model aims to be a novel contribution to the representation and organization of knowledge in this area. In this paper we provide new model to represent CPG focused in sharable and reusable elements, derived from the application of CPG among several healthcare institutions in Spain.

Practice Guidelines, medical practice management, Clinical Decision Support Systems, integrated health care systems, semantics

Introduction

Major efforts are being undertaken in the health domain today towards the standardization of healthcare processes, which have undergone a considerable development in the last few decades, in terms of both magnitude and complexity . Such complexity is due to the universalization of medical care among the population, at all the levels of the health organization. The collaboration between the different agents involved in the health system is a key problem in order to provide a high-quality care. This cooperation must be made possible by some degree of ubiquity in processes and organizations. From the point of view of business organization, the need for personalization and standardization is becoming increasingly clear. This is so because medical care tends to be individualized and homogeneous at any point of the system. Individualized in the sense that each patient has their own attention process but based on common resources for all the patients in the health system. We said homogeneous in the sense that all patients are over the same clinical environment. The existence of an integral clinical information and process management system in hospitals has a positive impact on the quality of assistance and the efficiency of the health personnel . Achieving this successfully saves institutions from dedicating an excessive part of their human resources, included doctors themselves, to documentary and bureaucratic routines. Furthermore, a more efficient information management can be achieved, better supporting the work of doctors, who are thus not constrained to do without relevant information about her/his patients because retrieving it at the right time is not feasible. To achieve this combination of goals it is essential to rely on suitable organizational means, such as Business Process Management (BPM) methodologies , and appropriate Information and Communication Technology (ICT) infrastructures for knowledge management in health structures. For this reason, enterprise management techniques need to be implemented in healthcare organizations, along with normalization standards, e.g. driven by symptomatology, techniques, or diagnosis. In this sense, the standardization of patient care through clinical practice guidelines (CPG) provides significant benefits, since:

- Procedures are normalized, as guidelines establish the standard to guide the doctor's action.
- Clinical evidences are systematized, allowing a fast knowledge transfer between organizations sustained by contrasted clinical evidences.
- Guidelines establish the relevant information domain for a process, simplifying the access and management of this information.
- Patient care is personalized. Guidelines define the specific care system activity for a particular patient, rather than all possible patients. Assistance can be proactive and planned instead of reactive and spontaneous.
- Guidelines help the fast dissemination of new work practices, and help structure all the knowledge of a healthcare organization. When a new evidence or technique suggests the modification of guidelines, these are modified and transmitted to all the personnel in a homogeneous and immediate way.

CPG are a helpful tool for the administration of medical care. They should not be just a set of rigid regulations. They should be characterized by their flexibility, clinical applicability, clarity, documentation and elaboration after a suitably planned revision. A large number of CPG are cur-

rently available that have been developed by different public and private organizations. The application of CPG in the context of the new ICTs is still fairly scarce today , , . Much work remains to be done in the scope of the automation of CPG execution, and despite important initiatives on repositories of formalized guidelines, there is a lack of a wide public repository of interpretable CPG. The overall goal of our work is to provide support for the execution of guidelines in heterogeneous and distributed health systems. Our research, by the date, is focused on the validation of our ontology for the representation of CPG, which is described next.

Some reasons to adopt ontology as a representational model to CPG

It is a need, in the actual scenario of health, to share, reuse, distribute and understand the enormous amount of information daily generated in any health institution, laboratory, research centre, etc. in a similar way. The representation and dissemination without ambiguities of the complex medical concepts described is a foremost question in order to achieve this objective. By means of clinical domain ontologies it is possible to solve this need . However, in the context of CPG, there is a lack of a normalized, semantically representative and generally adopted definition of what does a clinical guide means. Ontologies, as formal representation tools, are natural solutions to fill this lack.

In the design or redesign of CPG modeling phases, the use of ontologies lets the users a high flexibility and easy reutilization of elements. Some individual elements of a guide like, for example, the way by means a clinical analysis must be done or the monitoring of a treatment in a concrete patient, could be easily reused in other guide or adapted to cover the special needs of a new guide. This is a natural reuse of elements of the ontology, which facilitate the design of new guides with common elements from other previous CPG. By the reutilization of information shared between CPG, unique and commonly accepted, it is possible a quick and efficient deploying of innovative information not only within the organization which adopts the guide, but also between different organizations. As an example of the reutilization of concepts we have the action *degree of tabaquism* is modeled in different processes like *Cholesterol* and *Tabaquism*. The reutilization of elements of huge clinical guide repositories could lead to an enormous and very difficult work. This is the reason to define explicit relations between all the elements sharing the same elements or being specializations of some more general ones of the ontological models. This guideline conception enables the reutilization of elements in a different way to those used in GLIF guidelines, as we show in figure 1.

All the previous reasons are something enough to adopt ontologies as representation formalism for the definition and interoperability of CPG. In addition and based on the aspects that characterize a CPG definition formalism identified in , SCPG addresses further areas not covered by prior proposals, concerning the organization of plans and the representation of goals.

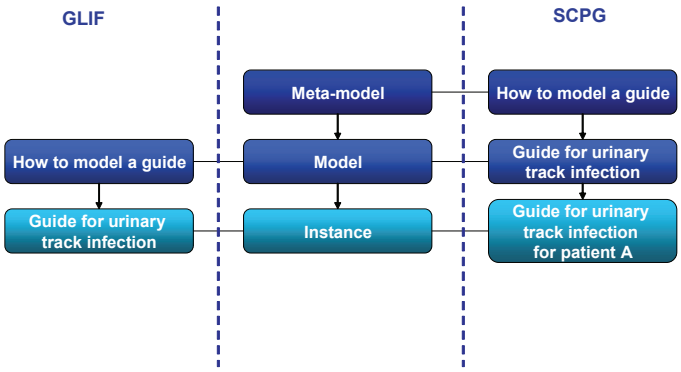

Figure 1 – Differences on SCPG conceptual model

In the remaining aspects, namely, action models, decision models, expression languages, interpretation of data and abstractions, medical concept models, and patient information models, a similar functionality is covered, but based on ontologies. Furthermore, SCPG incorporates the notion of roles, typically not included in this type of representations to date.

Concrete new proposals for our model

In SCPG we are introducing a kind of new concepts in order to enrich the descriptions of the clinical process to be modeled. The foremost ones are described in advance.

In the area of plan organization, SCPG introduces the concept of encounter, which represents the interaction between the patient and the medical staff in a certain space and time. The encounter represents the context in which a set of clinical activities take place. With SCPG there are different ways to represent a clinical attention process. For example, in the clinical guideline for VIH, here is a first encounter which is followed by an undetermined number of encounters for the continuous patient supervision. But in contraposition to this model, the guideline on *Cholesterol* has up to eleven different encounters. The encounter labeled *Middle Risk with LDL<130* has a total of eight actions, but when the LDL Cholesterol is over 160, the related encounter has a total of eleven actions. The difference between the two encounters is based on actions that analyze hormones (like TSH) or enzymes (like CPK, ALT or AST). Figures 2 and 3 (both in Spanish) shows the Protégé ontology model for the first encounter *Cholesterol* and a partial fragment of the actions involved in that

encounter. With this modeling freedom, SCPG is not restricted to a linear conception of medical care.

The representation and exploitation of clinical goals has been only addressed to a limited extent in the available literature on clinical guidelines representation formalisms. This is addressed in SCPG for two fundamental reasons: a) in the clinical domain, it is particularly true that there is a difference between performing an action, and the action having the desired effect; and b) the goals can be extremely useful to exploit the formal representation, enabling a better evaluation of the care processes, the recommendation of clinical guidelines, goal based planning, etc. This way, each action, encounter, and process in SCPG can have a set of associated valuable goals, which describe the guideline in terms of what is the intended purpose, rather than what has to be done.

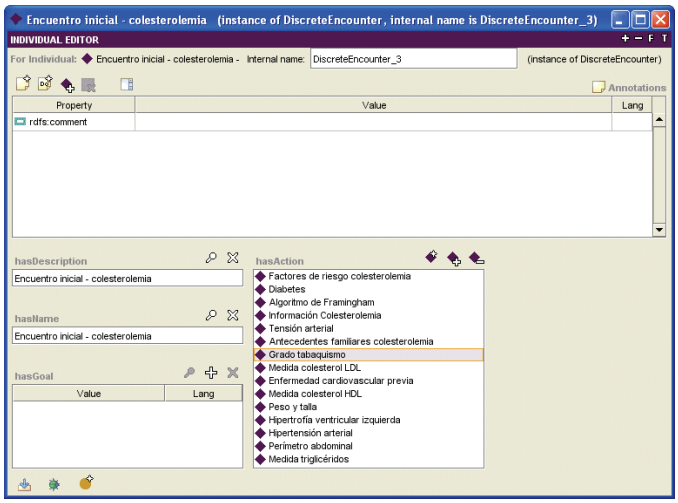

Figure 2 – Protégé definition for the first Cholesterol encounter

Regarding roles, they represent the skills of the medical personnel in charge of actually carrying out the actions prescribed by the guideline. Whilst such information might seem of rather institutional than clinical nature, this is not quite exact. Roles have a strong clinical component, insofar as they represent a set of clinical skills required from the personnel assigned to peform a certain action.

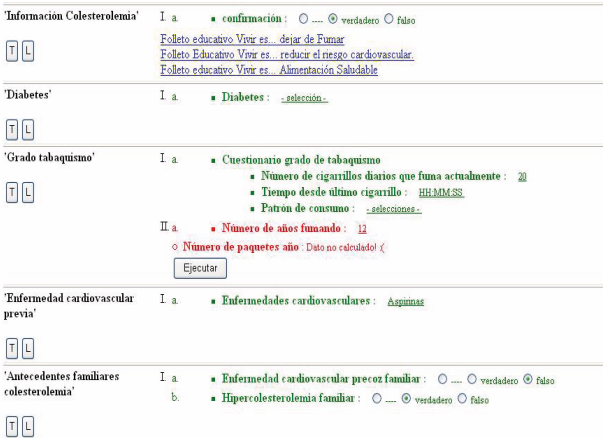

Figure 3 - Partial fragment of the actions involved in a Cholesterol encounter

In addition to the direct advantages of the proposed model in the area of executable CPG representation, the SCPG ontology enables further potential added value in areas such as interoperability, reuse and inference. As mentioned earlier, in realistic settings, CPG need to be executed in heterogeneous and distributed environments, and, in addition, act as transmissions for medical knowledge. Therefore, a high degree of interoperability is required, both syntactic and semantic, between the different involved systems. This problem is addressed in the Semantic Web field by means of the definition of ontologies. Since SCPG is based exclusively on such ontological descriptions, it has the potential to benefit from any progress achieved in the area of interoperability by Semantic Web technologies.

With regards to the problem of the scarce availability of formalized and executable clinical guidelines, the ontology based approach in SCPG allows the definition of a set of classes that represent a complete guideline. Such classes are easily reusable and can be restricted, versioned and manipulated by sub classification, inheritance, and the definition of constraints, in order to produce new guidelines. Thus, SCPG greatly facilitates the formalization of medical knowledge.

Finally, the guidelines represented in SCPG have a much more powerful logic component than other formalizations achieved to date. With our model, represented in OWL, reasoners can be employed to validate the logic correction of guidelines, avoiding potential inconsistencies in the model which, otherwise, would be difficult to detect except by an exhaustive set of system tests, without a completely guaranteed proof of correctness. On the next section we are going to present our proposal for modeling CPG.

Modeling CPG by means of SCPG

SCPG is an ontology for the representation of executable CPG which was conceived in order to apply the Semantic Web vision to the fields of Healthcare and process representation. The ontology has been defined in OWL, using the Protégé environment as an editing tool. SCPG comprise a set of clinical domain related ontologies. Their complete description of classes and relations can be found in [15].

In a common process between a patient and his family doctor, they both have different encounters in the same place but in different times. This concurrency is modeled in SPCG by means of the encounter concept. During an encounter some activities described as actions are carried on. For example, to ask for the patient weight and height, to compute her BMI (Body Mass Index) or to give a diet are example of actions. These actions provide some data about the patient, which are represented in SCPG as data items. In addition to these actions there is an objective associated with the diet: to lose about 5 to 10 kg. In SCPG this is modeled by means of objectives. One of the differences between actions and objectives is that with objectives there is an intention, but there are no guarantees for the consecution. Suppose that 3 months latter there is a new encounter. With the previous data and related with the objective consecution, the doctor has to take a decision: to continue with the diet (previous action), to give some drugs (new action) or to recommend surgery (new action). Therefore, a clinical guide provides the following aspects modeled by means of the set of ontological components:

- The formal representation of the guide, which represents the flow of the attention supplied to the patient. Clinical guides are organized into processes and this has encounters. A formal description of the described process (the order of the encounters carried on in the example), in this formal description, the patient doctor encounters are chained in the basis of the process itself, the patient state, the clinical staff decisions and, finally, due to temporal restrictions. Each encounter is made of a set of actions that must be carried on by the staff. With this model SCPG it is no restricted to a lineal conception of the clinical attention in opposite to other languages proposed to date.
- The clinical actions, which represents the different activities carried out during the attention process by the clinical staff (for example to ask for the patient weight and height; to give a diet, to give some drugs against obesity). An action could represent from a sophisticated surgical activity over a patient, to the supply of a drug or the acquisition of a concrete data from the patient. One can guess that the set of clinical actions it is too large, with lot of possibilities. Therefore it is a need to represent all the actions and their possibilities in a flexible way. With SCPG it is possible to link each action with a clinical objective in order to justify the reasons for that action and to harness such a kind of information also. There is also a link between actions and clinical roles. Each action could be taken off by a specific clinical staff, and this thing is possible to be modeled also.
- The patient data, which has the entire data patient related, previously acquired or acquired during the attention (weight, height and BMI). It is necessary to take into account the amount of data derived from the application of any monitored process to a patient. These data could be modified also in a period of time, so it is desirable to increase the relevance of a good data model.
- Clinical roles, which define the skills of the clinical staff giving attention. They are commonly used in the business management description context. In the previous example, the doctor must have some endocrinology knowledge to give some diet or some drugs.
- Clinical objectives, which represents the set of desirable objectives as a result of the supplied attention.

Integrating vocabularies

Finally it is significant to remark that all the factors included are by means of ontology descriptions, in order to achieve the objectives pointed at the beginning of the 2nd heading. As we mentioned above, in order to use and to annotate elements of a clinical guide to reach a general common understanding, we need to get domain ontologies. And this is a very important question. How we can do this?

As is well known and generally accepted, nowadays there is a set of clinical vocabularies like (ICD ; LOINC ; SNOMEDCT ; UMLS ; etc.) which represents different clinical knowledge. UMLS try to assemble a set of these languages, extracting and integrating the semantic associated from each one in order to get a common representation. However, there are some semantic defects mainly derived from polysemic words. The UMLS creators admit these defects that could be palliated by means of semantic analysis techniques as in ONIONS . In ONIONS it is described a methodology for the semantic analysis and integration of clinical vocabularies. This methodology is a part of a big project called GALEN whose objective is to supply with a common ontology and a language to represent vocabularies to allow the definition of terminologies that could be integrated in a common ontology . In our ontology we are integrating vocabularies by means of a specific class in the model. This class allows

us to refer to different actions in an encounter by means of the concept they are defined with. For example, an action that has to order a laboratory test for the enzyme CPK, could be defined as an instance of that class, which is an entry of the UMLS vocabulary also.

Conclusions and future work

The proposed approach to the formalization of clinical processes aims to bring novel contributions in several aspects. First, SCPG introduces new concepts in this area, such as the definition of patient encounters, and the explicit consideration of clinical goals. On the other hand, techniques imported from other areas, such as the Semantic Web, are brought to meet recently identified needs, such as the execution of guidelines in distributed and heterogeneous environments.

The value of the SCPG model is such insofar as it is possible to exploit the model to automate and improve the quality of medical assistance. In this respect, we are pursuing further investigation in diverse areas, such as the semiautomatic recommendation of guidelines, the semiautomatic generation of guidelines for a given symptomatology, and the optimization by aggregation of parallel guidelines over a single patient. Currently, we are completing the development of the SCPG guideline representation model, and implementing care assistance prototypes in several county level healthcare institutions (servicing above 150.000 patients). It is our goal to achieve, along the present year, the first executable clinical guidelines on SCPG, using the BMPS-e3 process management engine developed by BET Value.

Acknowledgments

This research was supported by the Spanish Ministry of Industry (FIT-350300-2005-33 and FIT-350300-2006-27). This project is being developed in cooperation between BET Value[1] and the NETS[2] team from the Universidad Autónoma de Madrid (Spain).

The International Classification for Nursing Practice (ICNP®) Programme:Terminology Management and Maintenance

Claudia Bartz[a] , Amy Coenen[a]

[a] *College of Nursing, University of Wisconsin-Milwaukee, WIsconsin, USA*

Abstract

Clinical terminologies must be dynamic in order to represent up-to-date and clinically relevant content for use in electronic health records. The International Classification for Nursing Practice (ICNP®) Programme involves a number of management and maintenance processes in order to assure quality and facilitate use of the ICNP® terminology. Some of these processes include (a) research and development activities, (b) a formal review process, and (c) applications in healthcare systems. Terminology management processes must be formal, while still being open and facilitating participation. Although the ICNP® Programme is centralized, it is essential to have mechanisms that support worldwide involvement of experts at the regional and local levels. Examining the ICNP® Programme management and maintenance processes can identify issues that need to be addressed to assure the continuous high quality of the programme

Keywords:

unified nursing language system, nursing terminology, International Classification for Nursing Practice, terminology maintenance

Introduction

ICNP® Version 1.0 was launched in May 2005 at the International Council of Nurses (ICN) Congress in Taipei, Taiwan. ICN is a federation of 129 national nurses associations. It was founded in 1889 and has headquarters in Geneva, Switzerland. ICNP® has been under development since 1989, with an alpha version, beta 1 and beta 2 versions, and now Version 1.0. The ICNP® vision is to be an integral part of the global information infrastructure informing health care practice and policy to improve patient care worldwide. This paper will address the methods by which a global terminology for nursing demonstrates constant advancement by leveraging simultaneous centralized and decentralized research and development, system improvements using transparent processes for participation, and applications in healthcare systems. A state of the art nursing terminology that can be used worldwide will document the work of nursing consistently and accurately and will contribute to safe and effective health care.

Materials and methods

ICNP® is a unified nursing language system and a compositional terminology that facilitates cross-mapping of local terms and existing terminologies. ICNP® Version 1.0 was developed using web ontology language (OWL) within the Protégé ontology development environment to support a unified language and compositional approach. A unified nursing language system allows users' natural language to be mapped to standard meanings. The benefits of using a description logics approach are explicit definitions, the possibility of multiple classifications, greater granularity, and sensitivity to variation in language and culture. ICNP® conforms to ISO Standard 18104:2003, reference terminology models for nursing diagnosis and nursing action [1]. ICNP® is HL7 registered. Experts in nursing, informatics, terminology, and software development are all essential participants in ICNP® research and development, system improvements and applications in healthcare systems.

Research and development

ICN-accredited ICNP® Research and Development Centres provide opportunities for nurse experts and related consultants to advance ICNP®. The work of the Centres is monitored by ICN through a structured process including review of goals and objectives, periodic re-accreditation, annual reports of work progress in the ICNP® Bulletin, and invitations to present work processes and products at the biennial Centres Consortium meetings held in conjunction with ICN conferences.

ICNP® catalogues are subsets of the terminology, specifically nursing diagnosis, outcome, and intervention statements for a selected population and health priority [2]. Catalogues will fill a practical need in building health information systems by describing nursing diagnoses, outcomes and interventions appropriate for the selected area of care.

Translations of ICNP® are a third important area for research and development. Some translations are appropriately done by nurses in one country. Other translations may be multi-country, e.g., Germany, Austria and Switzerland; Chile and Spain.

Review process

ICNP® continues to increase in size and complexity as more concepts are added to the classification and as methods evolve for ontological modeling with attendant software support. A structured maintenance approach [3] can support the consistency and credibility of ICNP® as it is developed, mapped to other classifications, applied in health information systems, and used in clinical practice and research. The three stages of ICNP® review process are data collection, evaluation and revision.

Applications in healthcare systems

The ability to collect data about the work of nursing worldwide will allow for data-based research, decision-making and policy development. ICNP® use in client or patient care settings, either as the interface terminology or as the reference terminology in electronic health records, will allow care data to be stored in data repositories for access by researchers. Real-time ICNP® data are currently being generated in several regions and countries.

Results

Research and development

ICN-accredited ICNP® Centres activities include concept validation, bibliometric analysis, the development of ICNP® catalogues, translations, electronic health record applications, organizing conferences, intra- and inter-country collaboration, presentations at professional conferences and professional publications.

In addition to ICNP® Centres, nurses in many settings worldwide work with ICNP® to further its development and application to practice. A list of projects worldwide is available on the ICNP® website as interested experts comply with the request to sign a Use Agreement with ICN. Projects are organized by country and by topic, including research (concept validation, description logic models, model testing), development (ICNP® catalogues, translations, browsers), integration (cross-mapping, minimum data sets), and health information systems (electronic health record, telehealth, computer-user interface). In addition to the projects, a reference list of publications about ICNP® is also available on the ICN website.

ICN has developed a prototype catalogue titled "Partnering with Clients and Families to Promote Adherence to Treatment." Pre-coordinated concepts for the catalogue's nursing diagnoses, interventions and outcomes will be given unique identifiers and added to ICNP® Version 1.1. ICN's intent is to collect ICNP® catalogues that are in use and to facilitate validation of catalogues with nurse experts in various practice areas or dealing with particular client health conditions (e.g., diabetes, mental health) or nursing phenomena (e.g., pain, self-care).

Translations have been completed in Korean, Japanese, Portuguese (Portugal) and Arabic. While some translations are appropriately done by nurses in one country, other translations are conducted across a number of countries, e.g., Germany, Austria and Switzerland. An open source, web-based translation tool has been developed and used by the German Speaking User Group ICNP® Centre. The ICNP® translation tool facilitates the distribution of work among geographically separated participants. There are plans to test the tool with other language work groups. ICN requires that a Translation Agreements be signed by anyone planning translation of ICNP®, in order to coordinate efforts across countries and languages.

Review process

The ICNP® Review Process is available in print and on the ICN website so that submitters, reviewers and users are all aware of the process by which concepts may be added, modified or deleted. Since the publication of the alpha version of ICNP®, hundreds of terms have been added to the ICNP®.

ICN moderates the process of review but the key decisions about submissions are made by expert nurse reviewers around the world. It is essential that domain experts participate in the review of ICNP® content. The use of expert nurse reviewers also helps to ensure evaluation across cultures and languages. New concepts may be submitted from nurses in the field, found in the literature or in clinical data, or they may arise during cross-mapping projects. The concepts of dignified dying [4] and informal settlement [5] are examples of validation studies conducted by nurses for potential revisions to ICNP®.

During the evaluation phase, the characteristics of the concept, or its definition, are reviewed. The concept's position and use in different cultures or nursing contexts is also considered. Each concept is then modeled in OWL and its place in the 7-Axis model representation of ICNP® is described. During the evaluation phase, the concept is examined for its compatibility with ICNP® Version 1.0 and any synonyms are identified. Expert nurses then review the concept and its related documentation. Concept recommendations may be incorporated (add, retire existing concept, revise existing concept), rejected, or sent out for an expanded review.

During the revision phase of review, the accepted concepts must be coded, definitions finalized, and modeled in OWL Protégé for addition to ICNP® Version 1.1. Concepts may also be added to one or more ICNP® catalogues. This iterative process is supported by experts from nursing, modeling and informatics.

Applications in healthcare systems

Nurses in several countries, in concert with their health ministries and health care systems, and supported by infor-

matics specialists and technicians, have integrated ICNP® Version 1.0 into their electronic health record systems. Hospitals in Korea and Portugal are, for example, using ICNP® as the standard for collecting nursing data in point-of-care documentation of nursing practice in electronic systems. The data can then be stored and retrieved for re-use, e.g., research, with appropriate safeguards for human subjects protection. The developers and users of these applications provide valuable feedback to the ICNP® Programme.

Discussion

ICN aims to expand the number of ICN-accredited ICNP® Centres for Research and Development. The centre members are seen as leaders in the worldwide dissemination and implementation of ICNP® with the ultimate goal of large data sets for research-based health care delivery, decision-making, and policy development.

The compelling need in catalogue development is to foster creativity, collaboration and product development while also ensuring a consistency in quality and representation of nursing practice content. Nurses at the point of care delivery cannot reasonably be expected to use ICNP® as a whole in their work. Rather, nurses are focused on selected client populations and health priorities to include various combinations of health conditions, particular specialties or settings, and nursing phenomena, e.g., pain, self-care.

The process of translation is challenging in that the English ICNP® concepts cannot simply be translated word for word from the source language to the target language. Rather, each concept's meaning and usefulness in the health care environment of the target language must be analyzed and agreed to by the translation team. ICN is establishing guidelines for translation based on existing standards and experience from teams undertaking ICNP® translations.

An established, well-tested process for system maintenance will ensure that sound decisions are made concerning existing or new ICNP® concepts. The process is also designed to integrate new technologies and ontological capabilities in order to remain state of the art for worldwide dissemination and use.

With a unified nursing language system such as ICNP®, the nursing profession is finally able to articulate its practice and generate worldwide data for research-based clinical care, administrative and clinical decisions, and the development of healthcare policy.

Conclusion

ICNP® is a large and robust clinical terminology for nursing. Its contribution to the nursing community and to worldwide healthcare requires formal centralized and decentralized processes. These processes involve the work of hundreds of nurses worldwide, the support of health ministries, healthcare organizations, and collaboration among experts in nursing, terminologies, informatics and technology. Ongoing examination of the ICNP® Programme management and maintenance processes is essential to assuring continuous quality improvement.

International Council of Nurses

MEDINFO August 2007

ICNP®

- Programme of the International Council of Nurses
- Version 1.0 launched in 2005
- Unified nursing language
- Compositional terminology that facilitates cross-mapping local terms and existing terminologies
- Conforms to ISO Standard 18104:2003

ICNP® Vision

ICNP® is an integral part

of the global information infrastructure

informing health care practice and policy to improve patient care worldwide.

Materials and Methods

- **How a global terminology for nursing demonstrates constant advancement by leveraging**
  - **Simultaneous centralized & decentralized research and development**
  - **System improvements using transparent processes for participation**
  - **Applications in health care systems**

Research & Development

- Translation Guidelines from ICN
- ICN requires signed Translation Agreement
- Translations
  - Arabic, Japanese, Portuguese, Korean completed
  - Eleven translations in-progress

Research & Development

- **ICN-accredited ICNP® Research & Development Centres**
  - **Concept development**
  - **Translation**
  - **NMDS, iNMDS**
  - **Knowledge development, data repositories**
- **Five centres to-date**
- **Annual updates in ICNP® Bulletin**
- **Three-year cycle for re-accreditation**

Research & Development

- **Catalogue Guidelines from ICN**
- **Catalogues**
  - **Subsets of ICNP® for use at point of care**
  - **Address nursing phenomena, specialties, settings, health conditions/diseases**
  - **New catalogues: adherence, palliative care**

Research & Development

- R&D project descriptions on website
  - Concept validation, ontologies, logic models
  - Catalogues, translations, browsers
  - Cross-mapping, NMDS, telehealth
  - EHRs, computer-user interface
- ICNP-related publications on web site
- All work with ICNP® requires Use Agreement

Concept Review Process: Add, Modify, Delete

- Concept analysis using research methods
  - Literature review
  - Definition and defining characteristics, e.g., using Delphi technique
  - Clinical testing
- Submission of concepts for
  - Addition, modification, deletion
- Volunteer to be a reviewer (see website)

Concept Review Process: Pre-coordinated concepts

- Identification of pre-coordinated concepts from catalogues
  - Nursing diagnoses, interventions, outcomes
- All accepted concepts
  - Modeled in OWL in Protégé software
  - Given unique identifiers (codes)

Applications in Healthcare Systems

- **Integrate ICNP® with EHRs**
  - **E.g., Portugal, Korea**
- **Collect and analyze iNMDS data for**
  - **Nursing and patient care information**
- **Data repository supports re-use of data for**
  - **Clinical research at progressive levels**
    - **Local, regional, national, international**
  - **Decision-making and policy development for healthcare worldwide**

Abstract

Whilst SNOMED-CT has developed extensively as a terminology, it has done so at a pace separate from that of the vast majority of end users and products. The experience and lessons learnt from implementation projects have highlighted significant clinical achievements and variation between solution capabilities and user expectations. This has resulted in an understanding of what factors impact on success including the need to address what a "SNOMED-CT enabled", or a "SNOMED-CT supported" application actually means, the need for cross-vendor consistency, and convergence of terminology support.

A solution capability matrix for SNOMED-CT, which assists in promoting communication and understanding between stakeholders has been developed. Care will be required by all stakeholders when, in the future, local solutions comprise a mix of solution support levels as they cannot readily interoperate without restrictions being imposed. Only when all solutions are at the highest level described in the model, Level 2, will the full benefits of SNOMED-CT be realised. Until that time sophisticated and iterative workarounds will need to be in place and utilised by all users and systems.

Keywords:

systematized nomenclature of medicine, stakeholders, software implementation

Introduction to SNOMED-CT

Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT) is an international medical terminology which has been developed over time, from several source terminologies, by the College of American Pathologists and the UK National Health Service. This comprehensive clinical language is used to encode clinical data in electronic patient records, which may subsequently be used within decision support. It currently consists of 400,000 healthcare concepts, over 1 million descriptions and nearly 1.5 million semantic relationships. As with all clinical terminologies it is, and will always be, a work in progress. SNOMED–CT differs from most previous health terminologies because it aims to achieve domain completeness throughout healthcare. As such it is capable of representing the minutiae of clinical information and is designed to be used by generalists, specialists, indeed all clinical practitioners, including doctors, nurses and allied health professionals.

However whilst SNOMED-CT has developed extensively, it has done so at a pace separate from that of the vast majority of end users and software products.

Value of SNOMED-CT

SNOMED-CT is the foundation stone for achieving the vision of continually improving healthcare outcomes and efficiencies by enabling communication and data analysis at patient, local, national and international levels as indicated in Figure 1. As such, the successful implementation of SNOMED-CT is imperative to patients, care professionals, healthcare organisations, product vendors and the nation as a whole. All parties need to be aware of their role and responsibilities in that achievement. Failure to adopt SNOMED-CT and standardise its use, will ultimately impact:

- safe interchange of clinical information
- decision support's ability to provide consistent responses for safer care delivery
- secondary use of data for research, healthcare improvement and commissioning decisions

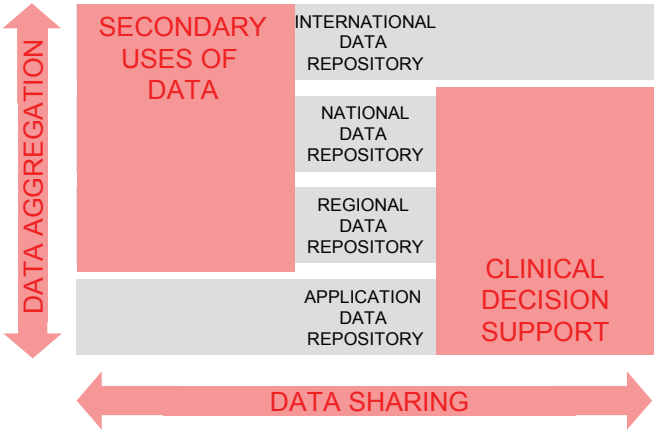

Figure 1- SNOMED-CT enabled data utilisation

Increasingly, clinical information is exchanged at national and international levels for individual and epidemiological use. Countries such as Denmark have used SNOMED-CT as the lingua franca in outsourcing radiology reports to India, so that local resource constraints can be managed. However, product and messaging limitations have compromised the efficiency and effectiveness of this.

In the arena of clinical terminology and messaging there is an immediate benefit, and therefore clear need, for a defined approach to terminology use if communication between different healthcare organisations is to become more effective. In the longer term, benefits of a common terminology used at the point of care will enable clinical statements to be understood and reused, not only at the individual patient level but also when aggregated. This will derive benefits in clinical audit, research and governance, epidemiology and healthcare commissioning.

Supporting clinicians

Clinical terminology supports what clinicians care about by ensuring clinical records meet their needs. Clinicians desire system components that work reliably together; the ability to easily express the clinical information they wish to enter; and the ability to retrieve information to support delivery of care and analysis of aggregated data.

Effective use of codes and medical terminology within clinical information systems is fundamental to maximising the benefit of much of the clinical functionality. This will have an impact on information:

- presented in the system outputs (e.g. discharge summary)
- shared with other organisations or aggregated in a data warehouse
- used to trigger care plans and care pathways
- available in patient medical summary views
- available for clinical decision support
- shared with third party systems (e.g. pharmacy)
- used for clinical/management reporting

Lessons learnt from early implementation

The experience and lessons learnt from implementation projects Dolin RH, Mattison JE et Kaiser Permanente CMT Team. Kaiser Permanente Convergent Medical Terminology. Medinfo 2004. M.Fieshi et al (eds) Amsterdam ,Lopez et al. A Practical Approach to Advanced Terminology Services in Health Information Systems. 2006 Medical Informatics Department, Hospital Italiano of Buenos Aires, Argentina have highlighted significant clinical achievements and variation between solution capabilities and user expectations.

In England the new and ambitious challenge of implementing SNOMED-CT has resulted in a greater understanding of what factors impact on success. These include the need to address what a "SNOMED-CT enabled", or a SNOMED-CT supported" application actually means, the need for cross-vendor consistency, and convergence of terminology support

Semantic interoperability and SNOMED-CT

Semantic interoperability will be the key to successful development and implementation of future Electronic Health Records (EHR)[1] and integrated Electronic Patient Record[2] systems that deliver complex clinical functionality spanning care settings. Such functionality will include clinical decision support, integrated care pathways, enterprise scheduling, and workflow management.

There is increasing awareness and interest from software providers and their purchasers, who are investigating, and in some cases acting on, the application of international standards to help achieve semantic interoperability.

The development and adoption of international standards for patient record interoperability is essential for:

- sharing patient health and care information between health professionals in a multi-disciplinary, shared-care environment
- interoperability between organisations within an enterprise-wide, regional or national healthcare system, and perhaps in the future across national borders
- supporting functional and semantic interoperability between software from different vendors

Such standards cover the important tools within health informatics including messaging, health record architecture, health record extracts, terminology, and logical data models. SNOMED-CT is the internationally adopted standard for terminology and is core to the achievement of semantic interoperability. However, SNOMED-CT must be constrained to be used effectively as there are innumerable ways to express clinical information using SNOMED-CT. Such flexibility left unconstrained will prevent meaningful queries, data extraction and data comparison.

Whilst standards exist for messaging (HL7 v3), health record architecture (openEHR), health record extracts (prEN13606 soon to be CEN13606, HL7 v3 CDA), reference models (openEHR, HL7v3 RIM) and terminology (SNOMED-CT), it is far less clear how they interrelate or should be used together in harmony. One such area of

1 We define Electronic Health Record as the combination of a patient's electronic records held in different systems to form a combined patient electronic record.

2 We define Electronic Patient Record as the patient's electronic record held within a facility (e.g. Hospital)

ambiguity is reference models where HL7 v3 has defined a Reference Information Model for messaging purposes which is insufficient as a reference model for a healthcare record architecture. Whereas the Reference Model and associated models in openEHR are designed for a health record architecture, and are used in CEN13606 for health record extracts. There is clear overlap between the reference models provided by both standards. Figure 2 attempts to crudely illustrate the complexity of how these standards currently overlap.

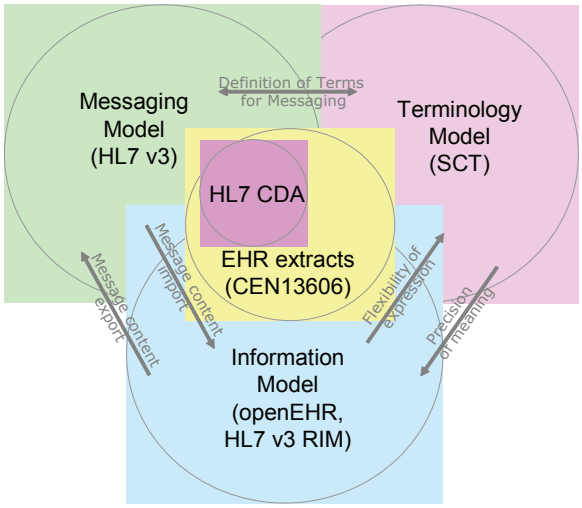

Figure 2- A view of the complexity of how standards overlap

There are several pieces of work underway that will help address how these standards will work together, for example:

- TermInfo – relationship between HL7v3 and SNOMED-CT
- HL7 13606 Implementation Guidance project – relationship between HL7 v3 and CEN13606

The output of such work will guide software vendors in design of their systems to ensure that SNOMED-CT is implemented in a controlled and interoperable way. Successful applications of the future will embrace these standards and learn to unify them into a cohesive application.

In this way SNOMED-CT will assist in:

- translating data entered by users using an interface terminology or SNOMED-CT directly
- transmitting clinical data between applications via messaging or other means whilst maintaining data integrity and meaning
- transmitting aggregated data to common data repositories for secondary use such as reporting

Stakeholder interface

Increasingly the assumption of purchasers will be that SNOMED-CT is used as the common terminology which drives the clinical functionality within products. However the majority of systems and applications have not been designed around a terminology as large and complex as SNOMED-CT.

There is an ever increasing user and customer demand for SNOMED-CT based products with a driver on the vendor community to develop their products and their data models accordingly. This demand for SNOMED-CT based products will increase as all nations are faced with the complexities of an aging population and workforce, with associated complex disease management requirements. Those vendors who have made the investment in developing their products to use SNOMED-CT at its core will be best placed to compete within this evolving market.

Electronic clinical record system providers or solutions who can support post co-ordinated SNOMED-CT will still be constrained by the limitations of others, especially departmental solutions (pathology, radiology, pharmacy being key) for some time to come. These new SNOMED-CT based vendors will add their voice to the increasing demand for SNOMED-CT based solutions.

The implementation of SNOMED-CT requires software applications that exploit its features to meet the real and perceived needs of users. The users of SNOMED-CT are not restricted to end-users who enter or retrieve clinical information experiencing SNOMED-CT through a configured application that uses the terminology. Users also include those who design, commission and configure software for use in a particular clinical environment and those who utilise population and other aggregated data.

Solution capability matrix

A significant risk to SNOMED-CT implementations is that financially and politically costly user implementation and technology strategies are developed and implemented without a clear vision of the end point. It is therefore imperative that there is national and international agreement on the role of SNOMED-CT and the level of support required

The adoption of SNOMED-CT will, by necessity, be incremental. In this extended implementation period, solution providers will need to support workarounds such as maintaining separate clinical terming and classification coding processes. Therefore, there will be a mixed population of systems and users that either can or cannot support SNOMED-CT. This presents new problems. A solution capability model for SNOMED-CT has evolved during the process of implementing at a multi organisational, depart-

mental and cross health care boundary level, which assists in promoting communication and understanding between the stakeholders. This model considers solution capabilities as follows:

Level	Description
0	Systems do not internally support SNOMED-CT. They may not be capable of working in a SNOMED-CT world at all, or may be provided with a mapping function to map outbound messages containing local codes into messages containing SNOMED-CT codes to support communication with other systems or for reporting.
1	Systems support SNOMED-CT internally but with restrictions, which may include shortened descriptions, restricted subsets of terms and limited hierarchical browsing. They will not support inbound post-coordinated expressions. Most existing systems with some SNOMED support would be in this category. Some systems (in the US) have pushed the upper limits but require extensive maintenance overhead to maintain pre-coordinated ('ready defined') terms in line with needs.
2	Systems support post-coordinated expressions and can communicate with other Level 2 systems using messages containing post-coordinated expressions (which adds additional qualifiers to 'terms' to improve clinical detail). They will have potentially many styles of user interface to support different users and user contexts (eg nurses on wards, surgeon in theatre) and their requirements to add information to patient records. These systems would also be able to exploit the encoded data within decision support rules. With its ability to store detail and fully interoperate with similarly supportive systems, level 2 would need substantive development of the existing solutions in terms of user interfaces, processing and database structures, to support the encoded data meaningfully. They also need configuration tools to enable the system to relate to the appropriate SNOMED-CT subsets (also known as reference sets) and hence inbuilt maintenance processes to respond to changes in SNOMED-CT content.

Table 1 –SNOMED-CT Solution Capability Model

This model and its presented levels do not constitute a roadmap for solutions and their development. Level 0 solutions, by definition, cannot be readily engineered to become Level 1 and similarly for Level 1 to Level 2. At best, software vendors need to understand how they can achieve higher support for their products within a level, recognising the constraints imposed by that level. They will then need to determine the re-engineering required to provide an equivalent solution at a higher level.

The model is being further extended to incorporate the roles and impact on other stakeholders. The combined effect of solutions with mixed capabilities in supporting SNOMED-CT, combined with disparate purchasers, timetables, political, economic and clinical imperatives, results in a complex picture. However, building on the model will enable understanding of the interplay, and interaction of each stakeholder's issues.

Conclusion

Going forward, care is required by all stakeholders when, in the future, local and national solutions comprise a mix of Level 1 and 2 solutions. Level 1 solutions cannot interoperate with messages from Level 2 solutions unless the Level 2 solutions comply with the restrictions imposed by each of the Level 1 solutions. As a result, only when all solutions are Level 2 will the full benefits of SNOMED-CT be realised. At this stage solutions will be built around SNOMED-CT and will likely provide sophisticated native SNOMED-CT terminology services. At this point, external (standalone) terminology services are likely to be limited to the distribution/syndication of maintenance releases for clinical content.

The Solution Capability Model has value in enabling understanding of the complexity of the environment in which implementation is to take place, so that careful planning can be undertaken, and a successful outcome achieved. The Solution Capability Model also makes it clear that this will not be achieved overnight.

Acknowledgments

We would like to thank many colleagues and friends who have contributed their thinking and experiences, this includes associates at BT, Ernst and Young and those who agreed to be interviewed as part of evolving the thinking behind this paper.

Supporting SNOMED-CT implementation through a Solution Capability Matrix

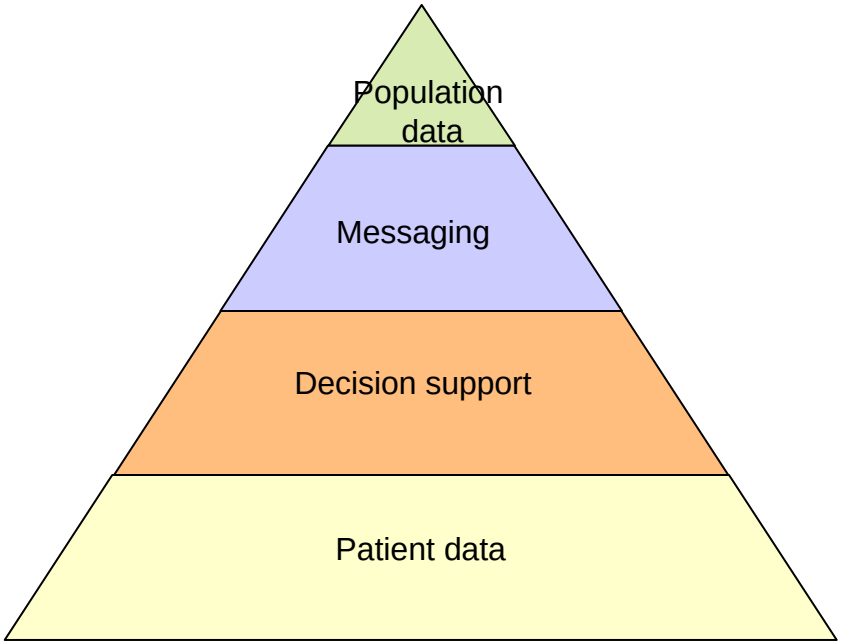
Janette Bennett
Centre for Healthcare Informatics Research and Development (CHIRAD),UK

Dr. Nick Booth
SNOMED International Editorial Board

Dr. Justin Whatling
BT Health Executive, London

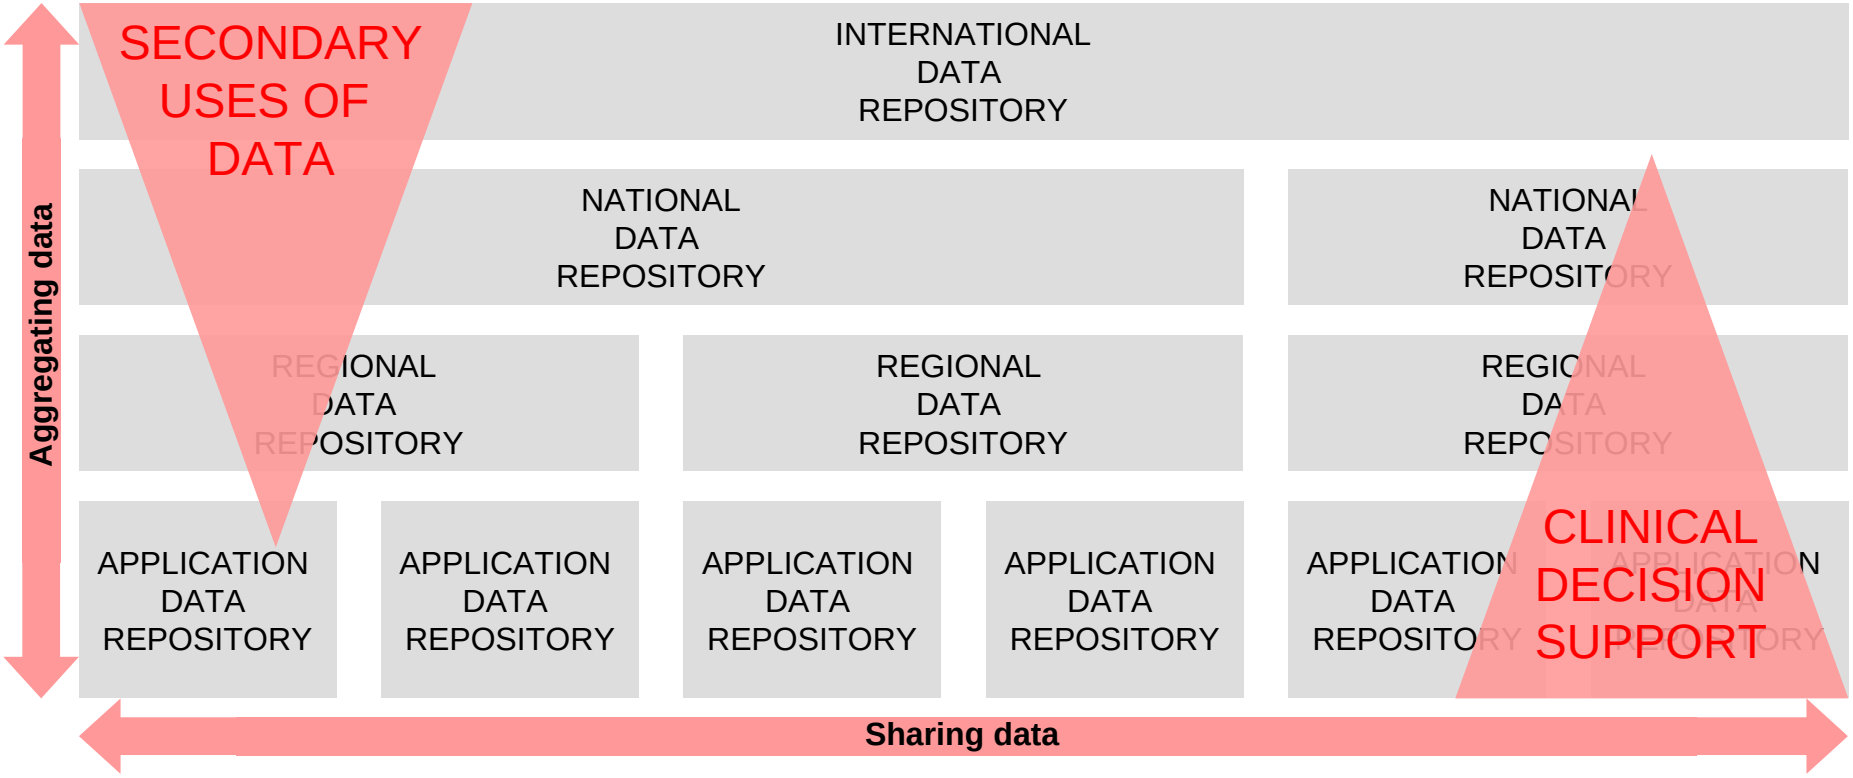
Introduction to SNOMED-CT

- International medical terminology used to encode clinical data in electronic patient records
- In 2006
  - 400,000 healthcare concepts
  - over 1 million descriptions
  - nearly 1.5 million semantic relationships
- As with all clinical terminology it is, and will always be, a work in progress



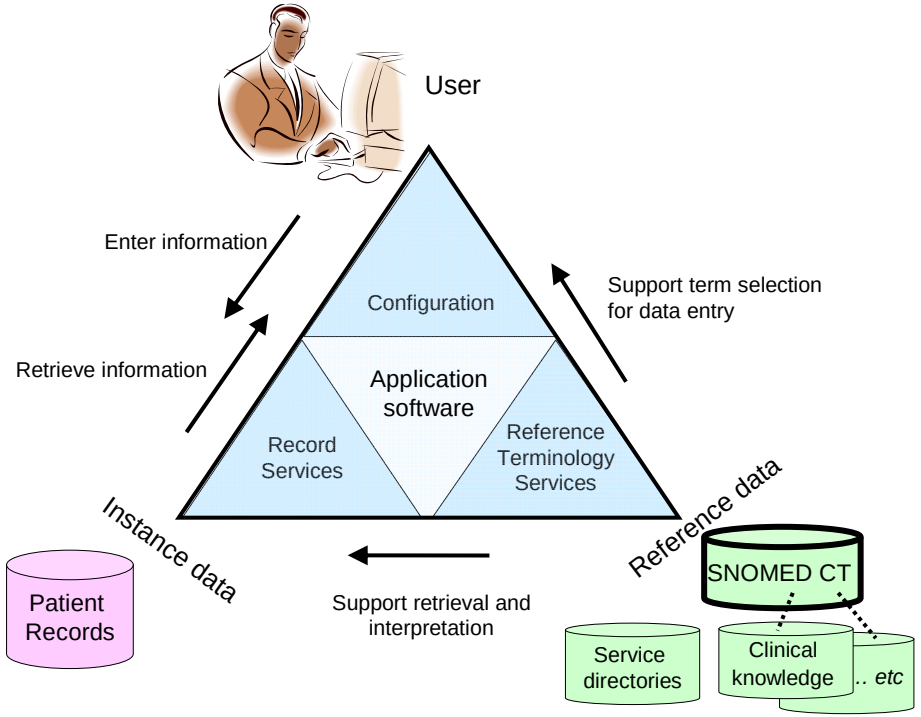
SNOMED-CT use

Vision of SNOMED-CT use



SNOMED-CT is the foundation stone for achieving the vision of continually improving healthcare outcomes and efficiencies by enabling communication and data analysis at patient, local, national and international levels

SNOMED-CT in single organisation



In supporting clinical practice, several different applications are used and these may be separately configured for users in different specialties and disciplines.

The role of SNOMED CT is to enable processable representation of meaning in forms that can be shared between a diverse range of disciplines, specialties and software applications.

Failure to adopt & standardise SNOMED-CT use, will impact on:

- *safe interchange of clinical information*
- *decision support to provide consistent responses for safer care*
- *use of data for research, healthcare improvement and commissioning*

SNOMED-CT lessons learnt

- SNOMED-CT has developed extensively at a pace separate from that of the vast majority of end users and products
- The lessons learnt from implementation projects have highlighted significant variation between solution capabilities and user expectations
- Now we have a better understanding of what factors impact on success, including the need
  - to address what a “SNOMED-CT enabled”, or a “SNOMED-CT supporting” application actually means
  - for cross-vendor consistency and convergence of terminology support

We have learnt a lot from current and past implementation projects

Supporting software vendors

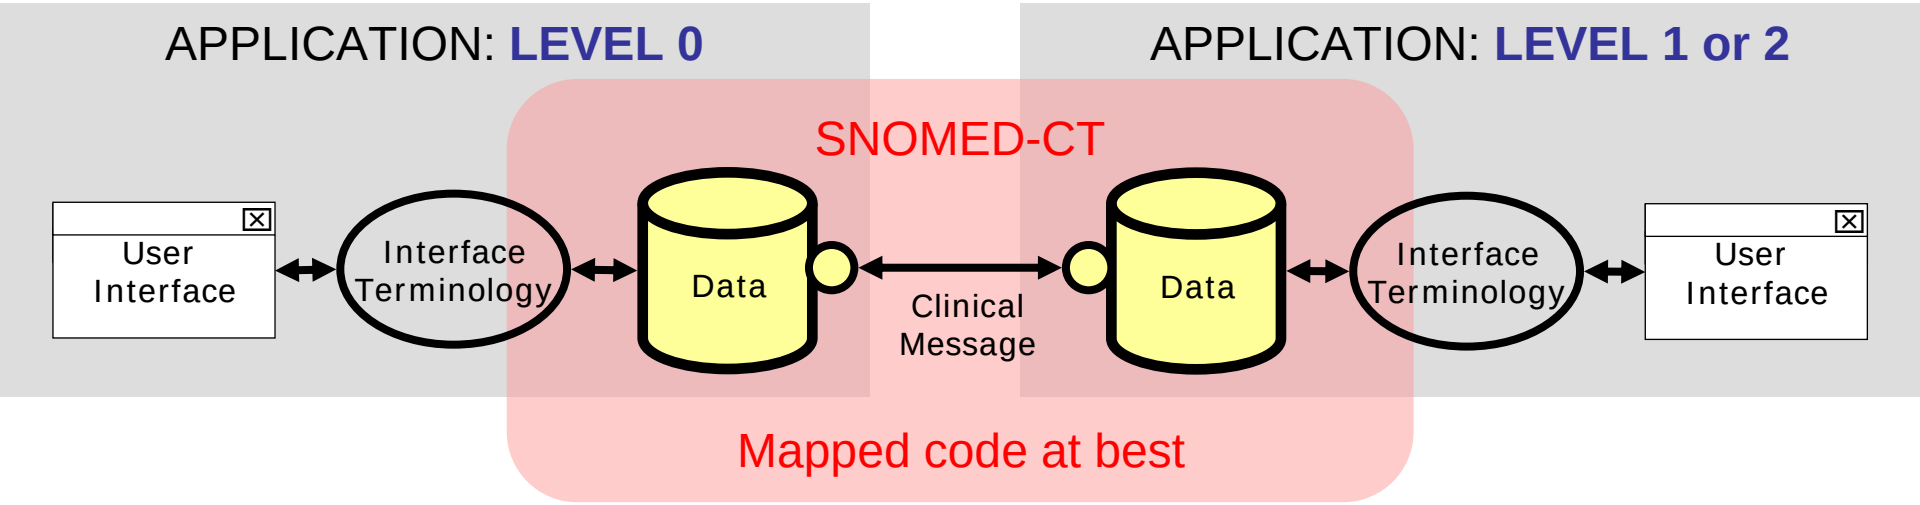
- The adoption of SNOMED-CT will, by necessity, be incremental
- In this extended implementation period, solution providers will need to support workarounds such as maintaining separate clinical terming and classification coding processes
- Therefore, there will be a mixed population of systems and users that either can or cannot support SNOMED-CT
- This will present new problems

A Solution Capability Matrix is required to support software vendors to promote communication & understanding between stakeholders

Solution Capability Matrix

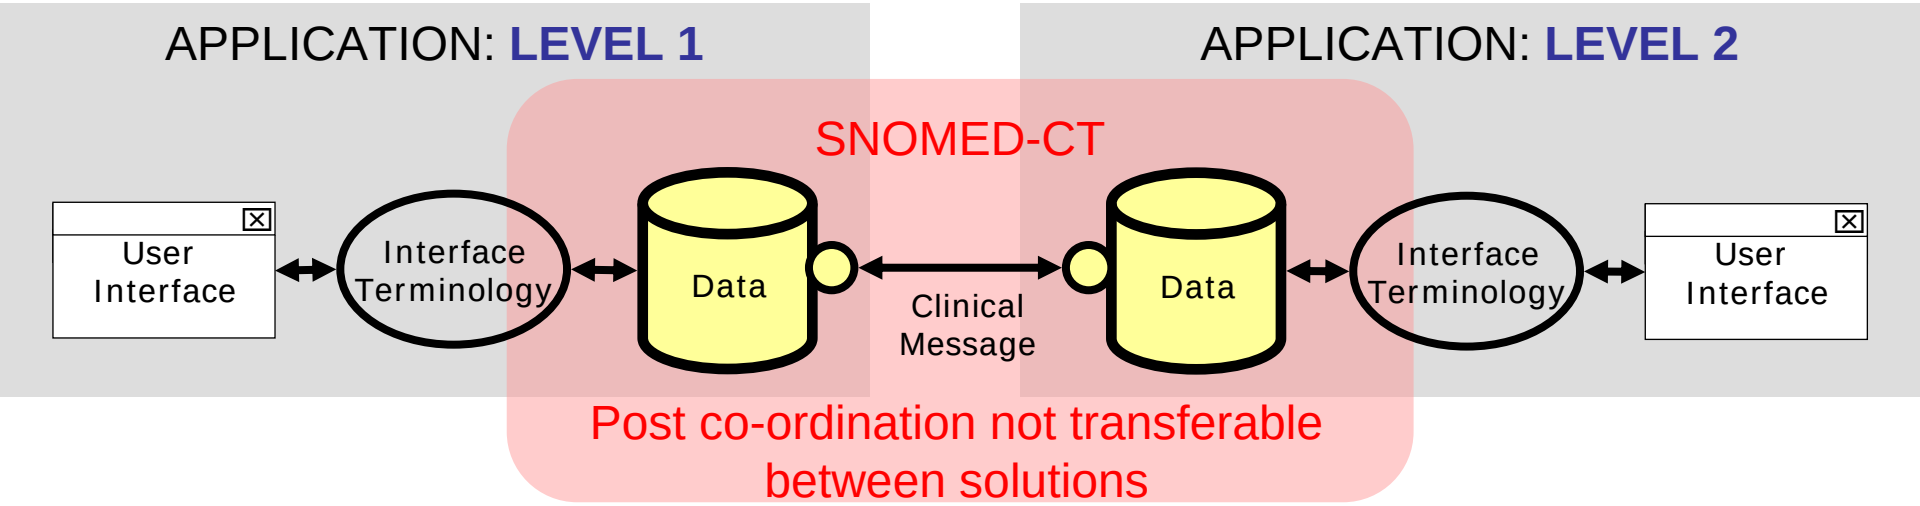
L0	Systems do not internally support SCT. They may not be capable of working in a SCT world at all, or may be provided with a mapping function to map outbound messages containing local codes into messages containing SCT codes to support communication with other systems or for reporting.
L1	Systems support SCT internally but with restrictions, which may include shortened descriptions, restricted subsets of terms and limited hierarchical browsing. They will not support inbound post-coordinated expressions. Most existing systems with some SCT support would be in this category. Some systems have pushed the upper limits but require extensive maintenance overhead to maintain pre-coordinated ('ready defined') terms in line with needs.
L2	Systems support post-coordinated expressions and can communicate with other Level 2 systems using messages containing post-coordinated expressions (which adds additional qualifiers to 'terms' to improve clinical detail). They may have many styles of user interface to support different users and user contexts (eg nurses on wards, surgeon in theatre) and their requirements to add information to patient records. These systems would also be able to exploit the encoded data within decision support rules. With its ability to store detail and fully interoperate with similarly supportive systems, level 2 would need substantive development of the existing solutions in terms of user interfaces, processing and database structures, to support the encoded data meaningfully. They also need configuration tools to enable the system to relate to the appropriate SCT subsets and, inbuilt maintenance processes to respond to changes in

Solution Capability Matrix: Level 0



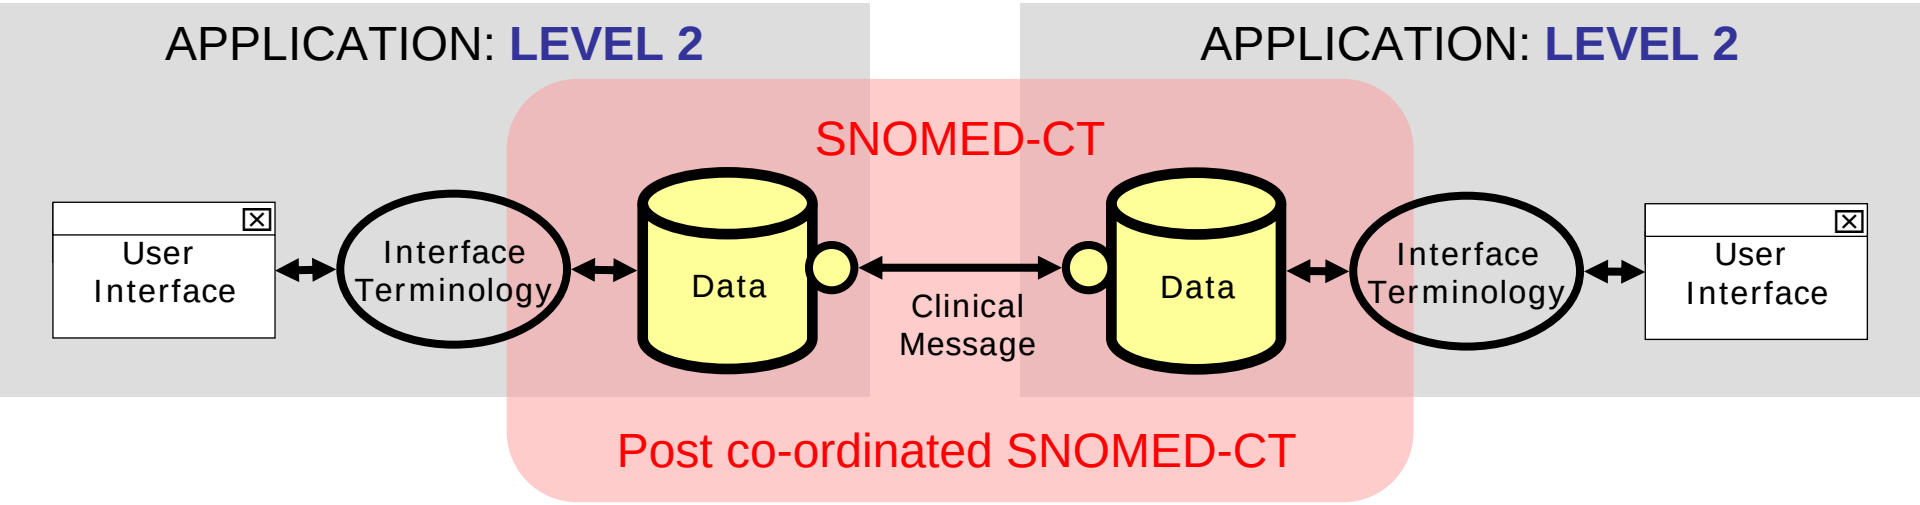
- Systems do not internally support SNOMED-CT
- Systems may not be capable of working in a SNOMED-CT world as they have not been designed and built around a terminology as large and as complex as SNOMED-CT
- Systems may be provided with a mapping function to map outbound messages containing local codes into messages containing SNOMED-CT codes to support communication with other systems or for reporting
- Post co-ordination is impossible and mapping restricted
- Sharing of termed data, and semantic granularity is limited
- Decision support is limited to the lowest level of system in which data is held
- Level 0 solutions cannot be readily engineered to become Level 1

Solution Capability Matrix: Level 1



- Systems support SNOMED-CT internally but with restrictions
  - e.g. shortened descriptions, restricted subsets, limited hierarchical browsing
- Systems will not support inbound post-coordinated expressions
- Most existing systems offering some SCT support would be in this category
- Some systems have pushed the upper limits but require extensive maintenance overhead to maintain pre-coordinated (‘ready defined’) terms in line with needs
- Sharing of data and decision support using data from more than one system is compromised
- Level 1 solutions cannot be readily engineered to become Level 2

Solution Capability Matrix: Level 2



- Systems support post-coordinated expressions and can communicate with other Level 2 systems using messages containing post-coordinated expressions (which adds additional qualifiers to ‘terms’ to improve clinical detail)
- Systems will have potentially many styles of User Interface to support different users and user contexts (e.g. nurses on wards, surgeon in theatre) and their requirements to add information to patient records
- These systems would also be able to exploit the encoded data within decision support rules

Drivers for SNOMED-CT adoption

- The implementation of SCT requires software applications that exploit its features to meet the real and perceived needs of users. Users include those who enter or retrieve clinical information, who utilise population and other aggregated data. and those who design, commission and configure software for use in a particular clinical environment
- Increasingly the assumption of purchasers is that SCT is used as the common terminology which drives the clinical functionality within products. However the majority of systems and applications have not been designed around a terminology as large and complex as SCT
- An increasing user and customer demand for SCT based products will drive the vendor community to develop their products and their data models accordingly
- Those vendors who have made the investment in developing their products to use SCT at its core will be best placed to compete within this evolving market
- Electronic clinical record system providers or solutions who can support post co-ordinated SCT will still be constrained by the limitations of others, especially departmental solutions (pathology, radiology, pharmacy)

New SNOMED-CT based vendors will add their voice to the increasing demand for SNOMED-CT based solutions

Conclusions

- The effect of products with mixed capabilities in supporting SNOMED-CT, combined with disparate purchasers, timetables, political, economic and clinical imperatives, results in a complex mixture
- However utilising the proposed capability matrix enables understanding of the interplay, and interaction of each stakeholders' issues
- Software vendors need to
  - understand how they can achieve higher support for their products within a level, recognising the constraints imposed by that level.
  - determine the re-engineering required to provide an equivalent solution at a higher level
  - recognise that such a model can not constitute a roadmap for their products
- To achieve Level 2 and support the encoded data meaningfully will need substantive development of many solutions in terms of user interfaces, processing and database structures
- Care is required by all stakeholders when, in the future, local and national solutions comprise a mix of Level 0, 1 and 2 solution support.
  - Level 1 solutions cannot interoperate with messages from Level 2 solutions unless the Level 2 solutions comply with the restrictions imposed by each of the Level 1 solutions
  - At this stage solutions will be built around SNOMED-CT and will likely provide sophisticated native SNOMED-CT terminology services
  - Until that time sophisticated and iterative workarounds will need to be in place and utilised by all users

Only when all solutions are Level 2 will the full benefits of SCT be realised

Establishing Sustainable Electronic Communication Across the Continuum

Julie Watson[a], Mark Angove[b]

[a] *Director Health Information Management Services, Sunshine Coast Health Service District, Queensland Heath, Australia*
[b] *Health Informatics Solutions Consultant, Queensland Health, Australia*

Abstract and objective

Without healthcare partners across the continuum having timely access to accurate information relating to patients' treatment, patients' health outcomes are placed at risk.

This paper documents a case report of the approach adapted by the Sunshine Coast Health Service District to establish sustainable electronic communication across the continuum.

The paper identifies how the Health Service District:

- Identified barriers and constraints to uptake (such as spoken and written language barriers, constraints impacting on introduction of appropriate technology, etc)
- Benchmarked key performance indicators to establish a baseline for assessment of introduction of electronic communication
- Established monitoring and registration processes
- Developed "change templates" to establish sustainable electronic communication in a community of health care partners

Most significantly, prior to the establishment of electronic communication in the District, discharge summaries were not available to GPs within 48 hours. In the first month of the capability being available 30% of summaries from all medical units across the District were available to GPs within 48 hours.

Testimonials from primary care community partners are positive. For example Dr Sandra Peters GP from Chancellor Park Medical Centre: "Timely discharge information sent electronically is accurate and we can follow up without delay."

ICT for Health System Sustainability: Needs and Challenges

Ahmad Khudair[a b], Ron Summers[b]

[a]*Dept of LIS, King Saud University, Saudi Arabia*
[b]*Research School of Informatics, Loughborough University, United Kingdom*

Abstract

This study highlights the role of Information and Communication Technologies (ICTs) in developing novel health systems in Saudi Arabia. A model for sustainability of the Saudi health system is proposed that provides a framework for developing generic e-health services. Existing and future challenges of procuring and implementing the e-service framework are discussed.

Keywords:

informatics, sustainability model, Saudi Arabia

Introduction

The health infrastructure of Saudi Arabia and its diagnostic, therapeutic and health prevention services have made important and increasing progress during the past decade [1,2]. The Kingdom's medical colleges and hospitals provide specialist diagnostic and therapeutic services and medical education and training programmes, while they also conduct health research in collaboration with other research centres [1-3]. However, Saudi health care is facing new challenges. Financial constraints are now forcing the Saudi Government to re-evaluate their health care policy in order to ensure the continuous upgrading of health services for its people [4]. Accordingly, the Saudi Ministry of Health has privatised some government hospitals, while encouraging and creating more opportunities for private sector participation in the health sector to lessen the burden on its budget [2]. A factor that affects the sustainability of Saudi healthcare is that hospitals are established individually and independently with no consideration for co-operation and co-ordination [5]. In practice, Saudi health is the least fortunate sector in utilising ICTs and most hospitals have a poor information infrastructure [6]. The majority still rely on traditional practices of 'pen and paper' [7]. There is no strategic plan for health information in the country [8,9] and many health professionals have insufficient ICT knowledge, experience and skills [7-10].

Methods

The research methods used to uncover the needs and challenges include: a review of the relevant literature, observation of activities and interactions, a web-based questionnaire survey of individual perceptions of needs and document analysis. A model-based sustainability component was developed from the findings of the application of these methods.

Results

Health professionals in Saudi hospitals view 'lack of training' as the major factor in introducing ICT into hospitals, followed by 'lack of co-ordination', 'poor management', 'lack of IT staff' and 'lack of IT policy'. Qualified management will play a major role in overcoming problems and obstacles which might cause failure in ICT implementation [8,10]. This highlights the need for a health information policy which is currently lacking [9]. The anticipated problems also raise again the issues of training and co-ordination.

Discussion

Saudi hospitals have been under tremendous pressure to reform to seek sustainability of their healthcare system. This has been driven by escalating costs and increased demands for healthcare development. The most difficult barrier to the full implementation of ICT in hospitals is their traditionally bureaucratic, complex and highly departmentalised structure within their leadership style. Potential conflicts exist: hospital relationship with health professionals and the need to avoid various dissatisfaction; and, hospital management philosophies and the need for organisational changes and development.

In discovering the challenges facing the health system in Saudi Arabia, a planning committee, involving professionals and experts, reviewed issues related to health system and ICT. The committee reached some vital conclusions and required urgent solutions to the problems. Part of which is: 1) the need to unite and define clinical computing and health information systems, 2) the importance of developing information infrastructure and a health information network among the Saudi Hospitals and research centres, and 3) the need for automation in the health sector and its administration. Crucially though, there have been no actions to impose these views [6].

In relation to the implementation of National Health Information Network, one of the challenges to be faced is designing a system network that meets users' needs, while reflecting a continuously changing organisational environment and to develop ICT that supports various organisational demands [10]. The ICT development process should avoid any possible confusion, poor quality, inefficiency, and unnecessary costs. The main tasks appear to be to coordinate the different visions and, in particular, clarify them, as well as to establish the impact that these visions would have on the forthcoming ICT application. In the process of development, hospital management and authorities should understand thoroughly what it is they are committing to, and what barriers they will encounter [10,11].

The proposed model comprises four components: knowledge management and diffusion; ICT implementation; health professional oriented approach; and, patient oriented approach.

Knowledge Management and Diffusion: in relation to information access and dissemination, there are two cultures - access or network-friendly culture; and a holdings or network-averse culture [11]. Information-sharing is essential between health professionals and hospitals. However, this vision would not be possible in the absence of a health information network [10]. Sharing of information, however, is a huge task that cannot be accomplished without a well designed information policy and formal co-operation [9,10]. The communication and sharing of health information has an important role in the delivery of quality healthcare in Saudi Arabia [6].

ICT implementation: ICTs promote various channels of communication and co-operation in the healthcare environment. Importantly, they will help the healthcare environment to move towards the establishment of a flourishing health information society by popularising the use of electronic resources, and describing the benefits and advantages of the electronic learning programmes.

Health Professional-Oriented Approach: this model component represents the delivery of knowledge on a convenience basis according to the various needs of health professionals. The health professionals-oriented approach may promote web patient/practitioner relationships. The combination of both health knowledge and ICT skills allows individuals to participate in e-health programmes.

Patient Oriented-Approach: the health system in Saudia has produced inevitable programmes of care for the public. However, there is a lack of patient-oriented educational programmes designed according to patients' local cultures and educational level.

Conclusion

There are numerous challenges to be overcome before ICT can achieve its full potential and successful implementation in the healthcare environment in Saudi Arabia. The country's decision makers, planner and professionals should work in establishing a clear strategy of implementation based on field projects and research considering the human factor as it described in the proposed sustainability model. Therefore, they should take a holistic view of the situation, as an integrated part of their plans for the development of the health system utilising the potentiality of information and communication technologies (ICTs).

- Saudi Healthcare System
  - Grown organically but ready for a step change
- Factors peculiar to Saudi Arabia
  - Including free access to health system at point of care
- Expectation of Development
  - Saudi population expects a high standard health service

Methods

- Literature Review
  - From 1986 to date
- Document Analyses
  - From Ministry of Health; Ministry of Planning; and individual Hospitals
- Observation
  - Non-participative observation across 11 Hospitals in Riyadh
- Sustainability Model Components
  - People aspects and System aspects

Saudi Health Service

- Saudi Healthcare Service is planned to provide efficient health services for increasing population through utilisation of resources and more equity in service provision and distribution.
- Studies revealed a Health-Service-Gap in metropolitan and rural areas.

ICT in Saudi Healthcare System

- Healthcare System infrastructure
  - Poor national health system infrastructure
- Healthcare Technology
  - High Tech devices vs. Health Information Technologies
- Health Information System
  - Hospitals, Primary Care Clinics
- Electronic Health Records (EHR)
  - Integrates health and social need

Challenges

- Health Services Management
- Hospital Management and Operation
- Stakeholders' Development Role
- Health Information Policy
- Health Information System
- System and Human factors
- Implementation (Success and failure)

Needs

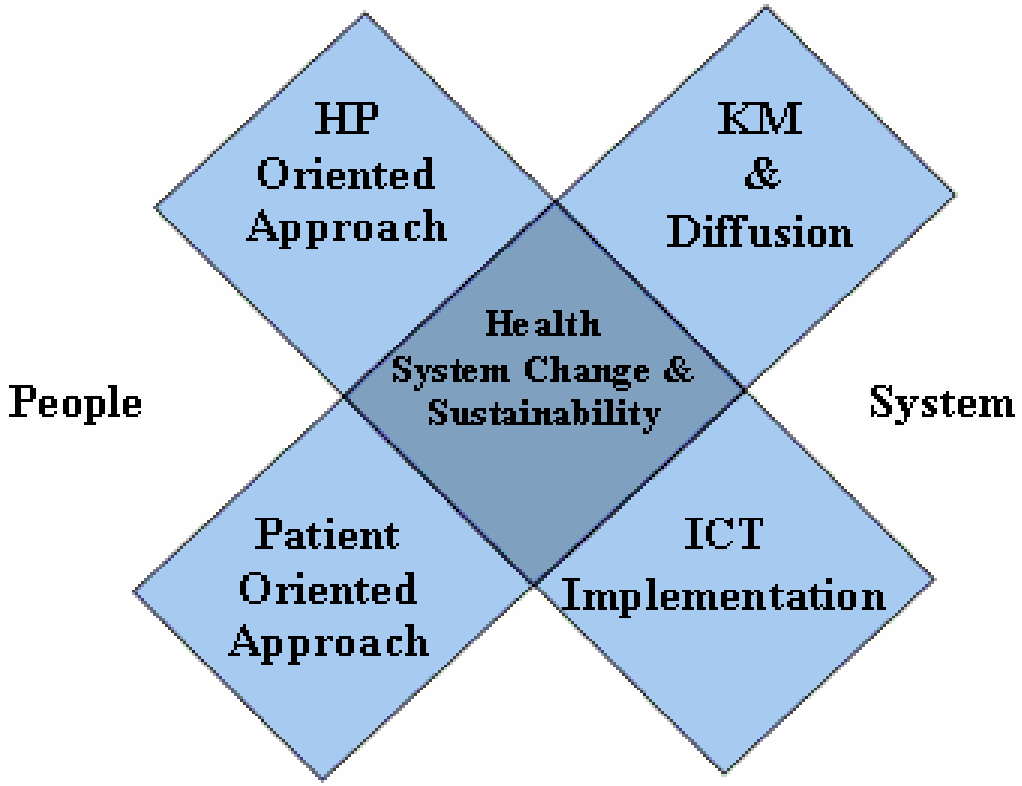
- Review of Administrative and Financial Systems
- National Information System Infrastructure
- National Health Information Policy
- Increase usage of Health Information Systems
- National Research Projects in HIS
- Holistic View of Approaches and Implementations

Sustainability Model (1of 2)

Sustainability Model Components

- Knowledge Management and Diffusion
- ICT Implementation
- Health Professional Oriented Approach
- Patient Oriented Approach

Sustainability Model (2 of 2)



Conclusion

- Saudi Health System ready for development
- Able to integrate innovative health technologies as there are few legacy systems
- Provision of standards-based electronic health records
- Holistic view taken of implementation

Thank You

Abstract

In Japan, two PCs (for example: EMR and PACS viewer) are commonly used for the Hospital Information System in one clinical unit. Many physicians have to enter a user ID and password to login to these systems. To solve the troublesome manipulation, we developed the function of the IHE-ITI Enterprise User Authentication (EUA) and Patient Synchronized Applications (PSA). We developed middle-ware for the EUA/PSA to reduce the implementation load among the EMR, PACS-viewer, report-viewer, radiation scheduling system and radiation information system. The EUA/PSA was based on the HL7 CCOW standard and did not support multi PCs. So we enhanced the EUA/PSA mechanism for use with several PCs. We realized that EUA/PSA were essential in a multi-system environment. Our middle-ware resolved the complexities of the application implementation. The established guideline was useful to unify the user interfaces of each application. We found that the EUA/PSA function will be inevitable for visual integration.

Keywords:

IHE IT Infrastructure,
Enterprise User Authentication (EUA),
Patient Synchronized Applications (PSA),
Context Area Manager

Introduction

In Japan, many large-scale hospitals have Computerized Physician Entry Systems. Recently, PACSs (Picture Archiving and Communication Systems) have also been rapidly spreading in the clinical environment. In the hospital physicians have to simultaneously manipulate these systems in out-patient clinics and wards. To reduce operation time, the concept of visual integration is necessary. Some methods of visual integration have been proposed, for example, the HL7 CCOW (Clinical Context Management Specification) [1]. By the definition of CCOW, the context manager is limited to one workstation or personal computer, which is not suitable for Japanese institutions. We analyzed the physicians' workflow and found that multiple workstations and/or personal computers should belong to the same context unit. We expanded the context unit to a "context area", which can cover several workstations and/or personal computers in one clinical unit.

For the implementation of visual integration, we adopted the EUA (Enterprise User Authentication) and PSA (Patient Synchronized Applications) integration profiles [2] that IHE (Integrating the Healthcare Enterprise) IT-Infrastructure [3] defined. To simplify the implementation we developed middle-ware that enables the EUA/PSA mechanism and modified our existing six systems. Our hospital specializes in particle radiation research and the hospital information system consists of the EMR, PACS, a reporting system (Report), radiation oncology-RIS (RO-RIS) and radiation schedule system (RSS). We thought that these systems should adopt the EUA/PSA.

The aims of this paper are (1) analysis of the effectiveness of the EUA/PSA, (2) the usefulness of the EUA/PSA middle-ware and (3) verification of the expanded function of the context manager defined by HL7 CCOW.

To study the effectiveness we counted the number of physicians' operations. We prepared middle-ware conforming to the EUA/PSA integration profile, developing several actor functions that the IHE ITI technical framework defined. We developed four types of libraries to satisfy the application's running environments. In this process we aim to know the validity of the library's algorithm.

The last purpose was to investigate the concept of the "context area" enhanced from the CCOW definition. The mechanism of the context area is the same as the context unit defined by CCOW. The management space was expanded to multiple computers from one computer.

Materials and methods

The CCOW Standard defines the specification of implementation only for a single desktop, one workstation or one PC. In the standard, there is one "Context", which is data set for the shared information between applications, and one "Context Manager", which is the process that controls the context information. A number of applications maintain information synchronized by the CCOW mechanism. IHE/ITI has defined the Integration Profile as the EUA and PSA with CCOW. EUA is an integration profile that recognized a single sign on by using shared user information, and PSA is an integration profile that maintains patient information among a number of applications by using shared patient information.

EUA that supports a single sign on is implemented by using "CCOW User Subject". First, each application joins the Context to send some messages to the Context Manager when an application starts. If the Context already has user information, the application retrieves the user information and then starts under the scope of authority of the user information. If not, the application presents a dialog box for the user to obtain the required information by user authentication, for example, user ID, password and so on. IHE has requested the Kerberos Authentication for the EUA. The authorized user information is sent to the Context Manager and then the information is set to the Context, after which other applications will use the information. This is the mechanism of the single sign on in IHE and CCOW.

The PSA that supports synchronized patient information is implemented by using "CCOW Patient Subject". When each application joins the Context and the user selects one patient in one application, that patient information is sent to the Context Manager and then set the patient information to the Context, after which the Context Manager send a message that one patient has been selected by other applications. This is a trigger that requests setting the patient for applications. When a user changes the patient, the same procedure is applied. All other applications then know that new patient information should be set. This is the mechanism of synchronized patient information.

Context Area Manager

We developed a new synchronized mechanism adapted to a number of desktop environments with Hitachi Medical Corporation. We expanded the mechanism of IHE and CCOW specifications, because it is useful and is easily understandable to use a standard procedure that has been already defined, so transactions and related information items in the new mechanism are the same as the specification and guide of CCOW and IHE. From an application point of view, some standardized functions or methods should be called up only when needed. The application is not concerned with the environments, whether a single desktop or a number of desktops. The developed environment supports such features.

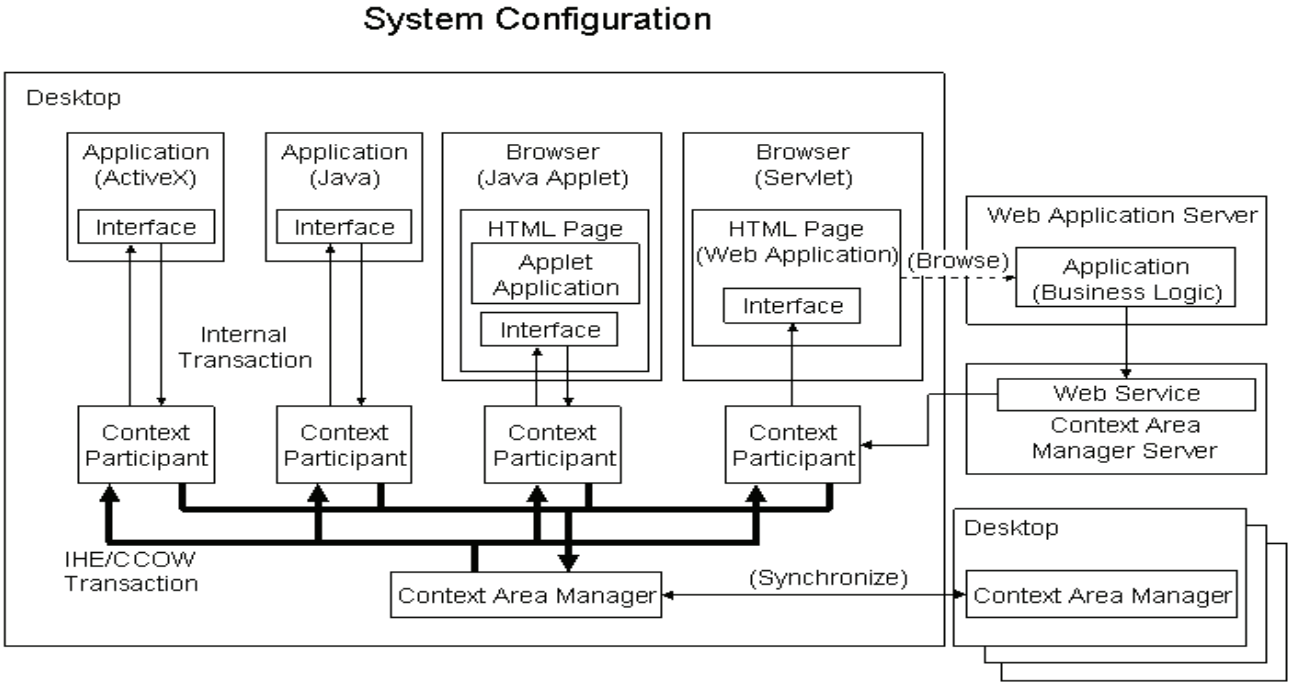

Figure 1 - Configuration of the context area manager and the relationship between the context area manager and applications

As shown in Figure 1, we defined "the Context Area Manager" and "the Context Participant" for a multi-desktop environment. The Context Area Manager is a new process that has expanded functions compared with the Context Manager specification. The Context Area Manager has the same functions as the Context Manager. The expanded function of the Context Area Manager is for communication with the Context Area Manager on other desktops (workstation and PC). If an application requests to change the Context, the Context Area Manager would broadcast that information to other Context Area Managers to synchronize the Context on all desktops. This mechanism allows synchronization of the Context on a number of desktops. From a user viewpoint, the information handled on a number of desktops remains synchronized.

The Context Participant is a special process that receives messages from the Context Area Manager and sends them to an application which receives messages from an application and sends them to the Context Area Manager. The Context Participant would be generated for each application. The relationship between the application and the Context Participant is one to one.

An application sends messages to the Context Participant by using libraries or methods or Java scripts. It is dependent on the implementation of an application. There are 4 types of implementations: ActiveX application, Java application, Java applet and Servlet. A library that sends and receives messages from/to the Context Participant for ActiveX application and for Java application has been developed. Also, for the Java applet, some Java scripts are written as applets to enable communication from/to the Context Participant. In the case of the Servlet system, the logic that allows the communication from/to the Context Participant is implemented on the server side. There are various complicated configurations for the Servlet system, but all systems have a basic configuration, the Context Participant and the Context Area Manager, and all applications communicate from/to the Context Participant to send messages from/to the Context Area Manager. The Context Area Manager enables communication to the Context Area Managers on other desktops to synchronize information in the Context Area.

Next we established guidelines for the implementation of the EUA/PSA. Table 1 shows the guidelines. The venders of the existing systems modified their applications according these guidelines.

Table 1 - Guidelines for implementation of the EUA/PSA

NO	Items
1.	To manipulate a context manager, unified procedures and man-machine interfaces are used.
2.	The conditions according to participation and breakaway from the context manager did not depend on the applications.
3.	We can confirm the participation/breakaway visually.
4.	When an application works with context manager, the application checks that the context manager is running correctly.
5.	When the context is changed, each participating application with un-saved data will ask the user to save the data.
6.	The displayed terms regarding the context manager are decided. Every application uses the same words and icons that show the status of participation.
7.	The dialog: Each application is set to default maneuvers: (1) always permit, (2) ask a user with a dialog box and (3) always refuse to change the context.

Target systems

The target systems were (1) EMR, (2) PACS, (3) report system, (4) RO-RIS and (5) RSS. The EMR is the HOPE/EGMAIN-EX C/S Edition, HOPE/DrABLE-EX and HOPE/LAINS-PC by Fujitsu. The EMR can open six patients simultaneously. We decided the synchronization using the PSA. The first patient is opened by the Context Area Manager, whereas, the last patient was synchronized by another application.

Our PACS consists of two systems, SDS-DicomViewer (PACS-1) by TechMatrix, and the SYNAPSE (PACS-2) by Fujifilm. The Report is F-REPORT by INFOCOM. The RO-RIS is RIGIA by Global-for. The RSS is the Particle Radiation Schedule Management System by Nippon Telegraph and Telephone East. Figure 2 shows the configuration of the NIRS Hospital Information system. When the EUA/PSA library was installed in all applications, the most suitable library was carefully selected from the four types (ActiveX application, Java application, Java applet and Servlet).

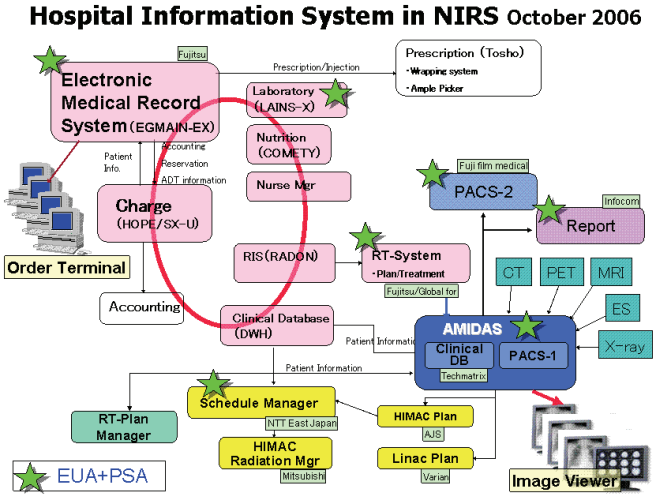

Figure 2 - Existing Hospital Information Systems. The star sign denotes the function of the EUA/PSA

Results

Our EMR has been running since October 2006 and uses the ActiveX module. PACS-1 uses the Java module. PACS-2 uses the ActiveX module. The Report uses ActiveX. The RSS uses the Java applet. RO-RIS uses the ActiveX. No system uses the Servlet module.

We set up the context area in our hospital. There are 23 context areas in the out-patient clinic and wards. Each context area covers several applications (EMR, PACS-1, PACS-2, Report, RSS and RO-RIS). Each context area consists of 2 personal computers, one which is used mainly for EMR and the other which is used mainly for the PACS/Report application and RSS application.

We examined the number of actions for the login and the selection of patients in each application. Table 2 shows the differences between operation with and without the EUA/PSA function. Each application can omit 2-3 operations by using the EUA/PSA mechanism.

Table 2 - The number of the actions we can omit during Login and Patient Selection by the EUA/PSA function

Application	Login	Patient Selection
EMR	2	2-3
PACS-1	2	3
PACS-2	2	2
Report	2	2
RSS	2	3
RO-RIS	2	3

(We count one for a mouse click and/or a consecutive keyboard input.)

The enhanced Context Area Manager is working with no serious problems, but if the number of participants in the same context area increases, the response time of the Context Area Manager also increases. We found that with two participants in the same context area, the response time was less than one second.

Discussion

Our hospital has six existing information systems. We wanted to reduce implementation problems and to unify the application interfaces: middle-ware could resolve these problems. We prepared guidelines for modification of the workflow. These guidelines include icons that indicate the status of an application, as shown in Figure 3. We developed two types of icons (small and large), which are useful for physicians to understand the status of the context manager. The "Participating" status means that each application communicates with a context manager and all applications cooperate. In this status, all applications are coordinated for the same log-in user and the same patient ID.

Figure 3 - The left two icons show "Participating", the right two icons show "Non-Participating"

The validity of the enhanced context area was confirmed. Our hospital information system consists of six systems (EMR, PACS-1, PACS-2, Report, RSS, RO-RIS). In the future, the necessity of t visual integration will increase, and implementation of the IHE ITI EUA/PSA will be popular among medical institutions and hospitals. The unified procedure for visual integration is very important, and we developed guidelines and icons. We consider that hospital information staff should prepare guidelines and rules to utilize the visual integration effectively.

The context manger function of the patient subject is limited to the patient ID. In future, integration of the patient ID should be enhanced to details of patient information such as the examination ID or image ID, especially for PACS/Report applications. The EUA/PSA defined by IHE ITI uses CCOW version 1.4, which defines the patient subject as the patient ID. CCOW version 1.5 defines detailed information about a patient such as DICOM objects. In future we want to improve the function of the PSA to support DICOM objects.

It is natural to be afraid of malpractice in clinical procedures. With a multi-vender information system it is troublesome for physicians to enter a user ID and a patient ID or to select a patient. The EUA/PSA mechanism will

solve such onerous problems, but if the Context Area Manager is down, the implications will become serious. We made the related applications foolproof and robust to eliminate malpractice. Each application can be executed without the EUA/PSA function and will ignore the Context Area Manager when the manager will not respond to a participant.

Conclusion

We developed four types of EUA/PSA middle-ware. Each application used suitable middle-ware for running environments and also enabled the simple implementation of a single sign on and patient selection. We modified six existing information systems to use the EUA/PSA middle-ware. These modifications require the considerable effort, but otherwise we achieved good seamless operation by the EUA/PSA functions. We believe that the EUA/PSA function will be indispensable for multi-vender information systems and useful for clinical safety.

Introduction

- Our hospital is specially designed for the heavy particle radiation therapy. Systems (HIS, PACS, clinical database and schedule management system) are running. Some systems were recently replaced. Then we made a modification to use the IHE ITI profiles.
- We planed to study the effectiveness and availability of IHE[1][2] IT-Infrastructure profiles in the Japanese environment. The final aim is to evaluate the availability of the integration profiles in Japanese environment.
- We expand the function of the EUA and PSA, because one clinical unit includes 2-3 personal computers in the outpatient clinic and the ward. We defined the context area for the context manager defined by the HL7 CCOW (Clinical Context Management Specification)[3]. We developed the middleware to realize the function of the EUA (Enterprise User Authentication) and PSA (Patient Synchronized Applications).

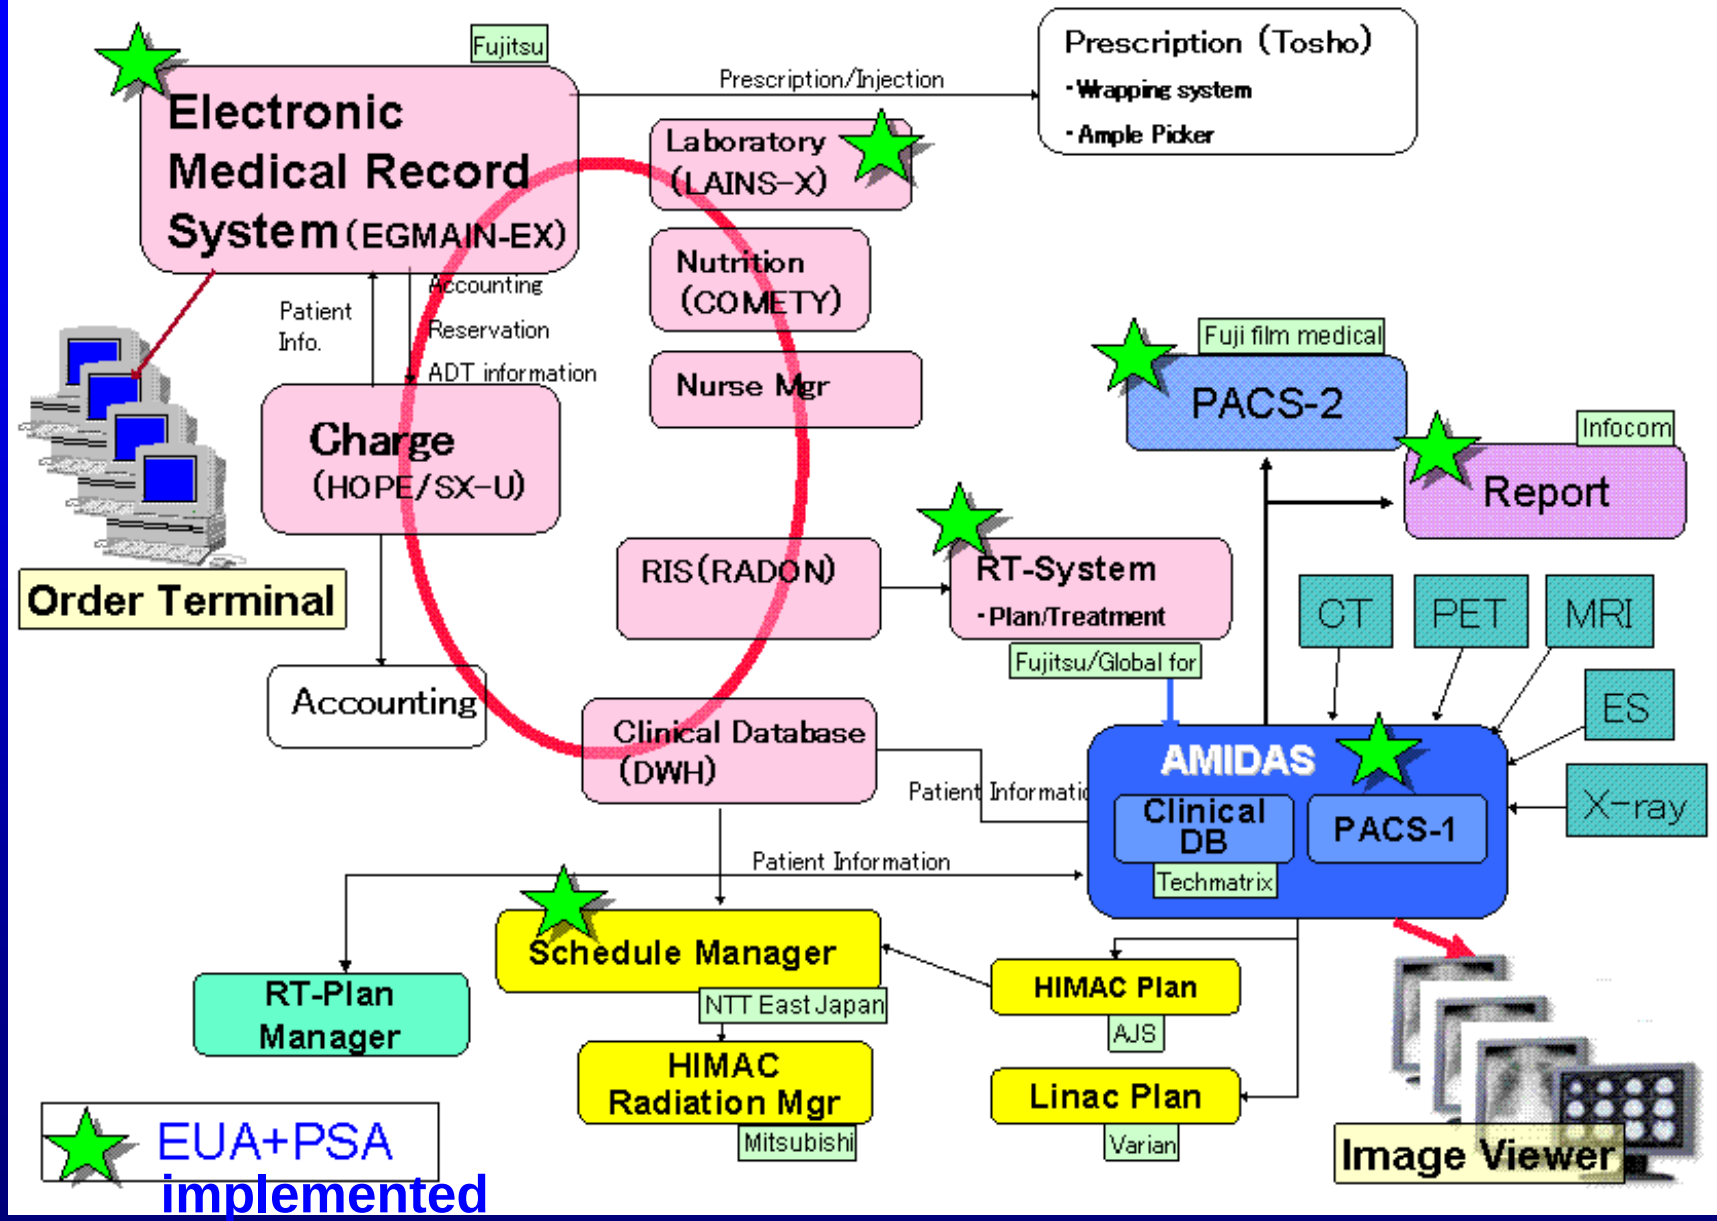
National Institute of Radiological Sciences Hospital

- Located at Inage, Chiba
- Beds for inpatients: 100 beds
- Outpatients: 70-100 patients/day
- Specialized for a radiation therapy with the heavy particle
- Film-less environment (August 2005)

Purpose

- To evaluate IHE IT Infrastructure Integration Profile (EUA, PSA, CT）
- To adapt the EUA and PSA to the Japanese clinical environment
- IHE IT Infrastructure Profile:
  - EUA: Enterprise user authentication
  - PSA: Patient synchronized application
  - CT: Consistent time

Hospital Information System in NIRS October 2006

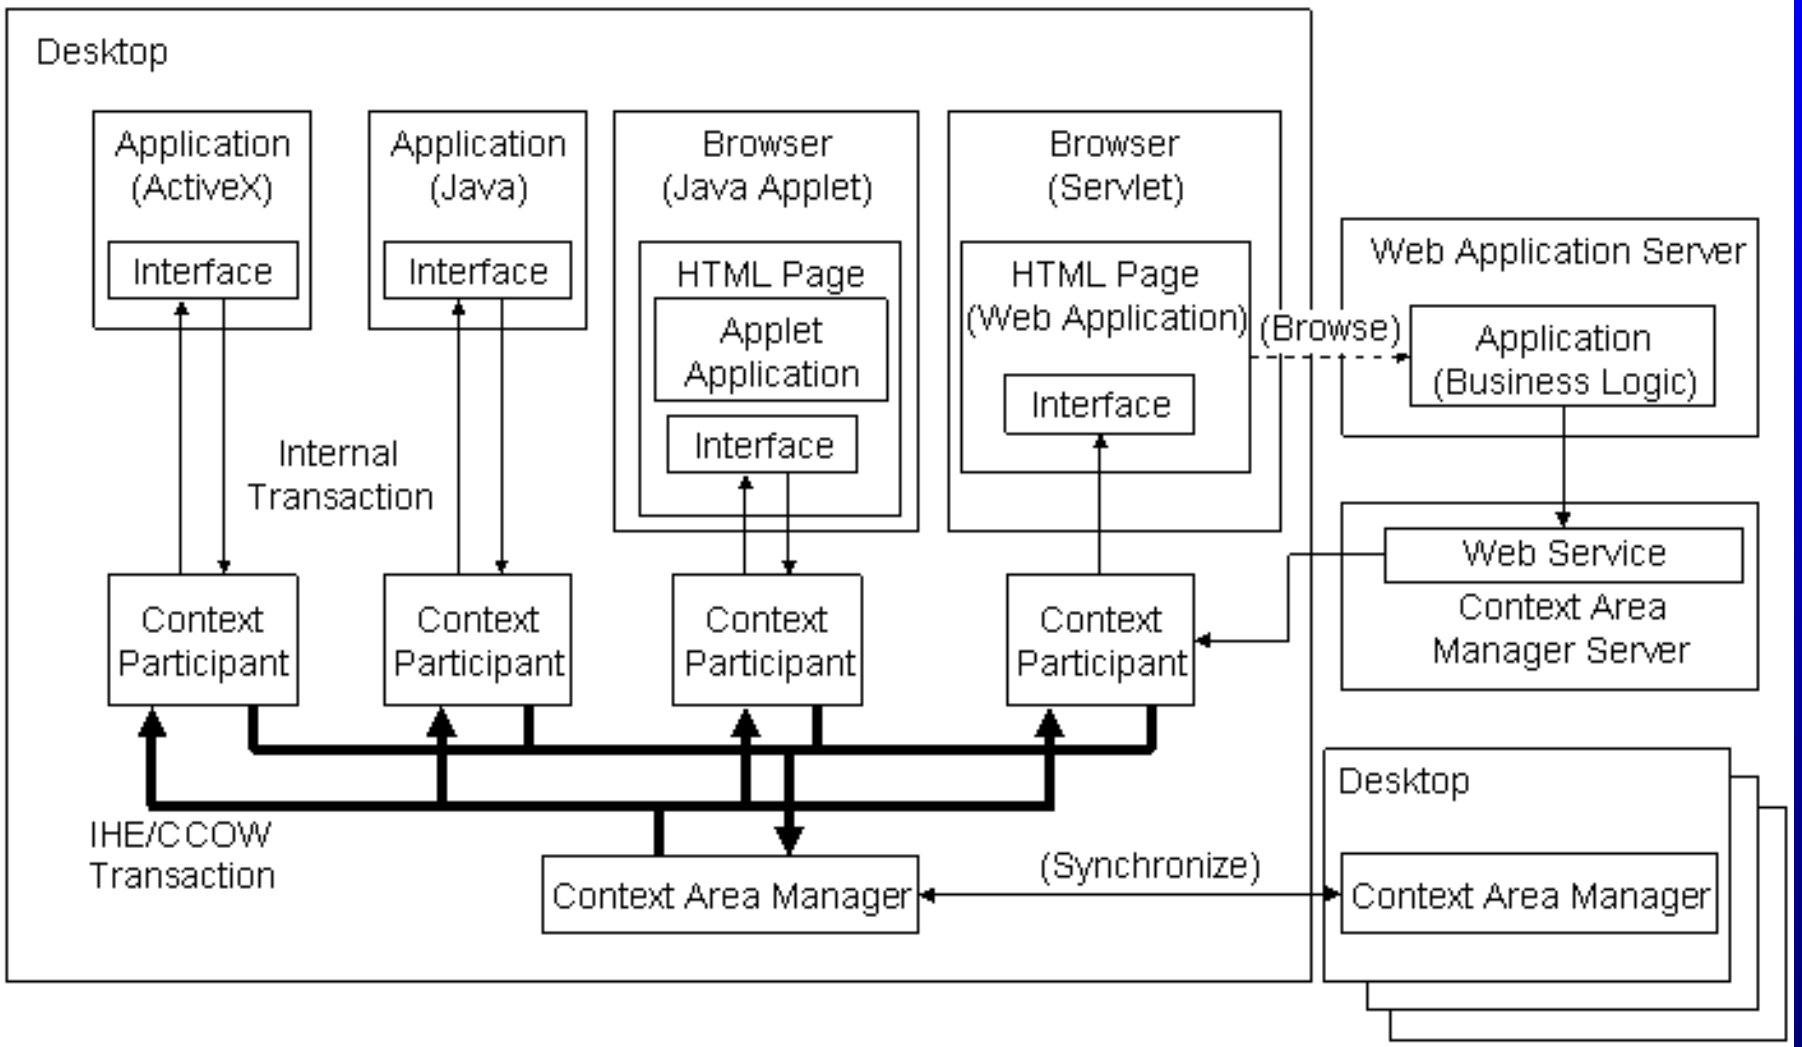


Target Systems

- (1) EMR: HOPE/EGMAIN-EX C/S Edition®, HOPE/DrABLE-EX®, HOPE/LAINS-PC® (Fujitsu)
- (2) PACS-1: SDS-DicomViewer® (TechMatrix)
- (3) PACS-2: SYNAPSE® (Fujifilm)
- (4) Report system: F-REPORT® (INFOCOM)
- (5) RO-RIS: RIGIA (Global-for)
- (6) Radiation schedule system: RSS (Nippon Telegraph and Telephone East)

These six systems were adapted by each vender.

Configuration of the context area manager and the relationship between the context area manager and applications



Methods

- We developed four types of EUA/PSA middle-wares (ActiveX application, Java application, Java applet and Servlet).
- We use this middle-ware to communicate the context area manager each other. We analyzed the flow of the applications. We implemented the function of the EUA and PSA into the existing applications.
- Next we established guidelines for the implementation of the EUA/PSA. The venders of the existing systems modified their applications according these guidelines.
- We evaluate the functionality of the EUA and PSA by using the each application.

Result

- Our EMR has been running since October 2006 and uses the ActiveX module. PACS-1 uses the Java module. PACS-2 uses the ActiveX module. The Report uses ActiveX. The RSS uses the Java applet. RO-RIS uses the ActiveX. No system uses the Servlet module.
- We set up the context area in our hospital. There are 23 context areas in the out-patient clinic and wards. Each context area covers several applications (EMR, PACS-1, PACS-2, Report, RSS and RO-RIS). Each context area consists of 2 personal computers, one which is used mainly for EMR and the other which is used mainly for the PACS/Report application and RSS application.

Discussion

- We wanted to reduce implementation problems and to unify the application interfaces: middle-ware could resolve these problems. We prepared guidelines for modification of the workflow. These guidelines include icons that indicate the status of an application.

- The validity of the enhanced context area was confirmed. In the future, the necessity of t visual integration will increase, and the unified procedure for visual integration is very important.
- The EUA/PSA defined by IHE ITI uses CCOW version 1.4, which defines the patient subject as the patient ID. CCOW version 1.5 defines detailed information about a patient such as DICOM objects.

Conclusion

- We developed four types of EUA/PSA middle-ware. Each application used suitable middle-ware for running environments and also enabled the simple implementation of a single sign on and patient selection.
- We modified six existing information systems to use the EUA/PSA middle-ware. These modifications require the considerable effort, but otherwise we achieved good seamless operation by the EUA/PSA functions. We believe that the EUA/PSA function will be indispensable for multi-vender information systems and useful for clinical safety.

A Case Report of First Steps Taken at an European Agency, ECDC to Introduce Knowledge Management Services (description of knowledge sources and 'extraction' of metadata in practice)

László Balkányi[a]

[a] *Unit of Scientific Advice, European Centre for Disease Prevention and Control , Stockholm, Sweden*

Abstract

As part of efforts toward building knowledge based services at the new European Centre for Disease Prevention and Control (ECDC), authors investigated content and extracted metadata from a large document base.

ECDC has been created to strengthen Europe's defenses against infectious diseases, aims to pool health knowledge, to develop authoritative scientific opinions about the risks. A quickly accumulating body of ~ thirty thousand electronic documents was analyzed. As a way out from the provisional, start-up state, it was found that a set of systematic measures among them notably introduction of metadata enhanced templates (using Dublin Core NSMetadata Initiative) and ontology based tagging should be applied. As an innovative approach we used the existing arbitrary file and folder structure to be translated to content characterizing metadata. We hope that the in the next future we will be able to build up a knowledge repository with enhanced navigation facilities, using the existing electronic content – but made it much more transparent and easy to use source of knowledge for internal and external users at ECDC.

Keywords:

information management, public health informatics, communicable disease control, knowledge based services, document management, standard tools, European Centre For Disease Prevention and Control, ECDC

Introduction

This paper describes the first steps taken at a European agency, European Centre for Disease Prevention and Control, ECDC to introduce knowledge management (KM) services. Describing the chain of thoughts while planning the services and the experiences of the analytic work hopefully help others with similar tasks to understand the nature of information handling at their organization and to plan better KM services.

ECDC is an EU agency that has been created to help strengthen Europe's defense against infectious diseases. The mission of ECDC is to identify, assess and communicate current and emerging threats to human health posed by infectious diseases. To achieve this mission, ECDC works in partnership with national health protection bodies across Europe. ECDC aims to pool Europe's health knowledge, so as to develop authoritative scientific opinions about the risks posed by current and emerging infectious diseases. The Centre, currently staffed with ~ 80 experts and management, will have an over € 50 million budget by 2010 and its staff will grow to 300 over the coming years.

Establishing a knowledge-base (KB) and a set of knowledge-based services (KBS) is clearly a key issue for the full blown operation of ECDC. KBS's developed for human- and KBS's developed for machine (that is software) users will serve all activities / all units of ECDC.

ECDC has a matrix organization with three technical units, an administrative unit and seven horizontal disease-specific projects. The three technical units are the following: The Scientific Advice Unit (SAU), the Unit for Preparedness and Response (PRU), and the Surveillance and Communication Unit (SCU). SAU's main tasks are to provide sound and independent technical and scientific advice; do and maintain an inventory of communicable disease related resources; build an operational network of experts and scientists in Europe; build further on the scientific competence and experience of the scientific community for communicable diseases, actively participate in all key scientific conferences and meetings. PRU's main task is to keep track of emerging health threats inside and outside the EU, provide rapid risk assessment and coordinate a timely response to such threats, done by operating the Early Warning and Response System (EWRS), organizing training programs for public health, and supporting outbreak missions of MS experts. SCU's main task is to take over and operate the surveillance of communicable diseases at the EU level from the designated surveillance networks. Data will be analyzed and the information disseminated to those who need it for public health decision taking in Europe. The ECDC disease specific activities are organized within seven horizontal projects with team members from all technical units: 1) influenza, 2) tuberculosis, 3) food- and water-borne diseases, 4) other diseases of environmental and zoonotic origin, 5) vaccine preventable diseases and invasive bacterial infections,

6) HIV-STI and blood-borne viruses, and 7) antimicrobial resistance and nosocomial infections.

In ECDC we plan to establish a knowledge base for human users to serve as electronic information source, enhanced / supported by specific services i.e. knowledge mapping, intelligent search, cross-referencing, and other tools to navigate in the information space. It might be equally, or on the long run even more important to establish KB services that can be used also directly by other information systems, the surveillance networks, the Early Warning and Response System such as terminology services and later also by other advanced systems / functions, enabling high level, standardized reporting, (semi-) automated extraction of critical information, semantic crosschecking of information gained form independent sources, etc.

At planning these services, we want to avoid 'reinventing the wheel' and as a strategic decision, we want to stick to international standards ensuring interoperability and long run transparency of emerging systems/modules/functions. Fortunately, recently, a number of general and medical informatics knowledge representation and handling tools became more and more mature, and available as tools for such tasks on several levels from data formats to knowledge representation and process & system modeling (the XML family, UML, OWL, etc). The buzzwords 'semantic web' and 'web 2.0' describe a set of emerging tools / methods that should be considered at planning a future proof solution portfolio.

The below described work is one of the first steps taken toward the realization of KM services at ECDC. A knowledge needs assessment revealed that there is a pressing need for better information retrieval, handling of the already existing and rapidly growing electronic document set of ECDC. It is clear, that on the long run, as part of the integrated ICT services, ECDC will have to have an integrated electronic content management system dealing with the internal documents and also the ever-growing, mostly open partly restricted web content. Planning, procuring and implementing such a system takes at least 1,5 – 2 years, so we needed an interim solution, that serves also as a sort of sandbox for the final application. We describe here the analytic parts of the work, the thinking about metadata, some innovative methods we choose and show the results of these preparation tasks.

Materials and methods

Materials

Our objects, materials to study were the electronic documents accumulated on the drives of ECDC since its operations started in May 2005. The 'snapshot' of the files – folders structure was taken in August, 2006, after roughly one and half year of ECDC operations. Only files and folders of the technical (scientific) units were analyzed – that of the administration, financing, human resources and routine emailing were not drawn into the analysis. All files generated during this period were taken in account, classified into documents[1], spreadsheets, presentations, and 'all others' categories.

Methods

To prepare later seamless introduction of content management, we decided to take three steps

- an analytical step to understand the build-up process, the accumulation of information
- extraction of metadata and setting up a keyword library
- establishing a set of metadata "augmented" documents

This paper focuses on the first and on the second, closely related steps of this process.

To achieve the goals, simple tools were used as follows:

- command line tools and disk cataloging utilities for extraction of file / folder structures
- a Unicode text editor for building/editing xml files
- an online word processor for producing ODF compliant document templates
- a spreadsheet application for file statistics

Results

ECDC stores its electronic documents on file servers, where a shared space (a 'drive') was set up to store documents that should be reached across all the units, and 'unit specific' spaces (virtual 'unit drives') were assigned to the three above mentioned units, the SAU, the PRU and the SCU. The data characterizing file accumulations and distribution of the first one and a half year were analyzed in depth. The following numbers just summarize the most characteristic aspects. The document distribution in folders was investigated with the following results – see table1:

Table 1 - The number of folders/ subfolders existing at each level of the folder- tree

Subfolder depth level:	No. of folders in "shared" drive	PRU drive	SAU drive	SCU drive
root folder	14	30	41	42
2nd	44	156	84	187
3rd	177	240	152	276
4th	384	183	68	142
5th	661	178	24	81
6th	383	91	9	42
7th	245	12	12	39

1 (working) docs, and (to be published) pdfs

Subfolder depth level:	No. of folders in "shared" drive	PRU drive	SAU drive	SCU drive
8th	194	8	1	
9th	188	1		
10th	109			
11th	80			
12th	27			
13th	9			
14th	1			
Sum of folders	**2516**	**899**	**391**	**809**
Total no. of folders:	**4615**			

These numbers and some others following below are analyzed in the discussion section of this paper. It has to be noted, that the folder structure is the result of a non-regulated, 'organic' growth of the document set in a just formed, new organization, where highly autonomous and highly educated experts worked mostly either alone or in ever changing, problem oriented, ad-hoc teams on emerging problems. Roles and tasks were not yet 'frozen', most experts did extensive multi-tasking and took part also in building up activities. Information communication technology services were focused on providing a stable, robust office services background and electronic communication services, with no emphasis on electronic workflow support or organization of content – due to lack of capacities. However the amount of accumulating documents was / is staggering – be aware that the value axis below is logarithmic! See figure 1.

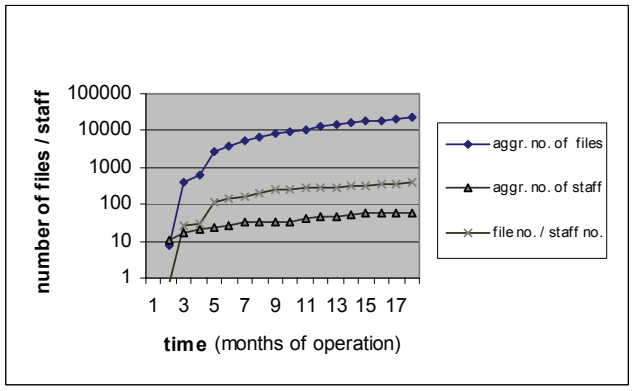

Figure 1 - The growth of staff and the aggregated numbers of scientific document files on ECDC servers

The distribution of files is detailed according to the most frequently used file types in table 2.

Table 2 - file type distribution

location of files		documents	spreadsheets	docs to publish (pdf-s)	presentations	miscellaneous (jpgs, html, txt, rtf, etc.)	all
shared 'drive'	abs	5797	557	4048	1167	6695	18264
	rel	32%	3%	22%	6%	37%	100%
PRU 'drive'	abs	2508	328	897	390	3337	7460
	rel	34%	4%	12%	5%	45%	100%

Discussion

Discussion of the results focuses on understanding and interpreting what is behind the numbers.

First, the files / folders structure: It is obvious, that it is almost hopeless to navigate efficiently (i.e. quickly and easily) in such a tree. The depths of more than ten levels and the (sub-)folder numbers ranging from one to more than six hundred (on depth level 5 of the 'shared drive) is remarkable. According to a classic, widely accepted paper [1] of cognitive science the pan of short time memory allows us to handle 7(+-2) "chunks" of information at any give time, due to inherent limitations of short term memory. Working in complex folder hierarchies, we use short term memory, therefore this well documented phenomenon should push us to reorganize our file/folder structure into embedded hierarchies of roughly 7 by 7 matrices (not much more than 7(+- 2) subfolders in a folder and not much more than 7(+-2) files in folder). The material, we deal with, however does not allow such a grouping. Concerning searching and retrieval in such a large, complex information space, does a simple or even an enhanced "brute force" search engine help? We think not, as desktop search engines have a significant limitation: they can search only by the string existing within the information object. If we have thousands of documents on very similar topics, the search by strings (words or parts of them) will be never specific enough to find a particular information object among them. Such a search will also be not helpful to find a set of related documents, connected not just by having the same words, but by some other characteristics, as e.g. referring to a geographic region, whilst in the text only countries or cities are named (e.g. in case of an out-

break investigation). Using metadata is of course the answer to this problem [2]. If a well maintained keyword vocabulary is used to tag the content and other characteristics of the documents, such problems can be solved. Even better if the 'vocabulary' is based on a logically sound ontology, meaning that later on we will have the option of semantic operations, of complex searches at hand. Before discussing the metadata issue, it is worth to discuss *a second aspect: the growth of the information heap*, resulting in almost thirty thousand information objects in one and half years, as seen on figure 2. below.

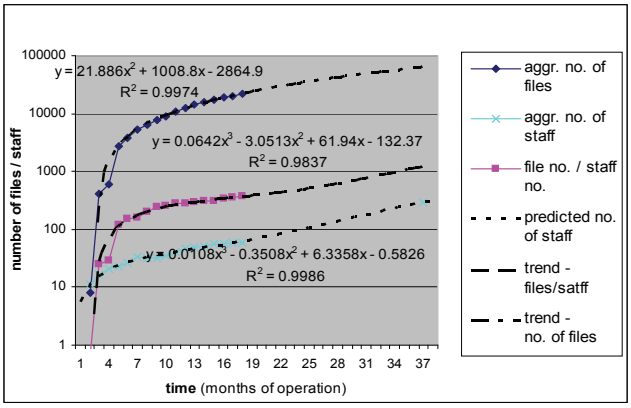

Figure 2 - trends of the growth of staff and the aggregated numbers of scientific document files on ECDC servers

ECDC will grow to the predicted staff of ~ 300 in the coming two years. Using this number trends can be examined concerning the future number of files and the file to be handled by a given staff member. Well fitting trend lines show that the number of files will reach nearly a hundred thousand and each staff member will be 'responsible' for more than a thousand file. This predictions might be disputed as more and more 'services' of ECDC will become 'operational': like the surveillance networks and the organization will turn to a 'normal operation' mode from the current build–up period. However most of the functions 'producing' information are already functional, even if only in skeletal format, and the curves show that the characteristics of the buildup period (sort of 'combinatory growth' of staff & information) became already more 'leveled' after the first nine months.

The last, third issue before we can discuss the required metadata in details, is the *distribution of files types* and its consequences: *Table 2* shows us, that while the single most frequent information object is the 'document' file (31% of all), there is a huge heterogeneous set, containing raw txt, html, gif, jpg, rtf, eml, etc. and some other, special files used to develop databases and applications. The difficulties to reach, to make available the information 'hiding' in these files if using normal search tools, stresses again the need for proper metadata tagging.

As a result of the discussed facts, we can conclude, that an inescapable condition of a consistent, transparent knowledge management at the ECDC is to establish a common, shared metadata structure for all information objects. In keeping with our commitment to internationally accepted standards and protocols, we think, that an appropriate metadata structure can be created using the Dublin Core Metadata Initiative [3]. The goal of this initiative is to standardize the names of the metadata elements with which an object is tagged. This results in great benefits with respect to electronic processing, since the metadata set of an object will be portable across different systems. As the DCMI matures, more DCMI-aware applications will become available, increasing the usefulness of the metadata.

As a preparation step to managing metadata, a set of document templates has been provided which incorporate the recommended metadata structure. The templates were selected to cover a set of common documents which are created at the ECDC on a regular basis. The specific types were selected based on the observed recurrence of documents in the shared folders and using feedback from semiformal interviews. The motivation for using these templates is that a significant subset of the metadata will be preset for each document. Since the templates are linked to each other based on a principle of inheritance, creating new templates is a more straightforward process. In other words, an SCU mission report template was created by extending the generic mission report template which was in turn created by extending the basic ECDC root template. As a result, all templates inherit the metadata of their parent template and add new elements specific to their additional characteristics. By using templates staff members will be relieved from the bulk of metadata tagging, only content specific metadata (akin to traditional 'keywording') has to be added.

What are the sources of these content–specific metadata elements, in DCMI terms: subjects and keywords?

Term Name: subject	
URI:	http://purl.org/dc/elements/1.1/subject
Label:	Subject and Keywords
Definition:	The topic of the content of the resource.

Figure 3 - DCMI definition for content specific metadata

ECDC has to run in the future among others the integrated database of surveillance networks of communicable diseases operated for the EU, the Threat Tracking Tool that monitors suspicious events, publishes Eurosurveillance, a periodical that has many decades experience in keywording papers related to communicable diseases. Variables of all the mentioned databases and the corpus of Eurosurveillance provided the core set of key word list that is under

evaluation of the ECDC expert staff at the time of writing this paper.

However, the folder/subfolder/filename structure of the present document library can be seen also as metadata characterizing the information object: See some typical examples:

> 'Directory of R:\Epidemic Intelligence \ RiskAssessment \ Guidelines\Retrospective on U_S_ Health Risk Assessment_files'

or

> 'Directory of T:\Surveillance Networks\+Evaluation docs\Evaluation documents\Web Questionnaires\Epi-ContactPoint.aspx_files'

These character strings, although presently part of an arbitrary folder structure are actually describing the documents with features, characteristics that are not necessarily availably from within the object. Therefore we are using the folder (subfolder names as candidates for future keywords and also they will be used as "subject metadata" in a later planned migration to a metadata using content management system. Besides parsing there is obviously a data-cleaning, filtering step, that has to be done, finding redundancies, correcting misspellings etc. and establishing preferred set of terms.

All the resulting terms will be collected and will be used to establish the ECD core terminology, behind that a 'core ontology' will serve to maintain consistency and transparency of the terms set as well.

Conclusions

Numerous off the shelf solutions exist which could address the issues of knowledge management in ECDC. Software such as document management systems and virtual file systems will at least partially solve these tasks. However, they are designed mostly to integrate into a business workflow model and address archival requirements which differ from an organization such as the ECDC. Largely, the solutions available are still document-centric and target a different set of priorities. As the official European source for information on, and related to, communicable diseases, the ECDC has a specific set of requirements which differ from those of both private companies and academic institutions. ECDC needs

- efficient data archival and retrieval:

Unlike information such as accounting data, processed and stored using well-defined methods, the scientific information in ECDC is more open-ended and has more complex inter-relationships, requiring something more feature-rich than a basic filing system. The experts working at the ECDC will not be primarily concerned with the administrative processes of archiving and retrieving information, but with the content. Archiving and retrieval should happen as transparently as possible, reducing procedural overhead. Unlike academic institutions, ECDC may not always have a single standard mode of operation. During, for example, a serious outbreak, information may need to be found, processed and stored within much narrower time constraints ("peace mode" – "war mode" procedures)

- easy referencing of information:

A document-centric approach solves the problem of relating a set of data with a set of conclusions by embedding both into a single document. Inter-document references are handled using citations the most efficient of which make use of identifiers such as ISBN or ISSN numbers. For ECDC an equally unambiguous solution is required but intended for a more heterogeneous knowledge management solution, which goes even further, allowing many-to-many relationships. The method of referencing information must also be usable by both human and automated agents (this follows from the previous requirement).

- a long information life cycle:

While the length of information retention at an average IT company may be measured in years, the length of information retention at the ECDC may be estimated in decades (in this case we are not considering backups, but information stored in primary storage and readily accessible). This includes the raw and processed data, the ability to flexibly process the data, and any references that exist between sets of data and between data and analysis results and conclusions. This profoundly affects all of the information requirements. We must consider that most of the popular file formats in use today are only a few years old and that users are already experiencing problems when attempting to read files only two decades old. In order to address these requirements in a way that will provide the most benefit to the organization in the years and decades to come, some groundwork needs to be laid out.

Policies and mechanisms are required which standardize the following across all units and horizontal activities:

- establishing and using a core ECDC terminology, with ontological basis
- establishing a metadata set which can be applied in whole or in part to all individual information entities and which will incorporate also the keyword set
- a well-chosen set of acceptable data formats for use in the knowledge repository

  (Note: there is a need to decouple of data formats from the applications used to read and write the data. Any file which can only be read using a particular proprietary application is not suitable for an information life cycle of the length which we are considering here)

- having a commitment to formats and protocols conforming to internationally accepted standards

Summing up our experiences, an envisioned implementation for managing the information contained by the internal electronic document set will incorporate several key methods and tools:

- using open document format and general XML encoding
- using metadata embedded into documents for redundancy (using metadata enriched templates)
- establishing a database which will hold the extracted metadata for processing during normal execution
- using controlled vocabularies with ontology 'back-up' to enforce consistency
- establishing a unified search interface making the entire knowledge space available to the end users.

We hope, that the above presented experiences and ideas will help others to establish similar services at different organizations.

Abstract

This paper reports author's work toward building knowledge based services at the new European Centre for Disease Prevention and Control (ECDC). As part of this work, electronic content was analysed and metadata were extracted from a large document base.

ECDC, a scientific agency has been created to strengthen Europe's defenses against infectious diseases, aims to pool health knowledge, to develop authoritative scientific opinions about the risks. A quickly accumulating body of ~ thirty thousand electronic documents was analyzed.

As a way out from the current start-up phase, it was found that a set of systematic measures among them introduction of metadata enhanced document templates (using Dublin Core Metadata Initiative) and ontology based tagging should be applied.

As an innovative approach we used the existing arbitrary file and folder structure to be translated to content characterizing metadata. We hope that the in the next future we will be able to build up a knowledge repository with enhanced navigation facilities, using the existing electronic content – but made it much more transparent and easy to use source of knowledge for internal and external users at ECDC.

Introduction

ECDC[1] is a **scientific agency,** strengthening Europe's defence against infectious diseases.

The agency has four technical units **(Scientific Advice - SAU**, **Preparedness and Response - PRU**, **Surveillance - SUN** and **Health Communication – HCU - units**), an administrative unit and seven horizontal disease-specific projects[2]:

1) influenza,
2) tuberculosis,
3) food- and water-borne diseases,
4) other diseases of environmental and zoonotic origin,
5) vaccine preventable diseases and invasive bacterial infections,
6) HIV-STI and blood-borne viruses, and
7) antimicrobial resistance and healthcare associated infections.

Knowledge-based services (KBS) for human- and for machine users will be a key issue.

The *planned knowledge based services* are:

(a) electronic information sources service (content management)
(b) terminology services;
(c) other advanced systems / functions as knowledge navigation, decision support

In the area of knowledge management ECDC wants to avoid 'reinventing the wheel' and to stick to standards[3] ensuring semantic interoperability and transparency.

[1] ECDC will have a >50 M€ budget by 2010, staff will be ~ 300.
[2] At the time of the 'snapshot' for document analysis three units, SAU, SU and PRU were active, HECO was established later.
[3] on several levels: as the XML family, UML, OWL, DCMI etc.)

László Balkányi
ECDC Scientific Advice Unit

Materials and Methods

Our **materials** were the electronic documentation, accumulated since May 2005. Documents are stored on file servers, a common space serves shared documents, while virtual drives were assigned to relevant organizational units. A ‘snapshot’ of this structure was taken in August, 2006.

Files were classified into documents[1], spreadsheets, presentations, and ‘all others’ categories. **Methods:** Command line tools and disk cataloging utilities for extraction of file / folder structures were used; a text editor served for building/editing xml files, a spreadsheet application for file statistics.

[1] (working) docs, and (to be published) pdfs

Results

Characteristics of file accumulation and distribution were analyzed.
Numbers in **table 1** summarize just the most characteristic aspects.
The folder structure is the result of a non-regulated, ‘organic’ growth in a just formed organization, where highly autonomous and highly educated experts worked mostly either alone or in ever changing, problem oriented, ad-hoc teams on emerging problems and most experts did extensive multi-tasking.
However **the amount of accumulating documents was / is staggering[1] (fig1.)**
The distribution of files is detailed according to the most frequently used file types in **table 2. Trends were calculated concerning file numbers (fig1)**.

[1] be aware that the value axis of fig. 1 is logarithmic!

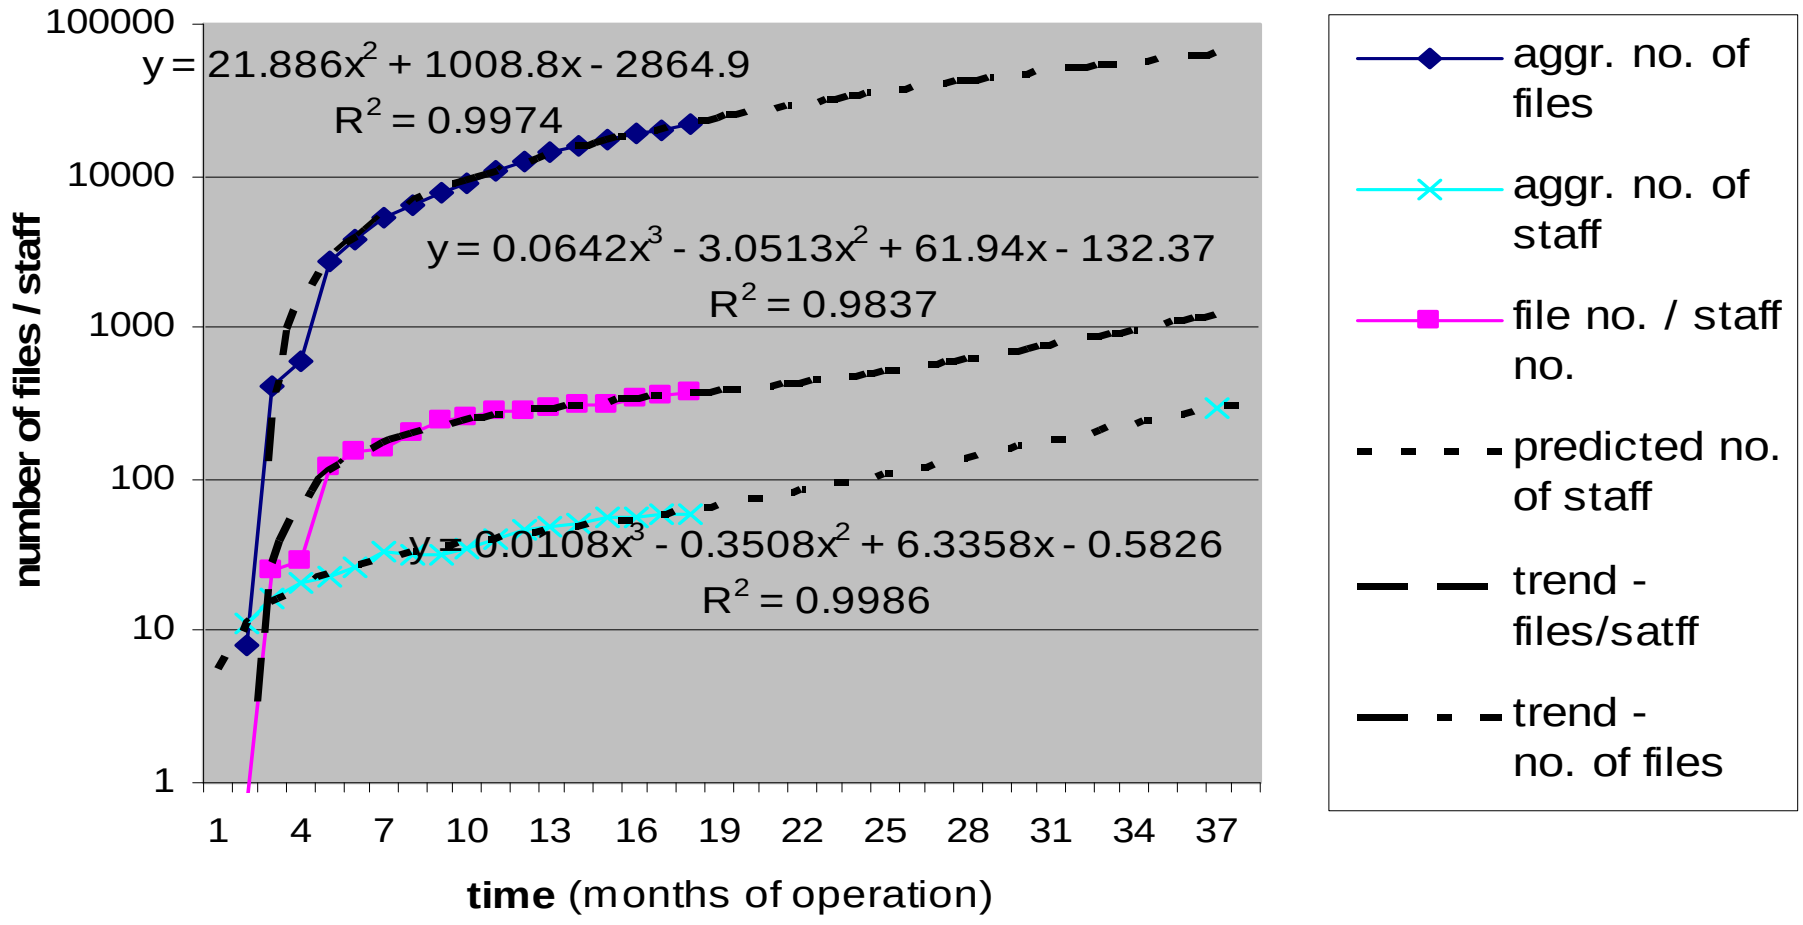
Figure 1 - **Trends of the Growth of Staff and the Aggregated Numbers of Scientific Document Files on ECDC Servers**



Discussion

Discussing files / folders structure:

It is almost hopeless to navigate efficiently in such a complex folder hierarchy tree. (Table 1)

The pan of short time memory (while working in folder hierarchies), allows us to handle 7(+-2) “chunks” of information at any given time [1]. The material, we deal with, however does not allow such a grouping – we have to opt for other organization methods as e.g. multidimensional localization by metadata.

Concerning search and retrieval:

Having thousands of documents on very similar topics, a conventional search engine will be never specific enough. Also, such a search will not find sets of (conceptually) related documents. Using metadata is of course the answer to this problem as well [2].

The metadata ‘vocabulary’ should be based on ontology, so that later on we will have the option of semantic operations as well.

László Balkányi
ECDC Scientific Advice Unit

Discussion – continued ….

Concerning the growth of the information heap:

ECDC will grow to size of ~ 300 staff in two years.

Well fitting trend lines (fig. 1.) show that the **file numbers will reach nearly a hundred thousand** and each staff member will be ‘responsible’ for more than a thousand file.

These predictions might be disputed even to be low-key, as more and more ‘services’ of ECDC will become ‘operational’.

Distribution of files types:

Table 2 shows us, that while the single most frequent information object is the ‘document’ file (31% of all), there is a huge heterogeneous set, containing raw txt, html, gif, jpg, rtf, eml, etc. and some others.

The difficulties to reach, to make available the information ‘hiding’ in these files if using normal search tools, stresses again the need for proper metadata tagging.

László Balkányi
ECDC Scientific Advice Unit

Conclusions

We can conclude that an inescapable condition of a consistent, transparent knowledge management at the ECDC is to establish a common, shared metadata structure for all information objects.

We suggest that an appropriate metadata structure can be created using the Dublin Core Metadata Initiative [3]. Besides the 'mundane' metadata as contributor etc., the content–specific metadata elements[1] are the most crucial.

ECDC has to run in the integrated EU database of surveillance networks of communicable diseases, a Threat Tracking Tool that monitors suspicious events, to publish Eurosurveillance etc.

Variables of all the mentioned databases and ECDC texts can nd will provide the core set of terms that is under evaluation of the ECDC expert staff.

[1] in DCMI terms: subjects and keywords

László Balkányi
ECDC Scientific Advice Unit

Conclusions – continued ....

The folder structure of the document library can be seen also as metadata characterizing the information object, a typical example is ‘Directory of R:\Epidemic Intelligence \ RiskAssessment \ Guidelines\Retrospective on US Health Risk Assessment_files’.

These strings are actually describing the documents with characteristics that are not necessarily availably from within the object. Therefore folder / subfolder names are “subject metadata”.

All these resulting terms will be collected and will be used to establish the ECDC core terminology, behind that a ‘core ontology’ will serve to maintain consistency and transparency of the terms set as well.

László Balkányi
ECDC Scientific Advice Unit

Summing up our future plans, we want to progress towards:

- establishing **a core ECDC terminology, with ontological basis**, later to be extended to a full terminology
- using core terms as **a metadata set applied to all information entities**, remaining committed to standard document formats;
- Using a core ontology as a source for **a unified search function,** making the entire ECDC knowledge space transparent, easy to navigate and available to the wide variety of end users.

László Balkányi
ECDC Scientific Advice Unit

Determining Appropriate Window and Level Settings for Displaying DICOM Images in a Desktop Publishing Format

Aaron W. C. Kamauu[a], Scott L. DuVall[a], Andrew P. Liimatta[b], Richard H. Wiggins III[a,c], David E. Avrin[a,c]

Abstract

When harvesting images from a Picture Archiving and Communication System (PACS), window and level settings continue to present a major obstacle for the conversion of images from the Digital Imaging and Communications in Medicine (DICOM) standard file format to the Joint Photographic Experts Group (JPEG) image format, a desktop publishing format. Evaluation of the window and level values in the DICOM header demonstrated that they cannot be relied upon for generation of useful JPEG images for key image selection. An algorithm was developed to automatically calculate window and level settings for Magnetic Resonance (MR) images. As images are received by a vendor-neutral digital teaching file server, pixel data is read and a histogram of the grayscale values is generated. A portion of the grayscale values are then used to calculate the appropriate window and level settings for image conversion, allowing exported series to be displayed in JPEG format. The algorithm was evaluated and found to be effective for appropriate window and level calculation for key image selection.

Keywords:

radiographic image enhancement, data display, radiology information systems

Introduction

Window and level settings are a major obstacle in exporting Digital Imaging and Communications in Medicine (DICOM) images from a Picture Archiving and Communication System (PACS) in desktop publishing format.[1] In a vendor-neutral environment, a digital teaching file (DTF) has limited ability to retrieve image metadata without requiring direct access to PACS or without receiving specific information from PACS.[2] Therefore it must rely on the metadata available in the image DICOM header. The window and level values contained in the DICOM header are assigned at the point of acquisition and are rarely subject to verification by the radiology technician. In addition, these values are not overwritten by the last viewed or optimum window and level settings applied by the radiologist at the PACS workstation. The DICOM header window and level values were evaluated for their reliability to generate identifiable JPEG images.

An algorithm has been developed to automatically calculate appropriate window and level settings for initial DICOM-to-JPEG conversion. It solves the window and level problem for conversion of Magnetic Resonance (MR) DICOM images to JPEG file format and allows for efficient key image selection without requiring user interaction.

This manuscript describes the innovative integration of open source technology and information management in solving the window and level problem encountered in the development of a vendor-neutral DTF based on ideal characteristics.[3] It outlines the obstacle of window and level settings in exporting MR DICOM images from PACS and the automatic window and level calculation algorithm as a proposed solution.

A word about window and level settings

An important aspect of medical imaging is the ability to manipulate the manner in which images are presented on the PACS workstation screen. In a digital format, the spatial resolution of an image is based on the number of pixels in each row and column (i.e., 128 x 128 or 512 x 512). Each pixel contains information regarding the color attribute and intensity of a specific location on the image. The collection of this information is the pixel data, which is referred to as contrast resolution. The range of grayscale values for typical medical images often far exceeds that which can be perceived by the human eye. For example, a Computed Tomography (CT) image may contain grayscale values from -1000 to +3000, defined as Hounsfield units (HU), that are physical representations of the density of the body part imaged (where 1 unit = 1/10 of 1% of the density of H_20 and H_20 density is set equal to 0 HU). MR images are also on a 12-bit or 4096 unit scale, however, the pixel values have no specific physical representation, and therefore are relative and unpredictable.[1] Although MR image pixel data may represent up to 4096 unique shades of gray, the human eye can only process ~256 grayscale variations.[4]

Manipulation of image presentation is necessary to solve the grayscale limitations of the human eye. In addition, visualization of specific tissue types or anatomical locations requires presentation of the image utilizing only a portion of the total grayscale range. Therefore, DICOM images employ settings to limit presentation of the image to only display the pixels within a more narrow range (window width or "window") with its midpoint applied at a specific location (window center or "level") within the total range of values. In the CT example above, a typical setting for appropriate demonstration of brain tissue is a window of 100 applied at a level of 50 resulting in an image with 256 shades of gray that represent 0 to 100 HU. "Windowing" and "leveling" an image is particularly important for display of the correct diagnostic and educational focus. It also plays an essential role for correct conversion from DICOM to another image file format.[5]

Materials and methods

DICOM header evaluation

During a 6 month testing period, 116 MR studies were sent from PACS to the Radiology Interesting Case Server (RadICS), a vendor-neutral DTF, by radiologists for the purpose of creating interesting cases.[2] The DICOM images from these studies were converted to JPEG files using the DICOM-specific WindowCenter and WindowWidth values from each DICOM header. One study was excluded because it did not contain physical body parts, but rather showed lines and graphs (a quality control study). Image studies were scored "-" if they were predominantly white or black and unidentifiable; otherwise they were scored "+". Evaluation of the included 115 studies (comprised of 778 total series) was conducted by the author (AK).

Automatic window and level calculator

In RadICS, the image server manages the DICOM Receive and DICOM-to-JPEG conversion process.[2] A DICOM Storage Server Class Provider (SCP), from the open source OFFIS DCMTK, handles all incoming DICOM files and moves them to a temporary directory.[6] A PERL script constantly monitors the temporary directory and the presence of a DICOM file initiates the rest of the image server processes. The image server parses the DICOM header using the OFFIS DCMTK and specific data is retrieved. The automatic window and level calculator (AWLC) is called on to determine appropriate window and level settings. These window and level settings are automatically communicated to the PERL script and are passed as parameters to the OFFIS DCMTK to generate new full-size and thumbnail JPEG files. Finally, the original DICOM and newly generated JPEG files are moved to the temporary file storage on the server. At this point the JPEG images are available for key image selection in the RadICS web application.[2]

The AWLC was built using the C++ programming language and uses the automatic window and level calculation algorithm. The algorithm follows a 5-step process: (1) read the image pixel data, (2) generate grayscale histogram, (3) exclude extreme values, (4) calculate median and standard deviation, and (5) calculate window and level settings.

The algorithm begins by reading the pixel data of the MR image. The BitsAllocated, BitsStored, HighBit and PixelRepresentation of the image, as retrieved from the DICOM header are required to read the pixel data. Once read, the pixels are grouped according to their grayscale value, the sum total of pixels per value is calculated, and a histogram is generated. Figure 1 illustrates the histogram. Large spike in the low values of the historgram corresponds to the black pixels surrounding the body part. The bottom fifteen percent (line #1) and top fifteen percent (line #2) of the grayscale range are excluded to account for the large number of black and white pixels in the image. The median and standard deviation of the remaining values are calculated. The median (line #3) is used as the level and a multiple of the standard deviation (line #4) is used as the window for the DICOM-to-JPEG conversion. For MR images with a pixel value range greater than 1000, the standard deviation is multiplied by four. For MR images with a pixel value range less than 1000, the standard deviation is multiplied by six. The fifteen percent exclusion threshold and the 1000 pixel value range threshold were determined empirically.

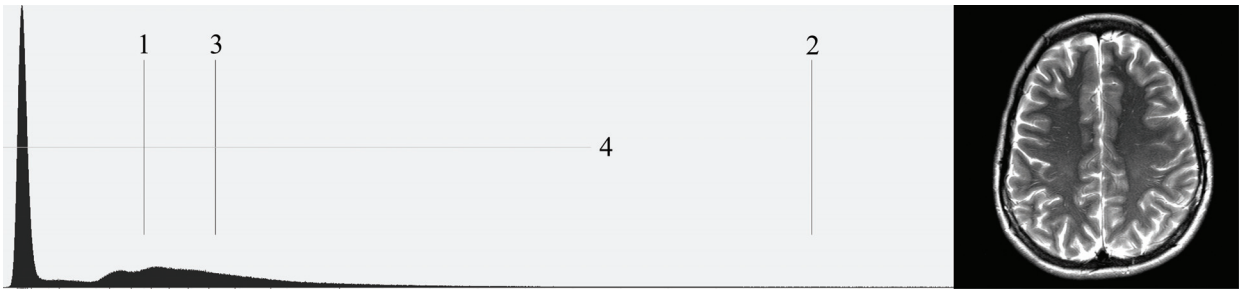

Figure 1 – Grayscale histogram (left) of a Magnetic Resonance (MR) image (right)

Algorithm evaluation

The algorithm was tested on 75 MR images: 25 each of abdomen, brain, and head and neck images. Two Certificate of Added Qualifications (CAQ) board certified radiologists (DEA and RHW) evaluated the automatic window and level calculation algorithm for its ability to generate JPEG images with appropriate window and level settings for key image selection. In addition, they evaluated the similarity between the JPEG image using optimum window and level settings, as defined by the evaluators, with the JPEG image generated using the automatically calculated window and level settings. They evaluated images within their area of expertise. The following evaluation procedure was used. First, a web application was developed to randomly select one MR image at a time from studies already sent to RadICS. The image then was displayed in an open-source, web-based Java DICOM viewer, obtained from the Nagoya Institute of Technology.[7] The evaluators made appropriate window and level changes to achieve optimum settings. At this point, the evaluators were blind to the automatically calculated image. After clicking the done button, the user-defined settings were used to convert the DICOM image to JPEG file format. In addition, a second DICOM-to-JPEG conversion took place using the window and level settings that were automatically calculated via the algorithm. The evaluators were then presented with both JPEG images, side-by-side on the same webpage, and were asked to score the following two comments: (1) The automatically calculated image is appropriate for Key Image Identification; (2) The automatically calculated image is identical to the optimal image (comparing w/l settings). The five possible responses are: (1) Strongly Disagree, (2) Somewhat Disagree, (3) Undecided, (4) Somewhat Agree, and (5) Strongly Agree.[8] Figure 2 is an example of the webpage presented to the evaluators. Scores were tallied for each comment.

Results

DICOM header evaluation

Evaluation of the window and level values in the image DICOM header found 18/115 (15.65%) of studies to be predominantly black or white and therefore unidentifiable.

Algorithm evaluation

Evaluation of the algorithm results in 25/25 (100%) of abdominal MR images, 24/25 (96%) of brain MR images, and 20/25 (80%) of head and neck MR images recorded as appropriate for key image selection. One head and neck MR image was recorded as undecided and the rest were recorded as inappropriate for key image selection. Overall, 69/75 (92%) of the study MR images were thought to be appropriate for key image selection, while 5/75 (6.67%)

Table 1 – Evaluation of the Automatic Window and Level Calculator

			5 Strongly Agree	4 Somewhat Agree	3 Undecided	2 Somewhat Disagree	1 Strongly Disagree
Appropriateness for KIS	AVG	N					
MR Abdomen	5.00	25	25	0	0	0	0
MR Brain	4.72	25	20	4	0	1	0
MR Head and Neck	4.36	25	19	1	1	3	1
Total	**4.69**	**75**	**64**	**5**	**1**	**4**	**1**
Similarity Comparison	AVG	N					
MR Abdomen	4.48	25	15	8	1	1	0
MR Brain	3.80	25	9	9	0	7	0
MR Head and Neck	3.52	25	8	8	0	7	2
Total	**3.93**	**75**	**32**	**25**	**1**	**15**	**2**

were thought to be inappropriate for key image selection and 1 was undecided (Table 1).

In addition, although not a goal of the algorithm, it was found that 23/25 (92%) of automatically calculated abdominal MR images, 18/25 (72%) of automatically calculated brain MR images, and 16/25 (64%) of automatically calculated head and neck MR images were scored as strongly agree or somewhat agree to being identical to their associated user-defined optimum images. One abdomen MR image was recorded as undecided and the rest were not considered identical. Overall, 57/75 (76%) of the study MR images were scored as strongly agree or somewhat agree to being identical to their associated user-defined optimum image, while 17/75 (22.67%) were not considered identical and 1 was undecided.

Discussion

The purpose of this project was to evaluate the reliability of DICOM header window and level values for MR and develop an algorithm to automatically calculate appropriate window and level settings for DICOM-to-JPEG image conversion in a vendor-neutral environment. This is the first automatic window and level calculator seamlessly integrated into the harvesting function of a radiology teaching file reported in the literature. Based on the results of the DICOM header evaluation, the window and level values in the MR DICOM header are unreliable. Therefore, this calculator provides the much needed ability to automatically process MR images into a desktop publishing format.

The algorithm was found effective for appropriate window and level assignment for DICOM-to-JPEG image conversion of MR images. The results demonstrate that these JPEG images are appropriate for selection of key images for case creation. The automatic window and level calculator was successfully implemented in RadICS which is in use at a large academic radiology department.[2]

Even though our objective was to generate JPEG images appropriate for key image selection, as a side note, the authors were interested in the degree of similarity between the automatically calculated JPEG image and a user-defined optimum JPEG image. The results demonstrate that a majority of the calculated images appeared identical to their associated optimum images. Although 22.67% of the images were not identical, the fact that 92% of the images were appropriate for key image selection demonstrates that the objective was met.

The algorithm was designed and tested specifically on MR studies. This modality was selected for its high degree of variable window and level settings from one image to the next and the inability to apply standard, pre-set window and level settings to the study as a whole, such as is possible with CT studies.

In reviewing the results, it is noted that six images scored a three or lower for the appropriateness for key image selection comment. Of these six images, one was in the MR brain group and the other five were in the MR head and neck group. Further evaluation of these images revealed that the one MR brain image was a scout image and not a diagnostic image. In addition, of the head and neck images, one contained a ferromagnetic artifact and a large amount of subcutaneous fat, and the other images were inhomogeneous MRI fields with fat saturation technique and contained areas of loss of fat saturation. A larger variability of calculated window and level settings in MR head and neck images is expected due to the diverse intensity of signals acquired. Also, when selecting a key image for a teaching file from a soft tissue neck MRI study, the ideal window and level setting for the entire image may be significantly different from the perfect window and level setting to best demonstrate a lesion, due to the extreme contrast differentiation between the extracranial head and neck fat, soft tissues, and the pathology of interest, such as a focal soft tissue mass. These factors likely affected the accuracy of the window and level calculation.

The automatic window and level calculation algorithm was designed and developed based on a training set of MR abdominal and MR brain studies. Thus, it is not surprising that it performed well during evaluation in those image groups. The results obtained from the MR head and neck group demonstrates that the algorithm can be efficiently generalized to MR images of other anatomical locations.

While the algorithm has been shown effective in MR images, formal evaluation should be completed to measure the generalizability for use with other image modalities. We anticipate that more sophisticated methods could address other modalities as well as the individual characteristics of images with different educational, anatomical, and diagnostic foci. The empirical exclusion threshold and pixel range cutoff could also be refined by expanding the test set used in their creation. Despite the limitations of the algorithm, it specifically addresses the problem of unreliable DICOM header data in MR images and could be adapted for use in applications other than DTF such as upon post-acquisition arrival of studies to PACS.

Incorporation of the automatic window and level calculator in the RadICS image server provides a fully automated solution for harvesting key MR images into a DTF. Once an interesting study is sent to RadICS, appropriate window and level settings are automatically calculated, and the images are automatically processed and made available for key image selection. Therefore, there is no disruption in clinical workflow.[2]

Conclusion

With the integration of the automatic window and level calculator in RadICS, users can efficiently send MR studies from PACS and access the images in desktop publishing format from a workstation with access behind the radiology department PACS firewall. All processes from the DICOM Receive to web-presentation of JPEG images are automated, enabling the flexibility of sending studies and creating interesting cases at the clinician's leisure.[2] The method described overcomes the obstacle of window and level settings for appropriate DICOM-to-JPEG conversion, without requiring user interaction.

Acknowledgments

This project was partially funded by the NIH NLM 2T15 LM07124 training grant.

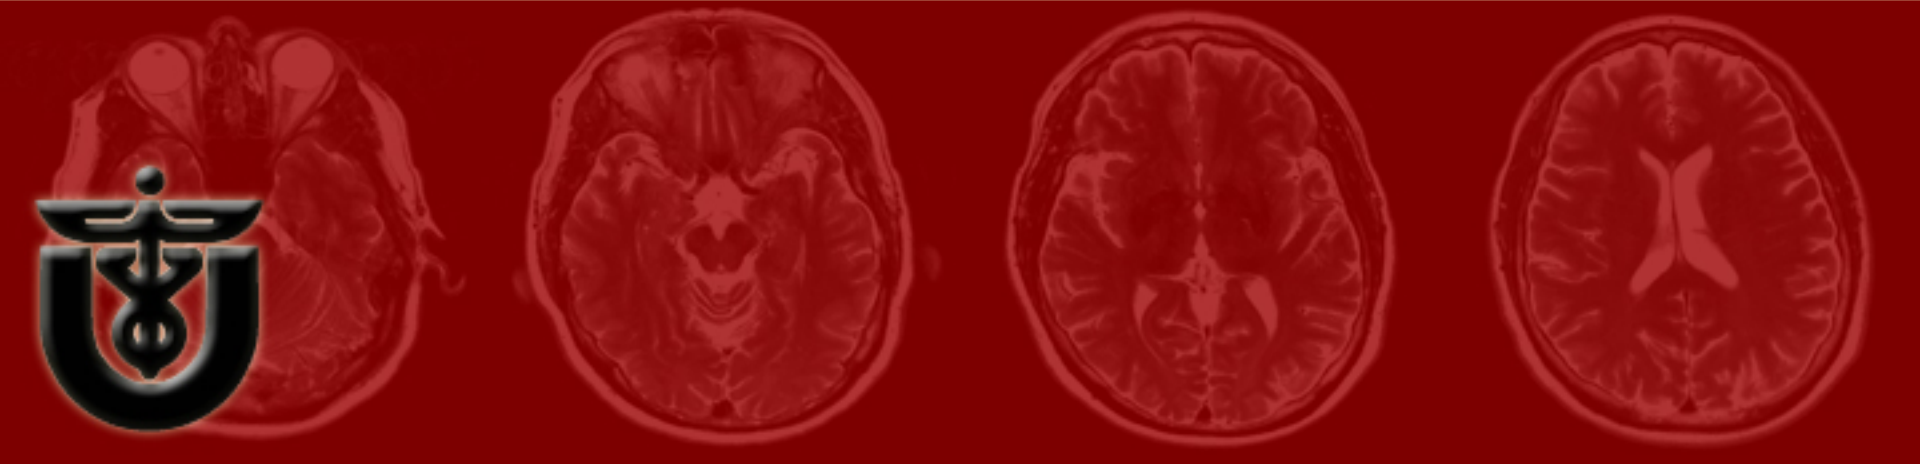
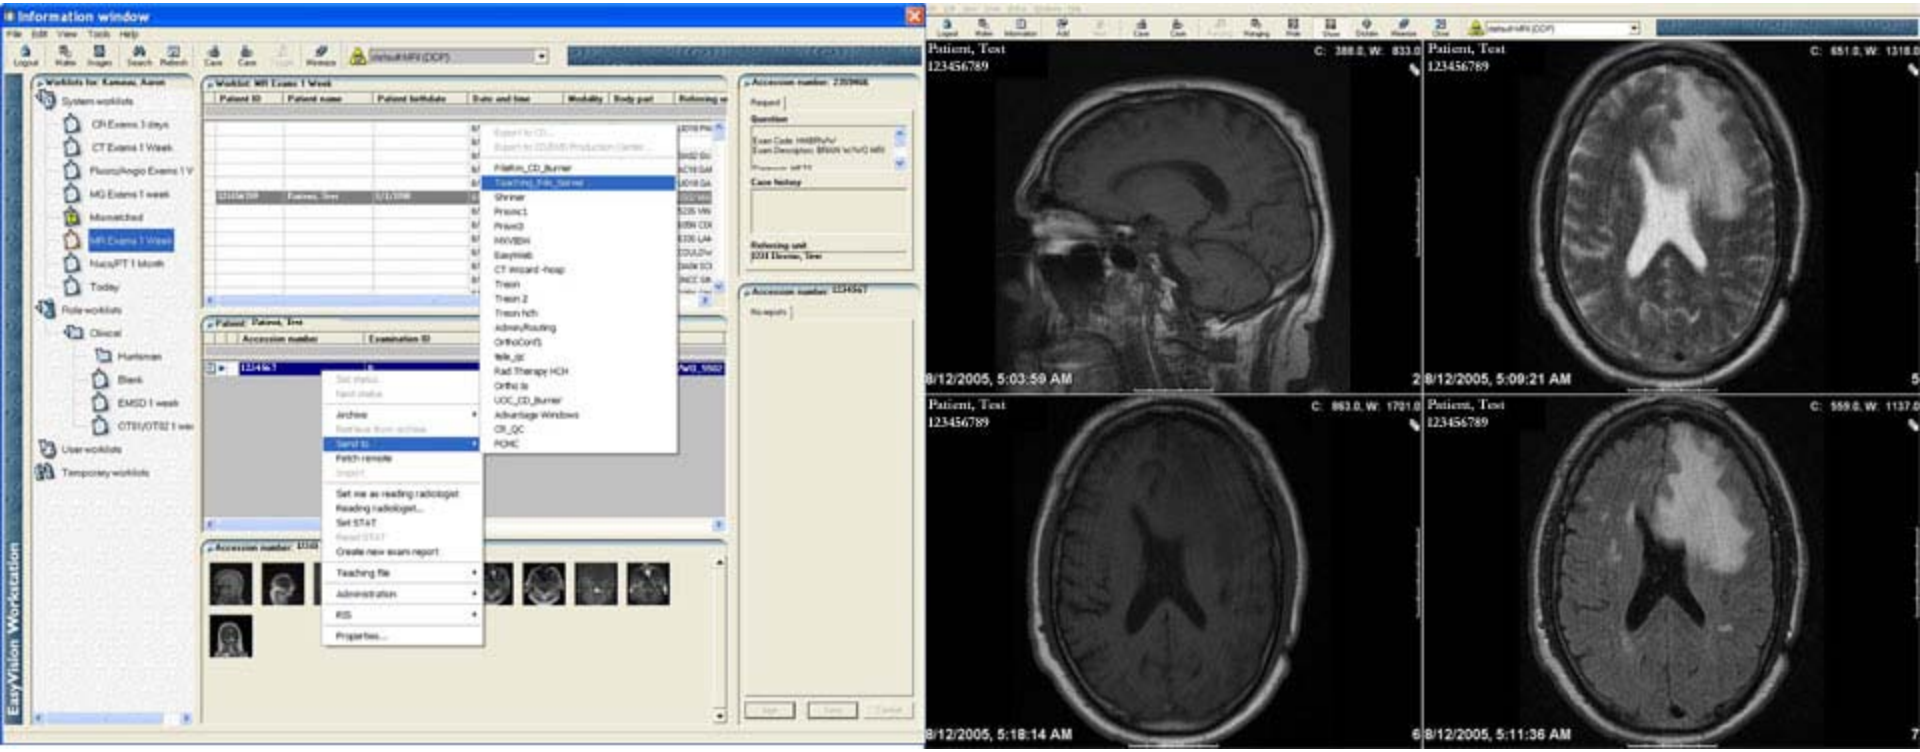
Automatic Window and Level Calculation for Magnetic Resonance DICOM to JPEG Conversion

Aaron W C Kamauu MD MS MPH, Scott L DuVall BS, Andrew P Liimatta BS,
Richard Wiggins III MD, David Avrin MD PhD



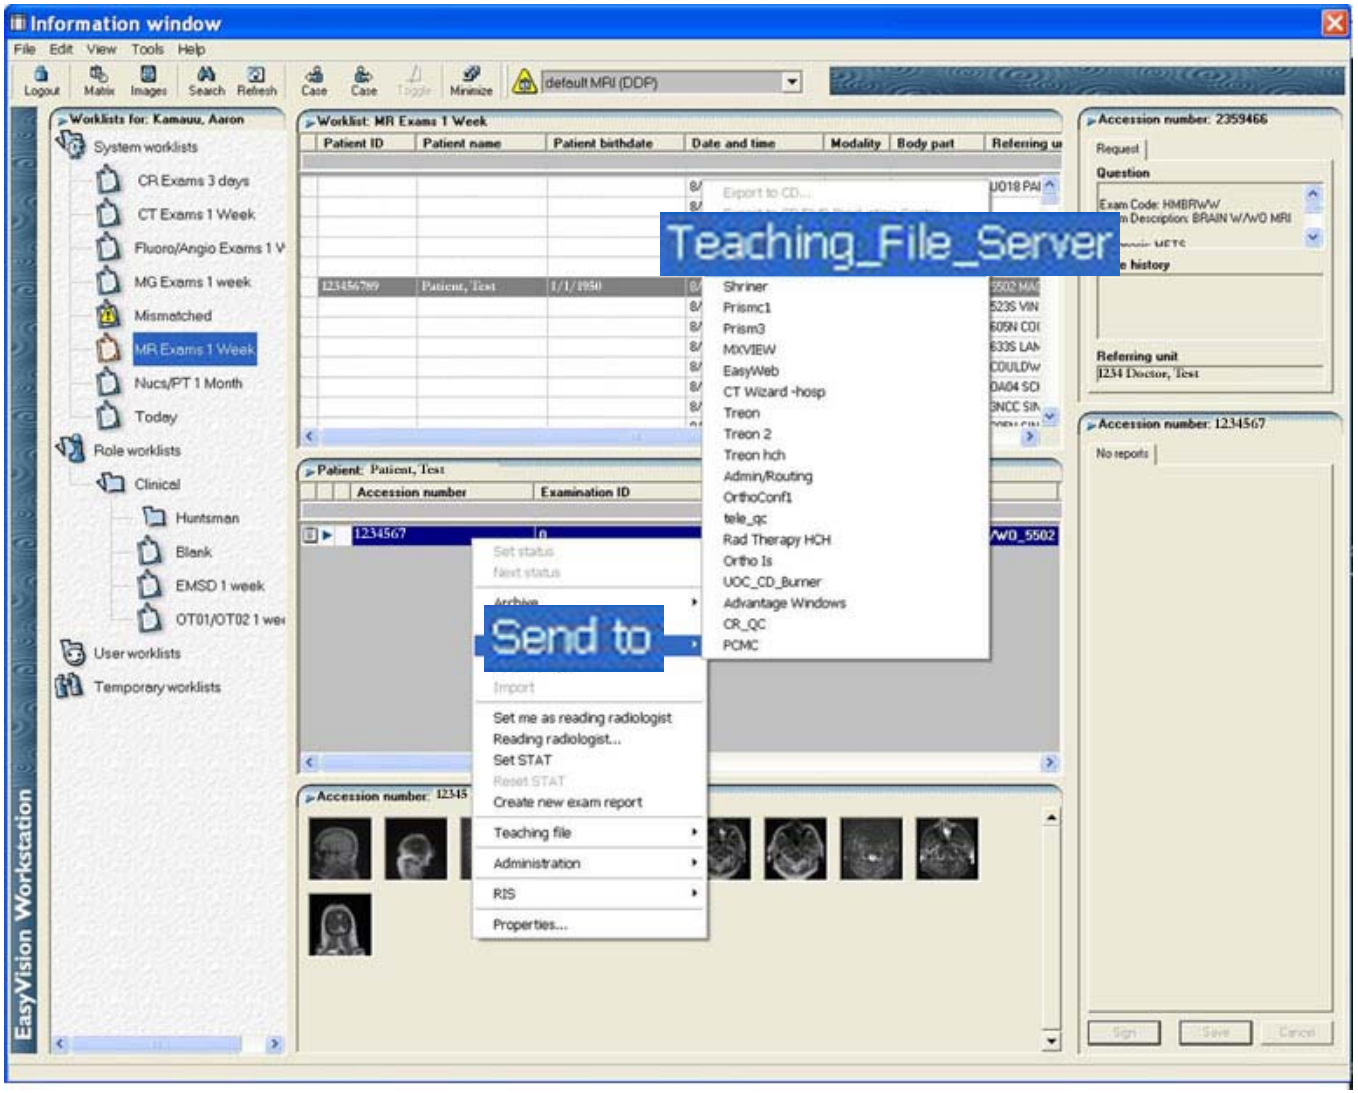
PACS Workstation



From the PACS workstation, the radiologist identifies an interesting case.

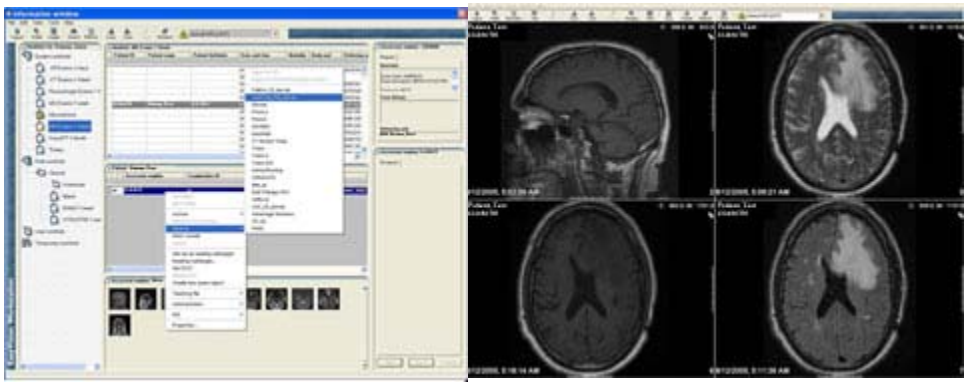
RadICS

Using the teleradiology functions built in to all PACS, the interesting case can be sent to the Radiology Interesting Case Server (RadICS) with just a few mouse clicks.



PACS Workstation → RadICS

RadICS

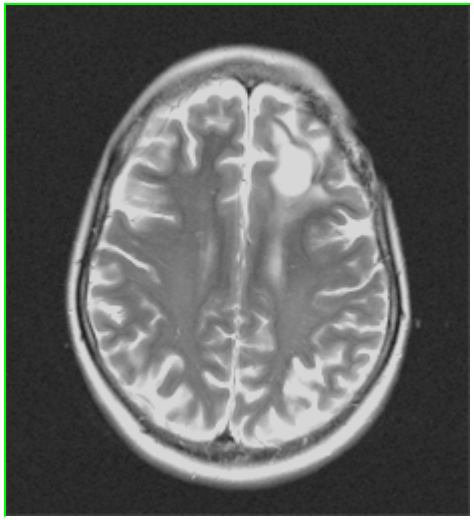


PACS Workstation

Because RadICS uses the standard DICOM RECEIVE, no vendor specific adjustments need to be made. As soon as RadICS is plugged in behind the Radiology department firewall, it is ready to receive interesting cases.

Automatic Window and Level Calculator

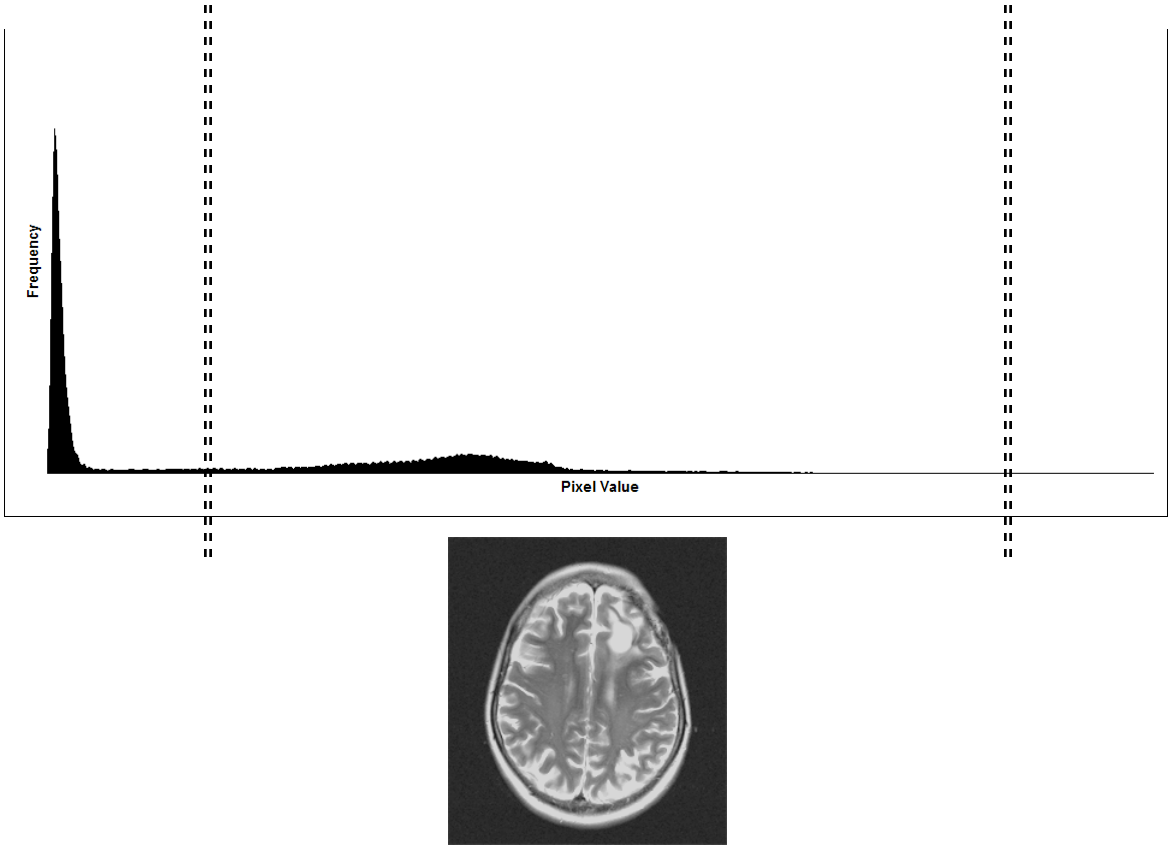
Vendor Neutral Teaching File



When cases arrive at RadICS, each image is analyzed and a near optimum window and level setting is calculated. These window and level adjustments allow the DICOM images to be converted into JPEG images for display and key image selection.

Automatic Window and Level Calculator

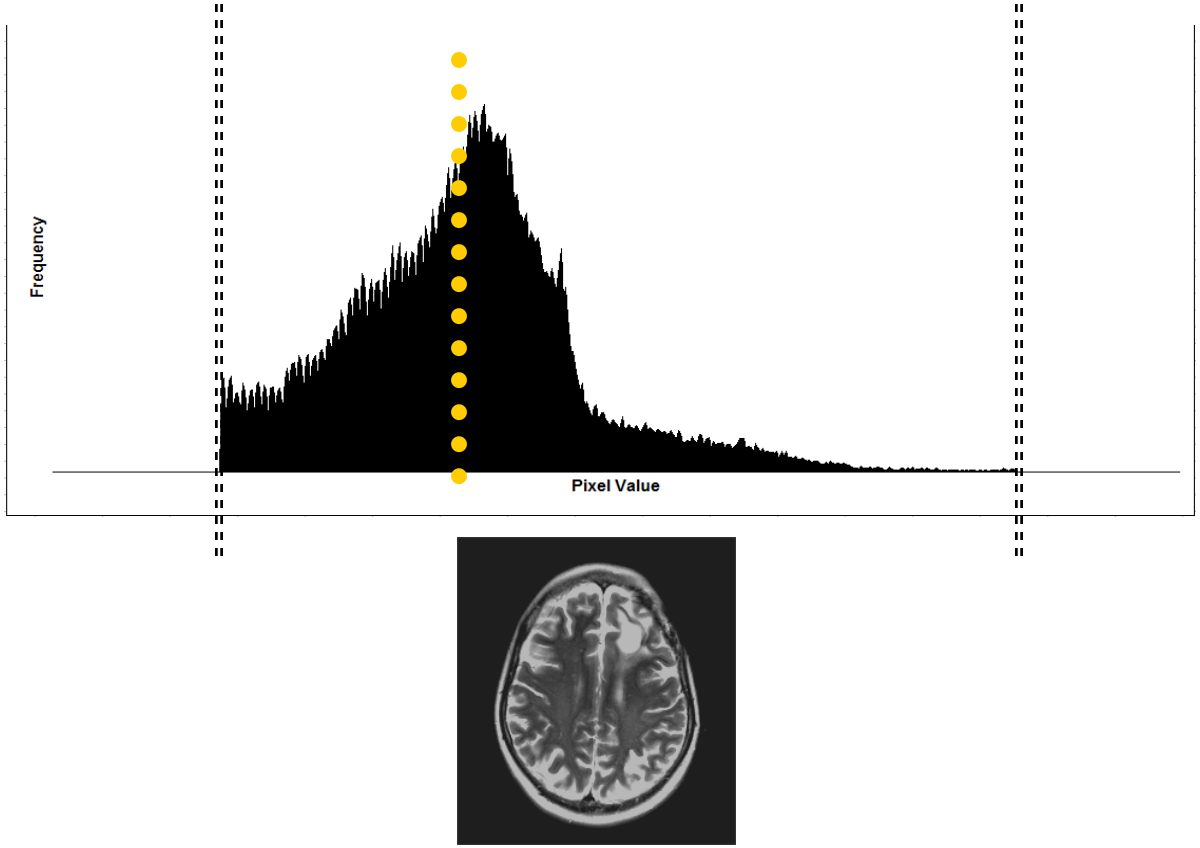
Vendor Neutral Teaching File



A histogram of the image is created and the top and bottom 15% of pixel values are truncated. The large spike of low values represent the black pixels surrounding the image.

Automatic Window and Level Calculator

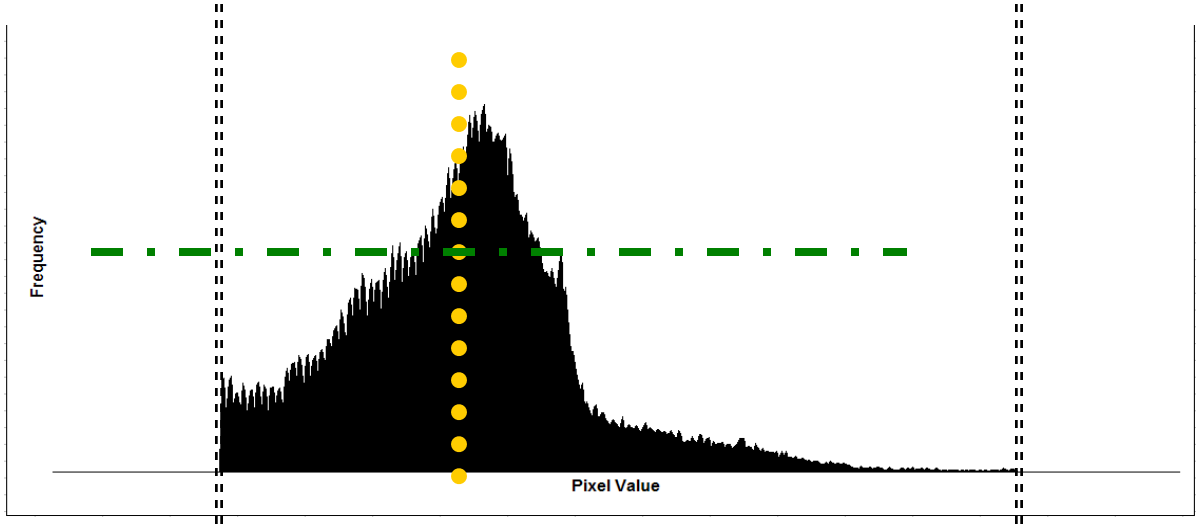
Vendor Neutral Teaching File

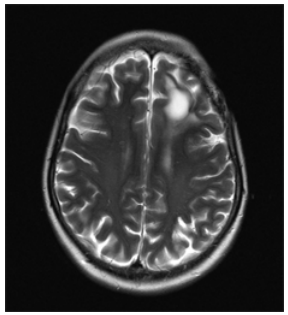


Zooming in after the top and bottom 15% of the histogram are truncated reveals the portion of the image containing the detail. The median is calculated and used as the level setting.

Automatic Window and Level Calculator

Vendor Neutral Teaching File

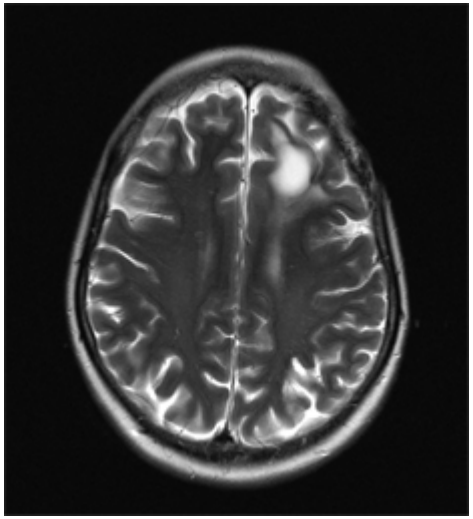




The standard deviation of the pixel values is also calculated and a multiple of the standard deviation is used as the window setting.

Automatic Window and Level Calculator

Vendor Neutral Teaching File



The calculated window and level settings are then applied to each image. The DICOM images are converted into JPEG images for display and key image selection. This entire process happens automatically each time an interesting case is sent from a PACS workstation.

Results

The algorithm was tested on 75 MR images: 25 each of abdomen, brain, and head and neck images. Two CAQ board certified radiologists evaluated the algorithm for its ability to generate JPEG images with appropriate window and level settings for key image selection. The evaluators were asked to score the following comment against each image: The automatically calculated image is appropriate for Key Image Identification.

			5 Strongly Agree	4 Somewhat Agree	3 Undecided	2 Somewhat Disagree	1 Strongly Disagree
Appropriateness for KIS	AVG	N					
MR Abdomen	5.00	25	25	0	0	0	0
MR Brain	4.72	25	20	4	0	1	0
MR Head and Neck	4.36	25	19	1	1	3	1
Total	**4.69**	**75**	**64**	**5**	**1**	**4**	**1**

Abstract

Resource shortages in the healthcare system has called into question its sustainability and has generated interest in alternative forms of service delivery. Delivering of complex services in the home at a lower cost and with improved outcomes has proven to be elusive. In this study, we discuss the development of a comprehensive remote patient monitoring system that facilitates self-care of nocturnal hemodialysis patients, a complex hospital-at-home therapy. An ethnographic analysis was undertaken, determining the barriers to adoption and design criteria for a system that would facilitate mediated patient self-care for a complex therapy. These data were then used to inform the development of a remote patient monitoring system. In our pilot testing, patients developed a dependency on the system, when it was expected to be needed only for their transitional phase. Patient accountability was increased through the use of the system when it was found that patients did not always dialyze as frequently as they reported. The development of a blood disconnect monitor proved to be a critical component of the system. The resultant system provided an increased level of comfort and reduced anxiety for patients, and for family caregivers in particular.

Keywords:

monitoring, ambulatory; hemodialysis, home; self care

Introduction

End-stage Renal Disease (ESRD) is a complex medical illness that is becoming more prevalent. Estimates of increased prevalence are as high as 7.5% per year. [1] The most common form of renal replacement therapy for ESRD is hemodialysis (HD), a costly, resource – intensive therapy that artificially sustains renal function, but can also contribute to a poor quality of life. The present form of therapy is what the health system can afford to deliver and what a patient can tolerate in terms of disruption to their lives. This treatment pattern is mostly a systemic limitation of the delivery of healthcare services, rather than what is medically efficacious for the patient.

Nocturnal hemodialysis (NHD) is essentially a more frequent form of the therapy, delivered for longer periods of time, as the patient sleeps at home. The improved health outcomes are dramatic. Patients enjoy improved cardiovascular health, improved peripheral circulation, improved sleep quality (despite undergoing dialysis treatment), and the elimination of dietary restrictions. [2, 3] Patients experience greater autonomy by being freed from institutional care. Despite the capital costs of providing a dedicated hemodialysis machine to a patient, the cost-effectiveness of NHD is clear when factoring in the greatly reduced nursing care and the reduction of medications. [4]

Although NHD has been shown to provide significant improvements in health outcomes and improved resource utilization for the health care system, the adoption of the therapy has been slow. NHD would require major changes to the way dialysis programs are delivered.

Beyond these systemic problems, there exist patient-related barriers to the adoption of NHD. Patients fear they will fail to perform dialysis adequately. They also fear that they will receive substandard care and that they will be socially isolated. [5]

Given the significant improvement of health outcomes associated with NHD, it is important that a means to reduce and overcome these barriers be developed to improve adoption.

To address these barriers, we proposed a method of supporting the patient in performing NHD by means of a virtual support system, replacing an aspect of the nursing support they received in the conventional setting. This will take the form of a remote patient monitoring system, which will relay vital signs and dialysis treatment parameters to hospital staff, which in turn, can act on information received as needed.

It is hypothesized that patients will have less anxiety and perceives greater self-efficacy with the notion of this support. This may lower the barrier to adoption of NHD as a therapy option. In addition, family members are also hypothesized as being more supportive of NHD therapy

with the inclusion of remote patient monitoring. There is some evidence that home hemodialysis adds a significant burden to family members [6]. Ultimately, the goal of the system is to have the patient reach a level of "supervised autonomy" in performing their therapy.

Research question to be addressed was "What specific design criteria must be met by the system, such that the patient will accept the system and feel that it contributes to their overall security and confidence to perform NHD?"

Methods

The assumptions of the use of remote patient monitoring as an intervention to reduce the barriers to the adoption of NHD were challenged through the use of patient-centric design method, beginning with ethnographic interviews of dialysis patient groups (nocturnal hemodialysis (NHD), conventional hemodialysis (CHD), and pre-dialysis patients). Specific data was gathered to inform the first iteration of the system development.

The number of informants used in the study was to be determined when sufficient saturation was achieved. In the end, saturation was achieved with seven patients in the NHD group, and six patients in each of the CHD and pre-dialysis patients groups.

A general inductive method was using in the analysis of the transcripts. Transcripts were read repeatedly and text segments were coded for potential themes. As the coding framework developed, transcripts were reanalyzed in light of new themes that may have emerged as a result. Once completed for a specific treatment group, major themes were derived that were relevant to the research question. Qualitative analysis software was used to code the interviews for emerging themes. These findings were then validated through a member-checking exercise with a focus group of NHD patients and family caregivers.

These data then informed the development of design principles. The purpose of these design principles was to guide the engineering team in their deliberations around specific functionality and design aspects of the system. In some sense, these principles become a rulebook for the engineering team, in which assumptions that are made through the course of development are tested against these principles to ensure adherence. Violations of these principles will likely result in a sub-optimal system and would no longer be adhering to a user-centric method of design.

Once implemented after a number of iterations, a small pilot study of eight patients were monitored for 3 to 10 months. Interviews of the patients were performed throughout the pilot to determine the outcomes in terms of perceived safety and facilitating adoption and adherence to NHD.

Results

Without exception, all the participants found the concept of remote monitoring for NHD patients as a positive development, although there were significant differences of opinion on specific aspects. There was varying opinion on the patient-type which remote monitoring should be applied to, as well as the duration, form, function, and purpose of the technology.

- Patients already had an expectation of the use of remote monitoring. Some patients presumed it was already in place and that they were to receive it upon installation of the machine in their home.
- Patients supported the transitional use of remote monitoring. Although some patients felt they required some form of monitoring on a permanent basis.
- Patients had varying levels of need for remote monitoring. From no monitoring to all, to monitoring through the transition, to a permanent installation. As well, patient had varying needs in terms of specific components of monitoring.
- There was some concern over privacy and the "Big Brother" effect of using remote monitoring. Patients expressed concern over the detailed knowledge their caregivers would have of the schedule, frequency and habits when dialyzing at home.
- Use of a camera was suggested by patients, and would be used by minority of patients. They viewed its purpose as useful for trouble-shooting as well as for safety.
- Remote patient monitoring is particularly supported by family-caregivers and is viewed as a surrogate to nursing care. Family caregivers viewed it as a backup, or safety net for themselves to reduce their anxiety and to address what they perceive as a lower level of care in an emergency, than what they would receive in-centre.
- There is concern by the patients of the physical obtrusiveness of monitoring and that this would produce adherence issues. Patients are concerned how further tethering themselves to the machine will affect their sleep and the mobility when addressing alarms.
- The suggestion of the use of wireless monitoring was well received and may address the issue of the obtrusiveness.
- The need for monitoring the integrity of the bloodlines was identified, as potential blood loss one of the most significant fears amongst patients.
- Patients were comfortable with the use of automation for alerting caregivers in an emergency. However, they expressed a need for human intervention in immediate response to this alerting.
- Pre-dialysis patients, unfamiliar with the process of hemodialysis, expressed concern over the need for

monitoring. Unless the patient is already aware of the risks involved in performing hemodialysis, patient may become alarmed at the need for monitoring.

Design principles

Based on these findings and the detailed themes as discussed above, the following design principles were developed:

1. The physiological sensors will be unobtrusive as possible to the patient, allowing them freedom of motion and will not be uncomfortable so as to interfere with their sleep.
2. The system will not add to the training requirements of the NHD patients.
3. The system must communicate more than just the status of the dialysis machine.
4. The system must communicate more than just the status of the dialysis machine.
5. The system will allow for transitional monitoring, such that installation can be done quickly and removed equally so.
6. The system will be entirely automated from the patient's perspective, leaving them only to apply the physiological sensors as necessary.
7. The patient will have the option to decline the use of any or all of the components of the system, including the camera, so as to respect their privacy and to meet their individual needs.
8. The system will address the need for ensuring bloodline integrity, without adding to complexity of the existing setup.
9. Automated alerting will result in direct contact by the caregiver-on-call to the patient. The system should scalable to allow a call-centre approach to addressing these alerts.
10. Data acquisition and transmission will be done securely and will comply with the standards of the healthcare organization and relevant legislation.
11. The system will be modular, where components can be removed and added as needed or appropriate.
12. The system architecture will be generic and abstracted, so that interfaces to other devices can be easily added as needed.The system will not add significantly to the cost of NHD delivery, be scalable, and will leverage existing data infrastructure.
13. The system will work within the existing workflows of the current NHD program.

These use of these design principles resulted in an initial system design consisting of the acquisition, transmission, storage, and processing of patient vital signs (heart rate, respiration rate, blood oxygenation, and blood pressure) and selected hemodialysis treatment parameters of the hemodialysis systems. Rules were developed through discussions with domain experts including nephrologists, nursing staff, and renal technologists. These rules would be applied to the data in real-time and alerts generated. In the first iteration of the system, these alerts would be sent to on-call staff who will receive the alerts and assist the patients as necessary. See figure. below.

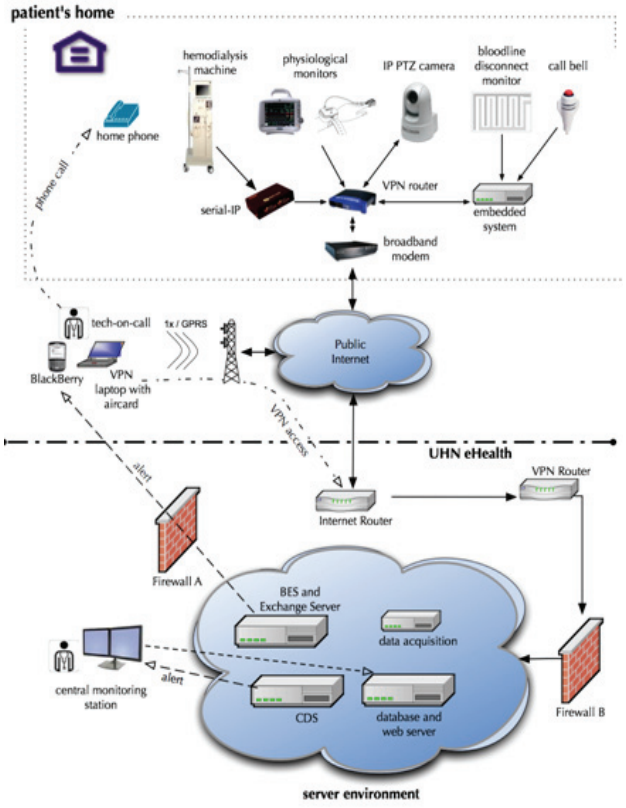

Figure 1 - UHN HEalth

Additional components included an IP-based pan-tilt-zoom (PTZ) video camera, to allow staff to observe remotely at the patient's discretion. This would aid in remotely troubleshooting the dialysis machine as well as have the ability to check on a patient during a serious alarm condition.

Also developed was a bloodline disconnection detector, utilizing a liquid-sensitive pad that would lie under the

patient and trigger an audible alarm if blood were to come into contact. The detector also cuts power to the HD machine, disabling the blood pump and stopping further blood loss. An IP-based message is then sent back to the technologist-on-call to notify them of the event. Incorporated into the system, was a patient call bell system. Much like the systems found in an in-patient setting, patients could simple press the call-bell button to alert the on-call staff via IP messaging.

The clinical decision support component of the system generates alerts based on criteria being developed by domain experts. These alerts are sent to the technologist-on-call through a mobile communication device. The alerts contain relevant information, current patient vital signs, and the patient's home phone number for quick access via the device's telephony capability. For further follow-up to the alert, the technologists can VPN into the system, access more physiological and dialysis data, and take control of the IP camera if necessary.

A clinical pilot of eight patients has been underway since January of 2006 and refinements to system are being made through feedback from clinicians and patients. Preliminary analysis of this phase of the study has found the following.

- Patients develop a dependency on the system, despite initially expecting only to need the monitoring during their transition. Particular aspects of the system they feel they cannot do without, including the bloodline disconnect monitor and the call-bell.
- The incidence of bloodline disconnects appears to be higher than is commonly reported. One incident occurred after only 3 months of deployment with only four patients being monitored.
- One patient felt that their privacy was being invaded when the nursing staff would challenge them on the frequency and duration of their dialysis. The patient was not adhering to what was prescribed and was alarmed that the hospital was aware of this level of detail in treatment information. This incident has demonstrated an added a level of accountability for patients that are being monitored that did not exist before. This has resulted in concern that patients are not adhering to their prescribed treatment levels and are therefore not fully benefiting from the therapy. The negative aspect of this finding is that use of the system in this manner could lead to trust issues between patient and provider, harming this relationship.
- Adherence to the use of vital signs monitoring remains a challenge, as patients are still fatigued using wireless sensors that are uncomfortable and interfere with their sleep and range of motion.

Conclusion

The study demonstrated the use of a patient-centric design method to facilitate the adoption of a hospital-at-home therapy. Therapies such NHD, which has been shown to deliver improved outcomes at lower costs, are vital for the future sustainability of the healthcare system. The delivery of hospital-at-home services will likely require some form of remote monitoring to mitigate risk and to improve patient adoption. A patient-centric approach to the design of this system has permitted the development of a scalable and flexible remote patient monitoring system to allow other hospital-at-home applications including CHF, chemotherapy, TPN, and palliative care.

Enabling Biomedical Research in Europe: Using the Dutch Experience as a Template

René Verheij[a], Tyrone Grandison[b], Frank Baas[c],

[a]*IBM Global Business Services -Netherlands, Johan Huizingalaan 765, P.O. Box 9999, 1006 CE Amsterdam, The Netherlands*

[c]*Academic Medical Center, Meibergdreef 9, 1105 AZ Amsterdam, The Netherlands*

Abstract

Medical centers in the Netherlands contain a wealth of patient information that could be leveraged by healthcare researchers to drive breakthroughs, to deliver innovation in healthcare and improve the quality of life for Dutch citizens. However, the sensitivity of this data, the fragmentation of patient records and the complexity of retrieving this information have inhibited advances in this arena. In order to open up clinical data to researchers, the Academic Medical Center (AMC) in Amsterdam has implemented a framework that addresses the problems outlined, mitigates the risk for practitioners and patients and enables medical innovation to proceed. In this paper, we describe the AMC environment, we present the system implemented and highlight the benefits of employing this technological approach. We purport that the AMC model can be used as a template for Biobanks across the world.

Keywords:

Biobank, healthcare research, data integration, data abstraction, privacy

Requirements

The main problems faced by the medical researchers at the AMC were how 1) to acquire data from multiple disparate systems within a reasonable timeframe, 2) to ensure that patient privacy is respected, and 3) to enable natural interaction with the computer systems (i.e. not mandate that medical researchers become computer specialists). These concerns raised three higher-level base requirements for a solution system:

- Data Integration – providing a consistent, global view of a patient, regardless of the locations of the records, the data formats or the database vendor.
- Disclosure Control – ensuring that patient privacy is not violated, organization security policy is adhered to and that proactive compliance is possible
- Usability – providing a simple interface that hides the complexity of the underlying infrastructure and allows researchers to easily query the system.

The deployed solution dealt with all the above problems, by leveraging a subset of IBM's Clinical Genomics Framework (Figure 1).

Query System: Data Discovery and Query Builder

DDQB provides an easy-to-use way of extracting information from data sources by allowing non-IT professionals to create queries using their own terminology. DDQB's central component is the Data Abstraction Model (DAM), which bridges the gap between the technical complexity of databases and the language and concepts that are familiar to end users. DDQB is accessible by means of a standard Internet browser (i.e. Microsoft Internet Explorer, Mozilla Firefox, etc.)

Disclosure Control: Hippocratic Database Technology

HDB receives user queries from DDQB and rewrites the queries so that the database will only return data that is consistent with company policies, applicable legislation, and customer preferences. Data that is not consistent is suppressed or encrypted.

Data Integration: WebSphere Federation Server

WFS uses federation technology to abstract a common data model across diverse and distributed data and content sources, and to access and manipulate them as though they were a single source. The federated system acts as a virtual database in which remote objects can be accessed similar to local tables.

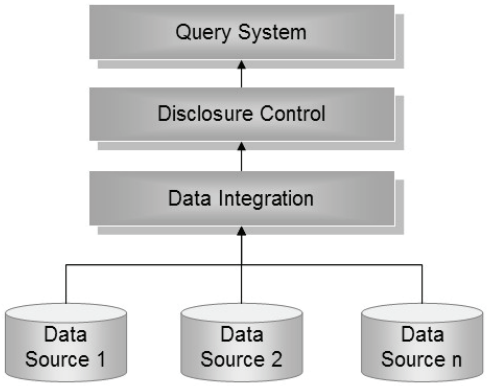

Figure 1 - Solution Architecture

Usage scenario

In a typical scenario, a researcher, let's call him Carlo, wants to retrieve information from systems in the departments of Internal Medicine and Clinical Chemistry in order to perform an analysis on pharmacological treatment of patients with Crohn's Disease. Carlo knows that each of these systems uses a different platform, different terminology and database technology, i.e. Internal Medicine uses Microsoft SQL Server on a Windows platform, and Clinical Chemistry uses a proprietary database on Linux. A further complication is that AMC's corporate policy states that for research purposes, patient numbers should never be shared in an unencrypted form and that medicinal doses should be disclosed on an opt-in basis per patient.

Carlo logs into the DDQB system, and verifies his user id and password with AMC's existing user directory. He pecifies a query through the menu-driven interface of DDQB. Carlo wants to select patients diagnosed with Crohn's Disease, between the ages of 25 and 50 years old, who have been treated with azathioprine. Carlo also instructs the system to retrieve plasma concentrations of liver enzymes, so that he can evaluate the toxicity of this drug for the liver. Fields are organized in a tree structure. Carlo selects the fields that represent the desired information by clicking on a link. Selection values can be chosen from a list, e.g. for the diagnosis field (Figure 2 Selecting patients based on diagnosis2), or entered using the keyboard, e.g. for the age limits. Carlo also select lab tests 'ALAT' and 'ASAT' from the Clinical Chemistry category. The system builds a list of query conditions (Figure 3) and fields to be returned. When Carlo indicates that his specification is complete, the application translates it into an SQL statement and submits this to HDB through its JDBC interface. HDB compares this statement to the policy rules that apply, and determines if Carlo has requested any information that he has not been granted access to. If this is the case, HDB rewrites the SQL statement, eliminating this information from the result list. It also determines at this stage if any information must be encrypted, and modifies the SQL statement accordingly. In this scenario, HDB will rewrite the SQL statement to display encrypted patient numbers and ensure that only patients who have consented will have their medicinal doses disclosed. The resulting statement is then returned to DDQB, which passes it to WFS.

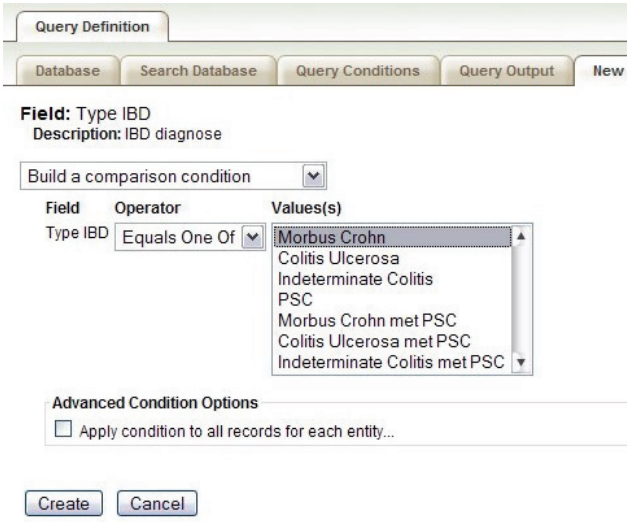

Figure 2 - Selecting patients based on diagnosis

WFS uses its knowledge of the location of the requested information to break up the SQL statement into parts, and submits each part to the appropriate data sources. It combines the result sets returned by the data sources into a single result set. This result set is then returned to DDQB. Finally, DDQB for mats the data and sends it back to Carlo's workstation (5). Note the encrypted patient id values in the 'patientnummer' column. Carlo can inspect the result of his work, store it in DDQB or in a file on his workstation, or feed the retrieved data into an analysis tool. He does not have to perform any manual data manipulation. Specifying and executing a query using the Clinical Genomics application can be completed in minutes. A complex query can be specified and executed in less than an hour, which is a few orders of magnitude faster than previously possible.

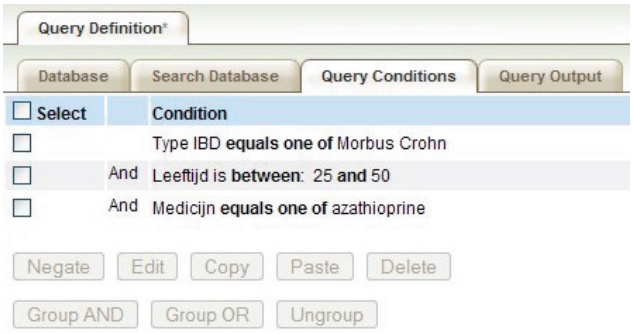

Figure 3 - Query conditions

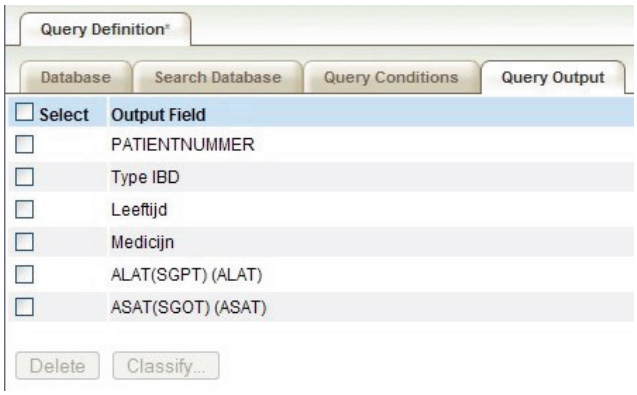

Figure 4 - Query output

System benefits

AMC's new system enables medical researchers to get the data they need efficiently. It is no longer necessary to manually obtain exported data from different systems that must be manipulated manually. This reduces the probability of errors occurring in the data. The researcher is not expected to understand the gory details of all the computer systems used across all the units he interacts with. The dependency on system administrator has been elimi nated. Privacy and security issues, often ignored in the manual process, are enforced (at the technology level) by the system. The process of selecting patient cohorts can now be completed in minutes or hours rather than weeks or months. This is a significant enhancement of researchers' productivity.

Abstract

In this study, an electronic home care visit platform: Nurse's e-Bag integrating popular distributed technologies, mobile hardware, and bio sensor was developed. This implementation is based on the service model of the home care center at National Taipei College of Nursing(NTCN) Hospital, which is one of the branch hospitals of National Taiwan University Hospital(NTUH) and serves as the disposition and case management for long term care. For enhancing the efficiency and quality care for home visiting nurses, e-Bag was introduced to integrate with a mobile electronic home care records system and become one application part of NTUH U-Care system and also an electronic home care visit platform. Light weighted Nurse's e-Bag not only reduces the loading comparing to the traditional home healthcare, but also provides the teleconsultation when home visiting nurse encounters problems at the patient's home.

Keywords:

home visiting nurse, home care, ubiquitous healthcare, electronic health records, nurse's bag

Introduction

E-Health (healthcare activities based on Information and Communication Technologies) is probably the most prominent of these e-business services that can have a major visible impact on the development of the society, as endorsed in the World Health Assembly in May 2005. Ubiquitous Healthcare (u-Health) focuses on e-Health applications that can provide healthcare to people anywhere at anytime using broadband and wireless mobile technologies.

National Taiwan University Hospital, one of the most renowned medical centers in Taiwan collaborates with its branch NTCN hospital and industry partners to develop a U-Care system, which is focusing on community healthcare and long term care. U-Care system utilizes the medical, IT and telecommunication environments. U-Care is an important research project of a Mobile Hospital (m-Hosp) research group in National Taiwan University [1]. Mobile Hospital is switched to Ubiquitous Hospital (u-Hosp) from 2006. m-Hosp/u-Hosp recruits many multi-disciplinary faculties and researchers from different colleges and also from several hospitals and other universities.

Nurse's e-Bag,, which was designed to provide the ubiquitous healthcare service and enhance the efficiency and quality care for home visiting nurses, was introduced to integrate with a mobile electronic health records system and become one important application part of NTUH U-Care system.[2] It also plays as an electronic home care visit platform by utilizing the information, communication and biomedical sensor technologies. As an important subgroup of u-Hosp research team, home visiting nurses at home care center of NTCN Hospital have the experience of implementation of electronic health record system and high acceptance of information technologies and collaborated with medical engineering and medical informatics experts to develop this application platform[3].

Methods

The basis of the design in Nurse's e-Bag is the service model of home care center at NTCN Hospital. Usually home visiting nurses at the home care center would receive referral notification of patients who need long term care or follow-up visits after discharge from NTU Hospital. For each referral, they would go to the patient's home for 1st time evaluation of health status. Then they visit the patient twice per month, re-evaluate the health status per four months, and make insurance claims for reimbursement (also per four months) until this case is deceased or home care is terminated. The principle business processes were deliberated as the following:

Mobile electronic home care records

When receiving a new case, a home visiting nurse first vfisits the patient to build personal data, health status evaluation, care plan suggestions, and an insurance claim profile. The health status evaluation contains thirteen

forms, divided into two groups: called 'A forms' and 'B forms'.

The 'A forms' contain data of cardiopulmonary vital sign, nutrition, and others. A nurse fills new healthcare information and adds them into the home care record in every visit. The 'B forms' contain summary data of 'A forms', and some extra data. Such as care plan suggestions, and insurance claims are produced every re-evaluation per four months. A care plan suggestion consists of care problems, care process, and evaluations. Each care problem has its default care processes to adopt. Contents of a care plan suggestion may be updated when necessary.

A home visiting nurse regular visits a patient twice a month, and fills new 'A forms' of the patient and re-evaluates the patient status per four month until the patient is recovery, moved, or dead. When one of these events occurs, the homecare is terminated and a 'closed case record' is built. With the mobile electronic home care records system, the data can be stored onsite and transmit to a server online via accessible Internet connection or synchronize in batch operation after the nurse return to office everyday.

Bio-sensor monitoring

The Nurse's e-Bag can also provides measurement and monitoring of bio-signals such as temperature, blood pressure, glucose, oxygen, respiration, ECG, and other vital signs. A bio-sensor network to record daily health status has been being developed in the U-Care system, so home visiting nurse can connect to the sensor network in the home setting or use the selective portable bio-sensors to records vital signs, and executes the home care record system which access results from sensor database into evaluation forms for the home care management.

Bidirectional Audio-video interaction

Another business process is the audio-video interaction among doctor-nurse and doctor-patient in mobility or at patient's home. A home visiting nurse can initiate a conference call via a built-in videoconference module on the portable computer or using the videoconference module of patient's U-Care system at home setting. The consultant doctor can be in real- time diagnosing the abnormal sign or bio-monitoring results of the patient. The vital sign was transmitted through Asynchronous Digital Subscribe Line(ADSL), Third Generation (3G) or General Packet Radio Service (GPRS) network. Therefore, the home visiting nurse can get more support from physicians to enhance the service quality

Results

System architecture

Full view of the system architecture can be separated into client side on a mobile light weighted computer and central server side (figure 1.). The server side is a simple system provides database management functions and queries. The mobile computer side contains two independent application systems, one is the electronic home care record system and another is the bio-sensor monitoring system.

The home care record system works with a local database which stores patients' records assigned to individual nurse. The mobile computers can be shared among colleagues by taking anyone of them with the e-bag when a nurse is scheduled to do the home visit. A nurse can download patient's data before she go out for work, and synchronize with the server when network available.

The bio-sensor monitoring system connects to sensors with their drivers and save data into another database. We can use thermometer, sphygmomanometer, glucometer, and pulse oximeter, peak flow meter and ECG. . This system works with another local database which retrieves bio-signal data via corresponding sensor drivers. The home care record system further integrates the bio-signal data and stores to its database.

User interface

A nurse can login into home care record system to perform data manipulate, download, and upload functions. If there is a new case, she would call the patient or go for the 1st visit to verify referral sheet come from hospital and fill the basic data forms in the system (figure 2).

When a nurse visits a patient, she can use the bio-sensor system to retrieve history data of biosensor monitoring (figure 3). Data are store into a JET database that a sensor uses a table in it. Data will be read by home care record system when the nurse fills evolution forms.

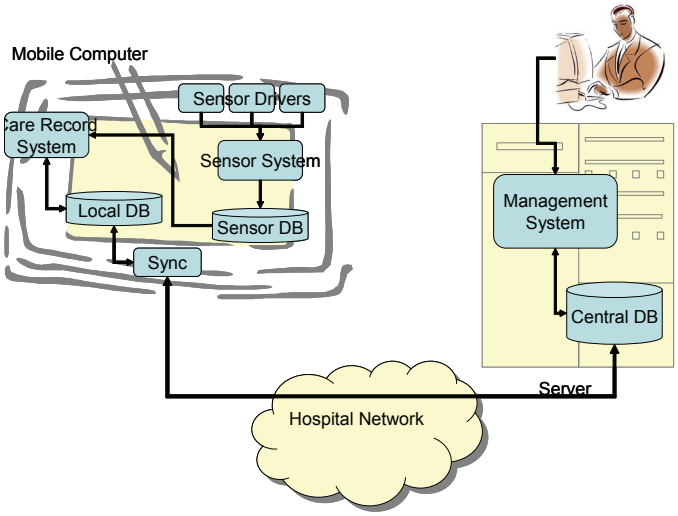

Figure 1 - The system architecture diagram

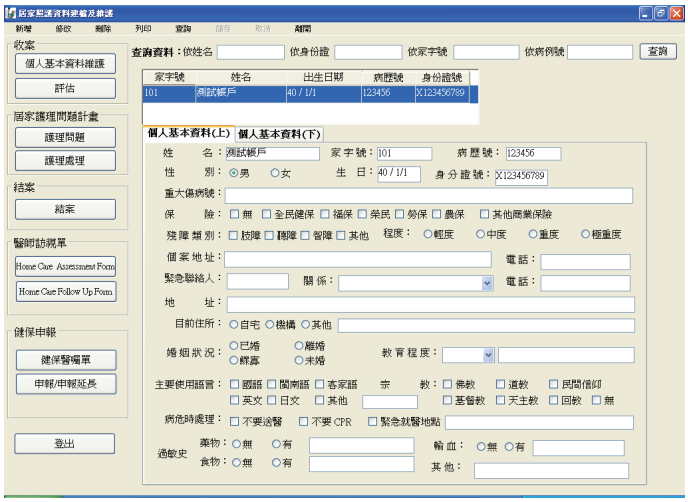

Figure 2 - Personal basic data form of home care records

Figure 3 - A history record of glucose level monitoring

Tele-consultation

If a home visiting nurse needs help from a doctor when she is visiting a patient who has unsolved problem, she may call the on-call doctor or patient's family doctor for consultation. In case it is a serious situation of a patient, the doctor might need to access the home care records in the server via his computer. At the same time he can also link to the patient's medical records from Hospital Information System if the patient is referred from same hospital. In this way, the quality of consultation is much improved comparing to traditional telephone consultation the nurse is the exclusive source of information.

The broadband and wireless telecommunication network such as home ADSL, Fiber to the home (FTTH), and 3G communication network have enabled videoconference function that the doctor can visually evaluate the situation of patient, and interpret the vital signs in real time. Nurse and doctor can use built-in video camera on mobile computers and free software to call videoconference easily.

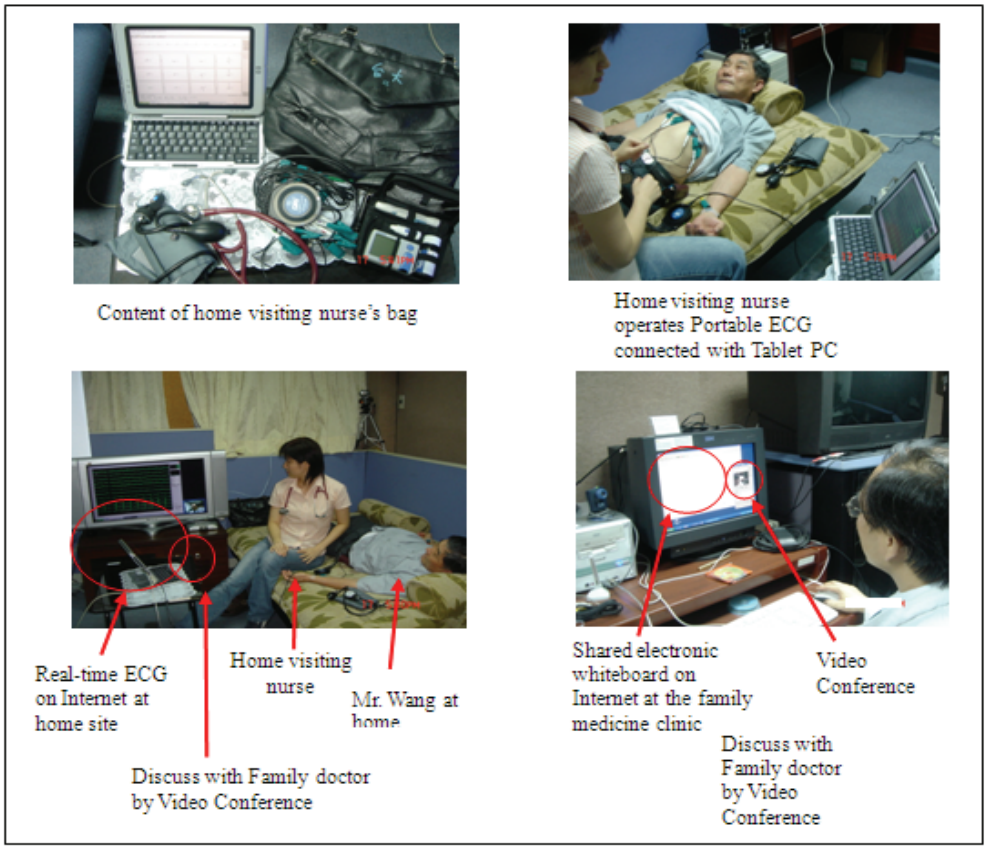

Figure 4 - Tele-consultation at patient's home

Discussion

Studies suggest that home visits can lead to improved medical care through the discovery of unmet health care needs. [4-6] Therefore, home visits will play an important role in long term care, and the electronic home care visit platform can significantly improve efficiency and quality of home healthcare comparing to the traditional nurse home visit. It makes the home care service be linked to a hospital-based health information system more easily. Moreover, the home visiting nurse and the patient's family doctor can easily collaborate to trace the history and clinical condition of patients. It is also convenient for survey or to evaluate the whole patient community through the electronic health records system, so the system can enhance the quality of medical service.

The implementation is fully based on the service model of the home care center at NCTN Hospital. A home visiting nurse visits 5 cases one day. The client of prototype platform using a light weighted notebook less than 1kg with long battery life is good for one day's work without charging. In general, the weight of paper healthcare records of five patients is equivalent to the notebook, and pc-based portable sensor devices are also less weighted than traditional physiological measurement equipment. Moreover, in U-Care system more and more biosensors will become standard remote monitoring devices installed at patient's home. Home visiting nurse will no longer need to carrier these devices. Therefore, home visiting nurse not only reduces the loading of her bag but also get the benefit of efficient case management by using this e-platform[7-8].

However, security and privacy issues are still the major concerns of an e-platform. There are many technologies along with ordinary user id and password which are applied on a mobile computer to ensure security, such as the finger print and Centralized Authentication (CA). Security problems might happen when download and synchronization of patients' data via network were performed. Since the wireless environment is not completely deployed in everywhere, the homecare record system is designed workable as off-line. There is a client program at mobile PC with a local database to store home care records. It raises the security issue that patient's data maybe unauthorized accessed. To reduce the risk of damage, only data of

patients assigned to the on duty nurse can be stored to the computer. If a patient should be reassigned to another nurse, or home care of a patient is terminated, his data in the computer of the original nurse will be clean when synchronizing. On the other hand, the data retrieval of biosignal could probably be another security hole. It is not a good idea to open our database to bio-sensor providers. So we propose a two tiers solution that ask sensor providers to export data of standard format from their sensor and save them into a JET database which is the default function of Windows OS and can be checked easily using Microsoft Access.

To representation of a full function e-platform home care visit rely heavily on high speed wireless and broadband network. At present, the bandwidth is still not enough to show full motion live video to the doctor, but in the near future, Taiwan will build high speed wireless network environment, such 3.5G High-Speed Downlink Packet Access(HSDPA) with 3.6 Mbps, WiMAX (Worldwide Interoperability for Microwave Access),

Conclusion

The prototype e-platform for home care visit materialized as a nurse e-bag which integrated with a mobile electronic home care records system, a biosensor measuring and retrieval system, and a videoconferencing and consultation system. The key element is a light weighted mobile computer with long battery life enhances the efficiency and reduces the total weight of bag content. The platform is flexible upon the working flow of the service model of the home care visit and serves as the disposition and case management tools for long term care. It involves popular mobile technologies and existing sensors that cost not too much. It also shows a good example for interoperability cross domain knowledge; include nursing, information technology, sensor technologies, and the outsourcing vendors. In the future, we expect more application and service models in long term care can be implemented with this e-platform.

A Prototype of Electronic Home Care Visit Platform: Nurse's e-Bag

Yaw-Jen Lin, Mei-Ju Su, Chia-Hui Chen,
Heng-Shuen Chen, Jin-Shin Lai

Introduction
- an electronic home care visit platform

- *For enhancing the efficiency and quality care for home visiting nurses:*
  - Nurse's e-Bag integrating popular distributed technologies, mobile hardware, and biosensor
  - based on the service model of the long term care of the home care center at NTCN and become one application part of NTUH U-Care system
  - integrate with a mobile electronic home care records system
  - Light weighted
  - provides tele-consultation

Introduction
- U-Care system

- *Nurse's e-Bag developed in U-care system:*
  - U-Care is an important research project of a Ubiquitous Hospital (u-Hosp) research group in NTU
  - Mobile Hospital is switched to u-Hosp from 2006. m-Hosp/u-Hosp at NTUH
  - many multidisciplinary faculties and researchers from different colleges and also from several hospitals and other universities.
  - Ubiquitous Healthcare focuses on providing healthcare to people anywhere at anytime using broadband and wireless mobile technologies.

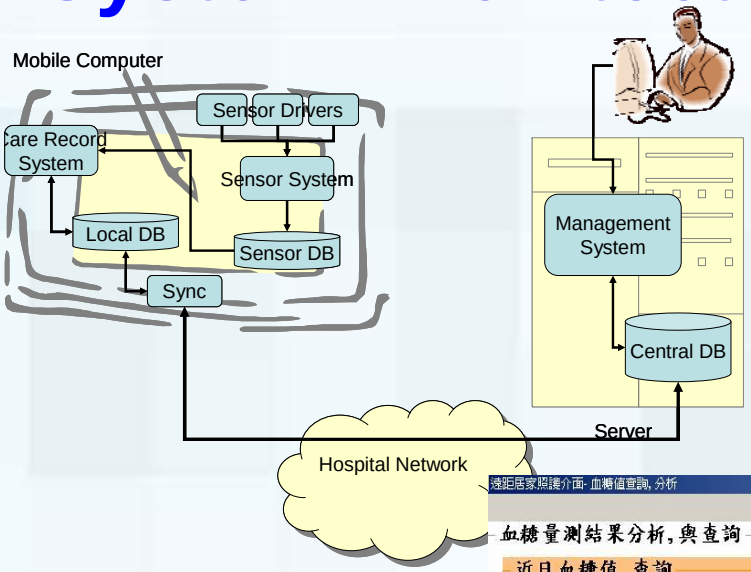
Methods :
Mobile electronic home care records

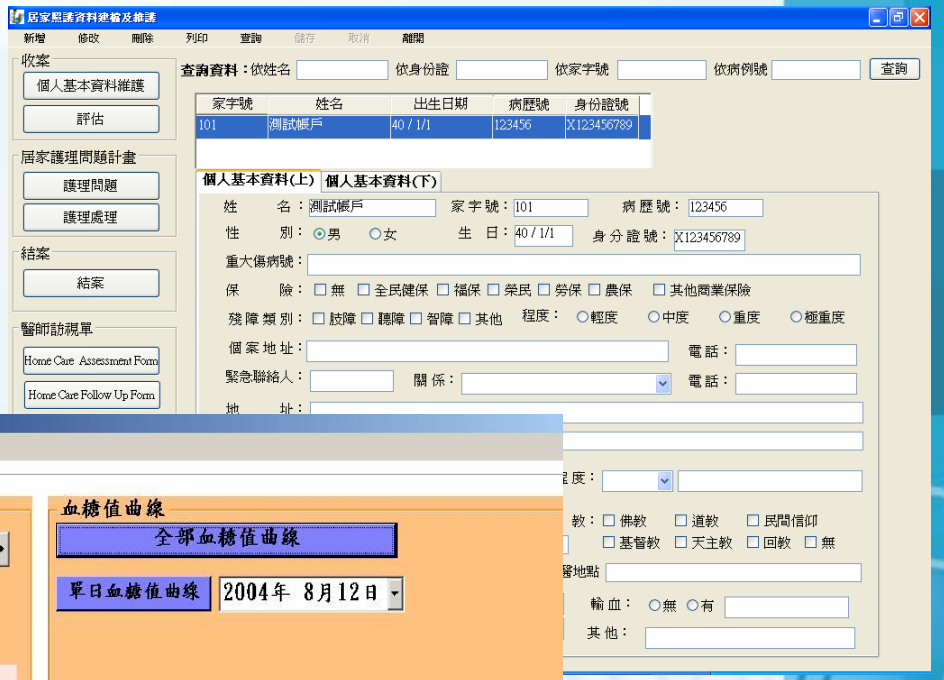
- Mobile electronic home care records system
  - the data can be stored onsite and transmit to a server online
  - or synchronize in batch operation after the nurse return to office everyday.
- A nurse fills new healthcare information and adds them into the home care record in every visit.
- Patient data divided two groups: called '*A forms*' and '*B forms*'.
- '*A forms*' contain data of cardiopulmonary vital sign, nutrition, and others.
- '*B forms*' contain summary data of '*A forms*', and some extra data, plan suggestions, and insurance claims.

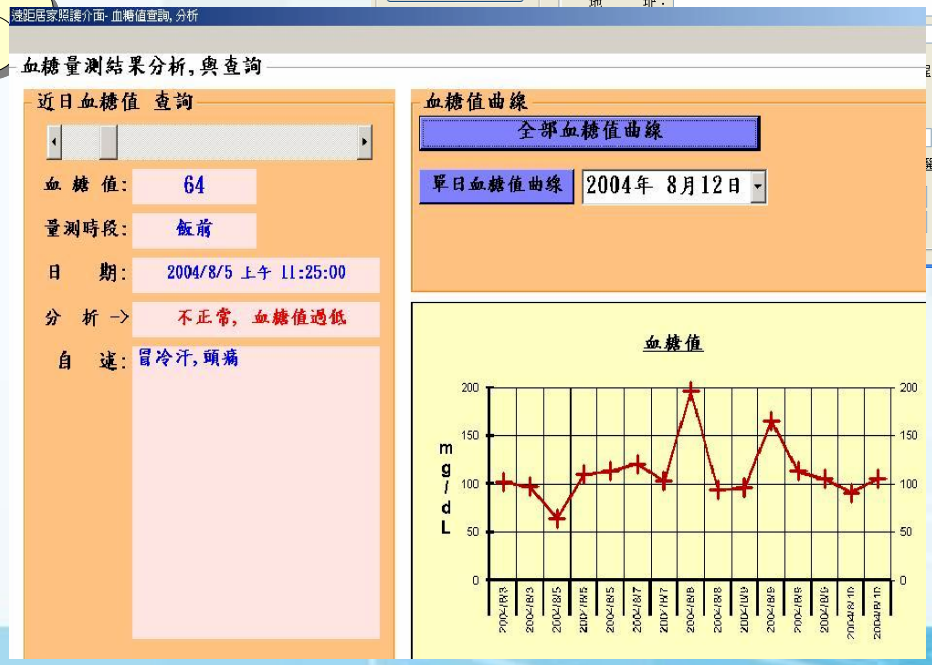
Methods :
Bio-sensor monitoring & Bidirectional Audio-video interaction

- provides measurement and monitoring of bio-signals:
  - temp, blood pressure, glucose, oxygen, respiration, ECG.
- U-Care system
  - record daily health status by the sensor network in the home setting or use the selective portable bio-sensors
- home care record system
  - access results from sensor database into evaluation forms for the home care management
- initiate a videoconference at patient's home
  - interaction among doctor-nurse and doctor-patient
- vital sign transmitted through ADSL, 3G or GPRS
- home visiting nurse can get more support from physicians to enhance the service quality

Results :
System Architecture & User interface







Results：Tele-consultation

Content of home visiting nurse's bag

Home visiting nurse operates Portable ECG connected with Tablet PC

Real-time ECG on Internet at home site

Home visiting nurse

Mr. Wang at home

Discuss with Family doctor by Video Conference

Shared electronic whiteboard on Internet at the family medicine clinic

Video Conference

Discuss with Family doctor by Video Conference

Discussion (1/3)

- Improve traditional nurse home visit
- home visiting nurse and the patient's family doctor can easily collaborate
- Enhance the quality of medical service :home care service be linked to a hospital-based HIS more easily
- based on the service model of the home care center at NCTN Hospital.
- reduces the loading of home visiting nurse's bag
- efficient case management

Discussion (2/3)

- security and privacy issues :
  - such as finger print and Centralized Authentication
- homecare record system is designed workable as off-line
- To reduce the risk of damage, only data of patients assigned to the on duty nurse can be stored to the computer
- data retrieval of biosignal
  - ask sensor providers to export data of standard format from their sensor
  - save them into a JET database

Discussion *(3/3)*

- the bandwidth is still not enough to show full motion live video to the doctor
- Taiwan will build high speed wireless network environment, such 3.5G HSDPA, WiMAX

Conclusion

- The prototype e-platform, nurse e-bag integrated with :
  - a mobile electronic home care records system,
  - a biosensor measuring,
  - retrieval system,
  - a videoconferencing,
  - consultation system
- cross domain knowledge:
  - nursing, information technology,
  - sensor technologies,
  - the outsourcing vendors
- In the future, we expect more application and service models in long term care can be implemented with this e-platform.

Effect of Direct Management of Clinical Documentation and Its Contents (Medical Record Items)

Yong Oock Kim[a], Young Ah Kim[b]

[a]Dept. of Plastic & Reconstructive Surgery, Yonsei Univ. College of Medicine,
[b]Dept. of Medical Informatics, Yonsei Univ. Medical Center

Abstract

Many clinicians need a rapid creation and change of clinical document according the fast change of medical environment. However, it is not easy to create new clinical document and it is more difficult to change its contents on the system of paper based clinical document. The Severance Electronic Medical Record (EMR) system was constructed and run on the basis of clinical documentation with XML format and its contents under the name of medical record (MR) item as a new concept. Each MR item has its characteristic and own attribute values. In this study, we tried to evaluate the effect of this direct management of clinical document and its contents (MR items) by the changes during 1 year after implementation.

Keywords:

EMR, medical record (MR), MR items

Introduction

The clinical document has a vast of variety by the department and individual clinician. Many clinicians need a rapid creation and change of clinical document according the fast change of medical environment, such as research and new devices. However, it is not easy to create new clinical document and it is more difficult to change its contents on the system of paper based clinical document. The main reason is that those change needs the process of consensus, confirmation, inspection, and registration, moreover this process is not so flexible to accommodate the promptness of clinician, and also impossible to create all the documents as clinicians please.

The Severance Electronic Medical Record (EMR) system was constructed and run on the basis of clinical documentation with XML format and its contents under the name of medical record (MR) item as a new concept. Each MR item has its characteristic and own attribute values.

The system has two main functional modules. One is clinical document editor, which enables creation or change of clinical document, and the other is MR item registration module, which register new MR item and change the attributes of MR item. On the blank board of clinical document editor, the clinicians can select MR items that they want and place them where they want. Through this, the creation or change of clinical documents was very fast and can be created as clinicians needs. MR items were gathered by fractionation of the every content item of paper clinical documents. In order words, it provides the maximum flexibility of customization of clinical document and contents to the clinicians.

In this study, we tried to evaluate the effect of this direct management of clinical document and its contents (MR items) by the changes during 1 year after implementation. We inspected the change of numbers by electronic calculation, and evaluate the process of new adaptive classification, and estimate the controllability of the in time recording. The result shows the dramatic rapider change of the clinical document and its contents than paper-based record.

On the basis of the results, we can conclude that there has been very insufficient reflection of clinician's needs on the clinical document in the previous paper-based recording system. And also we can sure that its main reason is easy and direct management of clinical documents and its item by themselves. So, if an institute wants to implement self evolutional EMR system, the maximum customization should be provided on the modules of clinical documentation and its contents.

Material & method

All data was retrieved from the Electronic Health Record (EHR) system of one hospital, Severance hospital, Seoul, Korea. The hospital has 8,000~12,000 Outpatients per day, 2,000 inpatients, 2,100 beds, 2,500 clinicians, 54 medical department, 57 general ward, 9 ICU, 5 specialized centers. The whole hospital information system has been constructed on the basis of EHR system that contains EMR and Computerized Patient Order Entry (CPOE, order communication system) system. On the EHR system, the other systems are integrated, such as 3 PACS, one Dynamic PACS, Enterprise resource system, Groupware, Dataware house, and Disaster recovery system.

Before retrieval of data, the number of paper based clinical document (PBCD) was checked before and just after revision of clinician for the conversion of electronic form.

During revision process, lots of new paper based clinical document was gathered from the clinical department and nursing field. After then, those are revised for electronic conversion. The number of the original categories and revised categories of PBCD was also checked. And then the number of initial electronic clinical document (ECD) was checked via EHR system.

The follow up of the changes of the ECD and MR item was checked monthly for 1 year. At the time of 8 months after implementation, the data was analyzed by the classification of the database of recording log of CD by

MS SQL according to classification of the ECD, number of new ECD, and the analysis of the changes of attribute of MR item and MR item itself. Through this procedure we postulate common ECD by its frequency of usage according to its clinical objectives. So, the commone ECD is a kind of reestablished current ECD of the institute. For this work, 1,677,434 patient's clinical records were examined. Through this work we identified number of available ECD from total patient's records by using above analysis process.

The estimation of the controllability on actual recording was done four specific limited ECD. Those documents are admission note, operation note. The occurrence time of events of admission and operation were compared with the recoding time of each records, and the existence of the recorded ECD of each records.

Results

Evaluation changes of CD, ECD, and MR items

Table 1 - Change of paper based clinical document

Before revision	After revision*
Medical 18, Nursing 40	Medical + Nursing : 960

*After revision involves not only revised document but also department managed (can be called hidden) document from whole clinical, nursing, and other supporting departments.

Table 2 - Change of ECD from revised paper document

Period	Number of clinical document
Pre-EMR (Paper)	960
Initial in EMR (Nov, 2005)	1,169
6~7 Mon later after EMR	5,370
1 year later, Present (Nov, 2006)	2,707

Table 3- Category of paper based clinical document (PBCD)

Original categories	Revised categories
No category ; Admission note Laboratory result report Examination result report Procedure result report Discharge note, Summary note, Progress note, etc < Other many record that was used without management of the medical record department.>	Four categories ; 1. Progress note – OPD progress note – IPD progress note – Operation note – Consult note – Anesthesia note – Treatment note – Doctor order note etc 2. Result report – Laboratory – Radiology – Pathology – Examination etc 3. Legal form – Consent form – Diagnostic certificate – Refer note etc 4. Education Document and Other

* Revised category was applied to the ECD in same.

	Pre- EMR	Present	Modification
MR Item	15,092	24,858 (+9,488, 41.7% Δ)	240 (1.8%)

Table 4 - Change of number of MR item

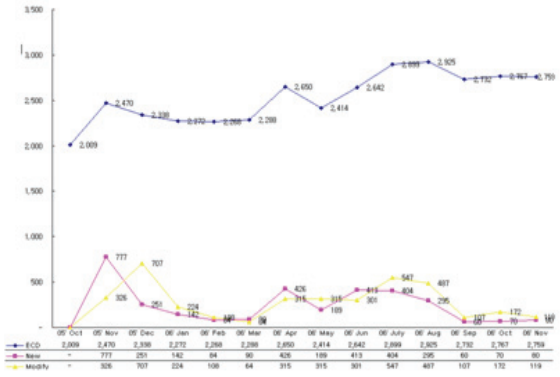

Figure 1 - Transition of ECD, frequency of new generation and modification

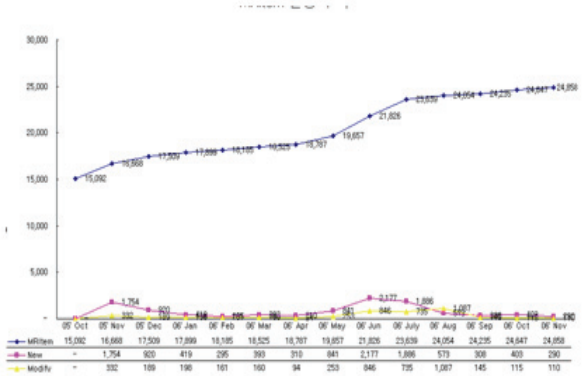

Figure 2 - Transition of MR item, frequency of new generation and modification

Extraction of common ECD at 8 month of implementation.

- Through 1,677,434 patients, 25,074,974 ECD was existed. Among these ECD we can identify available, in other word proper recording was done, ECD is 19,394,233. From these available ECD, we also identify 1,538 of new common

EMR was forced by the massive creation of CD by clinicians and departments which contained different contents (MR item) even though those are CDs of same purpose.

For this extraction, the new creation of ECD was measured in two ways. We treated the CD that has changed more than 50% in its MR item as a new ECD, and treated the others as a changed ECD. And the change of MR item was measured a log of modification of MR item database.

Estimation of controllability of ECD

The recoding time of admission note and operation note was checked. The frequency of completeness of recording within 48 hours has been increase very sharp after 5 months of implementation in admission note (Fig. 3). For the operation record the module of control of recording time was applied at the 11th months after implementation, so the frequency of completeness shows sharp increase at the time of 12th month of implementation (Fig. 4). This means that the adaptation of admission note is faster than the operation record. In other word, the work process of admission note has been changed gradually by ECD environment, but for the operation record, the habit of physician has not changed until the control module (time warning module) was applied. In paper based operation record, this kind of control was impossible.

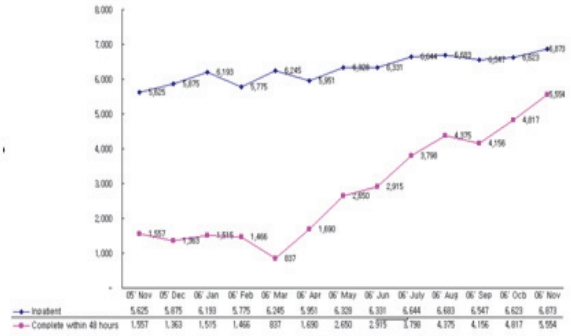

Figure 3 - Recoding time of admission note and number of inpatients

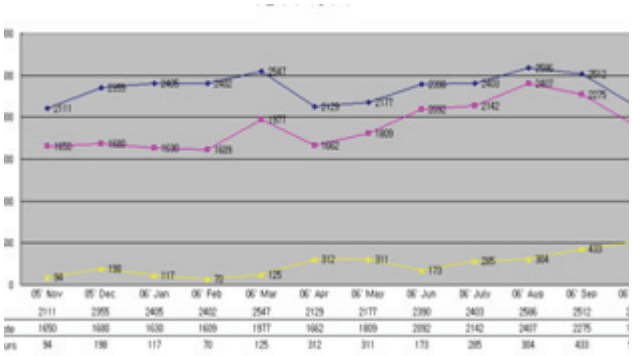

Figure 4 - Recoding time of operation note and number of OP-patients

Discussion

The expansion of medical information makes the evolution of the electronic management of the information. The expansion is not only its amount but also its variety.[1][2][4] In the last decade, it was possible to adapt the changing environment of the medical information through the paper based recording system, however nowadays it is impossible to adapt appropriately because the change is so fast and variable.[2][4] The institute of this study has started one clinical document, so-called discharge summary note, before 60 years. Before implementation of EHR system, the department of medical record has managed and archived only 58 clinical documents, however, there were lots of hidden clinical document that has been managed by individual department. So, the number of whole paper documents was collected up to 960 before implementation of EHR system. This change can be a evidence of hidden need of change of medical document of the institute during last 60 years(Table 1).

Before implementation the clinicians of the institute examined and revised their clinical document forms and its items as a preparation for the conversion of the EMR system.[1][2][3][5] The 5,370 CD was created as new one at the 8 months of implementation, this would be another evidence of need of diversity of clinical document. This 8 months' change of ECD makes a decision of provision of extraction of common ECD. As the result of extraction of common ECD and rearrangement, the 2,707 CDs were existed at 1 year of implementation (Table 2, Figure 2).
To achieve this direct management of CD and its contents by users, we have to create the new concept, so called, MR item. The terminology system is a collection of term.[5] Each term has its own meaning. However, we found that each medical term can have different meaning by specialty and situation, and also we found that medical term can involve image, grid, voice not only text. So, every clinician can not select the term in same meaning, and this makes impossible to select items of ECD by clinician. The concept of MR item was started from this insufficiency of current terminology system. The result of this concept makes two main modules, named *Clinical Document Editor*, and *MR Item Registration.* This enables clinician to create and change their ECD and its content directly whenever they need. The recorded ECD is stored XML format with electronic signature and MR item is stored into database sever. This enables confidentiality of records and reusability of information. From the items of content of revised paper CD, record items were unified, classified, and fractionated into 15,092 MR items at the time of implementation and then has increased 24,824 MR items after 1 year of implementation(Table 4, Figure 2). This change may reflect the clinician's needs of change of the terms.

The main objective of this study is whether clinicians have high need of direct management of CD and its contents. The observation of the change of ECD and MR items reveals that there is a high need (Table 2, 4). The progressive increase of ECD is somewhat unexpected phenomenon because the total revision was done by clinician themselves just before conversion of paper document to electronic one. We can sure that almost triple increment of ECD means explosion of high need for their clinical document. Also this means that there has been a limitation of expression on the previous system paper based clinical documentation.

The result of change of MR item means another desire of clinical documentation. The result shows that there was same need for the term itself. Clinicians want to use accurate term for their documentation. For example, the term 'time' can be a same item in two different clinical documents. However, it can be used year-month-day in one record and can be used hour-minute-second in other document. Previous paper document can hold this term 'time' in one meaning, though the real records is different. However, in the situation of direct management of items, clinician seek proper MR item, create item, and use it as a reflection of their desire of accurate description for better medical record. At this time MR item have different time attribute even though the name of item is same and they saved in different sector. This kind of addition of MR item has been occurred 24,858 times and time of change of attribute has been occurred 4,425 for 1 year. It also shows their adaptation of the new system as much as they use the system frequently. As another meaning, the simple collection of term, the terminology system should have any kind of intermediate tool that accelerate the usage of exact terminology like MR item.

By the above changes, the extraction of common ECD was possible, even though actual ECD is different from department and clinicians. For example, the items of discharge summary note is different in obstetrics and dermatology, however, they can be treated as a same discharge summary under tagging of department name of obstetrics and dermatology. Complete reconstruction of common ECD was possible by analyzing the changes of ECD and MR item at 8 months after the implementation of system. This would be another effect of direct management of ECD and MR items, because clinician left spontaneous consensus as well as difference of their record in the system. This traceable evidence makes easy transition of completeness of recording in time.

The estimation of completeness of medical recording [3] was greatly improved after reconstruction of essential ECD. The result of the time check of 2 time-limited medical records shows sharp increase of completeness (Figure 3). Completeness of operation note also has been more increased than initial of EMR (Figure 4). Clinicians can agree easily the time-limited document and accept the systemic alarming of time limitation. If they did not create their own record item and form of documentation, it is easy to make this kind of high completeness [3].

Other effect of direct management of ECD and MR item, the ECD for the research can be achieved. Even though we can not fully differentiate which one is ECD for research, we can sure that many portion of new ECD except essential ECD would be created for the research.

Conclusion

The direct management of ECD and its contents can satisfy clinician's need of expression, and extract their positive consensus of medical record, and also expected to accelerate their research mind. So, any institute should provide best tool for the direct management of electronic clinical document and its contents, when they implement new system, if they expect better return on investment.

Abstract

The purpose of this study is to analyze the functionalities of Health Information System in Public Health Centers focused on Health Business Program. Field research was performed in accordance with the business guidelines of the Ministry of Health and Welfare. After analyzing the users' requirement and the functionalities of the system, we suggest a model of functionalities for interoperable EHR system. This will help to promote application of health information system and to improve efficiency of Public Health Centers.

Keywords:

Health Information System, Public Health Centers, Health Business Program, Health Electronic Health Record

Introduction

The Electronic Health Record (EHR) has evolved to become center-stage in the national health informatics strategies[1].

But many incompatible Health Information Systems that cannot effectively exchange information have been implemented, and substantial duplication of effort has occurred as different jurisdictions address similar information management needs[2].

Health Information System in Public Health Centers has several sub-systems that support direct care, supportive care and Health Business Programs. Various Health Business Programs are performed in Public Health Centers as major business. sub-system that supports Health Business Program has many problems to manage systematically and efficiently. Although the sub-systems are connected among each other, it needs more interactions between Health Business Programs and other systems of health centers in a nation.

In this study we will analyze the process of Health Business Programs and functionalities of the system for EHR implementation.

Methods

There were many Health Business Programs in Public Health Centers. To analyze function, we had to choose several Health Business Programs, which were considered as a important business and each had different work processes.

Nine Health Business Programs which recognized as key Health Business Programs in Public Health Care were selected.

Then, they have classified into following three categories: The First includes the Health Business Program which was managed by the local Health Information System. Second category includes the Health Business Program which was not managed by the local Health Information System but was managed by web system in common. Consequently, the personnel in charge of Health Business Program can't manage the cases by using their own Health Information System. Third category includes the Health Business Program has no Health Information System, so it was performed manually.

The methods of this study are as follow.

Analysis of the work process

Questionnaires and field interview survey were conducted at six Public Health Centers in Korea. And people in charge of each health business program named business manager were interviewed. After their work processes were inspected carefully, the functions of health information system and works performed manually using MS Excel or Word were investigated.

To show the functionalities, Unified Modeling Language (UML) was used, which showed the work process functionally.

Analysis the system of health business programs

The functions of business process of Health Information System that the manager use were analyzed. Functions were categorized into following three: mega process, major process and sub process.

Results

Analysis the work process

The health business managers perform the work of Health Business Program. They register the clients in Health Business Program and perform it. For example, they visit client's home and provided health care service. They also support the medical finance to the clients that allowed to reimbursement. And then the business managers report the results and statistics to the superior part . By these process, the clients are managed.

In short, it was analyzed that they have three mega processes. We called these functions as "registration", "acting" and "management"(Figure 1).

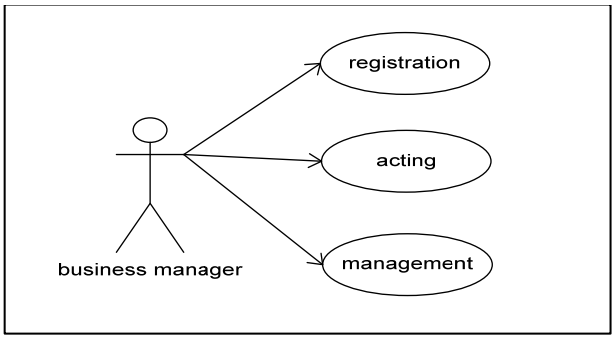

Figure 1. Usecase Diagram: Health Business Program

Each Mega process was analyzed more detail level as following usecase diagram.(Figure2, 3, 4)

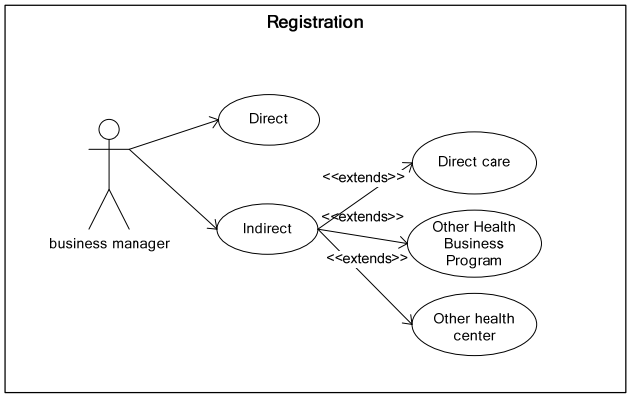

Figure 2. Usecase Diagram: Registration

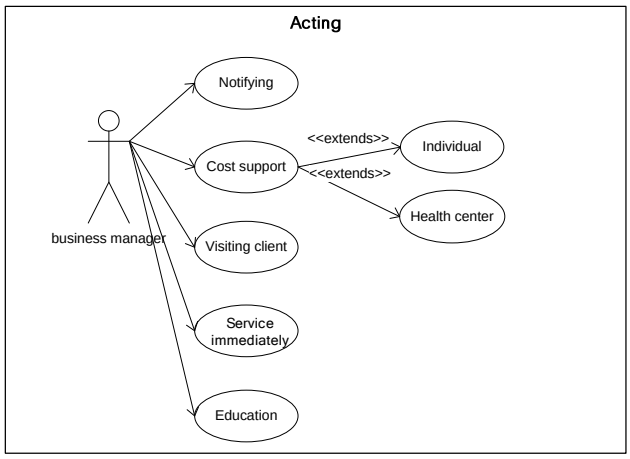

Figure 3. Usecase Diagram: Acting

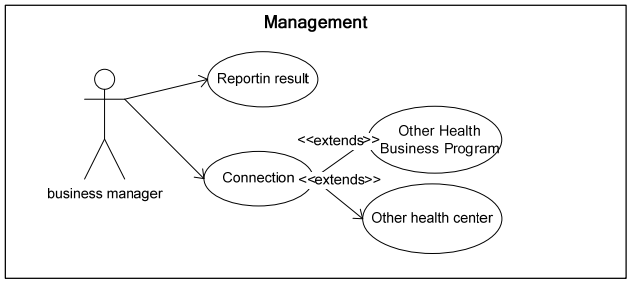

Figure 4. Usecase Diagram: Management

Analysis the system of Health Business Programs

In Health Business Program, Health Information System hardly has been developed . Even in the case that the Health Information System has been developed, the business managers rarely use Health Information System., because the Health Information system in Public Health Centers couldn't support the functions that can interface among other Health Business Programs, and communicate between Public Health Center and other Health Centers. They are the most important functions for the business managers to perform their work. The functions of interface also are the core functions for the interoperable EHR system.

There are categorized processes above Table1. Each Mega processes have Major processes, and also each Major processes have Sub processes. Similarly Each Sub processes have been performed by business managers, but each function was conducted in different ways.

So, several symbols are marked. A Mark "●" means that the function was performed by using Heath Information System in Public Health Center. A Mark "○" means that the function was performed by using website in common system. Finally a mark "◎" means that the function doesn't have any Health Information System, so business managers performed manually.

Table 1. Functional analysis of Health Information System

Mga process	Major Process	Sub Process	1.Using Health Information System†			2.Using website of other health center‡			3.No system (manual work)§

Manage ment	Reporting results	Reporting results	●	●	●	◎	◎	◎	○	○	○
	Connection	Other Health business program			○				○	○	
		Other Health Center	◎	◎	◎	◎	◎	◎	◎	◎	◎

† Using Health Information System: It means that works were performed by using Health Information System in Public Health Center.

‡ Using website of other health center: It means that works were performed by using website developed in other health center.

§ No system (manual work): It means that works were performed manually. For example, business manager used MS Excel or Word.

The name of each health business program is as follow;

A: Vaccination Program

B: Tuberculosis Control Program

C: Chronic Diseases Management Program

D: Rehabilitation Management Program

E: Sealing Program in Dental Health Care

F: Caner Screening Program

G: Medical Expense Subsidy for Caner Patient Program: Adults

H: Medical Expense Subsidy for Cancer Patient Program: Children

I: Smoking Cessation Management Program

It was analyzed that utility of health information system in public health center was poor.(Figure 2). In Registration, the coefficient of utilization of the System was 25%. Similarly in Acting, was 10%, and in Management was 15%.(Figure 5)

Business managers use other health centers' website or work manually in most of cases. It was showed 75% in Registration, 90% in Acting, 85% in Management when they use website or work manually.. Because of that, business managers feel inefficient and uncomfortable, thus they need the functions which could share the client's information efficiently.

These results showed that the Health Information system was in needs of functions that support interoperability between Health Information System in Public Health Centers and other health centers.

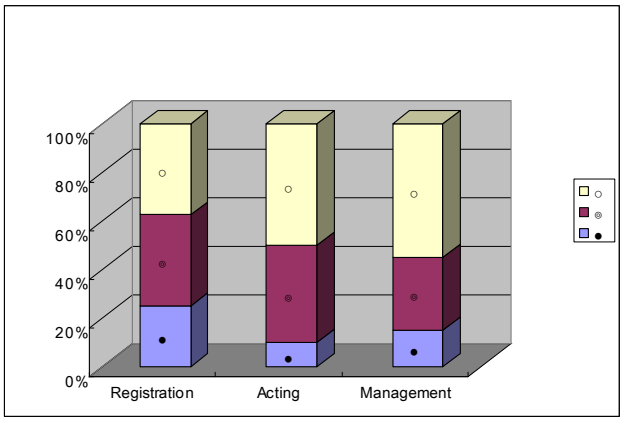

Figure 5. Rate of functional using the Health Information System (Sub process level)

Conclusions

Health business programs in public health center are recognized recently as essential activity of information system in Community Health. But actual condition can not support the effective management because there is little information system developed efficiently. From now on, establishing a health information system will be demanded for EHR system implementation.[3]

Health Information System offers an important infrastructure of efficient delivery and use of healthcare services. To develop the information system, it is important to develop a strategy covering the scope of work processes, public and private activities and adequate use of resources.[4]

So, in this study, we analyzed the function of Health Information System in Public Health Centers focused on Health Business Programs, which are recognized some core businesses in Public Health Centers.

In Public Health Centers, there are many different Health Business Programs. The Health Information System that supports the Health Business Programs was not integrated into a interoperable EHR system, but it has each Health Information System or has no Health Information System. This is why the functional analysis of Health Information System is significant.

We showed that it lacks for interoperability on relations with the Systems of other Health Business Programs and the Systems in other health centers.

For the EHR functionality, health information systems should include functions we suggested. The model for interoperable EHR system will be derived.(Figure 6)

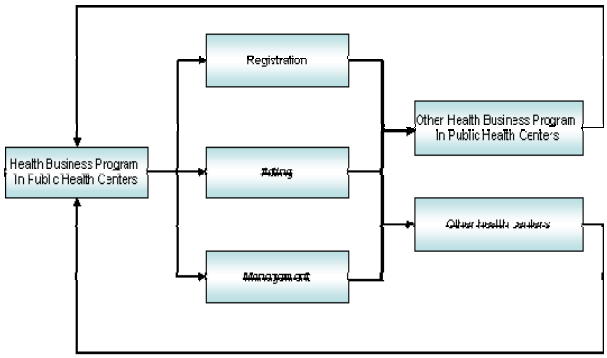

Figure 6. Model for interoperable EHR system in public health programs

Electronic Health Record (EHR) systems need to offer a flexible framework for recording the consultation process, and accommodate the individuality of the clinician.[5]

Health Information System should be developed reflecting the end users' requirements. Our study could be helpful to engineers who develop Health Information System , so they could have a good understanding of medical domain. And that can help to reflect the users' requirements. Furthermore, the Health Information System would be adopted various Health Business Programs. Eventually these make increasing the efficiency of the user's business and make sure the implementation of interoperable Electronic Health Record System.

Abstract

This paper represents a demonstration of custom designed HER for the street homeless.. Numerous barriers keep the street homeless from obtaining healthcare. Medical Street Outreach (MSO) programs are used to reach out to the homeless and offer healthcare services. Gathering relevant clinical information on the streets for the homeless is difficult. Carrying paper records in MSO is cumbersome and inefficient. Multiple complex healthcare record systems are available for collecting health data and for medical reference, for hospitals and outpatient. But, there are no systems designed for collecting health data on the streets. This article will discuss the model of a light weight Electronic Medical Record (EMR) built to address the process of healthcare on the streets. The EMR system has been designed for use on a Tablet Personal Computer (TPC) to collect, organize, and share clinical data between clinicians and provide quality healthcare to the homeless. This design can also be used in emergency situations.

demonstration. tablet PCs, healthcare for homeless, electronic medical record for homeless, medical street outreach

Introduction

Homelessness is a growing problem in the United States. A 2000 study by the Urban Institute estimated 444,000 to 842,000 homeless people. The number of homeless people counted in each state in 2005 totaled to 723,968 [1].71% of survey cities showed an average increase in request for emergency shelter by 6% in 2005 [2]. The homeless population in U.S. is composed of 43% single men, 33% families with children, 17% single women and 3% unaccompanied minors [3]. The majority of homeless population is men. However, studies have found that number of homeless women and families is growing.

In response to the federal government's 10-year plan to end homelessness, MSO programs have become a common feature of many community health service programs for the homeless[4-6]. In such programs, healthcare practitioners encounter homeless people in diverse settings—in meal programs, on the streets, under bridges, in encampments, and in shelters to improve their health, social functioning, or utilization of human services and resources[7].

Handheld technology on the streets

The method used in the Medical street outreach until recently has been to carry paper records. And carrying the paper records around to treat the homeless is very cumbersome. Scrambling through the records to find the patient's paper record is difficult and impractical. This disrupts the care workflow in MSO, resulting in reduced clinician-atient engagement and hence compromised care.

Health information is often poorly organized and not indexed in paper records. The paper records cannot be shared between multiple providers treating the same person. Inability to share records results in redundancy of records and insufficient patient information at the point of care. This inability to share patient information was the main impetus for the introduction of handheld computer technology into the healthcare delivery system for the urban street homeless in Houston.

Handheld technology like personal digital assistants (PDAs) are known for their mobility and flexibility in medical practice in the last few years [8-10]. Updated patient information available at the point of care shareable by all the clinicians enhances quality of care [11]. PDAs have their own limitations in memory, slow processing power, small screen size and a cumbersome input mechanism[8, 12].

Tablet Personal Computers (TPCs) is another handheld technology known for its use in the medical industry. It has a larger screen space, and a pen to write directly on the screen. Tablet PC offers mobility and fits well into the workflow for the MSO clinicians. The downside is that they are more expense and fragile than PDAs.

Two programs have tried to use PDAs for homeless healthcare. Boston's Health Care for the Homeless program used Palms devices to collect biomedical data. And Operation Safety Net (OSN) in Pittsburgh used IPAQ Pocket PCs. However, these were used in traditional clinical settings and not for medical outreach.

Methods

Healthcare for the Homeless – Houston (HHH) began using handheld technology to make medical street outreach more efficient for providers. In January 2001, HHH launched a personal digital assistant (PDA) system.

The use of Palm V Handheld Computers (PalmOne, Inc., Milpitas, CA) combined with customized software made it relatively easy to collect patient demographics and histories, as well as information on physical examination results, diagnoses, and medications. To prevent duplication of patient records, PDAs were synchronized into one main system. Informal interviews with the clinicians who pilot-tested the PDA platform revealed that they were satisfied with it as a method for collecting patient information. However, the limited memory available on the Palm became a major obstacle. Switching to the iPAQ H3765 Pocket PC (Hewlett Packard Company, Palo Alto, CA) improved the reliability of the system, but clinicians found the new hardware too slow.

Although PDAs proved ineffective, the positive feedback from clinicians in the pilot study [13] led to the development of a TPC platform in 2004. TPCs can record data with a digital pen, voice, keyboard, or mouse, while chart notes can be written or dictated. The display size of the Tablet PC is bigger and encompasses more data fields. The tablet PC used for street outreach by HHH is LS800 Mini TPC, from Motion Computing Inc., with a screen size of 21.34 cms and weighing only .997 Kgs. The EMR program is on a .NET framework and a MS Access Database.

EMR design

The Electronic Medical Record has been designed to enhance encounter workflow and data collection in street outreach for the homeless. Building the EMR involved data analysis from the pilot study on PDA[13] and involvement of the clinicians in an iterative heuristic process. Participation of the programmer in street outreach proved helpful in the logical design of the system.

The login on the TPC involves using fingerprints and username, password combination to comply by the HIPAA rules. Due to the mobile nature of the clinicians and the difficulty in bringing the programmers, implementation team and clinicians together, an audiovisual training module was developed. This training module proved effective in initial hands-on training with the system. The Go-live phase of the implementation involved participation of the implementation team in on-site training of the clinicians.

The EMR program has the capability of recording new encounters, new unlinked encounters, finding patient records and linking an unlinked encounter to a patient record. Patient record can be created using his name and demographics or even by any special appearance characteristics noted by the clinician. All fields have free text writing and typing options that makes taking clinical notes easier and quicker for the clinicians. There are drop-down menus for quicker selection for many of fields, for example: ethnicity. When entering a diagnosis the clinician can choose from the 20 most common diagnoses encountered in homeless on the streets or choose to view a list of more diagnoses. The system also has the capability of choosing a diagnosis by the ICD9 codes or by the abbreviations of the diagnoses. A summary page summarizes the patient encounter, goals and diagnosis. The summary page gets automatically populated at time of encounter data entry. Whenever one searches a patient file, it is the summary page that opens up, to give a comprehensive view in a jiffy. Patient file can be searched using his name, gold card number, or appearance characteristics.

The system has been designed to give the clinicians the mobility and flexibility to enter data on the fly. Before and after each street outreach visit the clinician goes to the clinic and synchronizes the data onto a common database. This way, each Tablet PC has the data from the other TPCs. Thus if a clinician has encountered a patient the other clinician encountered last week, he has all the patient data at the point of care. And there is not duplication of patient record. The enhanced information flow between clinicians helps provide improved quality of continued care.

Results

Despite the initial difficulties faced with the PDA and iPAQ use, there were beneficial lessons learned and a new system was designed with those feedbacks. With the Tablet PC, clinical information is accessible at all sites, by all physicians at the point of care. Data is replicated on the TPC hard drives from a repository on SQL Server. It has reduced the redundant documentation time and increased the encounter time for efficient patient care. Patient engagement has increased and clinicians are able to focus on building relationships with the homeless. The clinicians are able to devote time to addressing basic needs of the homeless, in addition to the medical needs.

The patients' attitudes toward and acceptance of technology has been surprising. Patient seemed nonplussed and flattered by the use of high-tech methods with them, instead of feeling anxious or intimidated by it.

From the lessons learned in the PDA development, we knew that user centered design was a critical first part of the TPC design [14]. The result has been an interface that requires little or no training and has been well accepted by the clinicians.

Future

The clinicians have been impressed by the flexibility with TPC use in street outreach medical care.

The research and programming team have been working on a Goal-Negotiated care (GNC) model of EMR [15]. The goal is to focus on patient goals and address patient needs directly, shifting the paradigm from a problem-based focus to a solution-oriented one. Goal negotiated care will help reduce feelings of powerlessness and increase self-efficacy. The GNC model allows clinicians to easily navigate through a care encounter between the goals and the encounter. In traditional care model, clinician moves linearly from history to diagnosis and treatment and the clinician drives the encounter, whereas in GNC, patient drives the encounter. Patient goal is the starting point and the clinician then moves forward or backward through the who, what, how, why, when and where components. An overview of the GNC logic model is presented in Appendix A. A set of goals commonly encountered in homeless patients aids in the process of selecting and generating the clinician and patient tasks. The entire process is more interactive for both clinician and patient, empowering and building the patient's self-efficacy by addressing his/ her specific goals and tasks.

GNC is currently being implemented and will be part of the demonstration.

Acknowledgments

Funding for this project was provided by Healthcare for the Homeless – Houston.

Introduction

Medicine is an art founded on experiential know-how, the basic sciences, and epidemiological data. There is a universal agreement that physicians must have knowledge of these two basic subjects, human physiology and anatomy. The corpus of data and knowledge underlying medicine is growing exponentially and Medical Education faces the great challenge of training students within this expanding data universe spanning from the "nano" to the macroscopic scales. All biological functions and their modulations thereof can be attributed to the interplay between the variable expression of specific genes, the functional variability and diversity of their protein products within multiple biochemical systems, and the interactions between the cells, tissues and organs in which the said genes are expressed.

Modern approaches to teaching and learning basic science include collaborative learning, problem-based learning and the use of computers. Computers and information and communication technologies (ICTs), the Internet and Internet-related resources are of special interest in physiology [1]. Available computer technology allows the use of dynamic models, making learning more efficient. Many difficult concepts in physiology are truly learned only when the student's brain converts heard or read words, static pictures and diagrams into moving models [2]. Computers are now sufficiently powerful and the Internet sufficiently fast to allow fast distribution of multimedia materials which are especially useful for teaching physiology [3]. Furthermore, the interactive capability of computer-based instruction (CBI) keeps the student involved so that learning is more interesting and not purely passive. Future CBI will also have to tackle the challenge of helping students master the wide and deep corpus of knowledge we evoked in the first paragraph.

Our current approach focuses on the scientific foundations of medicine, and combines Computational Integrative Physiology (CIP), Qualitative Modeling (QM), and Reasoning capabilities. The aim of CIP is to provide computer models of the human body's multi-scale biochemical and biophysical dynamics that are occurring in response to its environment [4].

Qualitative Modeling involves natural-language and common-sense representations of the physical world. Qualitative models can model complex physical systems and processes as well as produce natural language descriptions and summaries of simulated system behaviour [5]. This self-descriptive property conveys a central role to these models since reasoning processes such as tutoring can operate at a symbolic level where qualitative models constitute the *object* level..

Finally, a *trully interactive* CBI must exhibit *intelligent behavior* (e.g, reasoning capability). Indeed, for a CBI to "interact" with a user beyond responding to "start", "forward", or "backward" clicks, it must have an *understanding* of the current user-context and carry-out *meaningful actions* accordingly. Such an understanding

could not hold without the proper representations and semantics describing a user-context nor without the specific inference schemes to carry-out meaningful actions.

In this global conceptual context, our objective was to create freely accessible simulation tools and to put them on the web at learners' and teachers' disposal. In what follows we will focus on some of the multimedia resources that host our quantitative and qualitative computational models. System intelligence will be addressed in subsequent papers.

Materials and methods

Pedagogical content media types

Pedagogical multimedia contents include texts, static images (radiographies, magnetic resonance imaging (MRI), etc…), sounds (voice, cardiac and pulmonary sounds), dynamic recordings (echogram, videogram), dynamic two- (2D) or three-dimensional (3D) simulations. Each pedagogical content includes at least two frames: on the left side of the screen, the title and a short explanatory text of the lesson and on the right side, the multimedia material : videogram, 2 or 3D animation. Different buttons allow the learner to display more detailed explanations about the phenomena, to add sound, music, to hear the reading of the text, to navigate along the different pages of the session.

2D and 3D dynamic computer simulations

The 2D and 3D dynamic simulations of multiscale biological functions were generated using original IBC-made computer models coupled to a generic and multi-domain knowledge base [4] [5]. The IBC computer simulators are able to reproduce normal or pathological cases in a virtual reality context and from the cellular to the organic level.

Set-up and functioning of the website

A part of our 2D and 3D dynamic simulations are present on the website that we created in 2005 and that we described in a precedent paper [6]. This website, called the "Campus Numérique de Physiologie" (CNP) is accessible through the French Virtual Medical University (UMVF) site at the following adress: http://www.umvf.org, "virtual campus" heading. There is also a direct Internet access: http://www.campus-physiologie.org

Our first work was to update the Content Management System (CMS) of the platform with the latest version of Joomla, an open source Mambo-derived CMS which uses a MySQL database. The platform has also been more securized at the Apache webserver level.

Results

More than 30 pedagogical items are now available on the CNP, but for the moment we have focused our effort in the sole domain of the cardiovascular physiopathology: in this medical area, the cardiovascular hemodynamics and cardiac electrophysiology sections present several concepts usually considered to be of special difficulty for the student's understanding. This is the reason why we developed simulator-based 2D and 3D animations in those two sections. We present here some examples of the resources available in each section.

Cardiovascular hemodynamics section

This section allowed also us to introduce into the proposed resources a simplified but very useful 3D anatomical model. The learners can use this virtual human body containing important biological systems like the skin, the muscles, the skeleton or the cardiovascular sytem, as an anatomical relative position reference for various organs (see figure 1).

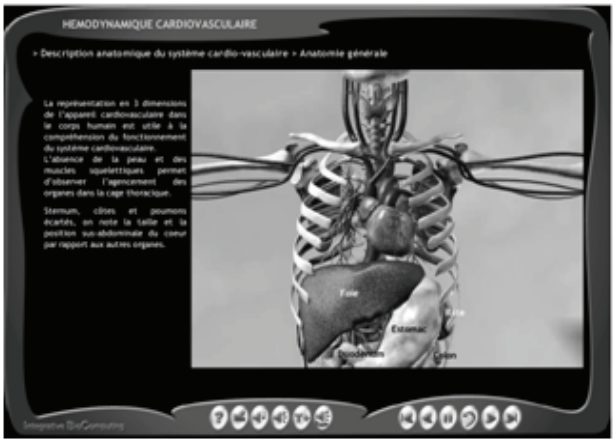

Figure 1 – 3D anatomical relative position reference

.In this section, students can watch in details hard to understand 3D phenomena such as the successive or slightly asynchronous mechanical events of the cardiac cycle and the corresponding cardiac hemodynamic recordings.

Figure 2 gives an example of mechanical and hemodynamic processes viewed in parallel for a better understanding.

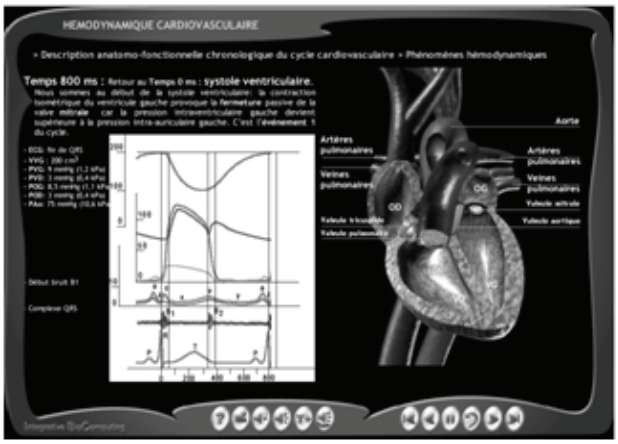

Figure 2 – Hemodynamics

Cardiac electrophysiology section

In this section, learners can watch in two dimensions a myocardic repetitive reentry process associated with the genesis of a ventricular tachycardia (see figure 3).

Figure 3 – A 2D simulated reentry

Students can also start the electric cardiac activation process: using an original IBC-made 3D chromatic simulation program [7], they are able to follow the step by step depolarization and repolarization pathways along the fast conducting system, the endocardium and epicardium. 3D visualization of the cardiac electrical signal moving forward is essential to understand the corresponding genesis of the normal and pathologic human heart EKG, which can be studied in any standard lead (see Figure 4).

Qualitative simulation

New resources are under developpment and we will soon add quantitative simulations to the list of available website resources. Within this new learning context, students will be able to analyse combined impulse formation and impulse conduction disturbances using different means: a crude depolarisation wavefront, a Lewis diagram, and the high level concepts that label (qualify) the simulated

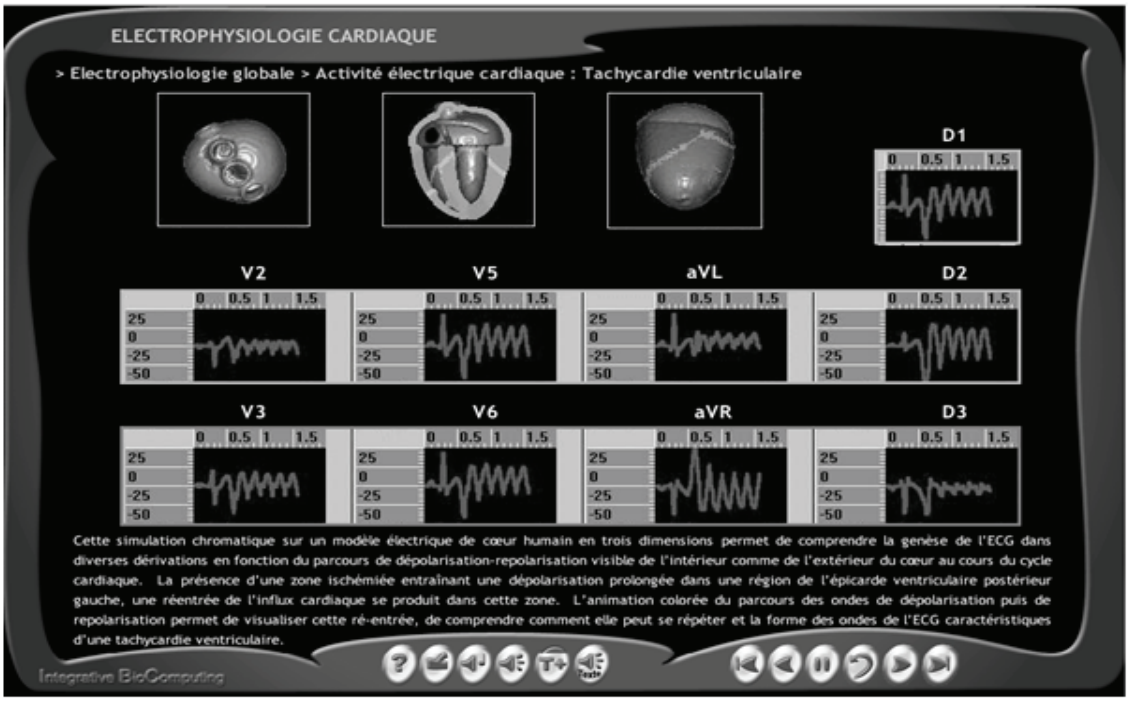

Figure 4 – 3D simulated ventricular tachycardia with a model-generated ECG

arrhythmia (see Figure 5). Given initial conditions, our QM generates these results in an ongoing fashion and in synchrony with the underlying electrical processes [8].

Discussion

Computer-assisted learning is generally assumed to be worth and to have a positive influence on student learning [3], [9-10]. Nevertheless, in agreement with the views of the teachers of the french "Société de Physiologie" and in opposition to classical virtual universities, it was decided before its development that the CNP would not be a web-based course aimed at distance learning. Learning materials of the CNP are not intended to become a surrogate for classical forms of teaching. ICTs and multimedia are uniquely used as tools for learning, providing learners with complementary knowledge in fundamental sciences necessary to scientific and medical education. Choosing to provide learners only with complementary teaching resources, we wanted to keep the possibility of face-to-face Physiology courses for on-campus students and to avoid

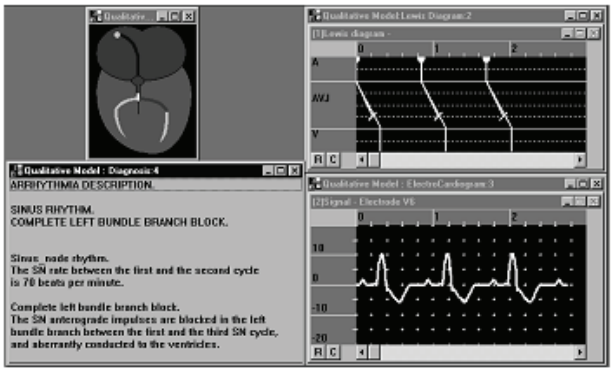

Figure 5 – Qualitative simulation of an arrhythmia

some dangers linked to complete on-line courses and confirmed by different surveys : the will of a physical classroom in preference to a virtual one is expressed by many students whose majority disagree with both synchronous and asynchronous electronic communication tools when a direct interactive aid by dedicated teachers is possible [9] [11].

Though the CNP is for the moment moderately interactive, medical first-cycle students of Rennes and several already graduate practitioners are highly enthusiastic about the complementary use of multimedia resources to improve

the understanding of physiopathological mechanisms and the possibility to re-active their memory before or after clinical reasoning learning or practical workshop sessions. This statement is in agreement with a recent survey [12] showing that medical students mostly use Internet in order to find additional learning information. Nevertheless, the CNP is in permanent evolution in order to improve its technical effectiveness and to come up to the users' expectation [13-14] and thus needs being appraised as precisely as possible: methods of assessing the effectiveness of our e-learning systems will be explored by inquiries about both customer satisfaction and service quality. A general questionary, established from examples of the literature will allow to verify the user's satisfaction level. E-learner satisfaction is linked to learner's performance. Assessment of learners' understanding level will be assessed by specific questionaries written by the authors in each teaching content. To reach this goal, the actual CMS Joomla will be replaced as soon as possible by a learning content management system (LCMS). LCMS are aimed to offer functionalities allowing easy construction of a questionnaire. After a preliminary inquiry in 5 french and 1 canadian universities, unpublished results show that Medical Physiology professors find the simulation tools of the CNP useful as complementary resources for a better understanding of the described biological mechanisms. The loud synthetic reading of the text does not seem to be very useful and more interactivity is required.

A part of the teaching quality of the CNP will be warranted by the teachers validating committee and by the administrator's control of the hardware and software efficiency and updating. Though it has been shown that in basic sciences and Physiology, didactic fashion is more efficacious than too much interactive style [10] and since it was demonstrated that understanding is the most useful in clinical reasoning [15-16], original IBC-made software tools will be used to develop movies from 3D colour images and photographs in the jpeg file format to give the learner the possibility of a real interactive navigation in a three-dimensional cardiovascular environment. Well designed computer-aided learning is useful for conceptually difficult topics [17] [3]. Furthermore, an original IBC-made cardiac simulator is in preparation, soon at teacher's disposal to create different scenarii of pathological affects.

Developing computer assisted learning applications is a lengthy process. Innovators within traditional courses who have often produced creative and high quality material to supplement existing courses are in a minority [14]. We hope that the rising success of the CNP will enhance the creativity of the teachers but the development of teaching scenarii using multimedia and the multiplication of the teaching contents of the CNP for the next years depends on both the vitality of the members of the French “Société de Physiologie” and the acceptation of the different teaching projects to be granted by the UMVF.

Conclusion

We have presented different multimedia resources incorporating quantitative and qualitative models that have been developed to help medical students with an active and easier understanding of complex physiopathological phenomena in the context of the complementary teaching resources of the CNP. It should be noted that the opposing view to classical virtual universities concerns *current* CBI technologies which generally have very little intelligence and therefore limited “real” interactivity with a mitigated acceptance by the students.

Related to this issue, we are currently developing an *interactive* CBI that will exhibit *autonomy* and *intelligent behavior* in a e-learning/e-training context. It will combine CIP and qualitative models with reasoning methods. Such developments are necessary if future CBI technologies have to carry-out the task of performing Problem-Based Learning and Clinical Reasoning Learning sessions in an autonomous fashion. For instance, good medical practice presupposes diagnostic ability that includes a solid grounding in physiopathology. Loosely speaking, in physiopathology-based diagnosis, solutions and explanations are provided by going "backwards" through the causal paths, from the observation to the cause(s) of a mental physiopathological model. This form of hypothesis-formation, called *abduction,* can be mimicked by computers capable of performing model-based diagnosis. Thus CBI technologies that perform abductive inference will be well tooled to tackle PBL sessions in an autonomous fashion.

Although these are long-term goals, we believe that model-based learning resources such as described in this paper and the experiences derived from their use in the classroom will provide valuable inputs to our more advanced developments in CBI technology.

Acknowledgments

We acknowledge the members of the GIP of the UMVF, the members of the Society of Physiology, the president of the University of Rennes 1 and the dean of the Faculty of Medicine of Rennes for supporting the development of the Campus Numérique de Physiologie.

Demonstration of GuideView, a Multi-platform System for Interactive, Multimodal Presentation of Clinical Advice

M. Sriram Iyengar[a], Jose Florez-Arango[a,b]

[a] School of Health information Sciences, The University of Texas Health Science Center at Houston
b School of Medicine, Universidad de Antioquia Medellin - Colombia

Abstract

There is an increasing need for technologies that can assist in providing medical guidance in situations where physician availability is low. Such situations include the growing number of aging individuals living independently, rural areas in developed countries, and substantial populations in less developed countries. We demonstrate GuideView, a system that enables interactive, structured, multi-modal delivery of clinical advice. It provides clinical guidelines simultaneously using voice, pictures, video, and animation. GuideView is multi-platform, executing on desktops, over the web, on Pocket PCs, and on Windows Mobile cell-phones. GuideView interfaces to medical instruments such as Pulse-Oximeters and can automatically follow treatment or diagnostic pathways depending on the input received. GuideView Author, is a simple GUI-based environment for developing GuideView compatible protocols (GuideViews).

Keywords:

practice guidelines, cellular phone, multimedia, telemedicine, software design, user-computer interface

Introduction

The need for medical and skilled nursing care continues to increase worldwide. In advanced countries aging populations place increasing demands on healthcare systems and in developing countries medical facilities are likely to be poorly staffed and equipped. In these countries, while the availability of medical supplies and drugs is a pressing issue, another problem is the lack of high-quality, standardized medical training.

We demonstrate *GuideView*, a system designed to assist non-physician care providers (NPCPs) such as community health practitioners, nurse assistants, and similar personnel in providing medical care. In addition, GuideView can potentially assist the elderly. The GuideView system enables delivery of structured, multi-modal delivery of clinical protocols on multiple platforms, presenting a very similar look-and-feel on desktops, laptops, Personal Digital Assistants, and cell-phones.

GuideView

GuideView technology was originally developed at NASA Johnson Space Center as an advanced research project exploring technologies for providing medical support to astronauts during deep space exploration missions.

GuideView consist of two components, a) *GuideView Author,* for developing guidelines in the GuideView format, and b) *GuideView Viewer,* used to execute and display these guidelines. For brevity, any guideline that has been developed and saved in the GuideView format, is called a *GuideView.*

Design considerations

The design of GuideView was informed by the following basic objectives.

- The system should be portable and support ubiquity
- It should be highly interactive
- Medical guidance should be provided in a structured manner, as a sequence of *steps*
- Cognitive load should be reduced:
  - At any step in the procedure there should be only a few choices leading to the next step.
  - The task to be performed at any step should be simple
  - Sufficient information, but not an overwhelming amount, should be provided at every step
- Information should be given in multiple, redundant modes
- Presentation and content should be strictly separated. One important benefit is that GuideView protocols can be developed in multiple languages; the GuideView Viewer and Author are agnostic to such content variations.
- The system should be able to acquire medical data from sensors and branch through the guideline accordingly

To achieve the objectives of portability and ubiquity, the Viewer has been designed to be multi-platform, and can execute over the web, stand-alone on Windows desktops and laptops, Personal Digital Assistants (PDAs), and on cellular phones running the Windows Mobile Operating

System. PDAs and cell-phones are an attractive platform due to their portability. Web-based GuideViews can be executed on recent versions of most web browsers running on most client operating systems (Windows, Linux, MacOS), although it has been tested most extensively on Internet Explorer 6.0.

User interaction

User interaction with the system depends on the platform. On desktops and laptops, the mouse is the primary medium of navigation. In addition, GuideView accepts voice commands from a limited vocabulary (currently only on Windows Clients). including 'Affirmative', 'Advance', 'Play Video' etc.. Voice input mode enables hands-free operation, a desirable feature enabling the caregiver to use both hands to assist a patient while receiving guideline instructions.

On Pocket PCs (PDAs), screen tapping using a stylus is used for navigation. On the mobile phone, directional and selection buttons on the phone's numeric pad are used.

GuideViews are highly structured and appear to the user as a sequence of simple steps capable of being accomplished by those without specialized training. Information on how to accomplish each step in a GuideView is presented simultaneously as text, voice, and still pictures or annotated full-motion video. The video can consist of live motion or animation or a combination of both. Presenting information in multiple modes simultaneously enables a rich instruction and guidance environment. The multiple modes enhance understanding by reinforcing and supplementing each other.

Within each step in GuideView the user is given only a limited number of choices for the next step. Thus a GuideView can be thought of as pathway consisting of nodes from each of which multiple branches emerge, leading to other nodes.

The system is able to directly take input from medical sensors when available, and branch the execution accordingly. The input can occur from wired serial devices or wirelessly by BlueTooth. The current implementation accepts input from a serial-port Pulse-Oximeter (Avant ®4000, Nonin Medical Inc, Plymouth, MN, USA) and branches automatically depending on the pulse rate sensed.

The authoring environment

GuideView format guidelines (i.e., GuideViews) are created, typically by teams of physicians and nurses, using GuideView Author, a GUI authoring tool that enables development, editing, and update. Text input for each step is entered directly into GuideView Author. Multi-modal content such as voice and video files are produced separately and merged into the protocol using the Author. Modularity and re-use is supported in the sense that an existing GuideView protocol can be incorporated into another easily using the Author.

The design of GuideView Author supports strict separation of presentation and content, in the sense that the GuideView Viewer software is agnostic to the specific multimodal content presented in a GuideView. Such content can be developed in any desired language, integrated into GuideView format by the Author and saved for later viewing by the Viewer.

Integration with an Electronic Medical Record System

GuideView has been integrated with BMIST-J (Battlefield Medical Information System Tactical, http://www.tatrc.org), an electronic medical record system operating on PocketPCs developed by the US Army Telemedicine advanced Technology Research Center. From BMIST-J GuideView can be accessed in a context-sensitive way. For example, if the chief complaint in a patient encounter is eye pain, foreign object, or redness, tapping on the GuideView button within BMIST presents a GuideView protocol addressing diagnosis and treatment of such problems. Integration of GuideView with BMIST enables delivery of clinical advice as well as automated documentation of differential diagnoses, treatment and related care.

User acceptance

A preliminary study of GuideView in a Human patient simulator environment using 10 subjects revealed positive acceptance of the GuideView system [1]. None of the subjects were trained physicians; all had received some amount of training in CPR or similar first-aid procedures. Voice output received the greatest acceptance and was rated indispensable by 60% of the subjects and useful or very useful by the remaining 40%. Video assistance was rated in the useful to indispensable range by 80%. This has interesting implications for the design of future GuideViews.

GuideViews

So far, a variety of GuideViews have been developed, between them we have airway triage, basic CPR, red-eye, saliva sample collections and decompression sickness. The Red-eye Guideview has been developed in both Spanish and English. A GuideView in a non-medical area has been developed to support maintenance of underwater photographic equipment during NEEMO 12, an extended stay mission at the US National Underwater Research Center, Key Largo, Florida.

Conclusion and Future Work

The demonstration will include all the features described above on multiple platforms including web, stand alone

desk/laptop, Pocket PC (Windows Mobile) and cell phone. Voice navigation will be demonstrated on the laptop implementation.

In general, GuideView may be thought of as a procedure assistant enabling 'virtual experts' to offer guidance in performing tasks (not necessarily from the medical domain) where and when needed.

Future work includes improving the user interface, interfacing to a variety of medical sensors, and improving voice navigation. More extensive usability studies and field testing are in planning stage.

Implementation of An Integrated Network for Health Research in Quebec

Allen Huang[a], Jacques Lemieux[b], Jean-Claude Bouchard[b], Michel Bourque[b], Robyn Tamblyn[b]

[a] *McGill University Health Centre, Montreal, Canada*
[b] *Clinical and Health Informatics Research Group, McGill University, Montreal, Canada*

Abstract

Health data warehouses represent a valuable resource for health research. We have developed an infrastructure capable of providing health researchers in the province of Quebec with a toolkit to access the clinical data warehouses contained in the major academic health centres and the provincial health administrative systems. This demonstration will highlight the components that allowed the successful implementation of an integrated network to accomplish this task. Acceleration of the pace and increases in the volume and quality of health research within the province, in other jurisdictions and possibly world-wide is now an attainable goal.

Keywords:

health databases, information management, patient data privacy, database management systems, computing methodologies, health services research

Introduction

Health research done in the conventional, paper-record environment is tedious, expensive and reliant on data with varying quality. Large repositories of health data are invaluable resources to researchers and planners in health care. In the province of Québec, Canada, these repositories are housed in clinical data warehouses within the large teaching hospitals and the administrative data warehouse at the Régie de l'assurance maladie du Québec (RAMQ) – the provincial health services payer. The Infostructure de Recherche Intégrée en Santé (IRIS) - Québec project is a Canada Foundation for Innovation funded initiative to construct an integrated network for health research in the province. Its goal was to create secure access to these data warehouses, enable the linkage of patient records through the use of a provincial Master Person Identifier (MPI) and ensure that resultant datasets returned to researchers conform to privacy standards.

Methods

The IRIS-Québec architecture is a distributed, federated data warehouse model. The RAMQ already manages the MPI. The research warehouses of clinical data were constructed to ensure the highest standards of data quality. People: Researchers wishing to access these data warehouses no longer have to queue for specialized data analysts and programmers. The researchers' toolkit is a web-based, user-friendly interface that drives a powerful system with the following functions: selection of variables from the extensive data dictionary across the warehouses, building of complex queries using logical operators, a temporal relation tool to define time-dependencies of variables, a crosstabs manager, and a data extraction manager. Previously onerous and lengthy authorization steps have been streamlined into an electronic approval process which is reliable, timely and track able. Privacy: A novel "inference controller" was developed to ensure individual data privacy. This software computes the probability of the presence of an unique, potentially re-identifying profile when multiple databases are linked. The researcher's toolkit allows the dynamic modification of data query parameters in order to achieve the desired data precision without violating privacy rules Processes: Data sharing agreements were established with each partner institution. Software agents were installed at each data source to manage queries, connectivity, linkages, and data flows. Each agent contains a copy of the inference controller engine. Performance: is maintained by de-coupling the phases of a research project from the raw data extractions. The creation of the complete cohort data cube is triggered only on submission of the finalized project profile. We will demonstrate the operation of the Toolkit through sample queries.

Conclusion

The architecture of our system can potentially be extended to other biomedical information sources such as genomics, proteomics and geneology databases and create new capacity for health and bio-medical research. This architecture can also be potentially replicated in other jurisdictions. Scaling such a system to the international level can result in enabling health and bio-medical research in the global community.
